About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data manual, rather a companion guide that should be used alongside the device-specific data manual to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data manual. This allows the data manual to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers may be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure can have one of multiple meanings:
    - Not implemented on the device
    - Reserved for future device expansion
    - Reserved for TI testing
    - Reserved configurations of the device that are not supported
  - Writing non-default values to the Reserved bits could cause unexpected behavior and should be avoided.

Topic **Page**

1.1 Introduction

This section describes the features, supporting subsystems, and architecture of this highly integrated, programmable device. A detailed summary of the key features, required usage information, and register descriptions is provided for the following primary components and subsystems:

- Microprocessor unit (MPU) subsystem based on the ARM® Cortex®-A8 microprocessor with ARM® NEON™ technology extension
- DSP Subsystem (DSPSS), including the C674x Megamodule and associated memory
- HD Video Co-processor Subsystems (HDVICP2) System MMU
- System MMU
- SGX530 graphics subsystem for 3D graphics acceleration
- HD Video Processing Subsystem (HDVPSS) for video capture and display
- Level 3 (L3) and Level 4 (L4) interconnects
- Device Clocking and Flying Adder PLLs
- Error Location Module for the General Purpose Memory Controller
- Inter-Processor Communications with Mailbox and Spinlock components
- Control module with all chip-level control and configuration registers
- Power, Reset, and Clock Management module
- Interrupt Controller
- Boot modes and booting procedures

1.2 MPU Subsystem

1.2.1 Introduction

The Microprocessor Unit (MPU) subsystem of the device handles transactions between the ARM core (ARM Cortex-A8 Processor), the L3 interconnect, and the interrupt controller (INTC). The MPU subsystem is a hard macro that integrates the Cortex-A8 Processor with additional logic for protocol conversion, emulation, interrupt handling, and debug enhancements.

Cortex-A8 is an ARMv7 compatible, dual-issue, in-order execution engine with integrated L1 and L2 caches with NEON SIMD Media Processing Unit.

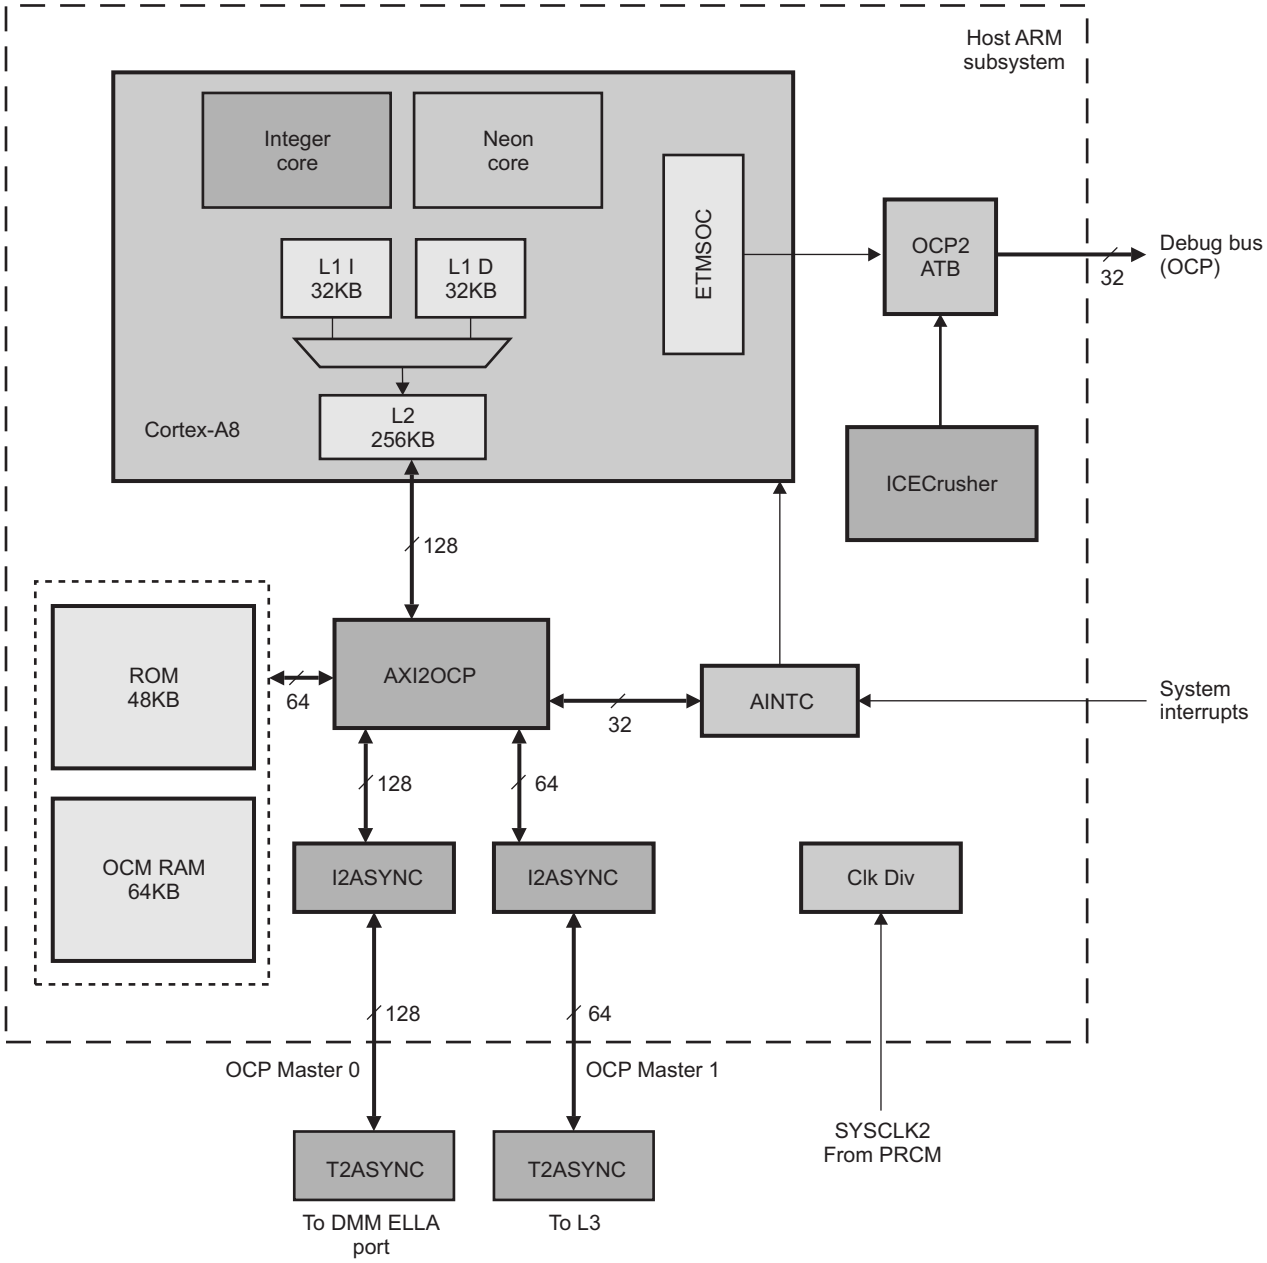
An Interrupt Controller is included in the MPU subsystem to handle host interrupt requests in the system.

The MPU subsystem includes ARM® CoreSight™ compliant logic to allow the debug subsystem access to the Cortex-A8 debug and emulation resources, including the Embedded Trace Macrocell.

The MPU subsystem has three functional clock domains, including a high-frequency clock domain used by the Cortex-A8. The high-frequency domain is isolated from the rest of the device by asynchronous bridges.

Figure 1-1 shows the high-level block diagram of the MPU subsystem.

Figure 1-1. Microprocessor Unit (MPU) Subsystem



1.2.2 Features

This section outlines the key features of the MPU subsystem:

- ARM Microprocessor
  - Cortex-A8 revision R3P2.
  - ARM Architecture version 7 ISA.
  - 2-issue, in-order execution pipeline.
  - L1 and L2 Instruction and Data Cache of 32 KB , 4-way, 16 word line with 128 bit interface.
  - Integrated L2 cache of 256 KB, 8-way, 16 word line, 128 bit interface to L1.
  - Includes the NEON media coprocessor (NEON) that implements the Advanced SIMD media processing architecture.
  - Includes the VFP coprocessor which implements the VFPv3 architecture and is fully compliant with IEEE 754 standard.
  - The external interface uses the AXI protocol configured to 128-bit data width.
  - Includes the Embedded Trace Macrocell (ETM) support for non-invasive debugging.
  - Implements the ARMv7 debug with watch-point and breakpoint registers and 32-bit Advanced Peripheral Bus (APB) slave interface to CoreSight debug systems.
- AXI2OCP Bridge
  - Support OCP 2.2.
  - Single Request Multiple Data Protocol on two ports.
  - Multiple targets, including three OCP ports (128-bit, 64-bit and 32-bit).
- Interrupt Controller
  - Support up to 128 interrupt requests
- Emulation/Debug
  - Compatible with CoreSight Architecture.
- Clock Generation
  - Through PRCM
- DFT
  - Integrated PBIST controller to test L2 tag and data ram, L1I and L1D data ram and OCM RAM.

1.2.3 MPU Subsystem Integration

The MPU subsystem integrates the following group of submodules:

Cortex-A8 Processor: Provides a high processing capability, including the NEON technology for mobile multimedia acceleration. The ARM communicates through an AXI bus with the AXI2OCP bridge and receives interrupts from the MPU subsystem interrupt controller (MPU INTC).

Interrupt controller: Handles the module interrupts (for details, see the *ARM Interrupt Controller (AINTC)* chapter).

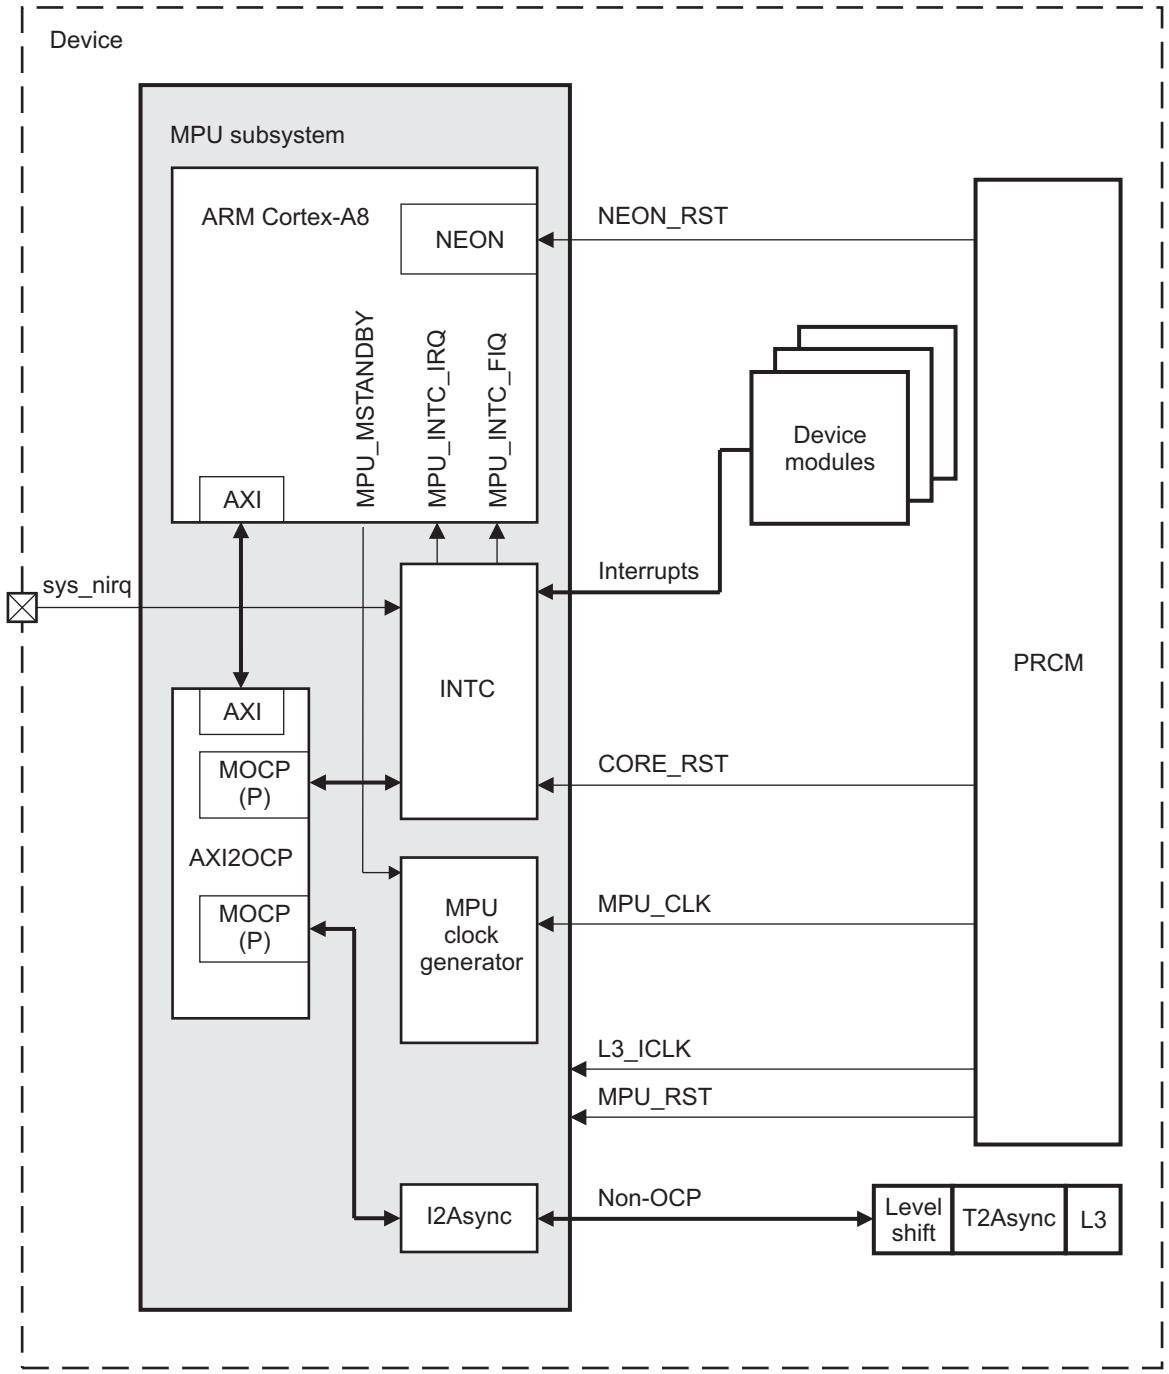
AXI2OCP bridge: Allows communication between the ARM (AXI), the INTC (OCP), and the modules (OCP L3).

I2Async bridge: This is an asynchronous bridge interface providing an asynchronous OCP to OCP interface. This interface is between the AXI2OCP bridge within the MPU subsystem and the T2Async bridge external to the MPU subsystem.

Clock Divider: Provides the required divided clocks to the internal modules of the MPU subsystem and has a clock input from SYSCLK2 that is applied by the power, reset, and clock management (PRCM) module of the device.

In-Circuit Emulator: It is fully Compatible with CoreSight Architecture and enables debugging capabilities.

Figure 1-2. MicroProcessor Unit (MPU) Subsystem Signal Interface



1.2.4 MPU Subsystem Clock and Reset Distribution

1.2.4.1 Clock Distribution

The MPU subsystem does not include an embedded DPLL. The clock is sourced from the PRCM module. A clock divider within the subsystem is used for deriving the clocks for other internal modules.

All major modules inside the MPU subsystem are clocked at half the frequency of the ARM core. The divider of the output clock can be programmed with the PRCM.CM_CLKSEL2_PLL_MPU[4:0]MPU_DPLL_CLKOUT_DIV register field, the frequency is relative to the ARM core. For details see the *Power, Reset, and Clock Management (PRCM)) Module* chapter.

The clock generator generates the following functional clocks:

ARM (ARM_FCLK): This is the core clock. It is the base fast clock that is routed internally to the ARM logic and internal RAMs, including NEON, L2 cache, the ETM core (emulation), and the ARM core.

AXI2OCP Clock (AXI_FCLK): This clock is half the frequency of the ARM clock (ARM_FCLK). The OCP interface thus performs at one half the frequency of ARM.

Interrupt Controller Functional Clock (MPU_INTC_FCLK): This clock, which is part of the INTC module, is half the frequency of the ARM clock (ARM_FCLK).

ICE-Crusher Functional Clock (ICECRUSHER_FCLK): ICE-Crusher clocking operates on the APB interface, using the ARM core clocking. This clock is half the frequency of the ARM clock (ARM_FCLK).

I2Async Clock (I2ASYNC_FCLK): This clock is half the frequency of the ARM clock (ARM_FCLK). It matches the OCP interface of the AXI2OCP bridge.

NOTE: The second half of the asynchronous bridge (T2ASYNC) is clocked directly by the PRCM module with the core clock. T2ASYNC is not part of the MPU subsystem.

Emulation Clocking: Emulation clocks are distributed by the PRCM module and are asynchronous to the ARM core clock (ARM_FCLK) and can run at a maximum of 1/3 the ARM core clock.

Table 1-1 and Table 1-2 summarize the clocks generated in the MPU subsystem by the MPU clock generator.

Figure 1-3. MPU Subsystem Clocking Scheme

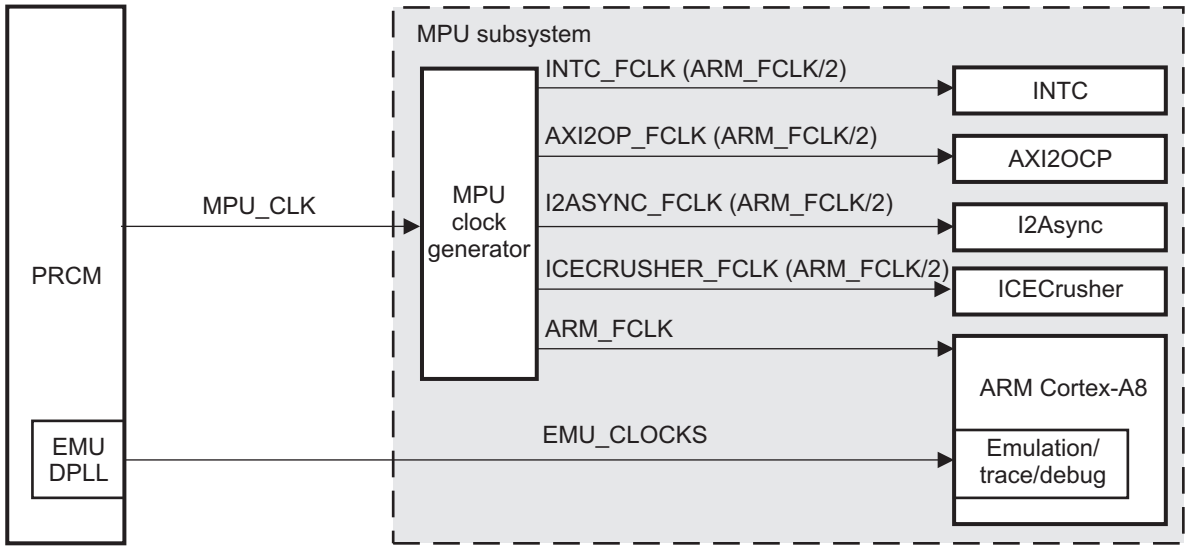


Table 1-1. MPU Subsystem Clock Frequencies

Clock Signal	Frequency	Comments
Cortex-A8 Core Functional Clock	MPUCLK	SYSCLK2 from PRCM
AXI2OCP Bridge Functional Clock	MPUCLK / 2	
IceCrusher Clock	MPUCLK / 2	
I2Async Bridge Functional Clock	MPUCLK / 2	

NOTE: The second half of the asynchronous bridges (T2ASYNC) going to EMIF and L3 are clocked directly by the PRCM module with the core clock for port. T2ASYNC half-bridges are not part of the MPU subsystem.

Table 1-2. MPU Subsystem Clock Input Signals

Clock Signal	Reference/Source Clock	Comments
MPU Clock	Non-Gated SYSCLK2 from PRCM	
Async bridge clock (core domain)	Gated SYSCLK6 from PRCM	T2ASYNC bridges only

1.2.4.2 Reset Distribution

Resets to the MPU subsystem are provided by the PRCM module and controlled by the clock generator module.

For details about clocks, resets, and power domains, see the *Power, Reset, and Clock Management (PRCM) Module* chapter.

Figure 1-4. Reset Scheme of the MPU Subsystem

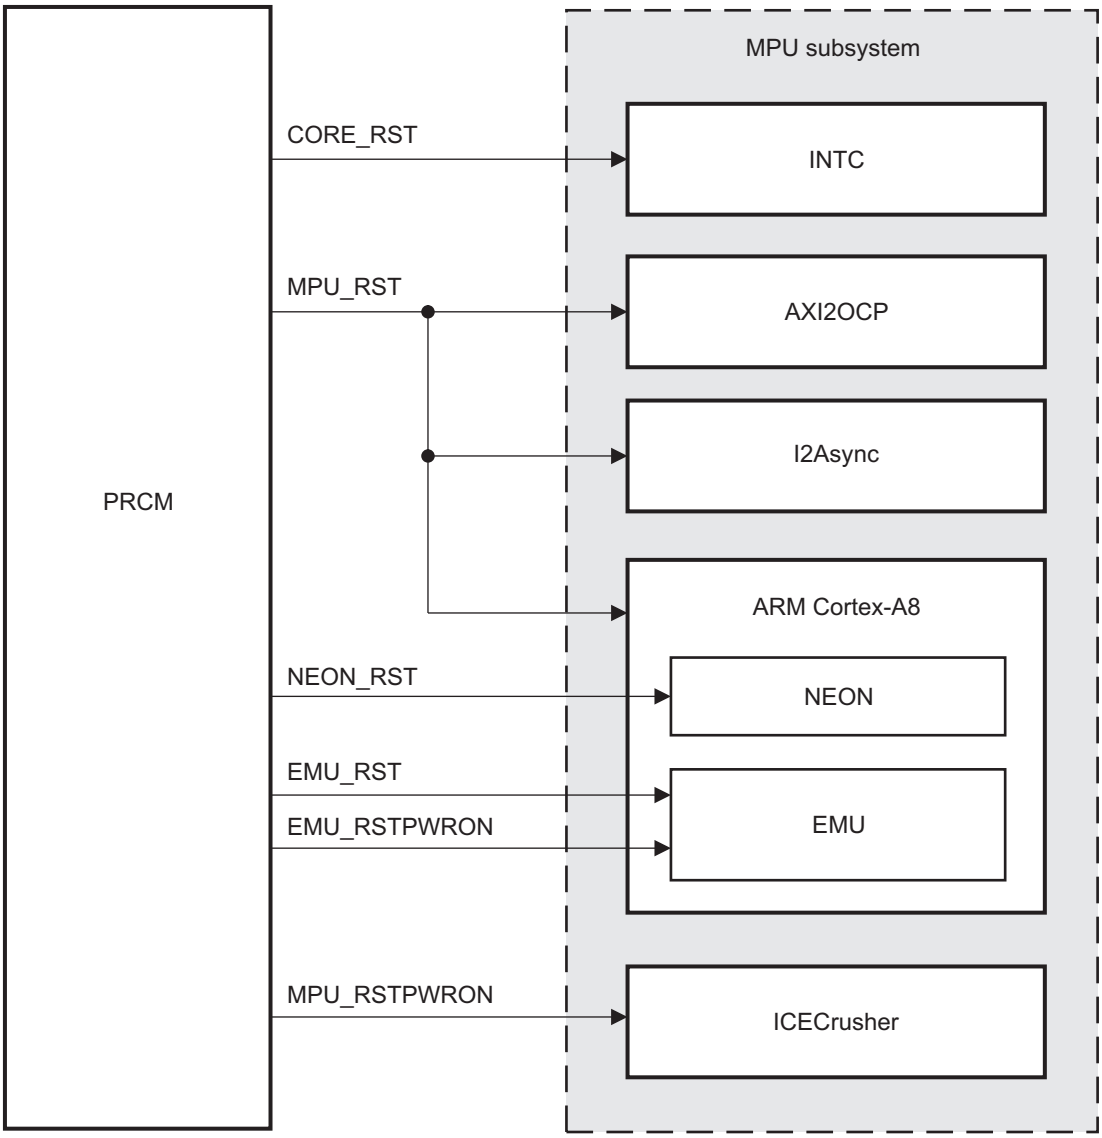

Table 1-3. Reset Scheme of the MPU Subsystem

Signal Name	I/O	Interface
MPU_RST	I	PRCM
NEON_RST	I	PRCM
CORE_RST	I	PRCM
MPU_RSTPWRON	I	PRCM
EMU_RST	I	PRCM
EMU_RSTPWRON	I	PRCM

1.2.5 ARM Subchip

1.2.5.1 ARM Overview

The ARM Cortex-A8 processor incorporates the technologies available in the ARM® ARM7™ processor architecture. These technologies include NEON for media and signal processing and ARM® Jazelle® Runtime Compilation Target (RCT) for acceleration of realtime compilers, ARM® Thumb®-2 technology for code density and the VFPv3 floating point architecture. For more information about the ARM Cortex-A8 processor, refer to the ARM® Cortex®-A8 Technical Reference Manual.

1.2.5.2 ARM Description

1.2.5.2.1 ARM Cortex-A8 Instruction, Data, and Private Peripheral Port

The AXI bus interface is the main interface to the ARM system bus. It performs L2 cache fills and non-cacheable accesses for both instructions and data. The AXI interface supports 128bit and 64-bit wide input and output data buses. It supports multiple outstanding requests on the AXI bus and a wide range of bus clock to core clock ratios. The bus clock is synchronous with the core clock.

For a complete programming model of the transaction rules (ordering, posting, and pipeline synchronization) that are applied depending on the memory region attribute associated with the transaction destination address, refer to the ARM® Cortex®-A8 Technical Reference Manual.

1.2.5.2.2 ARM Core Supported Features

Table 1-4 provides a list of main functions of the Cortex-A8 core supported inside the MPU Subsystem. For more information, refer to the ARM® Cortex®-A8 Technical Reference Manual.

Table 1-4. ARM Core Supported Features

Features	Comments
ARM version 7 ISA	Standard ARM instruction set + Thumb2, JazelleX Java accelerator, and Media extensions.
	Backward compatible with previous ARM ISA versions.
Cortex-A8 version	R3P2
L1 Icache and Dcache	32 KB , 4-way, 16-word line, 128-bit interface.
L2 Cache	256 KB, 8-way, 16-word line, 128-bit interface to L1. The L2 cache and cache controller are embedded within the Monza core.
	L2 valid bits cleared by software loop or by hardware.
TLB	Fully associative and separate ITLB with 32 entries and DTLB with 32 entries.
CoreSight ETM	The CoreSight ETM is embedded with the Monza core. The 32KB buffer (ETB) exists at the Chip Level (DebugSS)
Branch Target Address Cache	512 entries
Enhanced Memory Management Unit	Mapping sizes are 4KB, 64KB, 1MB, and 16MB. (Monza MMU adds extended physical address ranges)
NEON	Gives greatly enhanced throughput for media workloads and VFP-Lite support.
Flat Memories	176 Kbytes of ROM
	64 Kbytes of RAM
Buses	128-bit AXI internal bus from Cortex-A8 routed by an AXI2OCP bridge to the interrupt controller, ROM, RAM, and 3 asynchronous OCP bridges (128 bits and 64 bits)
Low interrupt latency	Closely coupled INTC to the Monza core with 128 interrupt lines
Vectored Interrupt Controller Port	Present.
JTAG based debug	Supported via DAP
Trace support	Supported via TPIU
External Coprocessor	Not supported

1.2.6 AXI2OCP and I2Async Bridges

1.2.6.1 Bridges Overview

The AXI2OCP Bridge is used to connect the AXI bus on the ARM A8 to the OCP native L3 interconnect (64-bit width), EMIF OCP port (128-bit width), and interrupt controller. It converts between AXI and OCP protocols and maintains a mapping of AXI tags to the OCP Tag ID. A memory region must be reserved for the interrupt handler. The bridge is required to do some minimal address decoding to decide where to forward the requests.

The AXI2OCP Bridge and the target modules (EMIF, L3) operate in different clock domains. The interface between the AXI2OCP Bridge and EMIF/L3 must go through an asynchronous bridge to properly synchronize signals to the opposite clock domain.

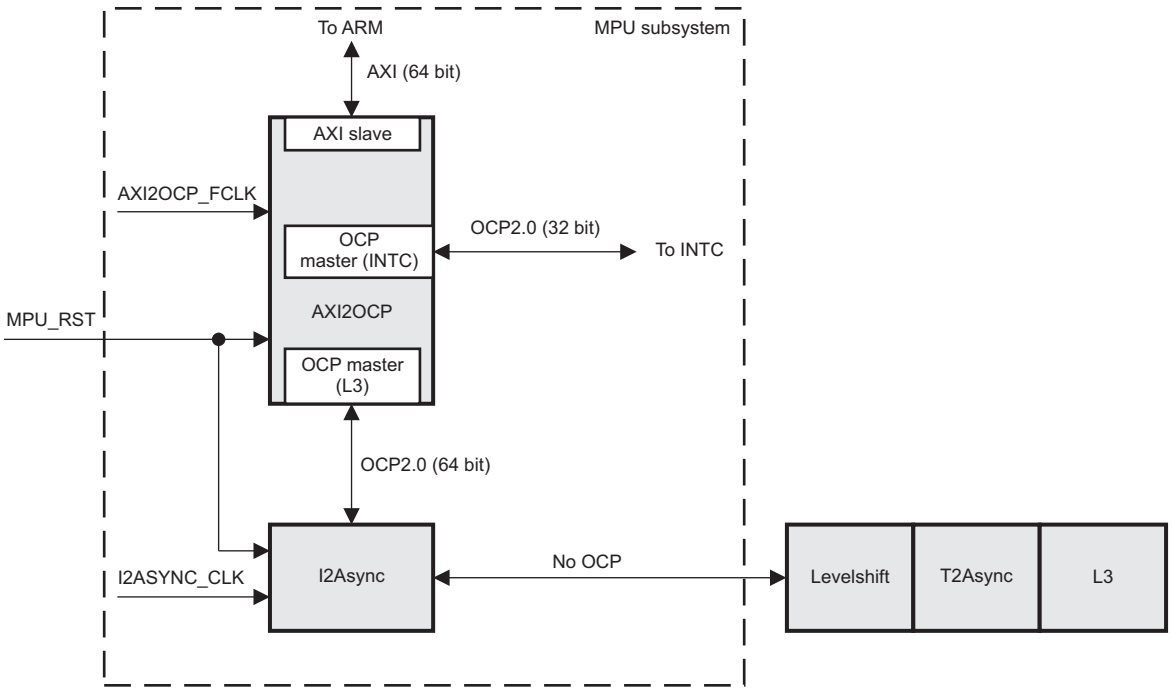
Bridging to the L3 is accomplished through an asynchronous interface involving the I2Async and T2Async modules. The I2Async module inside the MPU subsystem has an OCP port that is asynchronously transferred to the T2Async module and routed to the L3. T2Async is outside the MPU subsystem.

NOTE: The interface between I2Async and T2Async is not an OCP protocol.

1.2.6.2 Key Features

- Connects to the EMIF via a 128-bit OCP port and asynchronous bridge.
- Connects to the L3 interconnect via a 64-bit OCP port and asynchronous bridge.
- Connects to the interrupt controller via a 32-bit OCP port. (Only single transactions are supported)
- Supports Single-Request-Multiple-Data (data handshaking) burst mode to pipeline requests.
- Supports multiple outstanding requests.
- Emulation and boot-mode translation support.
- Exclusive accesses are translated to non-exclusive read/write in the bridge.

Figure 1-5. Overview of the AXI2OCP and the L3 Bridges



1.2.6.3 AXI to OCP Tag Mapping

Table 1-5 and Table 1-6 gives the Read and Write Channel AXI ID to OCP Tag Mappings

Table 1-5. Read Channel AXI ID to OCP Tag Mappings

AXI ID	Request type	OCP Thread[2]	OCP Tag	Outstanding Requests
4'b0000	NC/SO[1] data load	Thread_Mx	5'b00000	9 (one integer and up to 8 NEON)
4'b0001	Device data load	Thread_Mx	5'b00001	
4'b0011	peripheral	n/a	n/a	
4'b1110	Cacheable linefill into L1D	Thread_Mx	5'b01110	
4'b0100	NC/SO[1] instruction fetch	Thread_Mx	5'b00100	1
4'b0101	Device instruction fetch	Thread_Mx	5'b00101	
4'b1111	Linefills into L1I$ (line is L2 non-cacheable)	Thread_Mx	5'b01111	
4'b0110	NC/SO[1] Table-walk requests (instruction, data or PLE)	Thread_Mx	5'b00110	1
4'b1000	Cacheable linefills (I, D, TLB, PLE) #1, except linefill into L1D	Thread_Mx	5'b01000	1
4'b1001	Cacheable linefills (I, D, TLB, PLE) #2, except linefill into L1D	Thread_Mx	5'b01001	1
4'b1010	Cacheable linefills (I, D, TLB, PLE) #3, except linefill into L1D	Thread_Mx	5'b01010	1
4'b1011	Cacheable linefills (I, D, TLB, PLE) #4, except linefill into L1D	Thread_Mx	5'b01011	1
4'b0010	Reserved	n/a	n/a	n/a
4'b0111				
4'b1100				
4'b1101				

Table 1-6. Write Channel AXI ID to OCP Tag Mappings

AXI ID	Request type	OCP Thread[2]	OCP Tag	Outstanding Requests
4'b0000	NC/SO[1], or WT stores	Thread_Mx	5'b10000	Up to 8
4'b0001	Device writes	Thread_Mx	5'b10001	
4'b0011	Peripheral write	n/a	n/a	
4'b1000	Eviction #1 (including PLE)	Thread_Mx	5'b11000	1
4'b1001	Eviction #2 (including PLE)	Thread_Mx	5'b11001	1
4'b1010	Eviction #3 (including PLE)	Thread_Mx	5'b11010	1
4'b1011	Eviction #4 (including PLE)	Thread_Mx	5'b11011	1
4'b0010	Reserved	n/a	n/a	n/a
4'b0100				
4'b0101				
4'b0110				
4'b0111

4'b1101				
4'b1110				
4'b1111				

1.2.7 Interrupt Controller

The Host ARM Interrupt Controller (AINTC) is responsible for prioritizing all service requests from the system peripherals and generating either nIRQ or nFIQ to the host. The type of the interrupt (nIRQ or nFIQ) and the priority of the interrupt inputs are programmable. The AINTC interfaces to the Monza processor via the AXI port through an AXI2OCP bridge and runs at half the processor speed. The AINTC handles the interrupts directed to the HASS. It has the capability to handle up to 128 requests which can be steered/prioritized as A8 nFIQ or nIRQ interrupt requests.

The general features of the AINTC are:

- Up to 128 level sensitive interrupts inputs
- Individual priority for each interrupt input
- Each interrupt can be steered to nFIQ or nIRQ
- Independent priority sorting for nFIQ and nIRQ

1.2.8 Power Management

1.2.8.1 Power Domains

The MPU subsystem is divided into 5 power domains controlled by the PRCM module, as shown in Figure 1-6.

NOTE: The emulation domain and the core domain are not fully embedded in MPU subsystem.

Power management requirements at the device level govern power domains for the MPU subsystem. The device-level power domains are directly aligned with voltage domains and thus can be represented as a cross reference to the different voltage domains.

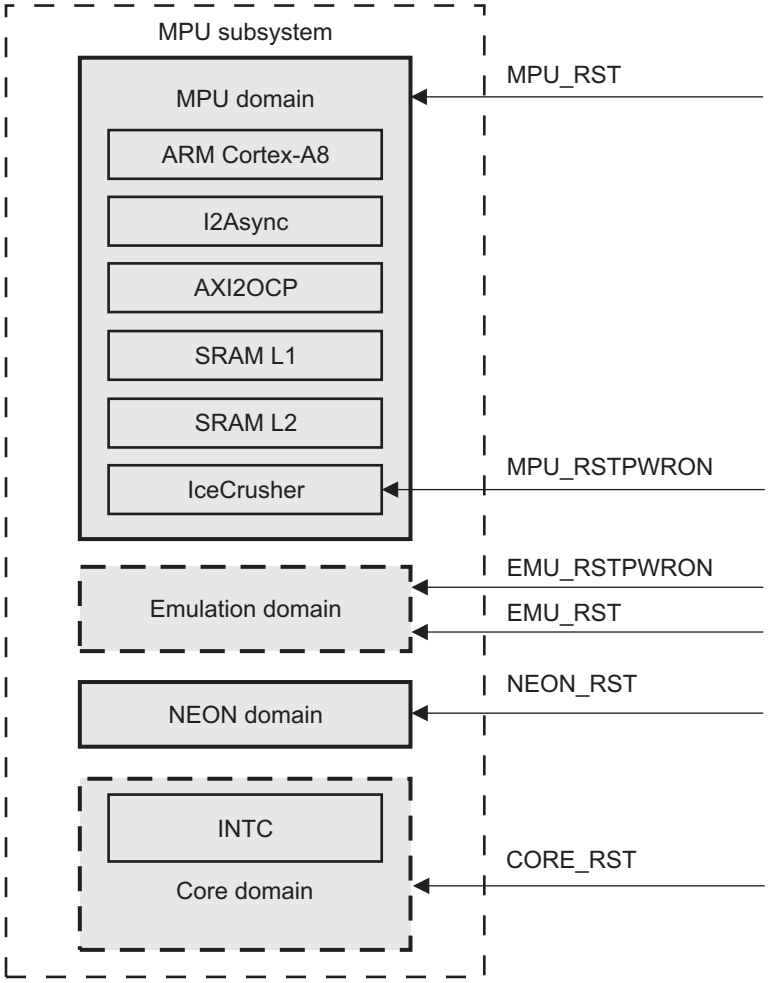
Table 1-7 shows the different power domains of the MPU subsystem and the modules inside.

Table 1-7. Overview of the MPU Subsystem Power Domain

Functional Power Domain	Physical Power Domain per System/Module
MPU subsystem domain	ARM, AXI2OCP, I2Asynch Bridge, ARM L1 and L2 periphery logic and array, ICE-Crusher, ETM, APB modules
MPU NEON domain	ARM NEON accelerator
CORE domain	MPU interrupt controller
EMU domain	EMU (ETB,DAP)

NOTE: L1 and L2 array memories have separate control signals into the in MPU Subsystem, thus directly controlled by the PRCM module. For details on the physical power domains and the voltage domains, see the *Power, Reset, and Clock Management (PRCM) Module* chapter.

Figure 1-6. MPU Subsystem Power Domain Overview



1.2.8.2 Power States

Each power domain can be driven by the PRCM module in 4 different states, depending on the functional mode required.

For each power domain, the PRCM module manages all transitions by controlling domain clocks, domain resets, domain logic power switches and memory power switches.

Table 1-8. MPU Power States

Power State	Logic Power	Memory Power	Clocks
Active	On	On or Off	On (at least one clock)
Inactive	On	On or Off	Off
Off	Off	Off	Off (all clocks)

1.2.8.3 Power Modes

The major part of the MPU subsystem belongs to the MPU power domain. The modules inside this power domain can be off at a time when the ARM processor is in an OFF or standby mode. IDLE/WAKEUP control is managed by the clock generator block but initiated by the PRCM module.

The MPU Standby status can be checked with PRCM.CM_IDLEST_MPU[0] ST_MPU bit. For the MPU to be on, the core (referred here as the device core) power must be on. Device power management does not allow INTC to go to OFF state when MPU domain is on (active or one of retention modes).

The NEON core has independent power off mode when not in use. Enabling and disabling of NEON can be controlled by software.

CAUTION

The MPU L1 cache memory does not support retention mode, and its array switch is controlled together with the MPU logic. For compliance, the L1 retention control signals exist at the PRCM module boundary, but are not used. The ARM L2 can be put into retention independently of the other domains.

Table 1-9 outlines the supported operational power modes. All other combinations are illegal. The ARM L2, NEON, and ETM/Debug can be powered up/down independently. The APB/ATB ETM/Debug column refers to all three features: ARM emulation, trace, and debug.

The MPU subsystem must be in a power mode where the MPU power domain, NEON power domain, debug power domain, and INTC power domain are in standby, or off state.

Table 1-9. MPU Subsystem Operation Power Modes

Mode	MPU and ARM Core Logic	AMR L2 RAM	NEON INTC	Device Core and ETM	APB/ATB Debug
1	Active	Active	Active	Active	Disabled or enabled
2	Active	Active	OFF	Active	Disabled or enabled
3	Active	RET	Active	Active	Disabled or enabled
4	Active	RET	OFF	Active	Disabled or enabled
5	Active	OFF	Active	Active	Disabled or enabled
6	Active	OFF	OFF	Active	Disabled or enabled
7	OFF	RET	OFF	OFF	Disabled or enabled
8	Standby	Active	Standby	Active	Disabled or enabled
9	Standby	Active	OFF	Active	Disabled or enabled
10	Standby	RET	Standby	Active	Disabled or enabled
11	Standby	RET	OFF	Active	Disabled or enabled
12	Standby	OFF	Standby	Active	Disabled or enabled
13	Standby	OFF	OFF	Active	Disabled or enabled
14	OFF	OFF	OFF	OFF	Disabled or enabled

1.2.9 Host ARM Address Map

Table 1-10. Address Map of the MPU Subsystem

Region	Address Range	Size
Internal Memory (Access not routed to external OCP ports)		
Reserved	0x4000_0000 – 0x4001_FFFF	1MB
ROM (48 KB)	0x4002_0000 – 0x4002_BFFF	
Reserved	0x4002_C000 – 0x400F_FFFF	
Reserved	0x4020_0000 – 0x402E_FFFF	1MB
SRAM (64 KB)	0x402F_0000 – 0x402F_FFFF	
Internal Reserved (Audio Back-End port not implemented on device HASS)		
Reserved	0x4010_0000 – 0x401F_FFFF	1MB
Private Peripheral Map (Access not routed to external OCP ports)		
ARM Interrupt Controller (AINTC)	0x4820_0000 – 0x4820_0FFF	4KB
Reserved	0x4820_1000 – 0x4827_FFFF	508KB
Reserved	0x4828_1000 – 0x482F_FFFF	508KB
128-bit OCP Master Port 0 (to EMIFs via DMM)		
EMIF0 / EMIF1 CS0	0x8000_0000 – 0xBFFF_FFFF	1GB
Reserved (EMIF0 / EMIF1 CS1)	0xC000_0000 – 0xFFFF_FFFF	1GB
64-bit OCP Master Port 1 (to L3)		
Boot Space [1]	0x0000_0000 – 0x00FF_FFFF	1MB
L3	0x0000_0000 – 0x5FFF_FFFF	(1.5GB – 1MB)
Tiler	0x6000_0000 – 0x7FFF_FFFF	256MB

1.2.10 ARM Programming Model

For detailed descriptions of registers used for MPU configuration, see the *Power, Reset, and Clock Management (PRCM) Module* and the *ARM Interrupt Controller (AINTC)* chapters.

1.2.10.1 Clock Control

For clock configuration settings, see the *Power, Reset, and Clock Management (PRCM) Module* chapter

1.2.10.2 MPU Power Mode Transitions

The following subsections describe transitions of different power modes for MPU power domain:

- Basic power on reset
- MPU into standby mode
- MPU out of standby mode
- MPU power on from a powered off state

1.2.10.2.1 Basic Power-On Reset

The power on reset follows the following sequence of operation and is applicable to initial power-up and wakeup from device off mode.

1. Reset the INTC (CORE_RST) and the MPU subsystem modules (MPU_RST). The clocks must be active during the MPU reset and CORE reset.

1.2.10.2.2 MPU Into Standby Mode

The MPU into standby mode follows the following sequence of operation and is applicable to initial power-up and wakeup from device Off mode.

1. The ARM core initiates entering into standby via software only (CP15 - WFI).
2. MPU modules requested internally of MPU subsystem to enter idle, after ARM core standby detected.
3. MPU is in standby output asserted for the PRCM module (all outputs guaranteed to be at reset values).
4. PRCM module can now request INTC to enter into idle mode. Acknowledge from INTC goes to the PRCM module .

NOTE: The INTC SWAKEUP output is a pure hardware signal to PRCM module for the status of its IDLE request and IDLE acknowledge handshake.

NOTE: In debug mode, ICE-Crusher could prevent MPU subsystem from entering into IDLE mode.

1.2.10.2.3 MPU Out Of Standby Mode

The MPU out of standby mode follows the following sequence of operation and is applicable to initial power-up and wakeup from device Off mode.

1. PRCM module must start clocks through DPLL programming.
2. Detect active clocking via status output of DPLL.
3. Initiate an interrupt through the INTC to wake up the ARM core from STANDBYWFI mode.

1.2.10.2.4 MPU Power-On From a Powered-Off State

1. MPU Power On, NEON Power On, Core Power On (INTC) should follow the ordered sequence per power switch daisy chain to minimize the peaking of current during power-up.

   NOTE: The core domain must be on, and reset, before the MPU can be reset.

2. Follow the reset sequence as described in the Basic Power-On Reset section.

1.2.10.3 NEON Power Mode Transition

When NEON power domain transition is configured to Automatic Hardware-supervised mode (CM_CLKSTCTRL_NEON[1:0] CLKTRCTRL_NEON bits are set to 0x3), it can not transition into idle unless MPU goes into Standby, because of the Hardware Sleep dependency between NEON and the MPU domain.

In that case, the MPU domain must also be configured in Automatic Hardware Supervised mode (CM_CLKSTCTRL_MPU[1:0] CLKTRCTRL_MPU bits must be set to 0x3) for the NEON power domain transition to happen.

For a complete programming model and more information about the ARM Cortex-A8 processor, refer to the ARM® Cortex®-A8 Technical Reference Manual.

1.3 C674x DSP Subsystem

1.3.1 Introduction

The DSP subsystem (Figure 1-7) includes TI's standard TMS320C674x megamodule and several blocks of internal memory (L1P, L1D, and L2). The DSP subsystem provides one slave port and one master port, which are connected to the L3 interconnect. It also provides three master ports for direct access to the HDVICP2 subsystem (the HDVICP2 and HDVICP2 SL2 ports). This section provides an overview of the DSP subsystem and the following considerations associated with it:

- Memory mapping
- Interrupts
- Power management

The internal architecture is an assembly of the following components:

- High-performance DSP derivative integrated in a megamodule, including local level 1 (L1) and level 2 (L2) cache and memory controllers for audio processing and general-purpose imaging and video processing
- L1 and L2 shared cache
- Dedicated enhanced data memory access (EDMA) engine to download/upload data from/to memories and peripherals external to the subchip
- Dedicated memory management unit (MMU) for accessing level 3 (L3) interconnect address space
- Local interconnect network
- Dedicated SYSC and wake-up generator (WUGEN) modules responsible for power management, clock generation, and connection to the power, reset, and clock management (PRCM) module

For more information, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5), the *TMS320C674x DSP CPU and Instruction Set Reference Guide* (SPRUFE8), and the *TMS320C674x DSP Cache User's Guide* (SPRUG82).

1.3.2 C674x DSP Features and Options

The C6000 devices execute up to eight 32-bit instructions per cycle. The C674x CPU consists of 64 general-purpose 32-bit registers and eight functional units. These eight functional units contain:

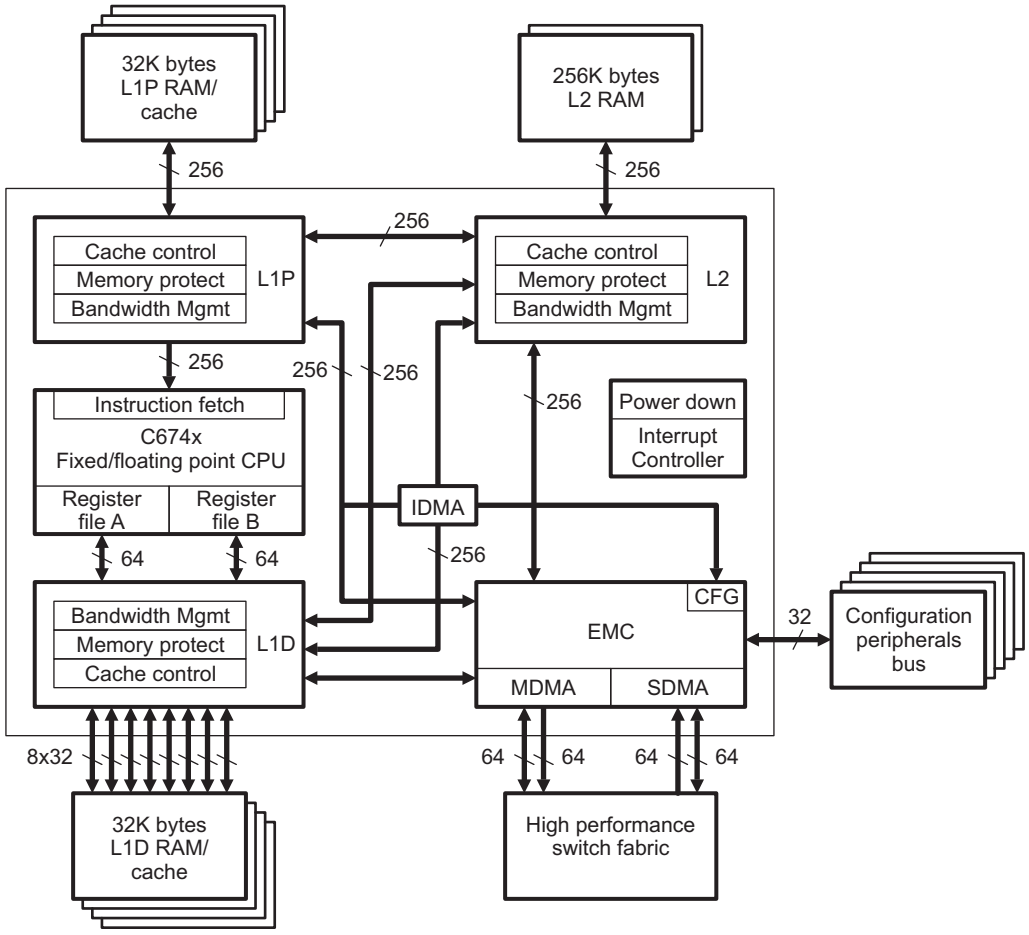
- Two multipliers
- Six ALUs

The C6000 generation has a complete set of optimized development tools, including an efficient C compiler, an assembly optimizer for simplified assembly-language programming and scheduling, and a Windows® operating system-based debugger interface for visibility into source code execution characteristics. A hardware emulation board, compatible with the TI XDS510™ and XDS560™ emulator interface, is also available. This tool complies with IEEE Standard 1149.1-1990, IEEE Standard Test Access Port and Boundary-Scan Architecture.

Features of the C6000 devices include:

- Advanced VLIW CPU with eight functional units, including two multipliers and six arithmetic units
  - Executes up to eight instructions per cycle for up to ten times the performance of typical DSPs
  - Allows designers to develop highly effective RISC-like code for fast development time
- Instruction packing
  - Gives code size equivalence for eight instructions executed serially or in parallel
  - Reduces code size, program fetches, and power consumption

Figure 1-7. TMS320C674x Megamodule Block Diagram



- Conditional execution of most instructions
  - Reduces costly branching
  - Increases parallelism for higher sustained performance
- Efficient code execution on independent functional units
  - Industry's most efficient C compiler on DSP benchmark suite
  - Industry's first assembly optimizer for fast development and improved parallelization
- 8/16/32-bit data support, providing efficient memory support for a variety of applications
- 40-bit arithmetic options add extra precision for vocoders and other computationally intensive applications
- Saturation and normalization provide support for key arithmetic operations
- Field manipulation and instruction extract, set, clear, and bit counting support common operation found in control and data manipulation applications.

The C674x devices include these additional features:

- Each multiplier can perform two 16 × 16-bit or four 8 × 8 bit multiplies every clock cycle.
- Quad 8-bit and dual 16-bit instruction set extensions with data flow support
- Support for non-aligned 32-bit (word) and 64-bit (double word) memory accesses
- Special communication-specific instructions have been added to address common operations in error-correcting codes.
- Bit count and rotate hardware extends support for bit-level algorithms.
- Compact instructions: Common instructions (AND, ADD, LD, MPY) have 16-bit versions to reduce code size.
- Protected mode operation: A two-level system of privileged program execution to support higher capability operating systems and system features such as memory protection.
- Exceptions support for error detection and program redirection to provide robust code execution
- Hardware support for modulo loop operation to reduce code size
- Each multiplier can perform 32 × 32 bit multiplies
- Additional instructions to support complex multiplies allowing up to eight 16-bit multiply/add/subtracts per clock cycle
- SPLOOP; hardware buffer for implementing hardware controlled pipelining. Resulting in smaller code size and interruptible tight loop for improved determinism.

The C674x devices are enhanced for code size improvement and floating-point performance. These additional features include:

- Hardware support for single-precision (32-bit) and double-precision (64-bit) IEEE floating-point operations.
- Execute packets can span fetch packets.
- Register file size is increased to 64 registers (32 in each datapath).
- Floating-point addition and subtraction capability in the .S unit.
- Mixed-precision multiply instructions.
- 32 × 32-bit integer multiply with 32-bit or 64-bit result.

The VelociTI architecture of the C6000 platform of devices make them the first off-the-shelf DSPs to use advanced VLIW to achieve high performance through increased instruction-level parallelism. A traditional VLIW architecture consists of multiple execution units running in parallel, performing multiple instructions during a single clock cycle. Parallelism is the key to extremely high performance, taking these DSPs well beyond the performance capabilities of traditional superscalar designs. VelociTI is a highly deterministic architecture, having few restrictions on how or when instructions are fetched, executed, or stored. It is this architectural flexibility that is key to the breakthrough efficiency levels of the TMS320C6000 Optimizing compiler. VelociTI's advanced features include:

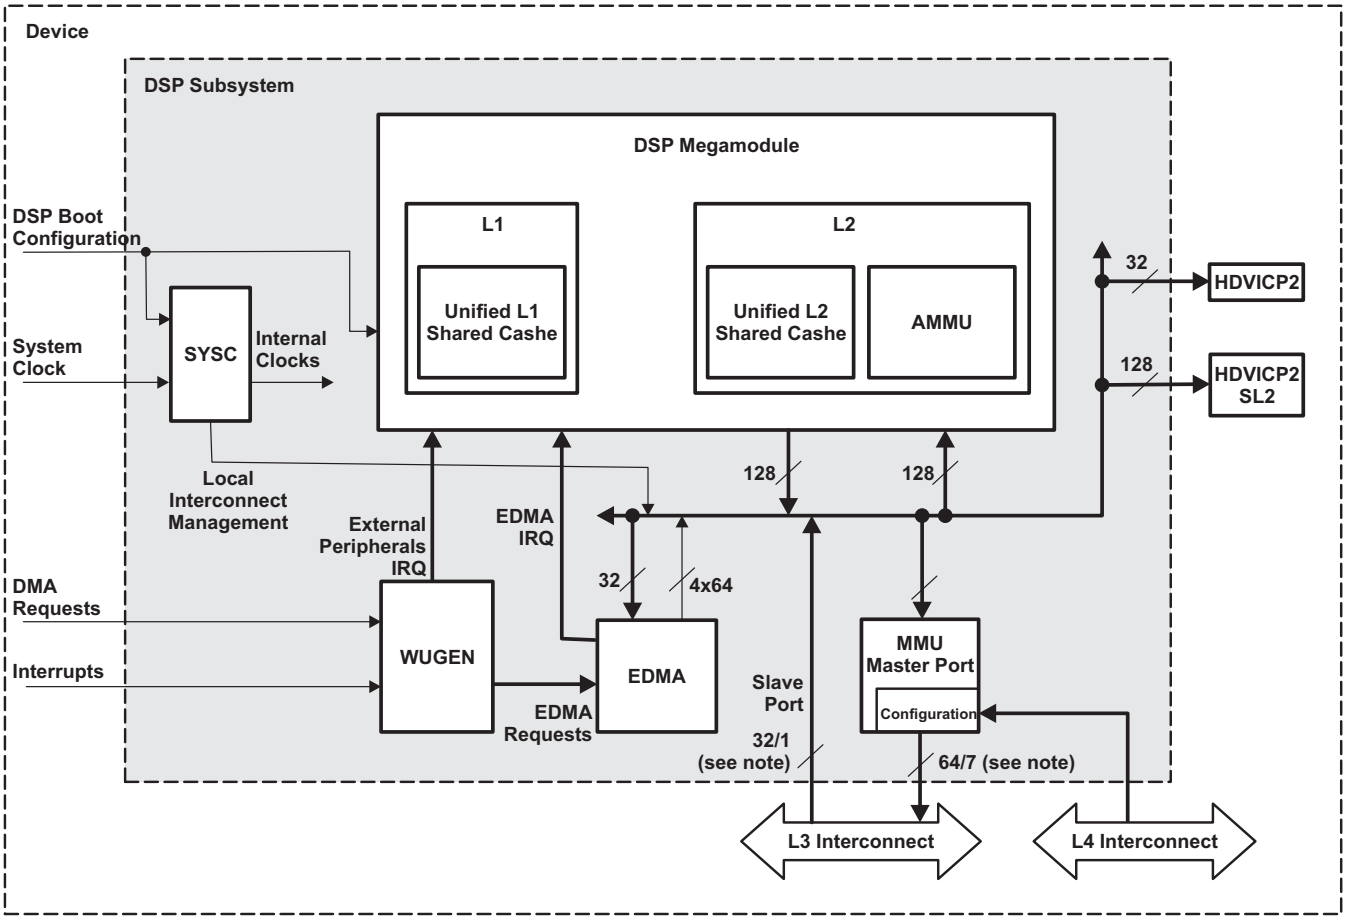
- Instruction packing: reduced code size
- All instructions can operate conditionally: flexibility of code
- Variable-width instructions: flexibility of data types
- Fully pipelined branches: zero-overhead branching.

1.3.3 DSP Subsystem Functional Description

The DSP subsystem is composed of a DSP megamodule coupled with several submodules that enable its integration in the device architecture. The DSP subsystem provides one slave port and one master port, which are connected to the L3 interconnect. It also provides three master ports for direct access to the HDVICP2 subsystem (the HDVICP2 SL2 ports).

Figure 1-8 shows the block diagram of the DSP subsystem.

Figure 1-8. DSP Subsystem Block Diagram



1.3.4 TMS320C674x Megamodule

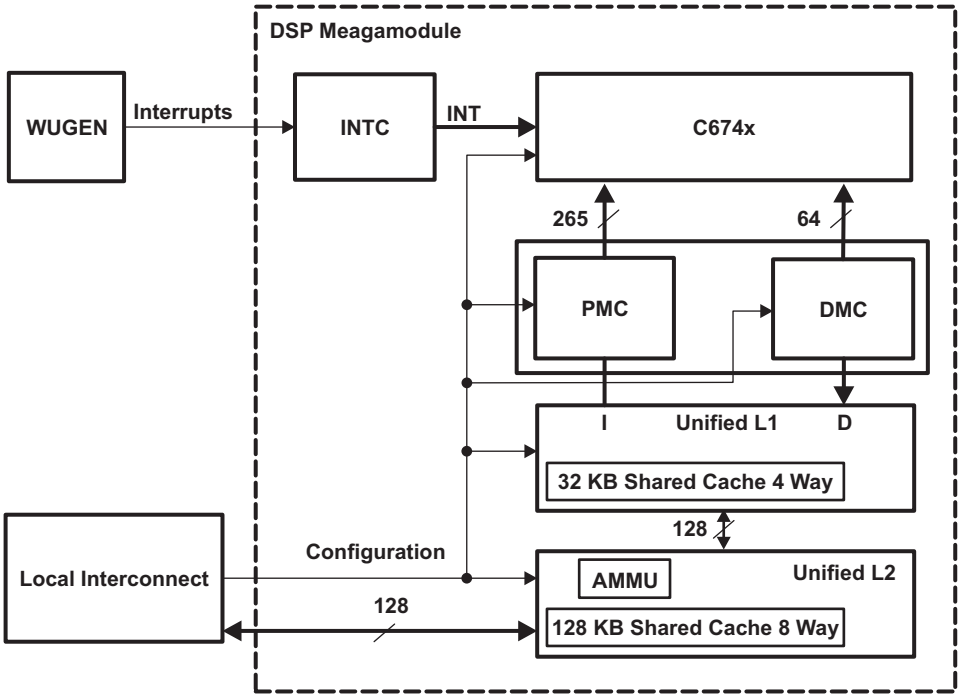
The C674x megamodule (Figure 1-7) consists of the following components:

- TMS320C674x CPU
- Internal memory controllers:
  - L1 program memory controller (PMC)
  - L1 data memory controller (DMC)
  - L1/L2 unified caches
- Internal peripherals:
  - Internal direct memory access (IDMA) controller
  - Interrupt controller (INTC)
  - Power-down controller (PDC)
  - Bandwidth manager (BWM)

- Advanced event triggering (AET)

Figure 1-9 shows a block diagram of the DSP megamodule.

Figure 1-9. TMS320C674x Megamodule Block Diagram



1.3.4.1 L1 Program Memory Controller (PMC)

The PMC delivers program fetch packets when they are requested by the DSP core. The PMC supports the following features:

- One 256-bit fetch packet per cycle (sustainable)
- DMA transfer from/to L1/L2 caches
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Block and global program-initiated cache coherence support (invalidate)
- Freeze mode

1.3.4.2 L1 Data Memory Controller (DMC)

The DMC reads or writes data from/to local memories, as requested by the DSP. The DMC supports the following features:

- One 64-bit memory access per cycle (sustainable)
- A memory access pair can be any combination of read and write, with no incurred penalty
- DMA transfer from/to L1/L2 caches
- Fair priority-based arbitration between the DSP, DMA, and cache controller for access to the SRAM
- Hardware coherence maintenance with L2 (snooping)
- Block and global program-initiated cache coherence support (write-back, invalidate, and write-back-invalidate)
- Freeze and bypass mode

1.3.4.3 Unified L1/L2 Cache

The following features are supported by the shared cache design:

- 32-KB L1 unified cache implemented with high-performance bit cell to run at full speed
- 128-KB L2 unified cache implemented with high-density bit cell to optimize area at half speed
- L1 cache is 32B line size, 4-way set-associative and organized as 16-bank
- L2 cache is 32B line size and 8-way set associative
- L1 cache supports snooping
- L2 cache slave port to support snooping from EDMA accesses
- Fully pipelined/supports critical-word-first
- Write-combining
- Fill and eviction buffers, and hit in fill buffer
- Dynamic sizing, I/D allocation
- Prefetch 4 lines/preload N lines
- Background preload/clean

1.3.4.4 Internal DMA (IDMA) Controller

The IDMA controller performs fast block transfers between any two memory locations local to the C674x megamodule. Local memory locations are defined as those in Level 1 program (L1P), Level 1 data (L1D), and Level 2 (L2) memories, or in the external peripheral configuration (CFG) memory. The IDMA cannot transfer data to or from the internal MMR space. The IDMA is fully described in the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

1.3.4.5 Attribute MMU

The attribute MMU (AMMU) for the shared cache provides the multi-access cache with a region-based address translation, read/write control, access type control, endiannism, and multilevel cache maintenance. The MMU is directly connected to the shared cache, and there is a dedicated interface for pipeline write policy management. L1 policies are queried at the allocation control of the cache, and L2 policies are propagated to the master interface. For flexibility, the MMU can be dedicated to an L1 or an L2 cache configuration, with or without address translation, or as an L1/L2 cache combination.

The AMMU supports different page sizes: large, medium, and small. The number of large pages, number of medium pages, and so on, is defined at design time. The maximum number of large pages is eight. This address space includes addresses for all eight regions. However, if the DSP subsystem defines only five large pages, only the first five addresses are valid.

1.3.4.6 Interrupt Controller (INTC)

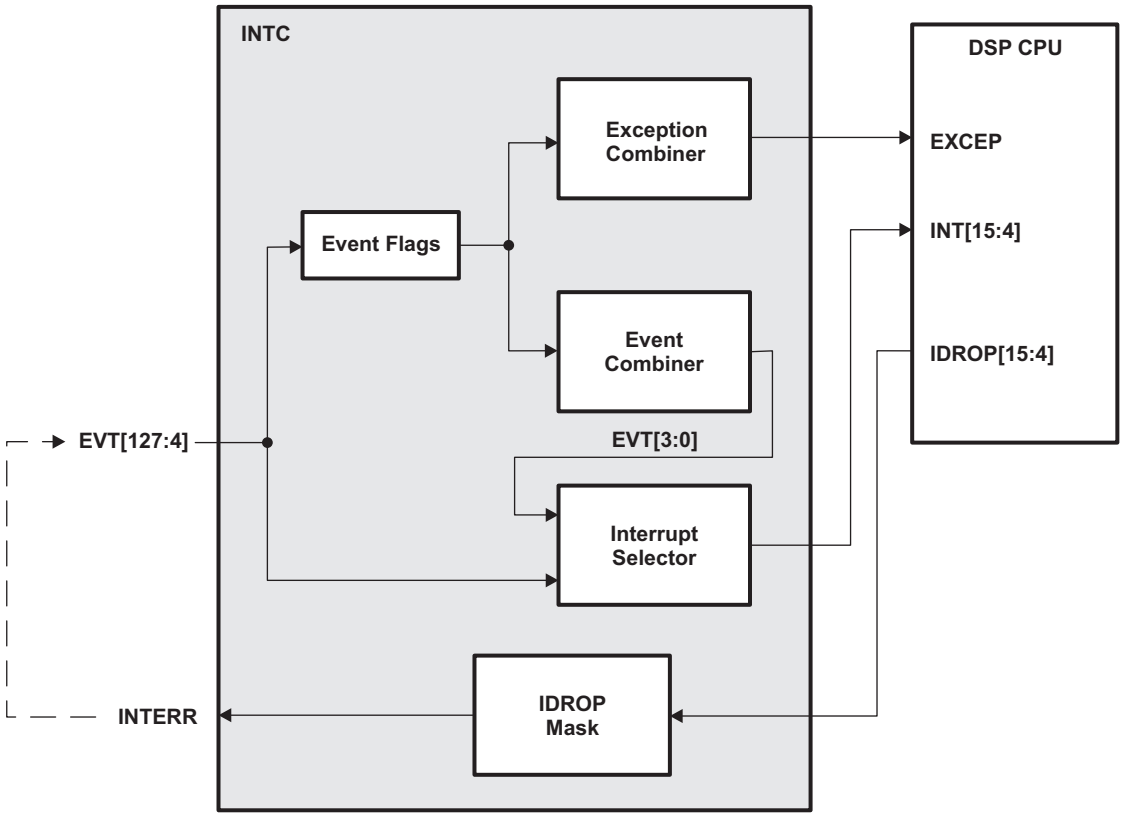
The DSP megamodule INTC detects, potentially combines, and routes up to 128 system events (internal and external) to the DSP CPU interrupt lines.

The DSP CPU has 12 maskable interrupts and one exception input. The INTC includes an interrupt selector, exception combiner, and event combiner. The interrupt selector allows the routing of any of the 128 system events (or a combination of them) to the 12 maskable interrupts of the DSP CPU, and software determines the priorities of those system events. To handle potential conflicts, the 12 CPU interrupts have fixed priorities. The exception combiner allows the combination of any of the 128 system events to the single exception input of the DSP CPU.

Figure 1-10 shows a block diagram of the DSP INTC megamodule.

For more information on the INTC, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

Figure 1-10. DSP Megamodule INTC Block Diagram



1.3.4.6.1 NMI Interrupt

In addition to the 128 interrupts, the DSP also supports a special interrupt that behaves more like an exception, non-maskable interrupt (NMI). The NMI interrupt is controlled by two registers in the System Configuration Module, the chip signal register (CHIPSIG) and the chip signal clear register (CHIPSIG_CLR).

The NMI interrupt is asserted by writing a 1 to the CHIPSIG4 bit in CHIPSIG. The NMI interrupt is cleared by writing a 1 to the CHIPSIG4 bit in CHIPSIG_CLR.

1.3.4.7 Power-Down Controller (PDC)

The C674x megamodule includes a power-down controller (PDC). The PDC can power-down all of the following components of the C674x megamodule and internal memories of the DSP subsystem:

- C674x CPU
- Program memory controller (PMC)
- Data memory controller (DMC)
- Unified memory controller (UMC)
- Extended memory controller (EMC)
- Internal Direct Memory Access controller (IDMA)
- L1P memory
- L1D memory
- L2 memory

This device supports the static power-down feature from the C674x megamodule. The *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5) describes the power-down control in more detail.

- Static power-down: The PDC initiates power-down (clock gating) of the entire C674x megamodule and all internal memories immediately upon command from software.

Static power-down (clock gating) affects all components of the C674x megamodule and all internal memories. Software can initiate static power-down by way of a register bit in the power-down controller command register (PDCCMD) of the PDC. For more information on the PDC, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

1.3.4.8 Bandwidth Manager (BWM)

The bandwidth manager (BWM) provides a programmable interface for optimizing bandwidth among the requesters for resources, which include the following:

- EDMA-initiated DMA transfers (and resulting coherency operations)
- IDMA-initiated transfers (and resulting coherency operations)
- Programmable cache coherency operations
  - Block based coherency operations
  - Global coherency operations
- CPU direct-initiated transfers
  - Data access (load/store)
  - Program access

The resources include the following:

- L1P memory
- L1D memory
- L2 memory
- Resources outside of the C674x megamodule: external memory, on-chip peripherals, registers

Since any given requestor could potentially block a resource for extended periods of time, the bandwidth manager is implemented to assure fairness for all requesters.

The bandwidth manager implements a weighted-priority-driven bandwidth allocation. Each requestor (EDMA, IDMA, CPU, etc.) is assigned a priority level on a per-transfer basis. The programmable priority level has a single meaning throughout the system. There are a total of nine priority levels, where priority zero is the highest priority and priority eight is the lowest priority. When requests for a single resource contend, access is granted to the highest-priority requestor. When the contention occurs for multiple successive cycles, a contention counter assures that the lower-priority requestor gets access to the resource every 1 out of *n* arbitration cycles, where *n* is programmable. A priority level of -1 represents a transfer whose priority has been increased due to expiration of the contention counter or a transfer that is fixed as the highest-priority transfer to a given resource.

1.3.5 Advanced Event Triggering (AET)

The C674x megamodule supports advanced event triggering (AET). This capability can be used to debug complex problems as well as understand performance characteristics of user applications. AET provides the following capabilities:

- Hardware Program Breakpoints: specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture.
- Data Watchpoints: specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture.
- Counters: count the occurrence of an event or cycles for performance monitoring.
- State Sequencing: allows combinations of hardware program breakpoints and data watchpoints to precisely generate events for complex sequences.

1.4 HD Video Coprocessor Subsystem

1.4.1 HDVICP2 Overview

The HDVICP2 is the image and video imaging hardware accelerator subsystem.

The HDVICP2 supports resolutions up to 1080 p/i with full performance of 60 fps (or 120 fields). The HDVICP2 subsystem supports the following codec standards natively; that is, all functions of standards are accelerated (without any intervention of the digital signal processor):

- H.264: BP/MP/HP Encode and Decode
- H.264: Fast Profile/RCDO Encode and Decode
- MPEG-4: SP/ASP Encode/Decode (No support for GMC)
- DivX 5.x & higher Encode/Decode (No lower version; for example, 3.11 and 4.x)
- H.263: Profile 0 and 3 for Decode, Profile 0 for Encode
- Sorenson Spark: V0 and V1 Decode (No encode support)
- MPEG-2 SP/MP Encode/Decode
- MPEG-1 Encode/Decode
- VC1/WMV9/RTV : SP/MP/AP Encode and Decode
- ON2 VP6/VP7 Decode
- RV 8/9/10 Decode
- AVS 1.0 Encode and Decode
- JPEG (also MJPEG) Baseline Encode/Decode
- H264 Annex H (MVC)

The HDVICP2 subsystem is composed of:

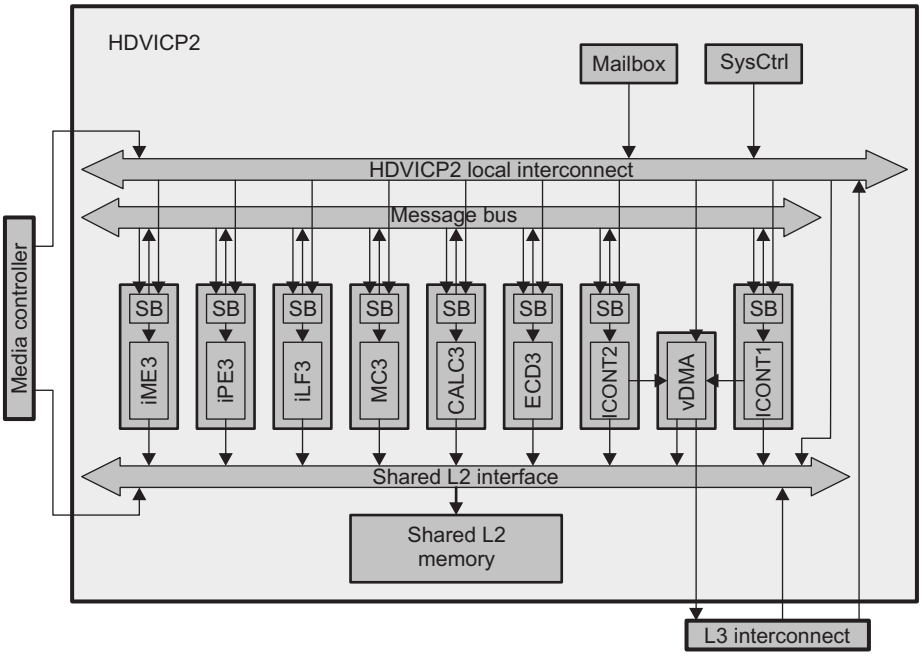
- A primary and a secondary sequencer: ICONT1 & ICONT2, which include its memories and an interrupt controller. Both these sequencers, ICONT1 and ICONT2, are identical.
- A video DMA engine: vDMA
- An entropy coder/decoder: ECD3
- A motion compensation engine: MC3
- A transform and quantization calculation engine: CALC3
- A loop filter acceleration engine: iLF3
- A motion estimation acceleration engine: iME3
- An intraprediction estimation engine: iPE3
- Shared level 2 (L2) interface and memory (of size 256 Kbytes)
- Local interconnect
- A message interface for communication between SyncBoxes
- Mailbox
- A debug module for trace event and software instrumentation: SMSET

TI has chosen eXpress DSP Digital Media (xDM) standard as the principle software interface to HDVICP2. The xDM standard defines application programming interfaces (APIs) through which an application invokes a particular class of codec, such as video, imaging, speech, and audio (aka VISA). The video and imaging classes for encode and decode apply to HDVICP2.

1.4.1.1 HDVICP2 Functional Description

Figure 1-11 shows the block diagram of the HDVICP2 subsystem.

Figure 1-11. HDVICP2 Block Diagram



1.4.1.2 SyncBox

The SyncBox is a configurable module that is in charge of scheduling all embedded hardware modules within the HDVICP2 subsystem. It handles all aspects of synchronization, data sharing, and parameters passing between accelerators. It also offers the possibilities to use asynchronous messages.

1.4.2 ICONTs

The ICONT module is an ARM968E-S based microcontroller with 32KB of instruction tightly coupled memory (TCM) and 16KB of data tightly coupled memory. It includes an interrupt controller (INTC), a local data mover, its own SyncBox module for synchronizing tasks with other modules and its associated SyncBox handler.

Two identical instances of the ICONT, ICONT1 and ICONT2, are present in the HDVICP2 subsystem. They can typically be used to perform high-level processing (at frame and slice level), control at macroblock-level bounding box computation and other vDMA processing tasks.

Software can map processing equally on either ICONT.

1.4.3 vDMA

The vDMA is a DMA engine to perform data transfer between external memories and shared L2 memory. The VDMA can also perform memory copies inside SL2 and inside external memory.

1.4.4 iME3

The iME3 accelerator is used to perform motion estimation for Video encoding. iME3 has its own embedded SyncBox module for synchronizing tasks with other modules.

The iME3 compares a current macroblock to a reference area and provides an area in the reference region (in terms of offsets) which is least different to the current macroblock. It can also interpolate a block with half or quarter pixel precision, thus producing 4 (half pixel) or 16 (quarter pixel) interpolated blocks from the original block. Additionally, the IME3 supports searching of the best matching block within the interpolated planes.

1.4.5 iPE3

The iPE3 accelerator is used to perform the intraprediction estimation for video encoding. The iPE3 has its own embedded SyncBox module for synchronizing tasks with other modules and an LSE to transfer data from internal memories to shared L2 memory.

The iPE3 supports two modes, depending on the video standard:

- Spatial intraprediction estimation for H264 and AVS. It creates intraprediction macroblocks with given intramodes from the original macroblock and provides a cost estimation between the original macroblock and each pseudo intraprediction macroblock, and then chooses a mode with the smallest cost to recommend it as an optimal intraprediction mode.
- Spatial activity for MPEG-1/2/4 and VC-1. It calculates the spatial activity of the original luminance samples with the specified block size. This mode is designed to provide information about the original Luma pixels. The values can be used to decide the coding parameters of the macroblock such as the coding mode and the quantization parameter.

1.4.6 MC3

The MC3 accelerator is used to perform the motion compensation. The MC3 has its own embedded SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It creates an interprediction macroblock with given motion vectors and modes from the reference data.

1.4.7 CALC3

The CALC3 accelerator is used to perform forward and inverse transform and quantization calculation. CALC3 has its own embedded SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It can perform transform/inverse transform, Q/iQ and DC/AC prediction.

1.4.8 iLF3

The iLF3 accelerator is used to perform deblocking filtering and boundary strength computation. The iLF3 has its own embedded SyncBox module for synchronizing tasks with other HWAs.

1.4.9 ECD3

The ECD3 accelerator is designed to encode and decode the stream. ECD3 has its own embedded SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It supports Huffman codes and arithmetic codes.

For encode, the ECD3 encodes the macroblock information and residual data into a bitstream. For decode, the ECD3 decodes the bitstream and recovers the macroblock information and residual data.

1.4.10 SL2 Interface

The shared L2 interface, SL2IF, is an arbitrator that allows 18 initiators to access to an interleaved set of eight memory banks.

The SL2IF has two sets of interfaces:

- Eighteen 128-bit interfaces for accesses from module's to shared L2 memories.
- Eight 128-bit memory interfaces for direct accesses to the memory banks.

1.4.11 Message Bus

The message bus is an arbitrator that allows eight initiators to access eight targets. It is used to dispatch messages generated by the SyncBox of the different IPs.

1.4.12 HDVICP2 Local Interconnect

The HDVICP2 local interconnect provides connectivity between two external host interconnects (Media Controller and L3), two local sequencers (ICONT1 and ICONT2) and video hardware accelerators (iME3, iLF3, ECD3, CALC3, MC3, iPE3), video DMA engine (vDMA), and local modules (mailbox and sysctrl).

1.4.13 MailBox

The function of the mailbox is to support a 2-way communication between two hosts through interrupts. It allows the software to establish a communication channel between processors through a set of registers and associated interrupt signals by sending and receiving messages.

The mailbox embedded inside the HDVICP2 subsystem implements a 2-way communication between three external users and one internal user. This communication is ensured through three pairs of mailboxes and four-message FIFO depth for each message queue.

NOTE: The internal user is one of the two ICONTs. ICONT1 and ICONT2 are connected on a shared interrupt line. The choice between ICONT1 and ICONT2 is done by masking mailbox interrupt on ICONT1 or ICONT2. ICONT1 and ICONT2 can access the mailbox through the HDVICP2 local interconnect.

1.4.14 HDVICP2 System Control

The SYSCTRL module of HDVICP2 is in charge of:

- Controlling clocks to the modules via software control and the hardware power handshaking state.
- Controlling power, reset, and clock management (PRCM) module power handshaking.
- Providing status of the above operation.
- Supporting synchronization through external event.

1.5 Memory Map Summary

The device has multiple on-chip memories associated with its processors and various subsystems. To help simplify software development a unified memory map is used where possible to maintain a consistent view of device resources across all bus masters.

1.5.1 L3 Memory Map

The L3 high-performance interconnect is based on a Network-on-Chip (NoC) interconnect infrastructure. The NoC uses an internal packet-based protocol for forward (read command, write command with data payload) and backward (read response with data payload, write response) transactions. All exposed interfaces of this NoC interconnect, both for targets and initiators, comply with the OCPIP2.2 reference standard.

Table 1-11 shows the general device level-3 (L3) memory map. The table represents the physical addresses used by the L3 infrastructure. Some processors within the device (such as Cortex-A8 ARM, C674x DSP) may re-map these targets to different virtual addresses through an internal or external MMU. Processors without MMUs and other bus masters use these physical addresses to access L3 regions. Note that not all masters have access to all L3 regions, but only those with defined connectivity. The L3 interconnect returns an address-hole error if any initiator attempts to access a target to which it has no connection.

DDR EMIF0/1 SDRAM(2)	C000 0000h	FFFF FFFFh	1GB	DDR
DDR DMM	1 0000 0000h	1 FFFF FFFFh	4GB	DDR DMM Tiler Extended address map – Virtual Views (HDVPSS only)

(1) These accesses occur through the DDR DMM Tiler Ports. The DMM will split address ranges internally to address DDR EMIF and DDR DMM control registers.

(2) DDR EMIF0 and DDR EMIF1 addresses may be contiguous or bank interleaved depending on configuration of the DDR DMM; for more details, see the DDR DMM documentation.

1.5.2 L4 Memory Map

1.5.2.1 L4 Standard Peripheral

The L4 standard peripheral bus accesses standard peripherals and IP configuration registers. The memory map is shown in Table 1-12.

Table 1-12. L4 Standard Peripheral Memory Map

Device Name	Start Address	End Address	Size	Description
L4 Standard Configuration	4800 0000h	4800 07FFh	2KB	Address/Protection (AP)

(1) These regions are decoded internally by the Cortex-A8 Subsystem and are not physically part of the L4 standard. They are included here only for reference when considering the Cortex-A8 memory-map. For masters other than the Cortex-A8, these regions are reserved.

1.5.2.2 L4 High-Speed Peripheral

The L4 high-speed peripheral bus accesses the IP configuration registers of high-speed peripherals in L3. The memory map is shown in Table 1-13.

Table 1-13. L4 High-Speed Peripheral Memory Map

Device Name	Start Address	End Address	Size	Description

1.5.3 TILER Extended Addressing Map

The Tiling and Isometric Lightweight Engines for Rotation (TILER) ports are mainly used for optimized 2-D block accesses. The TILER also supports rotation of the image buffer at 0º, 90º, 180º, and 270º, with vertical and horizontal mirroring.

The top 4-GB address space is divided into eight sections of 512MB each. These eight sections correspond to the eight different orientations as shown in Table 1-14.

Table 1-14. TILER Extended Address Memory Map

Block Name	Start Address	End Address	Size	Description
Tiler View 0	1 0000 0000h	1 1FFF FFFFh	512MB	Natural 0° View
Tiler View 1	1 2000 0000h	1 3FFF FFFFh	512MB	0° with Vertical Mirror View
Tiler View 2	1 4000 0000h	1 5FFF FFFFh	512MB	0° with Horizontal Mirror View
Tiler View 3	1 6000 0000h	1 7FFF FFFFh	512MB	180° View
Tiler View 4	1 8000 0000h	1 9FFF FFFFh	512MB	90° with Vertical Mirror View
Tiler View 5	1 A000 0000h	1 BFFF FFFFh	512MB	270° View
Tiler View 6	1 C000 0000h	1 DFFF FFFFh	512MB	90° View
Tiler View 7	1 E000 0000h	1 FFFF FFFFh	512MB	90° with Horizontal Mirror View

1.5.4 Cortex-A8 Memory Map

The Cortex-A8 includes a memory management unit (MMU) to translate virtual addresses to physical addresses which are then decoded within the Host ARM Subsystem. The subsystem includes its own ROM and RAM, as well as configuration registers for its interrupt controller. These addresses are hard-coded within the subsystem. In addition, the upper 2GB of address space is routed to a special port (Master 0) intended for low-latency access to DDR memory. All other physical addresses are routed to the L3 port (Master 1) where they are decoded by the device infrastructure. The Cortex-A8 memory map is shown in Table 1-15.

Table 1-15. Cortex-A8 Memory Map

Region Name	Start Address	End Address	Size	Description
Boot Space	0000 0000h	000F FFFFh	1MB	Boot Space

	5900 0000h	59FF FFFFh	16MB	HDVICP2-0 SL2 Port
	5A00 0000h	5AFF FFFFh	16MB	HDVICP2-1 Host Port
	5B00 0000h	5BFF FFFFh	16MB	HDVICP2-1 SL2 Port
	5C00 0000h	5FFF FFFFh	64MB	Reserved
	6000 0000h	7FFF FFFFh	512MB	TILER Window
DDR EMIF0/1 SDRAM[3][4]	8000 0000h	BFFF FFFFh	1GB	DDR
DDR EMIF0/1 SDRAM[3][4]	C000 0000h	FFFF FFFFh	1GB	DDR

(2) These accesses occur through the DDR DMM TILER ports. The DDR DMM splits address ranges internally to address DDR EMIF and DDR DMM control registers based on DDR DMM tie-offs.
(3) These addresses are routed to the Master 0 port for direct connection to the DDR DMM ELLA port.
(4) DDR EMIF0 and DDR EMIF1 addresses may be contiguous or bank interleaved, depending on configuration of the DDR DMM.

1.5.5 C674x Memory Map

Because the C674x DSP has specific hardwired address decoding built in, the C674x DSP memory map is slightly different than that of the Cortex-A8. The C674x DSP has a separate CFG bus which is used to access L4 peripherals and its UMAP1 bus has a direct connection into HDVICP2 SL2 (HDVICP2-0 and HDVICP2-1 only) memories. All C674x MDMA port accesses are routed through the System MMU for address translation.

Table 1-16. C674x Memory Map

L4 High-Speed Domain(3)	0A00 0000h	0AFF FFFFh	16MB	Peripheral Domain (see Table 1-13)
Reserved(3)	0B00 0000h	0FFF FFFFh	80MB	Reserved
C674x L1/L2(4)	1000 0000h	10FF FFFFh	16MB	C674x Internal Global Address
MDMA L3(5)	1100 0000h	FFFF FFFFh	3824MB	System MMU Mapped L3 Regions

(1) Addresses 0000 0000h to 017F FFFFh are internal to the C674x device.
(2) Addresses 0180 0000h to 01BF FFFFh are reserved for C674x internal CFG registers.
(3) Addresses 01C0 0000h to 0FFF FFFFh are mapped to the C674x CFG bus.
(4) Addresses 1000 0000h to 10FF FFFFh are mapped to C674x internal addresses 0000 0000h to 00FF FFFFh.
(5) These accesses are routed through the System MMU where the page tables translate to the physical L3 addresses shown in Table 1-11.

1.6 System MMU

1.6.1 MMU Overview

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit. MMU functions include translation of virtual addresses to physical addresses (that is, virtual memory management).

The device contains the following MMUs:

- System MMU for C674x DSP and other requestors (please refer to the device-specific data manual for other requestors)
- L1 Shared cache MMU
- ARM® Cortex®-A8 MMU
- SGX530 MMU

This section provides a detailed description of the System MMU. For more details on the Cortex-A8 MMU, refer to the ARM® Cortex®-A8 Technical Reference Manual.

1.6.2 MMU Integration

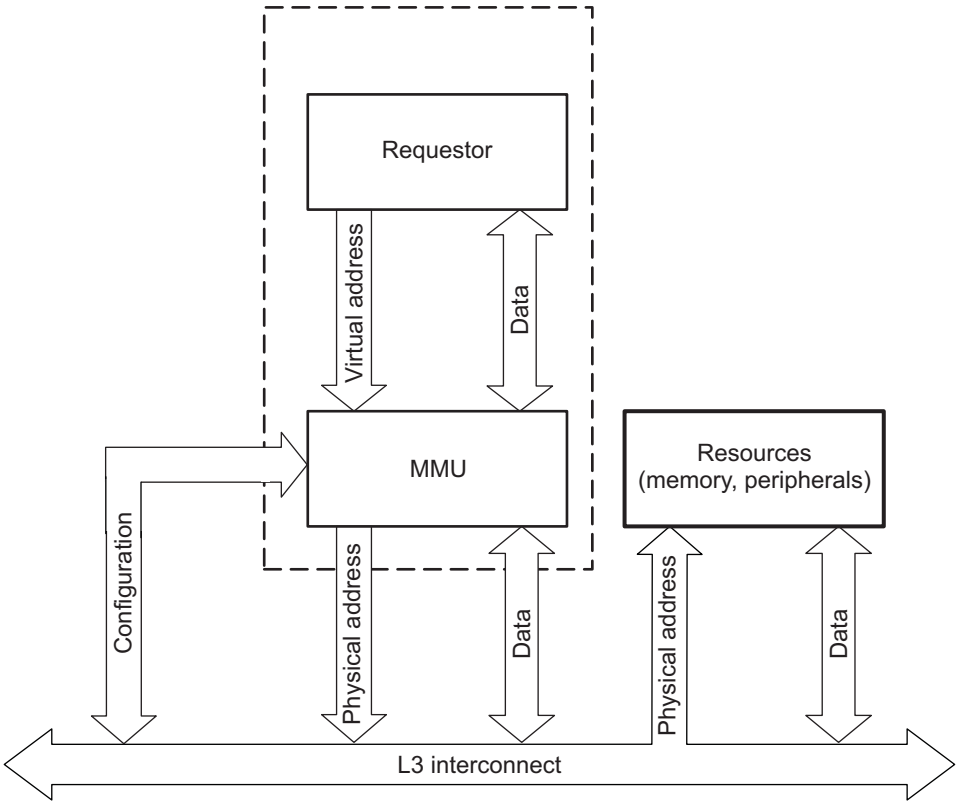
This section describes module integration in the device.

The MMU communicates accesses from the requestor (C674x DSPor Cortex-A8 MPU) to the L3 main interconnect, performing virtual to physical address translation. All MMUs are programmed (configured) through the L3 interconnect. For MMU interrupt details, refer to the device datasheet.

Figure 1-12 shows typical MMU integration.

The System MMU is dedicated to C674x DSP MDMA and other requestors. The system MMU configuration is done through MMU_CFG register (see the *Control Module* section). The MMU_CFG register is used to optionally route certain requestors through the System MMU. The C674x DSP MDMA port accesses will always be routed through the System MMU so no configuration bit is instantiated for C674x DSP.

Figure 1-12. Typical MMU Integration

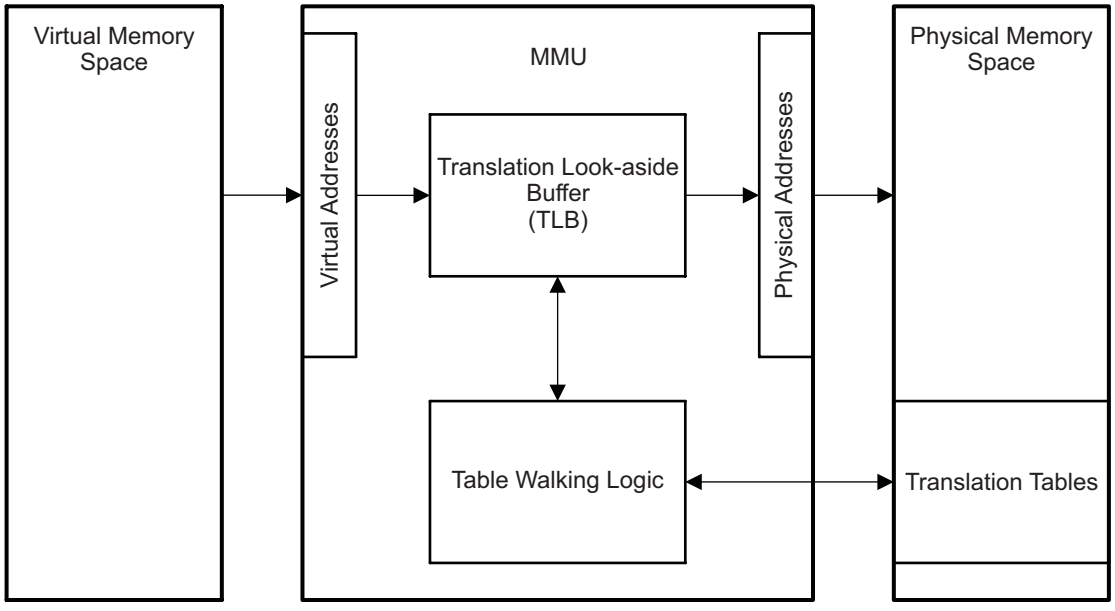


1.6.3 MMU Functional Description

1.6.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses, as well as endianness conversion. The MMU can be programmed through the L4 interconnect.

Figure 1-13. MMU Block Diagram



Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see Translation Tables.

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

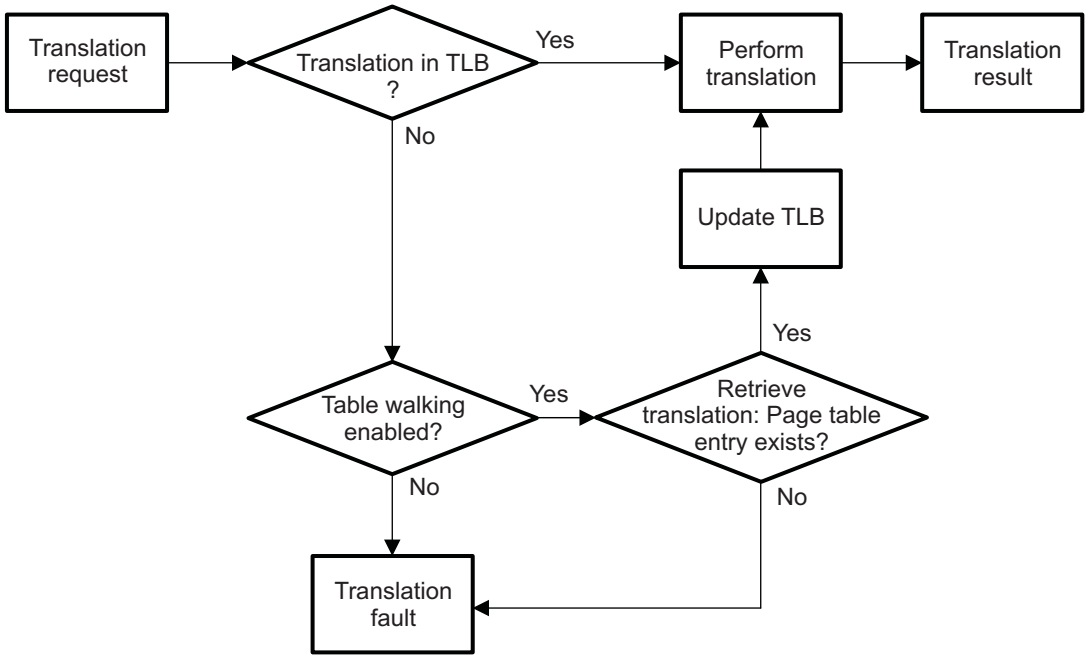
- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in this section.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

1.6.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. Figure 1-14 summarizes the process.

Figure 1-14. MMU Address Translation Process



1.6.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates
- Endianness, data access size, and the mixed property of this memory region

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

1.6.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4KB and 64KB pages, a 1MB section, and a 16MB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4KB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4KB memory pages with one translation table would require one million entries to span the entire 4GB address range. The table itself would be 32MB, a size that is not feasible.

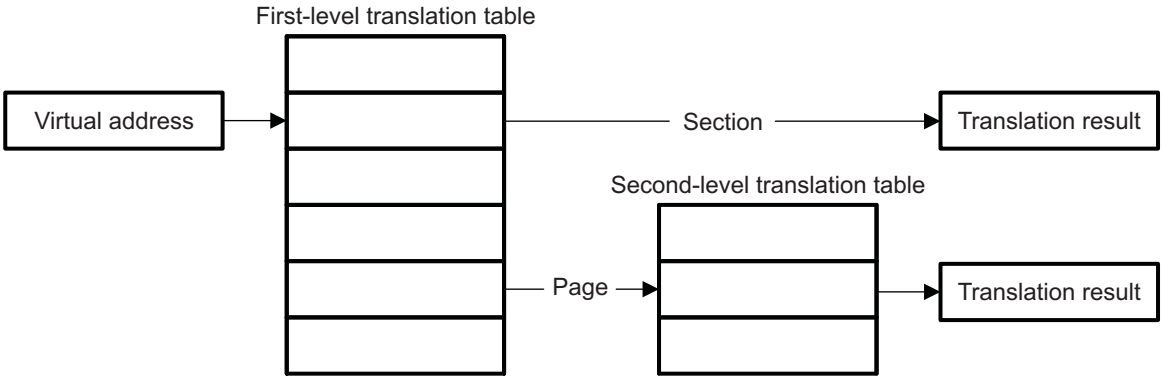
However, using bigger pages greatly reduces the functionality of the typical OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1MB memory regions.

Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1MB (section) or 16MB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.
- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1MB page of memory. These pages can be either 64KB (large page) or 4KB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used.

Figure 1-15. Translation Hierarchy



The structure of the first and second-level translation tables and their entries are described in more detail in First-Level Translation Table and Two-Level Translation.

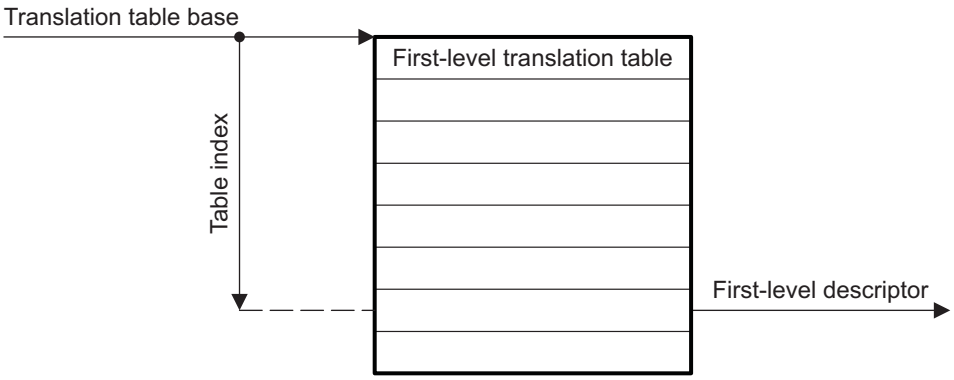
1.6.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1MB sections. To describe a 4GB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

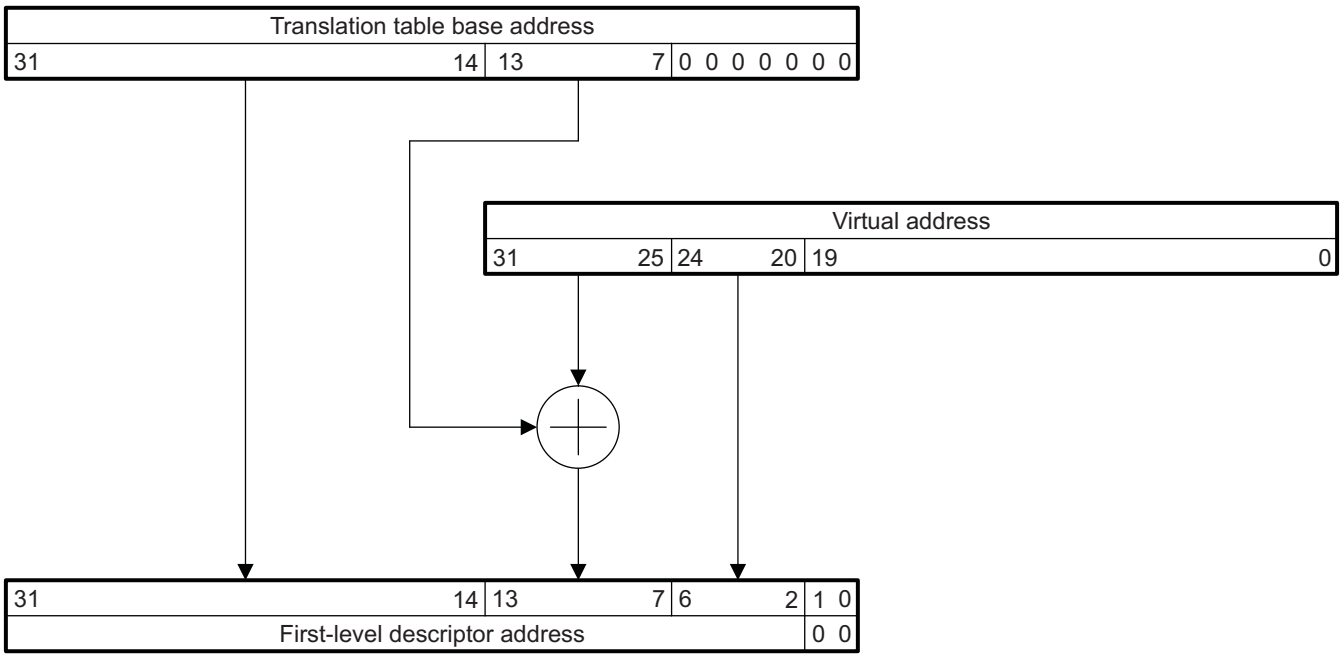
The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address.

Figure 1-16. First-Level Descriptor Address Calculation



To summarize, the translation table base and the translation table index together define the first-level descriptor address. The precise mechanism used to calculate this address is shown in Figure 1-17.

Figure 1-17. Detailed First-Level Descriptor Address Calculation



As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is:

0x8000:0000 + (0x123 <<2) = 0x8000:048C.

1.6.3.1.2.3 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1MB or 16MB sections or provides a pointer to a second-level translation table for 4KB or 64KB pages.

Table 1-17. First-Level Descriptor Format

31:24	23:20	19	18	17	16	15	14:12	11:10	9:2	1	0	
X										0	0	Fault
Second-level Translation Table Base Address									X	0	1	Page
Section Base Address		X	0	M	X	E	X	ES	X	1	0	Section
Super Section base Address		X	1	M	X	E	X	ES	X	1	0	Supersection
X										1	1	Fault

M = Mixed region: Don't care when E = 0. Set to 0 to ensure future compatibility.

E = Endianness: Set to 0 for little-endian. Big-endian mode is not supported.

ES = Element Size: Don't care when E = 0. Set to 00 to ensure future compatibility.

X = Don't care. Set to 0 to ensure future compatibility.

1.6.3.1.2.4 First-Level Page Descriptor Format

If a translation granularity smaller than 1MB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

1.6.3.1.2.5 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1MB section or a 16MB supersection.

NOTE: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1MB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

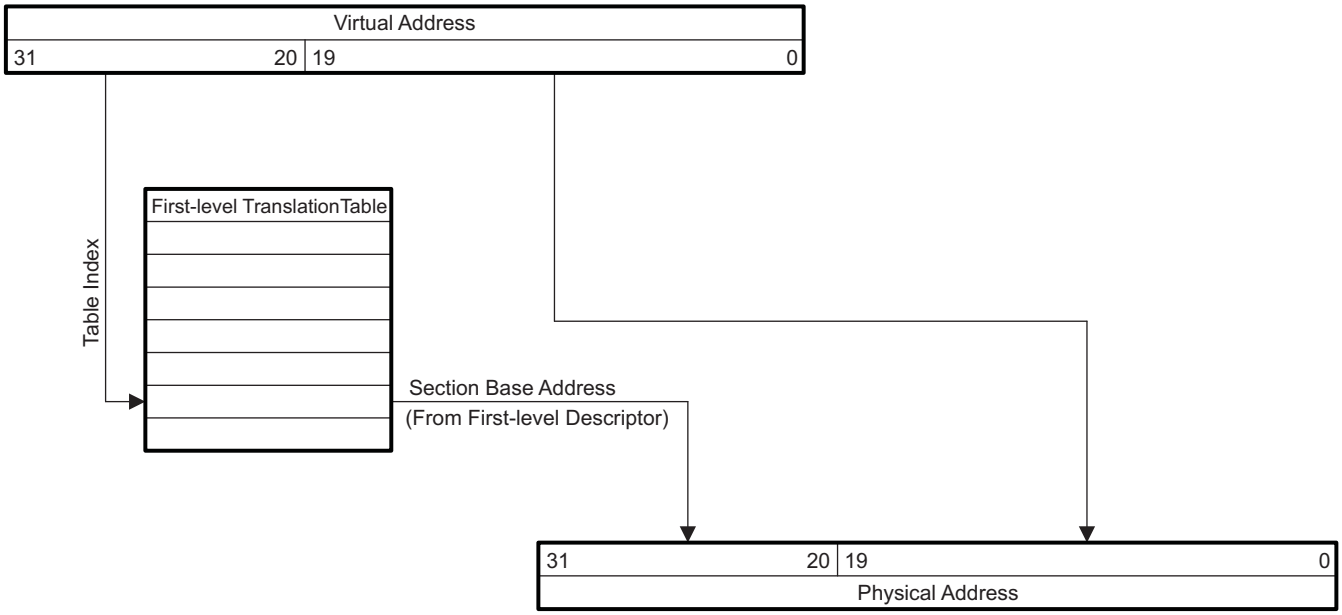
In addition to the address translation itself, three parameters are specified in the section descriptors:

- **Endianness -** The endianness parameter specifies whether the memory section uses a big- or little-endian data format. This parameter is locked to little endian. Big-endian mode is not supported.
- **Element Size -** The element size parameter can optionally specify the data access size (8, 16, or 32 bits) for all data items in the defined section.
- **Mixed Region -** The mixed region parameter specifies whether the information about the data access size is detected from the access itself (access-based detection) or if the specified element size parameter is used (page-based detection). For example, the specified element size parameter can be used when several smaller sized accesses are packed into a bigger sized access, such as two 16-bit accesses packed into one 32-bit access. In this case, with no specified data access size, 32 bits would be the access size detected, leading to an incorrect result. To avoid this problem, specify the data access size for the memory section.

1.6.3.1.2.6 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table.

Figure 1-18. Section Translation Summary



1.6.3.1.2.7 Supersection Translation Summary

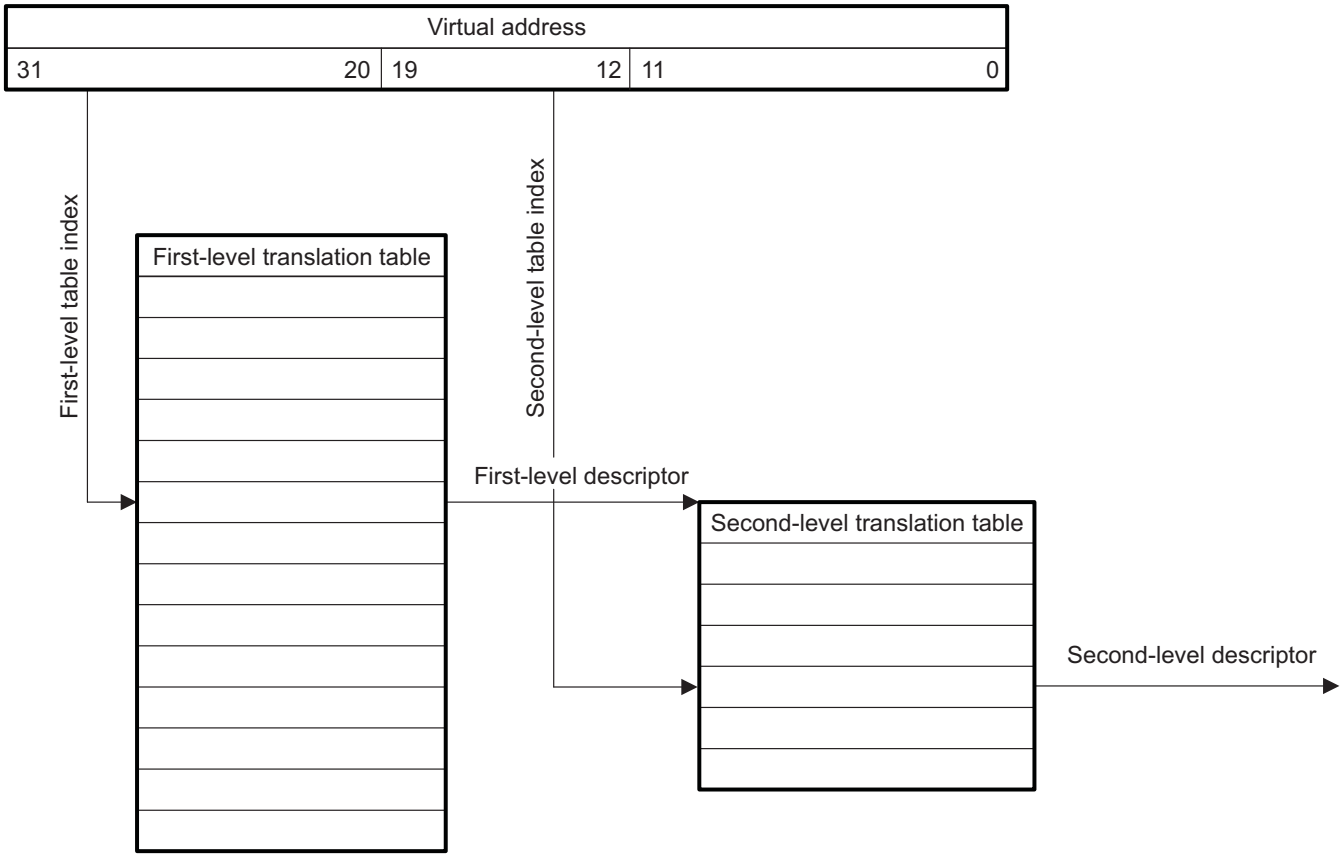
The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

Figure 1-19. Supersection Translation Summary

1.6.3.1.2.8 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1MB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address.

Figure 1-20. Two-Level Translation



Each second-level translation table describes the translation of 1MB of address space in pages of 64KB (large page) or 4KB (small page). It consists of 256 second-level descriptors describing 4KB each.

NOTE: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way."

1.6.3.1.2.9 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. The translation parameters (endianness, element size, and mixed region) have the same meaning as those for sections.

Table 1-18. Second-Level Descriptor Format

31:16	15:12	11	10	9	8:6	5:4	3:2	1	0	
X								0	0	Fault
Large Page Base Address	X	M	X	E	X	ES	X	0	1	Large Page
Small Page Base Address		M	X	E	X	ES	X	1	X	Small Page

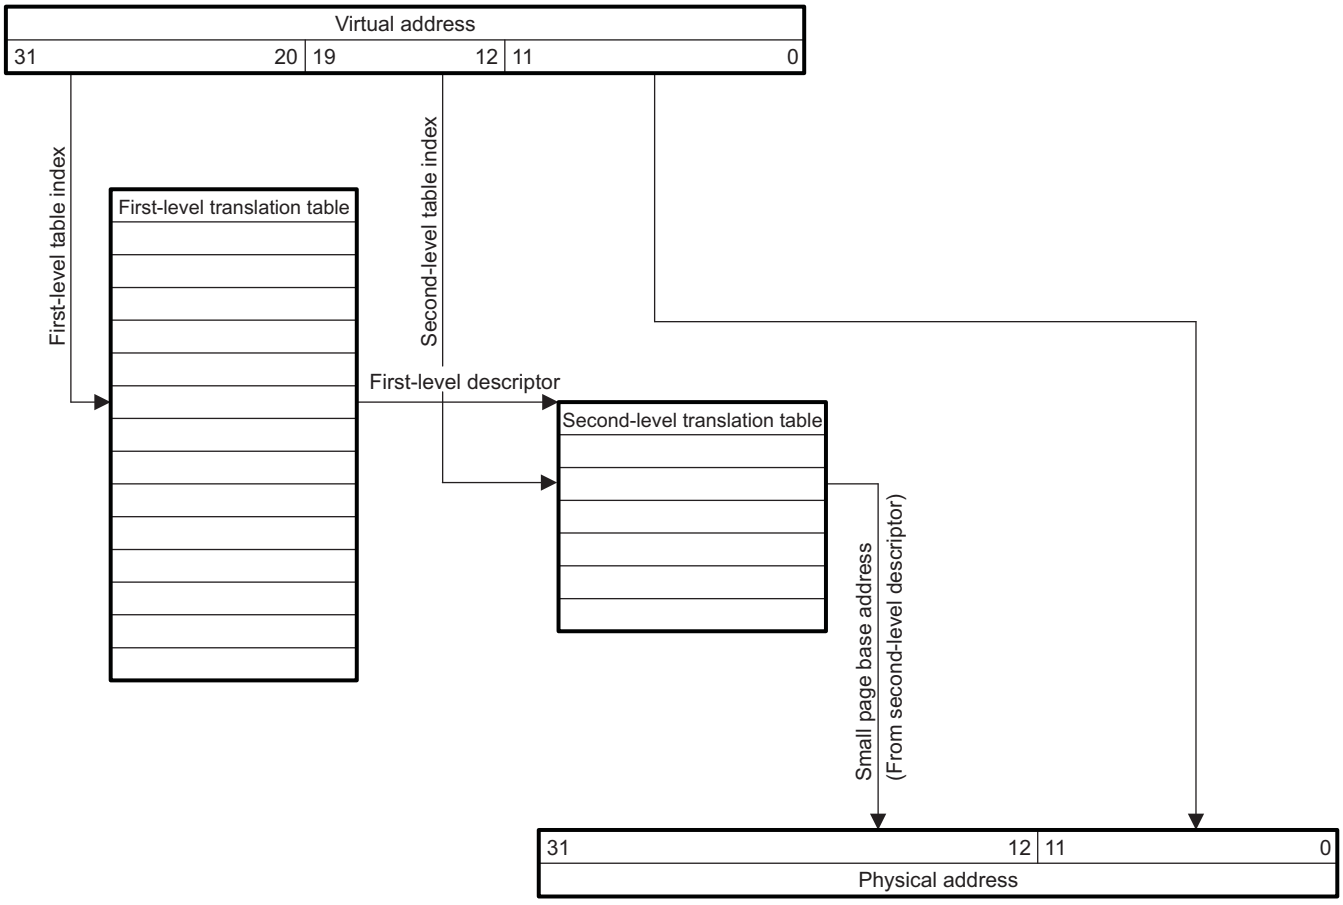
M = Mixed region: Don't care when E = 0. Set to 0 to ensure future compatibility.

E = Endianness: Set to 0 for little-endian. Big-endian mode is not supported

ES = Element Size: Don't care when E = 0. Set to 00 to ensure future compatibility

X = Don't care. Set to 0 to ensure future compatibility.

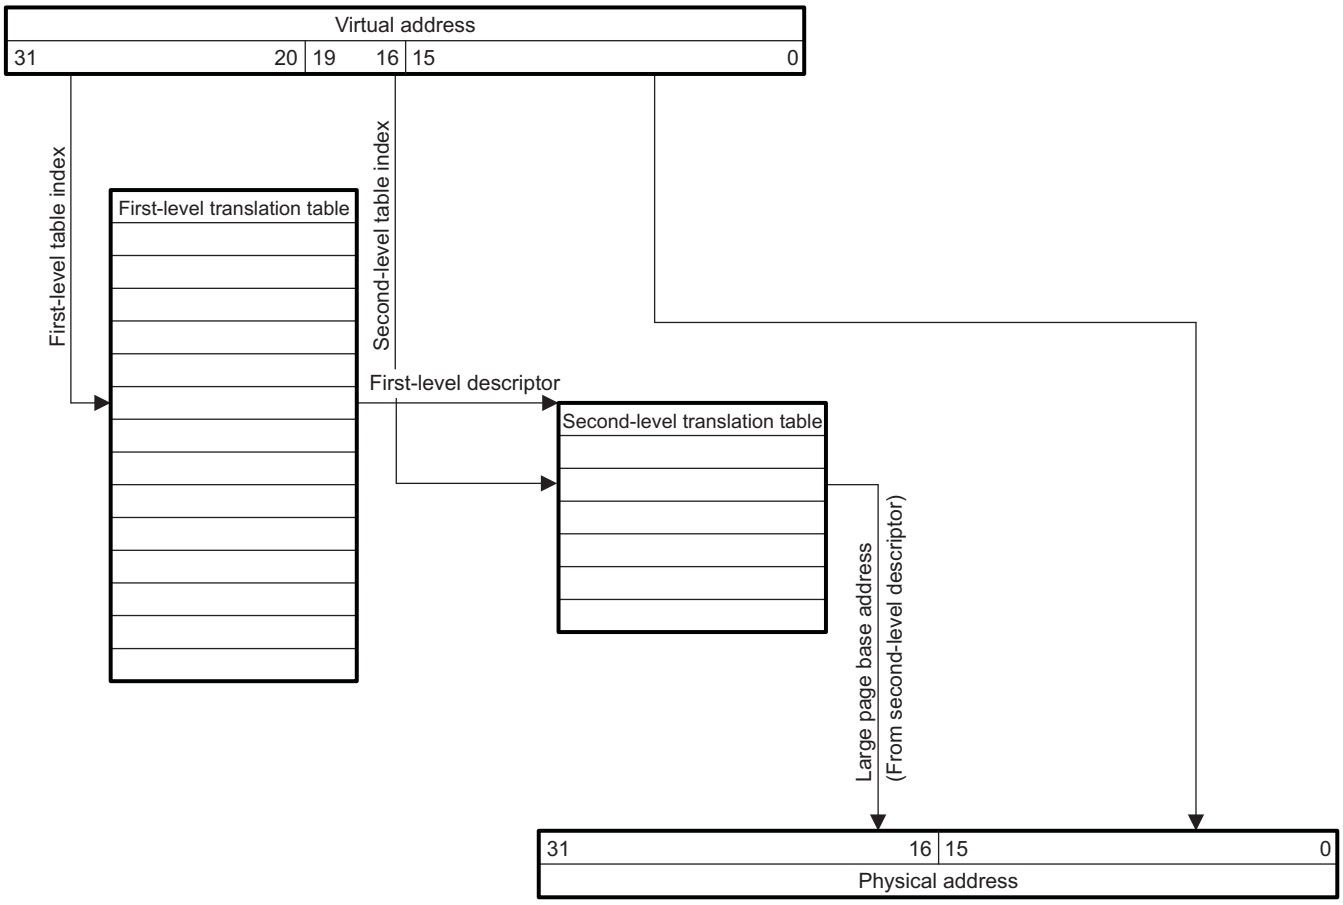
Figure 1-21. Small Page Translation Summary



1.6.3.1.2.10 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page.

Figure 1-22. Large Page Translation Summary



1.6.3.1.3 Translation Lookaside Buffer

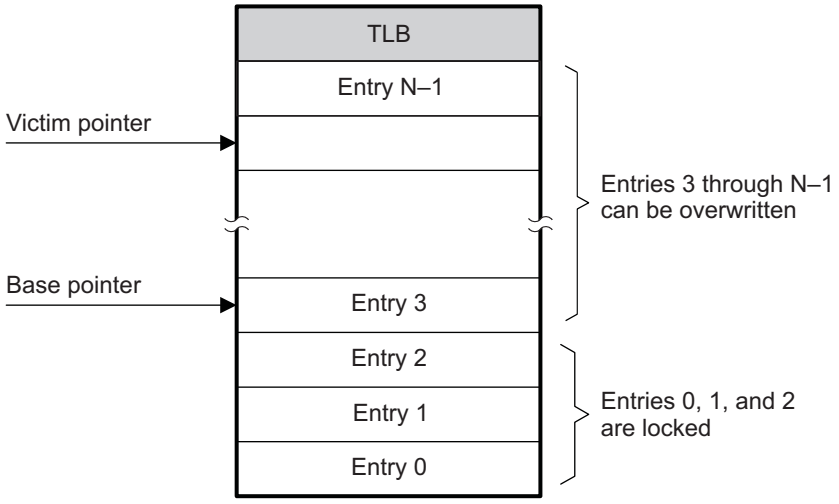
Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first n TLB entries, where n < Total Number N of TLB Entries , can be protected (locked) against being overwritten by setting the TLB base pointer to n . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 1-23 shows an example of the TLB with N TLB entries (ranging from 0 to N-1). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

NOTE: The last TLB entry (Entry N-1) always remains unprotected.

Figure 1-23. TLB-Entry Lock Mechanism



The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

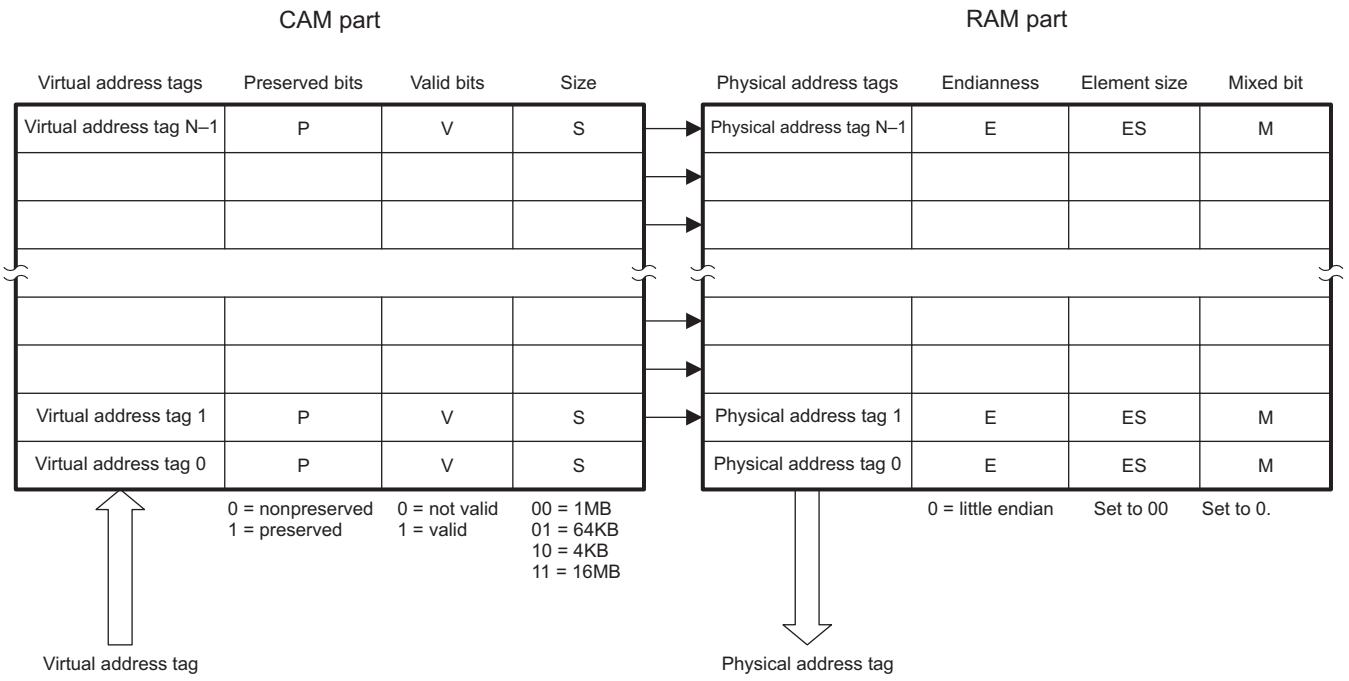
1.6.3.1.3.1 TLB Entry Format

TLB entries consist of two parts:

- The CAM part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the register table for more details.
- The RAM part contains the address translation that belongs to the virtual address tag as well as the endianness, element size, and mixed parameters described in First-Level Translation Table. See the MMU_RAM register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when [0] GLOBALFLUSH is set to 1. Preserved entries must be deleted manually.

Figure 1-24. TLB-Entry Structure



1.6.3.2 MMU Clock Configuration

There are two clock domains: The functional clock domain for the MMU, which is synchronous to the clock for the interconnect slave and master access ports; and the clock domain for the interconnect slave configuration port. As these clocks are matched, there is a single input clock with enables for each of the clock domains. If a clock domain should run at the same frequency as the input clock, that enable can be tied high.

Two clock enable signals exist, one to enable the interconnect data master and slave ports, and the other to enable the clock on the configuration L3 interconnect port. The clock signals are configured through the MMU_SYSCONFIG register. This is a system configuration register that controls the various parameters of the L3 interface.

1.6.3.3 MMU Software Reset

This section describes the software reset feature of the module. The MMU instances are reset together with their respective reset domains. See table Clocks and Resets for information about the reset domains of the different MMU instances.

To perform a software reset, write 1 in the MMU_SYSCONFIG[1] SOFTRESET bit. When the software reset completes, the MMU_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

1.6.3.4 MMU Power Management

As part of the device system-wide power management scheme, each MMU instance supports a communication protocol with the PRCM module that allows the PRCM module to request an MMU instance to enter a low-power state. When the MMU instance acknowledges a low-power mode request from the PRCM module, the clock to the instance is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock gating method in the local power management.

1.6.3.5 MMU Local Power Management Features

Table 1-19. MMU Local Power Management Features

Feature	Register
Idle modes	MMU_SYSCONFIG[4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG[9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG[0] AUTOIDLE

NOTE: The MMU_SYSCONFIG[9:8] CLOCKACTIVITY bits are read only.

1.6.3.6 MMU Interrupt Requests

Table 1-20. Events

Event Flag	Event Mask	Synchronous	Sensitivity	Map to	Description
MMU_IRQSTATUS[4] MULTIHITFAULT	MMU_IRQENABLE[4] MULTIHITFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to multiple matches in the TLB
MMU_IRQSTATUS[3] TABLEWALKFAULT	MMU_IRQENABLE[3] TABLEWALKFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to error response received during a Table Walk
MMU_IRQSTATUS[2] EMUMISS	MMU_IRQENABLE[2] EMUMISS				
MMU_IRQSTATUS[1] TRANSLATIONFAULT	MMU_IRQENABLE[1] TRANSLATIONFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS[0] TLBMISS	MMU_IRQENABLE[0] TLBMISS	Yes	Level	M3_IRQ_0	Error in L2 MMU due to unrecoverable TLB miss (hardware TWL disabled)

1.6.3.7 MMU Error Handling

Table 1-21. Error Handling

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU. Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending.
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU. This condition should be avoided by ensuring that no accesses are pending.
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.

L3 Interconnect configuration port: Accesses to undecoded register addresses must not give an error response.

To protect against changes to the address translation between a READEX and the corresponding write or during a burst the following configuration operations are protected against writes during these processes:

1. TLB update
2. Global flush
3. Flush entry
4. MMU disable

The protection is implemented by stalling the configuration interconnect transaction until the write can proceed safely.

1.6.4 MMU Low-level Programming Models

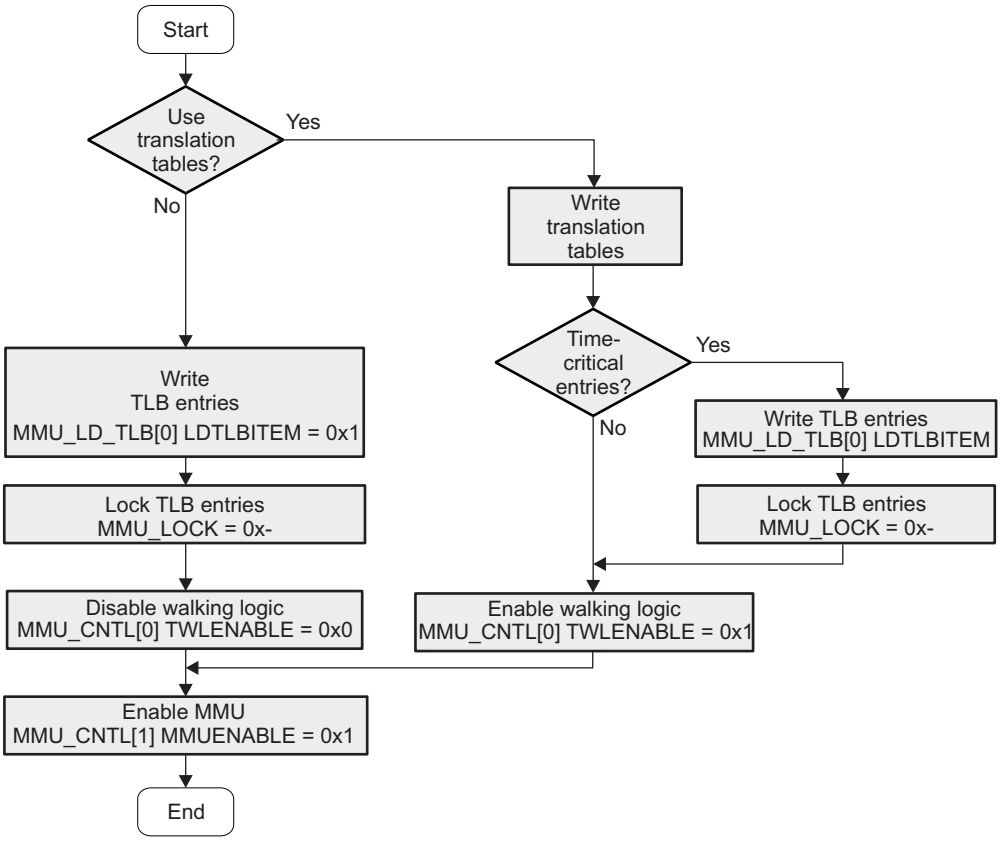
This section covers the low-level hardware programming sequences for configuration and usage of the module.

1.6.4.1 MMU Global Initialization

1.6.4.1.1 Main Sequence - MMU Global Initialization

The System MMU can be enabled or disabled in MMU_CFG register (see the *Control Module* section). Figure 1-25 shows the procedure to initialize the MMU after a power-on or software reset.

Figure 1-25. MMU Global Initialization



1.6.4.1.2 Subsequence - Configure a TLB entry

Table 1-22. Configure a TLB Entry

Step	Register / Bitfield / Programming Model	Value
Load the Virtual Address Tag	MMU_CAM[31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM[3] P	0x1
Validate the TLB entry	MMU_CAM[2] V	0x1
Define the page size	MMU_CAM[1:0] PAGESIZE	0x-

1.6.4.2 Operational Modes Configuration

1.6.4.2.1 Main Sequence - Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

Table 1-23. MMU Writing TLB Entries Statically

Step	Register/ Bitfield / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	Refer to table Configure a TLB Entry	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Define the endianness of the page (little endian or big endian)	MMU_RAM[9] ENDIANNESS	0x-
Select the element size	MMU_RAM[8:7] ELEMENTSIZE	0x-
Define mixed page attribute	MMU_RAM[6] MIXED	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

1.6.4.2.2 Main Sequence - Protecting TLB Entries

The first n TLB entries (with n < total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

Table 1-24. Protecting TLB Entries

Step	Register / Bitfield / Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

1.6.4.2.3 Main Sequence - Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

Table 1-25. Deleting TLB Entries

Step	Register / Bitfield / Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

1.6.4.2.4 Main Sequence - Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

Table 1-26. Read TLB Entries

Step	Register / Bitfield / Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	
Read CAM parts of the TLB entry	MMU_READ_CAM	

1.6.4.3 Recovery from a TLB Miss Error

It is possible for the DMMU to hang when used in Table-Walk Mode.

The following procedure must be considered for recovery from a TLB Miss Error:

1. Read MMU_FAULT_AD[31:0] FAULTADDRESS to get the misdefined virtual address value.
2. Write the physical address (corresponding to the misdefined virtual address derived in 1.) in the MMU_RAM[31:12]PHYSICALADDRESS register
3. Fault virtual address bits [31:12] reported in MMU_FAULT_AD[31:0] are copied to MMU_CAM[31:12]VATAG bit field.
4. Write 0xC in MMU_CAM[3:0] bits. This means:
   - P is set to 1 to preserve entry
   - V is set to 1 to validate entry
   - [1:0]PAGESIZE = 0x0 for a 1 MiB sized section
5. Read MMU_IRQSTATUS register.
6. Write the value from step 5. into the same (MMU_IRQSTATUS) register to clear the error.

1.6.5 MMU Registers

Table 1-27 provides a summary of the MMU registers. For the base address of these registers, see Table 1-12.

Table 1-27. MMU Registers

Address Offset	Acronym	Type	Section
00h	MMU_REVISION	R	Section 1.6.5.1
10h	MMU_SYSCONFIG	RW	Section 1.6.5.2
14h	MMU_SYSSTATUS	R	Section 1.6.5.3
18h	MMU_IRQSTATUS	RW	Section 1.6.5.4
1Ch	MMU_IRQENABLE	RW	Section 1.6.5.5
40h	MMU_WALKING_ST	R	Section 1.6.5.6
44h	MMU_CNTL	RW	Section 1.6.5.7
48h	MMU_FAULT_AD	R	Section 1.6.5.8
4Ch	MMU_TTB	RW	Section 1.6.5.9
50h	MMU_LOCK	RW	Section 1.6.5.10
54h	MMU_LD_TLB	RW	Section 1.6.5.11
58h	MMU_CAM	RW	Section 1.6.5.12
5Ch	MMU_RAM	RW	Section 1.6.5.13
60h	MMU_GFLUSH	RW	Section 1.6.5.14
64h	MMU_FLUSH_ENTRY	RW	Section 1.6.5.15
68h	MMU_READ_CAM	R	Section 1.6.5.16
6Ch	MMU_READ_RAM	R	Section 1.6.5.17
70h	MMU_EMU_FAULT_AD	R	Section 1.6.5.18
80h	MMU_FAULT_PC	R	Section 1.6.5.19

1.6.5.1 MMU_REVISION

The MMU_REVISION register is shown in Figure 1-26 and described in Table 1-28.

Figure 1-26. MMU_REVISION

31	0
REVISION	
R-20h	

LEGEND: R = Read only; -*n* = value after reset

Table 1-28. MMU_REVISION Field Descriptions

Bit	Field	Value	Description
31-0	REVISION	20h	IP Revision.

1.6.5.2 MMU_SYSCONFIG

The MMU_SYSCONFIG register is shown in Figure 1-27 and described in Table 1-29.

Figure 1-27. MMU_SYSCONFIG

31	16
Reserved	
R-0	

15 10	9 8	7 5	4 3	2	1	0
Reserved	CLOCKACTIVITY	Reserved	IDLEMODE	Reserved	SOFTRESET	AUTOIDLE
R-0	R/W-0	R-0	R/W-0	R-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-29. MMU_SYSCONFIG Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Write 0's for future compatibility; reads returns 0.
9-8	CLOCKACTIVITY	0	Clock activity during wake-up mode 00 Functional and Interconnect clocks can be switched off.
7-5	Reserved	0	Write 0's for future compatibility; reads returns 0.
4-3	IDLEMODE		Idle Mode
		0	Force-idle. An idle request is acknowledged unconditionally.
		1h	No-idle. An idle request is never acknowledged.
		2h	Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module.
		3h	Reserved
2	Reserved	0	Write 0's for future compatibility; reads returns 0.
1	SOFTRESET		Software reset. This bit is automatically reset by the hardware. During reads, it always returns 0.
		0	Read: always return 0
		1	Read: never happens
		0	Write: no functional effect
		1	Write: The module is reset
0	AUTOIDLE		Internal interconnect clock gating strategy.
		0	Interconnect clock is free-running.
		1	Automatic interconnect clock gating strategy is applied, based on the interconnect interface activity.

1.6.5.3 MMU_SYSSTATUS

The MMU_SYSSTATUS register is shown in Figure 1-28 and described in Table 1-30.

Figure 1-28. MMU_SYSSTATUS

31	1	0
Reserved		RESETDONE
R-0		R-0

LEGEND: R = Read only; -*n* = value after reset

Table 1-30. MMU_SYSSTATUS Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reads returns 0.
0	RESETDONE		Internal reset monitoring.
		0	Internal module reset is on-going.
		1	Reset completed.

1.6.5.4 MMU_IRQSTATUS

The MMU_IRQSTATUS register is shown in Figure 1-29 and described in Table 1-31.

Figure 1-29. MMU_IRQSTATUS

31	16
Reserved	
R-0	

15	5	4	3	2	1	0
Reserved		MULTIHITFAULT	TABLEWALKFAULT	EMUMISS	TRANSLATIONFAULT	TLBMISS
R-0		R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-31. MMU_IRQSTATUS Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Write 0's for future compatibility; reads returns 0.
4	MULTIHITFAULT		Error due to multiple matches in the TLB.
		0	Read: MultiHitFault is false.
		1	Read: MultiHitFault is true ("pending").
		0	Write: MultiHitFault status bit is unchanged.
		1	Write: MultiHitFault status bit is reset.
3	TABLEWALKFAULT		Error response received during a Table Walk.
		0	Read: TableWalkFault is false.
		1	Read: TableWalkFault is true ("pending").
		0	Write: TableWalkFault status bit is unchanged.
		1	Write: TableWalkFault status bit is reset.
2	EMUMISS		Unrecoverable TLB miss during debug (hardware TWL disabled).
		0	Read: EMUMiss is false.
		1	Read: EMUMiss is true ("pending").
		0	Write: EMUMiss status bit is unchanged.
		1	Write: EMUMiss status bit is reset.
1	TRANSLATIONFAULT		Invalid descriptor in translation tables (translation fault).
		0	Read: TranslationFault is false.
		1	Read: TranslationFault is true ("pending").
		0	Write: TranslationFault status bit is unchanged.
		1	Write: TranslationFault status bit is reset.
0	TLBMISS		Unrecoverable TLB miss (hardware TWL disabled).
		0	Read: TLBMiss is false.
		1	Read: TLBMiss is true ("pending").
		0	Write: TLBMiss status bit is unchanged.
		1	Write: TLBMiss status bit is reset.

1.6.5.5 MMU_IRQENABLE

The MMU_IRQENABLE register is shown in Figure 1-30 and described in Table 1-32.

Figure 1-30. MMU_IRQENABLE

31	16

PC	
R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 1-46. MMU_FAULT_PC Field Descriptions

Bit	Field	Value	Description
31-0	PC	0-FFFF FFFFh	CPU program counter value where cause MMU fault. The address value is captured at MMU_EMU_FAULT_AD EMUFAULTADDRESS bit field. Data-Read-access : corresponding PC. Data-write-access : not perfect accuracy due to Posted-write.

1.7 SGX530 Graphics Subsystem

This section describes the 2D/3D graphics accelerator (SGX) for the device.

NOTE: This section contains materials that are ©2003-2007 Imagination Technologies Limited.

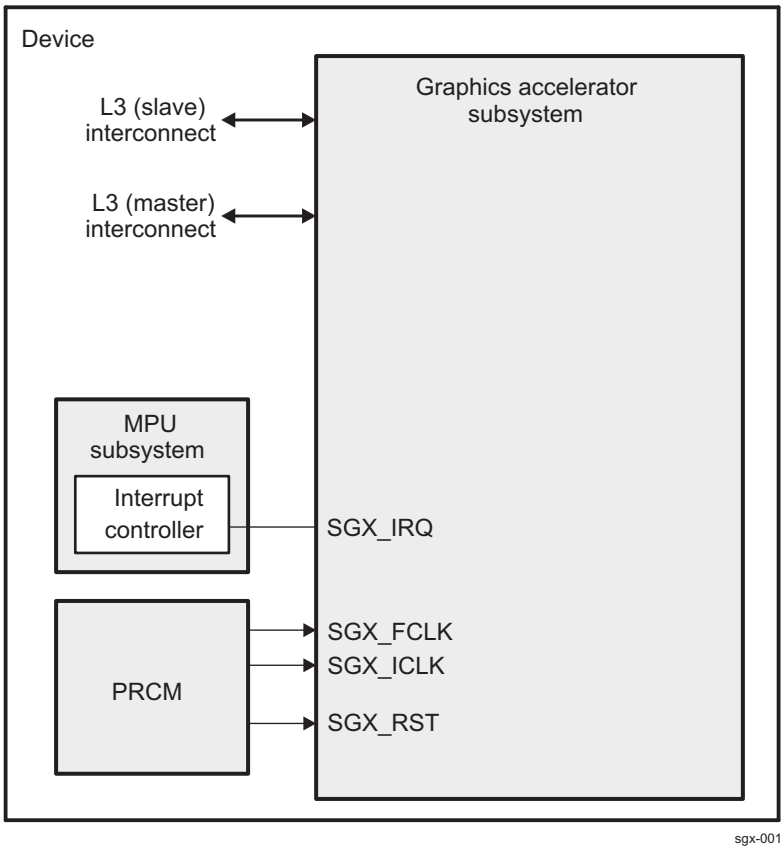
PowerVR® and USSE™ are registered trademarks or trademarks of Imagination Technologies Limited.

1.7.1 SGX Overview

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is a Texas Instruments instantiation of the PowerVR® SGX530 core from Imagination Technologies Limited. SGX is a new generation of programmable PowerVR graphic cores. The PowerVR SGX530 v1.2.5 architecture is scalable and can target all market segments from mainstream mobile devices to high-end desktop graphics. Targeted applications include feature phone, PDA, and hand-held games.

Figure 1-45 shows the SGX subsystem in the device.

Figure 1-45. Graphics Accelerator Highlight



The SGX graphics accelerator can simultaneously process various multimedia data types:

- Pixel data
- Vertex data
- Video data
- General-purpose processing

This is achieved through a multithreaded architecture using two levels of scheduling and data partitioning enabling zero-overhead task switching.

The SGX subsystem is connected to the L3 interconnect by a 128-bit master and a 32-bit slave interface.

1.7.1.1 PowerVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programming support for GP-GPU functions
- Tile-based architecture
- Universal scalable shader engine (USSE) – multithreaded engine incorporating pixel and vertex shader functionality
- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OpenGL2.0
- Industry-standard API support – Direct3D Mobile, OpenGL ES 1.1 and 2.0, OpenVG v1.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- PowerVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualized memory addressing for OS operation in a unified memory architecture
- Advanced and standard 2D operations [for example, vector graphics, BLTs (block level transfers), ROPs (raster operations)]
- 32K stride support

1.7.1.2 SGX 3D Features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
  - Cube map
  - Projected textures
  - 2D textures
  - Nonsquare textures
- Texture formats:
  - RGBA 8888, 565, 1555
  - Monochromatic 8, 16, 16f, 32f, 32int
  - Dual channel, 8:8, 16:16, 16f:16f
  - Compressed textures PVR-TC1, PVR-TC2, ETC1
  - Programmable support for all YUV formats
- Resolution support:
  - Frame buffer maximum size = 2048 × 2048
  - Texture maximum size = 2048 × 2048

- Texture filtering:
  - Bilinear, trilinear, anisotropic
  - Independent minimum and maximum control
- Antialiasing:
  - 4× multisampling
  - Up to 16× full scene anti-aliasing
  - Programmable sample positions
- Indexed primitive list support
  - Bus mastered
- Programmable vertex DMA
- Render to texture:
  - Including twiddled formats
  - Auto MipMap generation
- Multiple on-chip render targets (MRT).

  Note: Performance is limited when the on-chip memory is not available.

1.7.1.3 Universal Scalable Shader Engine (USSE) – Key Features

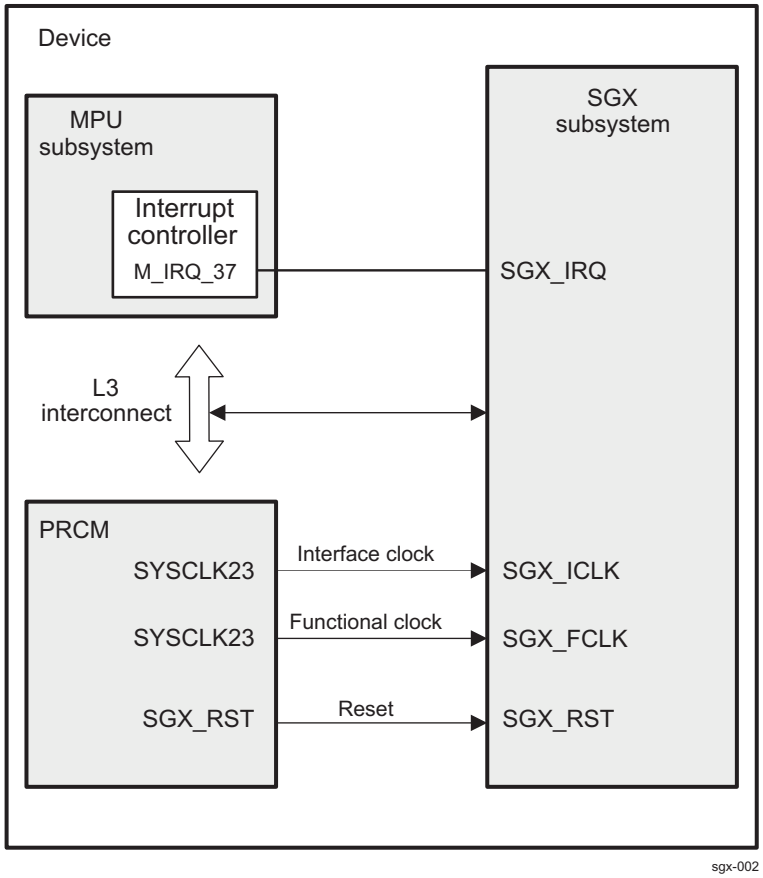
The USSE is the engine core of the PowerVR SGX architecture and supports a broad range of instructions.

- Single programming model:
  - Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
  - Zero-cost swapping in, and out, of threads
  - Cached program execution model
  - Dedicated pixel processing instructions
  - Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
  - 32-bit IEEE float
  - 2-way 16-bit fixed point
  - 4-way 8-bit integer
  - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
  - Subroutine calls
  - Loops
  - Conditional branches
  - Zero-cost instruction predication
- Procedural geometry:
  - Allows generation of primitives
  - Effective geometry compression
  - High-order surface support
- External data access:
  - Permits reads from main memory using cache
  - Permits writes to main memory
  - Data fence facility
  - Dependent texture reads

1.7.2 SGX Integration

Figure 1-46 highlights the SGX subsystem integration in the device.

Figure 1-46. SGX Subsystem Integration



1.7.2.1 Clocking, Reset, and Power-Management Scheme

1.7.2.1.1 Clocks

The SGX subsystem operates from two clocks: an interface clock (SGX_ICLK) and a functional clock (SYSCLK23). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device.

Table 1-47. Clock Descriptions

Signal Name	I/O[1]	Description
SYSCLK23	I	Functional clock → Functional clock domain
SGX_ICLK	I	Interface clock → Interface clock domain

(1) I =Input; O=Output

- SGX_ICLK interface clock manages the data transfer on the L3 master and slave ports.
- SGX_FCLK is the functional clock and is used inside the SGX subsystem to generate SGX 2D and 3D domain clock signals.

To Enable the SGX Functional and Interface Clock:

Program the PRCM.CM_SGX_CLKSTCTRL.CTLKTRCTRL to 0x2
Program the PRCM.CM_SGX_SGX_CLKCTRL.MODULEMODE to 0x2
Poll for the PRCM.CM_SGX_SGX_CLKCTRL IDLEST to be 0x0

To Disable the SGX Functional and Interface Clock:

Program the PRCM.CM_SGX_SGX_CLKCTRL.MODULEMODE to 0x0
Program the PRCM.CM_SGX_CLKSTCTRL.CTLKTRCTRL to 0x0

The SGX_ICLK and SGX_FLCK are sourced from SYSCLK23.

1.7.2.1.2 Resets

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX_RST signal in the SGX_RST domain. Software controls the release of SGX_RST using the PRCM.RM_SGX_RSTCTRL[0] SGX_RST bit.

NOTE: The APIs delivered with the SGX provide a software reset functionally equivalent to a hardware reset.

1.7.2.1.3 Power Management

The SGX subsystem has its own power domain (SGX power domain). See the *Power, Reset, and Clock Management (PRCM) Module* chapter for additional information about the SGX power domain.

The SGX subsystem receives two clock signals from the PRCM module. The functional clock is used inside the SGX to generate clock signals to the multiple internal module SGX clock domains. The division ratio depends on the PRCM registers setting. For more information, see the *Power, Reset, and Clock Management (PRCM) Module* chapter.

Three power-management modes are defined:

- Deep power sleep (All clocks are gated.)
- Idle (2D and 3D clocks are gated.)
- 3D (No clock is gated.)

These modes are fully managed inside the SGX and are handled by the related API delivered with the module.

The SGX handles the automatic clock gating performed on the multiple internal module clock domains.

1.7.2.2 Hardware Requests

1.7.2.2.1 Interrupt Request

The SGX subsystem can generate one interrupt (SGX_IRQ) to the MPU subsystem interrupt controller mapped on M_IRQ_37.

1.7.3 SGX Functional Description

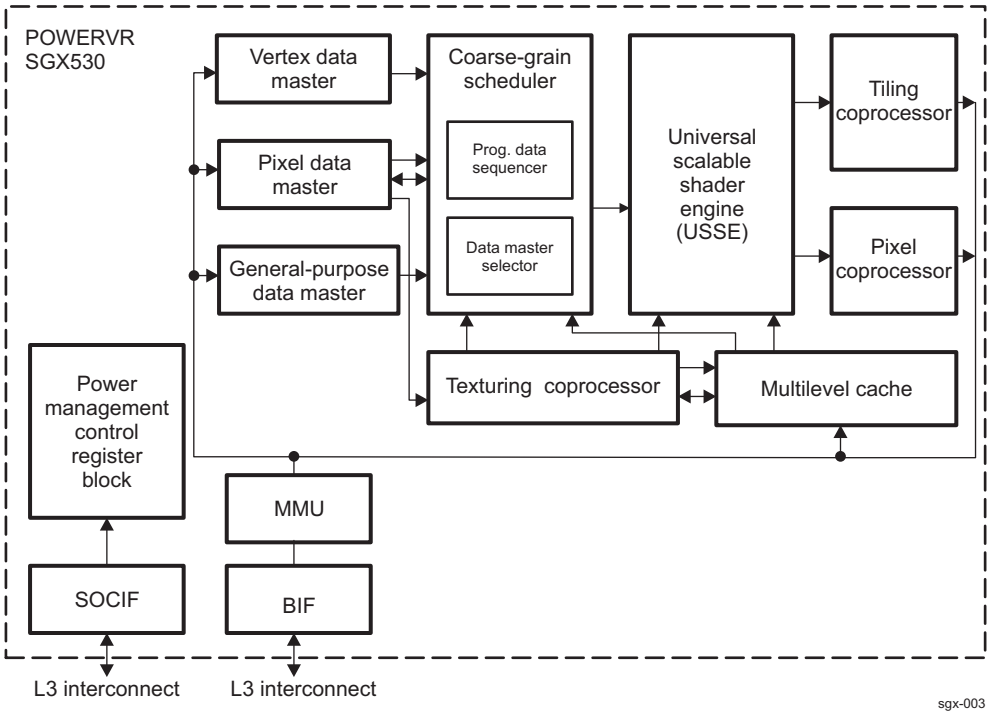
1.7.3.1 SGX Block Diagram

The architecture uses programmable and hard coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler
  - Programmable data sequencer (PDS)
  - Data master selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 1-47 shows a block diagram of the SGX cores.

Figure 1-47. SGX Block Diagram



1.7.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the PowerVR SGX architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an input control stream, which contains triangle index data and state data. The state data indicates the PDS program, size of the vertices, and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.
- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile, which allows for optimum efficiency within each pipe due to locality of data. It determines the amount of resource required within the USSE for each task. It merges this with the state address and issues a request to the DMS for execution on the USSE.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbiter/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration, as well as any required texture decompression, are performed between the three data streams.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests in the multilevel cache. Data returned from the cache are then formatted according to the texture format selected, and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer and then USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

1.7.4 SGX Registers

CAUTION

All SGX registers are limited to 32-bit data accesses, 8- and 16-bit accesses are not allowed because they can corrupt register content.

Table 1-48 provides a summary of the SGX registers. For the base address of these registers. see Table 1-11.

Table 1-48. SGX Registers

Offset	Acronym	Register Description	Section
FE00h	OCP_REVISION	OCP Revision Register	Section 1.7.4.1
FE04h	OCP_HWINFO	Hardware Implementation Information Register	Section 1.7.4.2
FE10h	OCP_SYSCONFIG	System Configuration Register	Section 1.7.4.3

1.7.4.1 OCP Revision Register (OCP_REVISION)

The OCP Revision Register (OCP_REVISION) is shown in Figure 1-48 and described in Table 1-49.

Figure 1-48. OCP Revision Register (OCP_REVISION)

31	0
REVISIONID	
R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 1-49. OCP Revision Register (OCP_REVISION) Field Descriptions

Bit	Field	Value	Description
31-0	REVISIONID	0-FFFF FFFFh	Revision value.

1.7.4.2 Hardware Implementation Information Register (OCP_HWINFO)

The Hardware Implementation Information Register (OCP_HWINFO) is shown in Figure 1-49 and described inTable 1-50.

Figure 1-49. Hardware Implementation Information Register (OCP_HWINFO)

31	3	2	1	0
Reserved		MEM_BUS_WIDTH	SYS_BUS_WIDTH	
R-0		R-0	R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 1-50. Hardware Implementation Information Register (OCP_HWINFO) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved.
2	MEM_BUS_WIDTH		Memory bus width.
		0	Memory bus width is 64 bits.
		1	Memory bus width is 128 bits
1-0	SYS_BUS_WIDTH		System bus width.
		0	System bus width is 32 bits.
		1h	System bus width is 64 bits.
		2h	System bus width is 128 bits.
		3h	Reserved.

1.7.4.3 System Configuration Register (OCP_SYSCONFIG)

The System Configuration Register (OCP_SYSCONFIG) is shown in Figure 1-50 and described in Table 1-51.

Figure 1-50. System Configuration Register (OCP_SYSCONFIG)

31 6	5 4	3 2	1 0
Reserved	STANDBY_MODE	IDLE_MODE	Reserved
R-0	R/W-2h	R/W-2h	R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-51. System Configuration Register (OCP_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved.
5-4	STANDBY_MODE		Clock standby mode.
		0	Force Standby mode.
		1h	No Standby mode.
		2h	Smart Standby mode.
		3h	Smart Standby mode.
3-2	IDLE_MODE		Clock Idle mode.
		0	Force Idle mode.
		1h	No idle mode.
		2h	Smart Idle mode.
		3h	Smart Idle mode.
1-0	Reserved	0	Reserved.

1.7.4.4 Raw IRQ 0 Status Register (OCP_IRQSTATUS_RAW_0)

The Raw IRQ 0 Status Register (OCP_IRQSTATUS_RAW_0) is shown in Figure 1-51 and described in Table 1-52.

Figure 1-51. Raw IRQ 0 Status Register (OCP_IRQSTATUS_RAW_0)

31	1	0
Reserved		INIT_MINTERRUPT_RAW
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-52. Raw IRQ 0 Status Register (OCP_IRQSTATUS_RAW_0) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	INIT_MINTERRUPT_RAW		Interrupt 0 - master port raw event.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: No action.
		1	Write: Set event (Used for debug).

1.7.4.5 Raw IRQ 1 Status Register (OCP_IRQSTATUS_RAW_1)

The Raw IRQ 1 Status Register (OCP_IRQSTATUS_RAW_1) is shown in Figure 1-52 and described in Table 1-53.

Figure 1-52. Raw IRQ 1 Status Register (OCP_IRQSTATUS_RAW_1)

31	1	0
Reserved		TARGET_SINTERRUPT_RAW
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-53. Raw IRQ 1 Status Register (OCP_IRQSTATUS_RAW_1) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	TARGET_SINTERRUPT_RAW		Interrupt 1- slave port raw event.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: No action.
		1	Write: Set event (Used for debug).

1.7.4.6 Raw IRQ 2 Status Register (OCP_IRQSTATUS_RAW_2)

The Raw IRQ 2 Status Register (OCP_IRQSTATUS_RAW_2) is shown in Figure 1-53 and described in Table 1-54.

Figure 1-53. Raw IRQ 2 Status Register (OCP_IRQSTATUS_RAW_2)

31	1	0
Reserved		THALIA_IRQ_RAW
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-54. Raw IRQ 2 Status Register (OCP_IRQSTATUS_RAW_2) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	THALIA_IRQ_RAW		Interrupt 2 - Thalia raw event.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: No action.
		1	Write: Set event (Used for debug).

1.7.4.7 Interrupt 0 Status Event Register (OCP_IRQSTATUS_0)

The Interrupt 0 Status Event Register (OCP_IRQSTATUS_0) is shown in Figure 1-54 and described in Table 1-55.

Figure 1-54. Interrupt 0 Status Event Register (OCP_IRQSTATUS_0)

31	1	0
Reserved		INIT_MINTERRUPT_STATUS
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-55. Interrupt 0 Status Event Register (OCP_IRQSTATUS_0) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	INIT_MINTERRUPT_STATUS		Interrupt 0 - Master port status event.
		0	Read: No event pending.
		1	Read: Event pending and interrupt enabled.
		0	Write: No action.
		1	Write: Clear event.

1.7.4.8 Interrupt 1 Status Event Register (OCP_IRQSTATUS_1)

The Interrupt 1 Status Event Register (OCP_IRQSTATUS_1) is shown in Figure 1-55 and described in Table 1-56.

Figure 1-55. Interrupt 1 Status Event Register (OCP_IRQSTATUS_1)

31	1	0
Reserved		TARGET_SINTERRUPT_ STATUS
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-56. Interrupt 1 Status Event Register (OCP_IRQSTATUS_1) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	TARGET_SINTERRUPT_STATUS		Interrupt 1 - slave port status event.
		0	Read: No event pending.
		1	Read: Event pending and interrupt enabled.
		0	Write: No action.
		1	Write: Clear event.

1.7.4.9 Interrupt 2 Status Event Register (OCP_IRQSTATUS_2)

The Interrupt 2 Status Event Register (OCP_IRQSTATUS_2) is shown in Figure 1-56 and described in Table 1-57.

Figure 1-56. Interrupt 2 Status Event Register (OCP_IRQSTATUS_2)

31	1	0
Reserved		TARGET_SINTERRUPT_ STATUS
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-57. Interrupt 2 Status Event Register (OCP_IRQSTATUS_2) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	TARGET_SINTERRUPT_STATUS		Interrupt 1 - slave port status event.
		0	Read: No event pending.
		1	Read: Event pending and interrupt enabled.
		0	Write: No action.
		1	Write: Clear event.

1.7.4.10 Enable Interrupt 0 Register (OCP_IRQENABLE_SET_0)

The Enable Interrupt 0 Register (OCP_IRQENABLE_SET_0) is shown in Figure 1-57 and described in Table 1-58.

Figure 1-57. Enable Interrupt 0 Register (OCP_IRQENABLE_SET_0)

31	1	0
Reserved		INIT_MINTERRUPT_ENABLE
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-58. Enable Interrupt 0 Register (OCP_IRQENABLE_SET_0) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	INIT_MINTERRUPT_ENABLE		Enable interrupt 0 - master port.
		0	Read: Interrupt is enabled.
		1	Read: Interrupt is disabled.
		0	Write: No action.
		1	Write: Enable interrupt.

1.7.4.11 Enable Interrupt 1 Register (OCP_IRQENABLE_SET_1)

The Enable Interrupt 1 Register (OCP_IRQENABLE_SET_1) is shown in Figure 1-58 and described in Table 1-59.

Figure 1-58. Enable Interrupt 1 Register (OCP_IRQENABLE_SET_1)

31	1	0
Reserved		TARGET_SINTERRUPT_ ENABLE
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-59. Enable Interrupt 1 Register (OCP_IRQENABLE_SET_1) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	TARGET_SINTERRUPT_ENABLE		Enable interrupt 1 - slave port interrupt.
		0	Read: Interrupt is enabled.
		1	Read: Interrupt is disabled.
		0	Write: No action.
		1	Write: Enable interrupt.

1.7.4.12 Enable Interrupt 2 Register (OCP_IRQENABLE_SET_2)

The Enable Interrupt 2 Register (OCP_IRQENABLE_SET_2) is shown in Figure 1-59 and described in Table 1-60.

Figure 1-59. Enable Interrupt 2 Register (OCP_IRQENABLE_SET_2)

31	1	0
Reserved		THALIA_IRQ_ENABLE
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-60. Enable Interrupt 2 Register (OCP_IRQENABLE_SET_2) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	THALIA_IRQ_ENABLE		Enable interrupt 2 - Thalia (core) interrupt.
		0	Read: Interrupt is enabled.
		1	Read: Interrupt is disabled.
		0	Write: No action.
		1	Write: Enable interrupt.

1.7.4.13 Disable Interrupt 0 Register (OCP_IRQENABLE_CLR_0)

The Disable Interrupt 0 Register (OCP_IRQENABLE_CLR_0) is shown in Figure 1-60 and described in Table 1-61.

Figure 1-60. Disable Interrupt 0 Register (OCP_IRQENABLE_CLR_0)

31	1	0
Reserved		INIT_MINTERRUPT_ DISABLE
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-61. Disable Interrupt 0 Register (OCP_IRQENABLE_CLR_0) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	INIT_MINTERRUPT_DISABLE		Disable interrupt 0 - master port.
		0	Read: Interrupt is enabled.
		1	Read: Interrupt is disabled.
		0	Write: No action.
		1	Write: Disable interrupt.

1.7.4.14 Disable Interrupt 1 Register (OCP_IRQENABLE_CLR_1)

The Disable Interrupt 1 Register (OCP_IRQENABLE_CLR_1) is shown in Figure 1-61 and described in Table 1-62.

Figure 1-61. Disable Interrupt 1 Register (OCP_IRQENABLE_CLR_1)

31	1	0
Reserved		TARGET_SINTERRUPT_DISABLE
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-62. Disable Interrupt 1 Register (OCP_IRQENABLE_CLR_1) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	TARGET_SINTERRUPT_DISABLE		Disable interrupt 1 - slave port.
		0	Read: Interrupt is enabled.
		1	Read: Interrupt is disabled.
		0	Write: No action.
		1	Write: Disable interrupt.

1.7.4.15 Disable Interrupt 2 Register (OCP_IRQENABLE_CLR_2)

The Disable Interrupt 2 Register (OCP_IRQENABLE_CLR_2) is shown in Figure 1-62 and described in Table 1-63.

Figure 1-62. Disable Interrupt 2 Register (OCP_IRQENABLE_CLR_2)

31	1	0
Reserved		THALIA_IRQ_DISABLE
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-63. Disable Interrupt 2 Register (OCP_IRQENABLE_CLR_2) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved.
0	THALIA_IRQ_DISABLE		Disable interrupt 2 - Thalia (core) interrupt.
		0	Read: Interrupt is enabled.
		1	Read: Interrupt is disabled.
		0	Write: No action.
		1	Write: Disable interrupt.

1.7.4.16 Configure Memory Page Register (OCP_PAGE_CONFIG)

The Configure Memory Page Register (OCP_PAGE_CONFIG) is shown in Figure 1-62 and described in Table 1-63.

Figure 1-63. Configure Memory Page Register (OCP_PAGE_CONFIG)

31	5	4	3	2	1	0
Reserved		OCP_PAGE_SIZE		MEM_PAGE_CHECK_EN	MEM_PAGE_SIZE	
R-0		R/W-2h		R/W-1h	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 1-64. Configure Memory Page Register (OCP_PAGE_CONFIG) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved.
4-3	OCP_PAGE_SIZE		Defines the page size on OCP memory interface.
		0	Page size is 4 KB.
		1h	Page size is 2 KB.
		2h	Page size is 1 KB.
		3h	Page size is 520 B.
2	MEM_PAGE_CHECK_EN		Enable page boundary checking.
		0	Page boundary checking is disabled.
		1	Page boundary checking is enabled.
1-0	MEM_PAGE_SIZE		Defines the page size on internal memory interface.
		0	Page size is 4 KB.
		1h	Page size is 2 KB.
		2h	Page size is 1 KB.
		3h	Page size is 520 B.

1.7.4.17 Interrupt Events Register (OCP_INTERRUPT_EVENT)

The Interrupt Events Register (OCP_INTERRUPT_EVENT) is shown in Figure 1-64 and described in Table 1-65.

Figure 1-64. Interrupt Events Register (OCP_INTERRUPT_EVENT)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved		INIT_MEM_REQ_FIFO_OVERRUN	INIT_READ_TAG_FIFO_OVERRUN	INIT_PAGE_CROSS_ERROR	INIT_RESP_ERROR	INIT_RESP_UNUSED_TAG	INIT_RESP_UNEXPECTED
		R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-65. Interrupt Events Register (OCP_INTERRUPT_EVENT) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	Reserved.
10	TARGET_INVALID_OCP_CMD		Invalid command from OCP
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: Clear the event.
		1	Write: Set event and interrupt if enabled (debug only).
9	TARGET_CMD_FIFO_FULL		Command FIFO full.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: Clear the event.
		1	Write: Set event and interrupt if enabled (debug only).
7-6	Reserved	0	Reserved.
5	INIT_MEM_REQ_FIFO_OVERRUN		Memory request FIFO overrun.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: Clear the event.
		1	Write: Set event and interrupt if enabled (debug only).
4	INIT_READ_TAG_FIFO_OVERRUN		Read tag FIFO overrun.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: Clear the event.
		1	Write: Set event and interrupt if enabled (debug only).
3	INIT_PAGE_CROSS_ERROR		Memory page had been crossed during a burst.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: Clear the event.
		1	Write: Set event and interrupt if enabled (debug only).

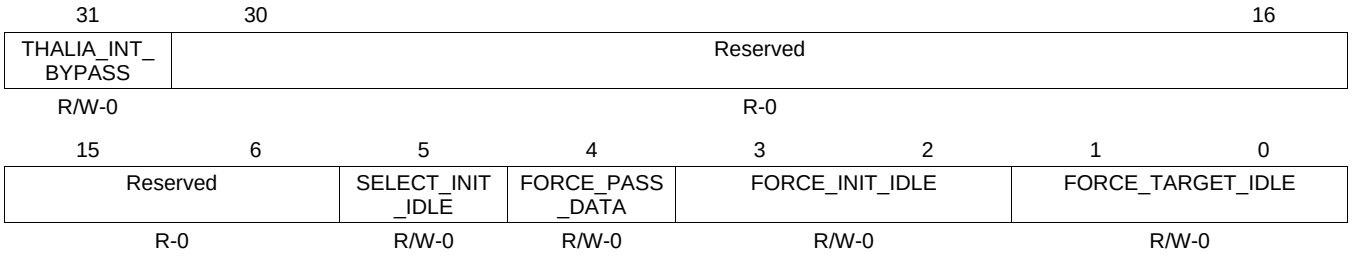
Table 1-65. Interrupt Events Register (OCP_INTERRUPT_EVENT) Field Descriptions (continued)

Bit	Field	Value	Description
2	INIT_RESP_ERROR		Receiving error response.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: Clear the event.
		1	Write: Set event and interrupt if enabled (debug only).
1	INIT_RESP_UNUSED_TAG		Receiving response on an unused tag.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: Clear the event.
		1	Write: Set event and interrupt if enabled (debug only).
0	INIT_RESP_UNEXPECTED		Receiving response when not expected.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: Clear the event.
		1	Write: Set event and interrupt if enabled (debug only).

1.7.4.18 Configuration of Debug Modes Register (OCP_DEBUG_CONFIG)

The Configuration of Debug Modes Register (OCP_DEBUG_CONFIG) is shown in Figure 1-65 and described in Table 1-66.

Figure 1-65. Configuration of Debug Modes Register (OCP_DEBUG_CONFIG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-66. Configuration of Debug Modes Register (OCP_DEBUG_CONFIG) Field Descriptions

Bit	Field	Value	Description
31	THALIA_INT_BYPASS		Bypass OCP IPG interrupt logic.
		0	Do not bypass.
		1	Bypass core interrupt to IO pin, ie disregard the interrupt enable setting in IPG register.
30-6	Reserved	0	Reserved.
5	SELECT_INIT_IDLE		To select which idle the disconnect protocol should act on 0.
		0	Whole SGX Idle.
		1	OCP initiator idle only
4	FORCE_PASS_DATA		Forces the initiator to pass data independent of disconnect protocol.
		0	Normal mode. Do not force.
		1	Never fence request to OCP.
3-2	FORCE_INIT_IDLE		Forces the OCP master port to Idle.
		0	Normal mode. No force.
		1h	Force port to be always Idle.
		2h	Forces target port to never be in Idle mode.
		3h	Normal mode. No force.
1-0	FORCE_TARGET_IDLE		Forces the OCP target port to Idle.
		0	Normal mode. No force.
		1h	Force port to be always Idle.
		2h	Forces target port to never be in Idle mode.
		3h	Normal mode. No force.

1.7.4.19 Debug Status Register (OCP_DEBUG_STATUS)

The Debug Status Register (OCP_DEBUG_STATUS) is shown in Figure 1-66 and described in Table 1-67.

Figure 1-66. Debug Status Register (OCP_DEBUG_STATUS)

31	30	29	28	27	26	25	24
CMD_DEBUG_STATE	CMD_RESP_DEBUG_STATE	TARGET_IDLE	RESP_FIFO_FULL	CMD_FIFO_FULL	RESP_ERROR	WHICH_TARGET_REGISTER	
R/W-0	R/W-0	R-0	R-0	R-0	R-0	R/W-0	

23	21	20	18	17	16
WHICH_TARGET_REGISTER		TARGET_CMD_OUT		INIT_MSTANDBY	INIT_MWAIT
R/W-0		R-0		R-0	R-0

15	14	13	12	11	10	9	8
INIT_MDISCREQ		INIT_MDISCACK	INIT_SCONNECT2	INIT_SCONNECT1	INIT_SCONNECT0	INIT_MCONNECT	
R-0		R/W-0	R-0	R-0	R-0	R-0	

7	6	5	4	3	2	1	0
TARGET_SIDLEACK		TARGET_SDISCACK		TARGET_SIDLEREQ	TARGET_SCONNECT	TARGET_MCONNECT	
R-0		R-0		R-0	R-0		

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-67. Debug Status Register (OCP_DEBUG_STATUS) Field Descriptions

Bit	Field	Value	Description
31	CMD_DEBUG_STATE		Target command state machine
		0	Idle.
		1	Accept command.
30	CMD_RESP_DEBUG_STATE		Target response state machine.
		0	Send accept.
		1	Wait accept.
29	TARGET_IDLE	0-1	Target idle.
28	RESP_FIFO_FULL	0-1	Target response FIFO full.
27	CMD_FIFO_FULL	0-1	Target command FIFO full.
26	RESP_ERROR	0-1	Respond to OCP with error, which could be caused by either address misalignment or invalid byte enable.
25-21	WHICH_TARGET_REGISTER	0-1Fh	Indicates which OCP target registers to read.
20-18	TARGET_CMD_OUT		Command received from OCP.
		0	Command WRSYS received.
		1h	Command RDSYS received.
		2h	Command WR_ERROR received.
		3h	Command RD_ERROR received.
		4h	Command CHK_WRADDR_PAGE received. Not used.
		5h	Command CHK_RDADDR_PAGE received. Not used.
		6h	Command TARGET_REG_WRITE received.
		7h	Command TARGET_REG_READ received.
17	INIT_MSTANDBY	1-0	Status of init_MStandby signal.
16	INIT_MWAIT	1-0	Status of init_MWait signal.

Table 1-67. Debug Status Register (OCP_DEBUG_STATUS) Field Descriptions (continued)

Bit	Field	Value	Description
15-14	INIT_MDISCREQ		Disconnect status of the OCP interface.
		0	State is FUNCT.
		1h	State is SLEEP TRANS
		2h	Reserved.
		3h	State is IDLE.
13	INIT_MDISCACK		Memory request FIFO full.
		0	Read: No event pending.
		1	Read: Event pending.
		0	Write: Clear the event.
		1	Write: Set the event and interrupt if enabled (debug only)
12	INIT_SCONNECT2		Defines whether to wait in M_WAIT state for MConnect FSM.
		0	Skip M_WAIT state.
		1	Wait in M_WAIT state.
11	INIT_SCONNECT1		Defines the busy-ness state of the slave.
		0	Slave is drained.
		1	Slave is loaded.
10	INIT_SCONNECT0		Disconnect from slave.
		0	Disconnect request from slave.
		1	Connect request from slave.
9-8	INIT_MCONNECT		Initiator MConnect state.
		0	State is M_OFF.
		1h	State is M_WAIT.
		2h	State is M_DISC.
		3h	State is M_CON.
7-6	TARGET_SIDLEACK		Acknowledge the SIdleAck state machine.
		0	State is FUNCT.
		1h	State is SLEEP TRANS.
		2h	Reserved.
		3h	State is IDLE.
5-4	TARGET_SDISCACK		Acknowledge the SDiscAck state machine.
		0	State is FUNCT.
		1h	State is SLEEP TRANS.
		2h	Reserved.
		3h	State is IDLE.
3	TARGET_SIDLEREQ		Request the target to go idle.
		0	Do not go idle, or go active.
		1	Go idle.
2	TARGET_SCONNECT		Target SConnect state.
		0	Disconnect interface.
		1	Connect OCP interface.
1-0	TARGET_MCONNECT		Target MConnect state.
		0	Target is in M_OFF state.
		1h	Target is in M_WAIT disconnect state.
		2h	Target is in M_DISC state.
		3h	Target is in M_CON state.

1.8 Device Interrupts

1.8.1 Interrupt Requests to Cortex-A8 MPU INTC

Table 1-68 shows the Cortex-A8 MPU INTC interrupt mapping.

Table 1-68. Cortex-A8 MPU INTC Interrupt Mapping

MPUSS Interrupt Number	Event	Interrupt Source	Description
0	EMUINT	MPUSS Internal	MPU Emulation(1)
1	COMMTX	MPUSS Internal	MPU Emulation(1)
2	COMMRX	MPUSS Internal	MPU Emulation(1)
3	BENCH	MPUSS Internal	MPU Emulation(1)
4	ELM_IRQ	ELM	Error Location process completion
5	Reserved	Reserved	
6	Reserved	Reserved	
7	NMI	External Pin	NMI Interrupt
8	Reserved	Reserved	
9	L3DEBUG	L3	L3 Debug Error Interrupt
10	L3APPINT	L3	L3 Application Error Interrupt
11	Reserved	Reserved

1.9 EDMA and EDMA Events

1.9.1 Overview

The device uses L3 crossbar architecture to control access between device processors, subsystems, and peripherals. It includes four third-party DMA transfer controllers (TPTCs) that provide four EDMA channels for transfer between L3 slaves. The device also makes use of the third-party channel controller (TPCC). The TPCC provides a user and event interface to the EDMA system. It includes up to 64 event channels to which all system synchronization events can be mapped and 8 auto-submit channels (QDMA).

Parameter RAM: Each EDMA is specified by an 8-word (32-byte) parameter table contained in Parameter RAM (PaRAM) within the TPCC. The number of PaRAM entries supported is 512.

QDMA: The quick DMA (QDMA) function is contained within the TPCC. The device implements all 8 possible QDMA channels. Each QDMA channel has a selectable PaRAM entry used to specify the transfer. A QDMA transfer is submitted immediately upon writing of the “trigger” parameter (as opposed to the occurrence of an event as with EDMA). The QDMA parameter RAM may be written by any bus master with an L3 connection to the TPCC CFG port.

1.9.2 EDMA Regions

In order to support multiple processors, the TPCC is configured with all eight interrupt regions implemented. This allows each processing element (Cortex-A8, DSP) to be interrupted upon completion of any EDMAs associated with its program flow independent of other EDMAs in the system. Assignment of the region interrupts is shown in Table 1-70.

Table 1-70. EDMA Regions

TPCC Region	Processor	Interrupt Name (Processor)
0	Cortex-A8	CCINT0
1	DSP	CCINT1
2	–	–
3	–	–
4	–	–
5	–	–
6	–	–
7	–	–

1.9.3 Synchronization Events

The EDMA supports up to 64 EDMA channels that service peripheral devices and external memory.Table 1-71 lists the source of EDMA synchronization events associated with each of the programmable EDMA channels. The association of an event to a channel is fixed; each of the EDMA channels has one specific event associated with it. These specific events are captured in the EDMA event registers (ER, ERH) even if the events are disabled by the EDMA event enable registers (EER, EERH). For more detailed information on the EDMA module and how EDMA events are enabled, captured, processed, linked, chained, and cleared, see the *Enhanced DMA (EDMA) Controller* chapter.

Table 1-71. EDMA Channel Synchronization Events

1.10 Device Clocking and Flying Adder PLL

1.10.1 Overview

This device has 4 on-chip PLLs and requires a 27-MHz reference clock that is generated by an on-chip oscillator. Figure 1-67 shows a high-level overview of the device clocking structure.

For detailed specifications on clock frequency and voltage requirements, see the device-specific data manual.

In addition to the reference clock, there is a 100-MHz differential clock input for the SATA and PCIe. A third clock input is an optional 32768-Hz clock input (no on-chip oscillator) for the RTC. All possible input clocks are described in Table 1-72 and System Clock Domains are described in Table 1-73. Figure 1-68 shows detailed clocking architecture on this device.

Figure 1-67. Top Level Clock Architecture

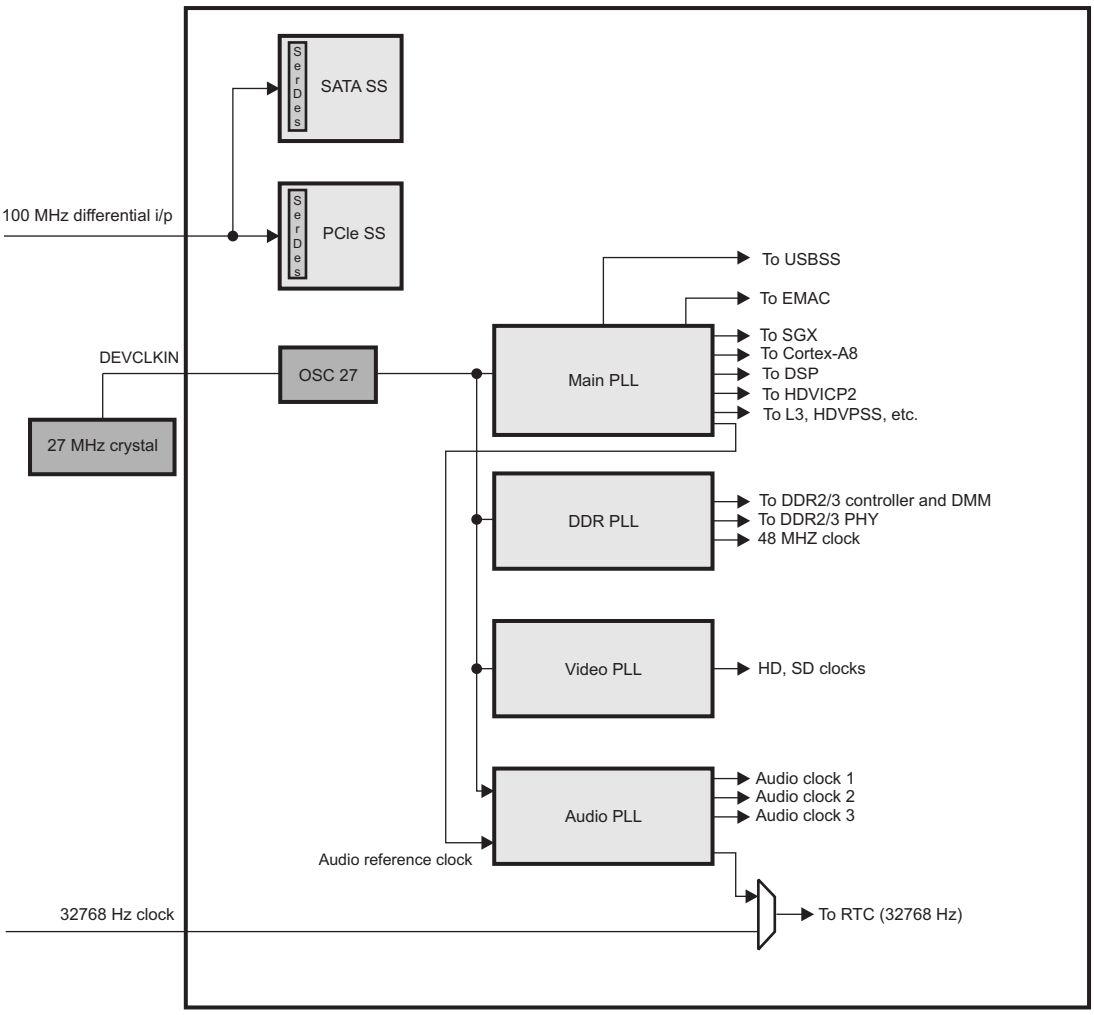

Table 1-72. Device Clock Inputs

Peripheral	Input Clock Signal Name
PLL	CLKIN1, CLKIN2
RTC	CLKIN32
JTAG	TCLK, RTCLK

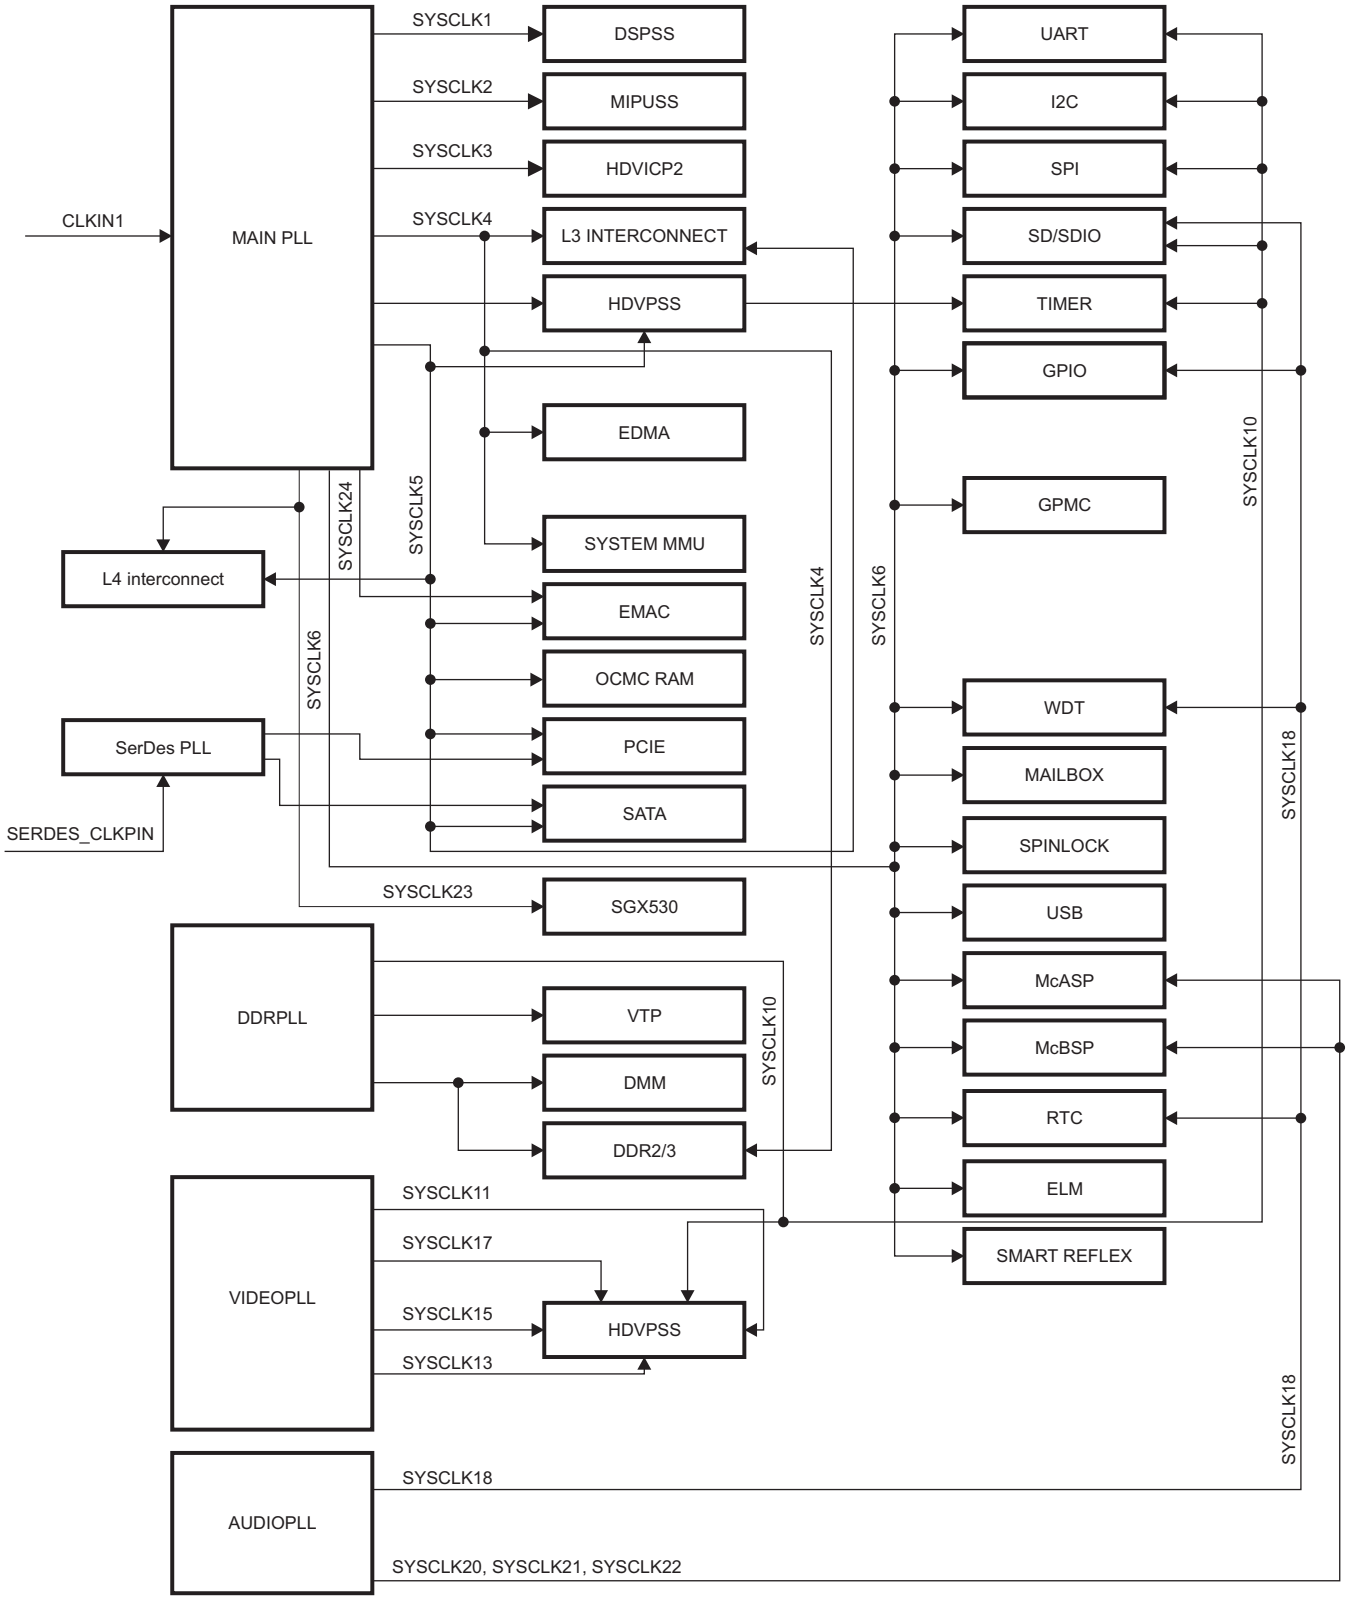
Figure 1-68. Detailed Clock Architecture



1.10.2 I/O Domains

The I/O domains refer to the frequencies of the peripherals that communicate through device pins. In many cases, there are frequency requirements for a peripheral pin interface that are set by an outside standard and must be met. It is not necessarily possible to obtain these frequencies from the on-chip clock generation circuitry, so the frequencies must be obtained from external sources and are asynchronous to the CPU frequency by definition. Table 1-74 shows the external Peripheral Clock Sources.

Table 1-74. External Peripheral Clock Sources

I/O (External) Domain Clock Source Options			
Peripheral	**I/O Domain Clock Frequency**	**Internal Clock Source**	**External Clock Source**
DDR2	333 to 533 MHz	SYSCLK8	
DDR3	333 to 800 MHz	SYSCLK8	
MTS	27 MHz	SYSCLK14, SYSCLK16	MTSI_DLCK
EMAC	125 MHz	SYSCLK24	EMAC[0]_TXCLK, EMAC[0]_RXCLK, EMAC[1]_TXCLK, EMAC[1]_RXCLK
MDIO	25 MHz	SYSCLK6

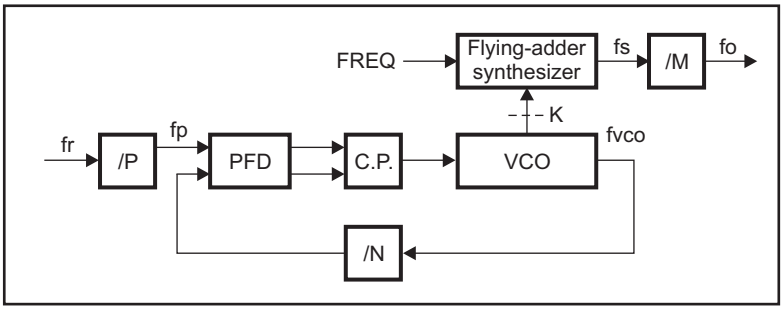
SD/SDIO	48 MHz	SYSCLK6	
MAINPLL, DDRPLL, VIDEOPLL, AUDIOPLL	27 MHz		CLKIN1

1.10.3 Flying Adder PLL

The device uses Flying Adder PLLs for all on-chip PLLs. Figure 1-69 shows basic structure of the Flying Adder PLL.

Figure 1-69. Flying Adder PLL



Flying Adder PLL (FAPLL) has two main components:

1. Multiphase PLL
2. Flying Adder Synthesizer.

The multiphase PLL takes input reference clock (f_r), mutliplies it with factor N and provides a K phase output to the flying adder synthesizer. The flying adder synthesizer takes this multi phase clock input and produces a variable frequency clock (f_s). There is post divider on this clock that takes in clock f_s and drives out clock f_o.

The f_{vco} frequency of the PLL is given by $f_{vco} = (N/P) \times f_r$

The f_s frequency of the FAPLL is given by $f_s = (f_{vco} \times K)/FREQ$

The f_o frequency of the Post divider is given by $f_o = f_s/M$

Where:

f_{vco} = VCO frequency. Range is 800 to 1600 MHz.

f_r = Input reference frequency

N = Multiplier is 9 bits and supported range is 1 to 511.

P = Pre-divider

K = Phase Output. 8 is the value for this device

f_s = FAPLL output

f_o = Post Divider output

FREQ = Supported integer range is 8 to 15 and fraction range is 0 to FF FFFFh.

M = Post Divider. Value ranges from 1 to 255.

There can be multiple flying adder synthesizers attached to one multiphase PLL to generate different frequencies. FREQ and M values can be adjusted for each clock separately based on the frequency needed.

NOTE: Maximum frequency of PLL out clock must meet minimum cycle limits requirements. Refer to the device-specific data manual for PLL Programming Limits.

1.10.3.1 PLL Types

This device has 4 on-chip PLLs:

1. MAIN PLL
2. DDR PLL
3. VIDEO PLL
4. AUDIO PLL

1.10.3.1.1 Main PLL

Figure 1-70 shows structure of Main PLL. The Main PLL has 5 flying adder synthesizers connected to the multi-phase PLL. The outputs of these synthesizers are muxed with the 27-MHz reference clock to allow its selection during PLL bypass mode. Table 1-76 lists the IPs that are clocked from each of these flying adder synthesizers.

As shown in Figure 1-70, there are five independently controllable clock outputs (asynchronous to each other) driven by the main PLL. The FREQ and post divider can be tuned independently to control each clock. This makes it possible to run DSP, Cortex-A8, HDVICP2 and interconnect independent of each other. However as the same multiphase PLL is used to generate all these clocks, the choice of possible frequencies will be limited. The set of available frequencies will depend upon choice of P and N for the multi phase PLL.

The Main PLL also provides a reference clock for the Audio PLL and the USB subsystem using programmable dividers (for audio PLL divider factor, see Section 1.16.1.2.14; for USB PLL divider factor, see Section 1.16.1.2.13). Table 1-77, Table 1-78, and Table 1-79 show examples for Main PLL System Clock generation for speed grade blank, grade 2, and grade 4, respectively. In these examples, Multiplier N is carefully set to 56 to allow 24 MHz USB clock generation and keep the VCO frequency less than 1600 MHz. Note that the SYSCLK frequencies listed in the examples are less than the maximum frequency listed in Table 1-76. This is because the minimum cycle limit has been applied by selecting a FREQ × M value that does not cause the instantaneous frequency to go over the maximum frequency.

Figure 1-70. Main PLL Structure

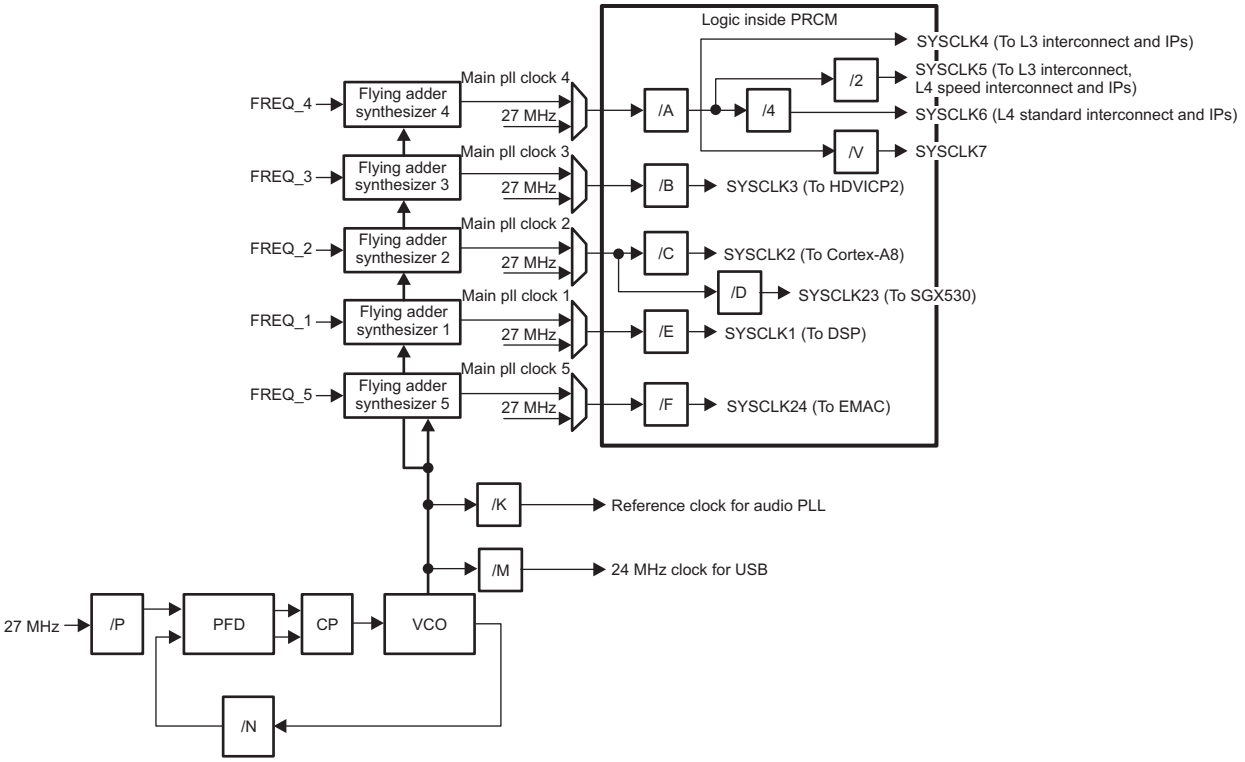


Table 1-75. MAIN PLL Dividers

Divider	Supported Divide Ratios	Default Value
A	1/1, 1/2	1/1
B	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
C	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
D	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/4
E	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
V	1/5, 1/6, 1/8, 1/16	1/5
F	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
K	See MAINPLL_DIV7[7:0] MAIND_DIV7 (Table 1-182)	1/4
M	See MAIN_PLL_DIV6[7:0] MAIND_DIV6 (Table 1-181)	1/72

Table 1-76. Main PLL SYSCLK Frequencies and Destination

SYSCLK	Device Speed Range[1]	Maximum Frequency (MHz)[2]	Destination

	4		

(1) For more information on the available device speed ranges for each part number, see the device-specific data manual

(2) Maximum frequency of PLL out clocks should meet minimum cycle limits. Refer to the device-specific data manual for PLL Programming Limits.

Table 1-77. Example for Main PLL Frequencies for Speed Grade Blank

Input Ref Freq	Pre-Divider	Mult	VCO Output Freq	4 Bits Integer	24 Bits Fract	FAPLL Output	Post Divider	Post Divider Output		PRCM Divider		System Clock Domain	SYSCLK Freq (MHz)
								Mean[1]	Max[2]				
f_r (MHz)	P[3]	N[3]	f_{vco} (MHz)	FREQ[3]		f_s (MHz)	M[3]	f_o (MHz)					
27	1	56	1512	8	0	1512	2	756	767	1		SYSCLK1	756
				13	0	930	1	930	954	1		SYSCLK2	930
										3		SYSCLK23	310
				12	0	1008	2	504	510	1		SYSCLK3	504
				13	0	930	2	465	473	1		SYSCLK4	465
										1	2	SYSCLK5	233
										1	4	SYSCLK6	116
										1	5	SYSCLK7	93
				12	0.096	1000	8	125	127	1		SYSCLK24	125

(1) Mean frequency is an average FAPLL output frequency over time when P, N, M, and FREQ are tuned.
(2) Maximum frequency is an instantaneous frequency when FAPLL generates clock at minimum clock cycle.
(3) The values of Pre-Divider (P), Multiplier (N), FREQ, and Post Divider (M) can be tuned in order to obtain different frequencies; however, the software must respect the limitations (and requirements) described in the device-specific data manual for PLL Programming Limits.

Table 1-78. Example for Main PLL Frequencies for Speed Grade 2

Input Ref Freq	Pre-Divider	Mult	VCO Output Freq	4 Bits Integer	24 Bits Fract	FAPLL Output	Post Divider	Post Divider Output		PRCM Divider		System Clock Domain	SYSCLK Freq (MHz)
								Mean[1]	Max[2]				
f_r (MHz)	P[3]	N[3]	f_{vco} (MHz)	FREQ[3]		f_s (MHz)	M[3]	f_o (MHz)					
27	1	56	1512	13	0	930	1	930	954	1		SYSCLK1	930
				11	0	1100	1	1100	1131	1		SYSCLK2	1100
										4		SYSCLK23	275
				11	0	1100	2	550	560	1		SYSCLK3	550
				11	0	1100	2	550	560	1		SYSCLK4	550
										1	2	SYSCLK5	275
										1	4	SYSCLK6	138
										1	5	SYSCLK7	110
				12	0.096	1000	8	125	127	1		SYSCLK24	125

(1) Mean frequency is an average FAPLL output frequency over time when P, N, M, and FREQ are tuned.
(2) Maximum frequency is an instantaneous frequency when FAPLL generates clock at minimum clock cycle.
(3) The values of Pre-Divider (P), Multiplier (N), FREQ, and Post Divider (M) can be tuned in order to obtain different frequencies; however, the software must respect the limitations (and requirements) described in the device-specific data manual for PLL Programming Limits.

Table 1-79. Example for Main PLL Frequencies for Speed Grade 4

Input Ref Freq	Pre-Divider	Mult	VCO Output Freq	4 Bits Integer	24 Bits Fract	FAPLL Output	Post Divider	Post Divider Output		PRCM Divider		System Clock Domain	SYSCLK Freq (MHz)
								Mean[1]	Max[2]				
f_r (MHz)	P[3]	N[3]	f_{vco} (MHz)	FREQ[3]		f_s (MHz)	M[3]	f_o (MHz)					
27	1	56	1512	12	0	1008	1	1008	1035	1		SYSCLK1	1008
				10	0	1210	1	1210	1247	1		SYSCLK2	1210
										4		SYSCLK23	303
				9	0.5	1273	2	637	649	1		SYSCLK3	637
				10	0.5	1152	2	576	586	1		SYSCLK4	576
										1	2	SYSCLK5	288
										1	4	SYSCLK6	144
										1	5	SYSCLK7	115
				12	0.096	1000	8	125	127	1		SYSCLK24	125

(1) Mean frequency is an average FAPLL output frequency over time when P, N, M, and FREQ are tuned.
(2) Maximum frequency is an instantaneous frequency when FAPLL generates clock at minimum clock cycle.
(3) The values of Pre-Divider (P), Multiplier (N), FREQ, and Post Divider (M) can be tuned in order to obtain different frequencies; however, the software must respect the limitations (and requirements) described in the device-specific data manual for PLL Programming Limits.

Table 1-80 is an example that shows the effect of a fractional FREQ causing the SYSCLK5 frequency to break the maximum frequency limit. The maximum frequency of SYSCLK5 for speed grade 2 is 280 MHz. When FREQ is set to integer 11, SYSCLK5 output mean frequency is 275 MHz and its maximum instantaneous frequency is 280 MHz, which is not over the maximum frequency limit. When FREQ is set to fractional 10.8, SYSCLK5 output maximum instantaneous frequency is 293 MHz, which is over the maximum frequency limit.

Table 1-80. Example of SYSCLK5 Frequency with Integer FREQ vs Fractional FREQ

Input Ref Freq	Pre-Divider	Mult	VCO Output Freq	4 Bits Integer	24 Bits Fract	FAPLL Output	Post Divider	Post Divider Output		PRCM Divider		System Clock Domain	SYSCLK Mean Freq (MHz)
								Mean[1]	Max[2]				
f_r (MHz)	P[3]	N[3]	f_{vco} (MHz)	FREQ[3]		f_s (MHz)	M[3]	f_o (MHz)					
27	1	56	1512	11	0	1100	2	550	560	1	2	SYSCLK5	275
				10	0.8	1120	2	560	587	1	2	SYSCLK5	280

(1) Mean frequency is an average FAPLL output frequency over time when P, N, M, and FREQ are tuned.
(2) Maximum frequency is an instantaneous frequency when FAPLL generates clock at minimum clock cycle.
(3) The values of Pre-Divider (P), Multiplier (N), FREQ, and Post Divider (M) can be tuned in order to obtain different frequencies; however, the software must respect the limitations (and requirements) described in the device-specific data manual for PLL Programming Limits.

1.10.3.1.1.1 Steps for Changing Main PLL Frequency

Refer to the appropriate subsection on how to program the MAINPLL clocks:

- If the MAINPLL is powered down (MAIN_PLLEN bit in MAINPLL_CTRL is cleared to 0), follow the procedure in Section 1.10.3.1.1.1.1 to initialize the MAINPLL.
- If the MAINPLL is not powered down (MAIN_PLLEN bit in MAINPLL_CTRL is set to 1), follow the procedure in Section 1.10.3.1.1.1.2 to initialize the MAINPLL multiplier.
- If the MAINPLL is already running at a desired frequency and you only want to change the SYSCLK FREQ and post dividers, follow the procedure in Section 1.10.3.1.1.1.3 to change the SYSCLK dividers.

Note that the MAINPLL is powered down after the following device-level global resets:

- Power-on Reset (POR)
- Warm Reset (RESET)
- Max Reset

1.10.3.1.1.1.1 Initializing and Enabling MAINPLL from Power Down Mode

If the MAINPLL is powered down (MAIN_PLLEN bit in MAINPLL_CTRL is cleared to 0), perform the following procedure to initialize the MAINPLL:

1. Set MAIN_BP bit in MAINPLL_CTRL to 1 to put MAINPLL in bypass mode.
2. Set MAIN_PLLEN bit in MAINPLL_CTRL to 1 to bring MAINPLL out of power-down mode.
3. Clear PWD_CLK1 to PWD_CLK7 bits in MAINPLL_PWD to 0 to bring individual output clocks of MAINPLL out of power-down mode.
4. Set or clear MAIN_LOC_CTL bit in MAINPLL_CTRL to select MAINPLL lock output polarity (MAIN_LOCK bit in MAINPLL_CTRL).
5. Program the required pre-divider and multiplier values in MAIN_P and MAIN_N bit fields of MAINPLL_CTRL.
6. If necessary, program MAIN_INTFREQx and MAIN_FRACFREQx bit fields and set MAIN_LDFREQx bit to 1 in MAINPLL_FREQx to load integer and fraction values into Main Synthesizer x.
7. If necessary, program MAIN_MDIVx bit field and set MAIN_LDMDIVx bit to 1 in MAINPLL_DIVx to load the Post Divider into Main Synthesizer x.
8. Wait for PLL to Lock: Poll for MAIN_LOCK bit in MAINPLL_CTRL to become 1, if MAIN_LOC_CTL bit in MAINPLL_CTRL was cleared to 0; else Poll for MAIN_LOCK bit in MAINPLL_CTRL to become 0, if MAIN_LOC_CTL bit in MAINPLL_CTRL was set to 1.
9. If MAINPLL is locked in step 8, then clear the MAIN_BP bit in MAINPLL_CTRL to 0 to bring MAINPLL out of bypass mode.

Where x = 1, 2, 3, 4, 5 Flying Adder Synthesizer.

1.10.3.1.1.1.2 Changing MAINPLL Multiplier

If the MAINPLL is not powered down (MAIN_PLLEN bit in MAINPLL_CTRL is set to 1), perform the following procedure to initialize the MAINPLL multiplier:

1. Set MAIN_BP bit in MAINPLL_CTRL to 1 to put MAINPLL in bypass mode.
2. Clear PWD_CLK1 to PWD_CLK7 bits in MAINPLL_PWD to 0 to bring individual output clocks of MAINPLL out of power-down mode.
3. Set or clear MAIN_LOC_CTL bit in MAINPLL_CTRL to select MAINPLL lock output polarity (MAIN_LOCK bit in MAINPLL_CTRL).
4. Program the required pre-divider and multiplier values in MAIN_P and MAIN_N bit fields of MAINPLL_CTRL.
5. If necessary, program MAIN_INTFREQx and MAIN_FRACFREQx bit fields and set MAIN_LDFREQx bit to 1 in MAINPLL_FREQx to load integer and fraction values into Main Synthesizer x.
6. If necessary, program MAIN_MDIVx bit field and set MAIN_LDMDIVx bit to 1 in MAINPLL_DIVx to load the Post Divider into Main Synthesizer x.
7. Wait for PLL to Lock: Poll for MAIN_LOCK bit in MAINPLL_CTRL to become 1, if MAIN_LOC_CTL bit in MAINPLL_CTRL was cleared to 0; else Poll for MAIN_LOCK bit in MAINPLL_CTRL to become 0, if MAIN_LOC_CTL bit in MAINPLL_CTRL was set to 1.
8. If MAINPLL is locked in step 7, then clear the MAIN_BP bit in MAINPLL_CTRL to 0 to bring MAINPLL out of bypass mode.

Where x = 1, 2, 3, 4, 5 Flying Adder Synthesizer.

1.10.3.1.1.1.3 Changing MAINPLL SYSCLK Dividers

This section discusses the software sequence to change the SYSCLK dividers.

1. If necessary, program MAIN_INTFREQx and MAIN_FRACFREQx bit fields and set MAIN_LDFREQx bit to 1 in MAINPLL_FREQx to load integer and fraction values into Main Synthesizer x.
2. If necessary, program MAIN_MDIVx bit field and set MAIN_LDMDIVx bit to 1 in MAINPLL_DIVx to load the Post Divider into Main Synthesizer x.
3. If necessary, further divide down the SYSCLKs by programming the respective PRCM registers to get the desired SYSCLK frequencies (see Table 1-75 for supported PRCM divider values).

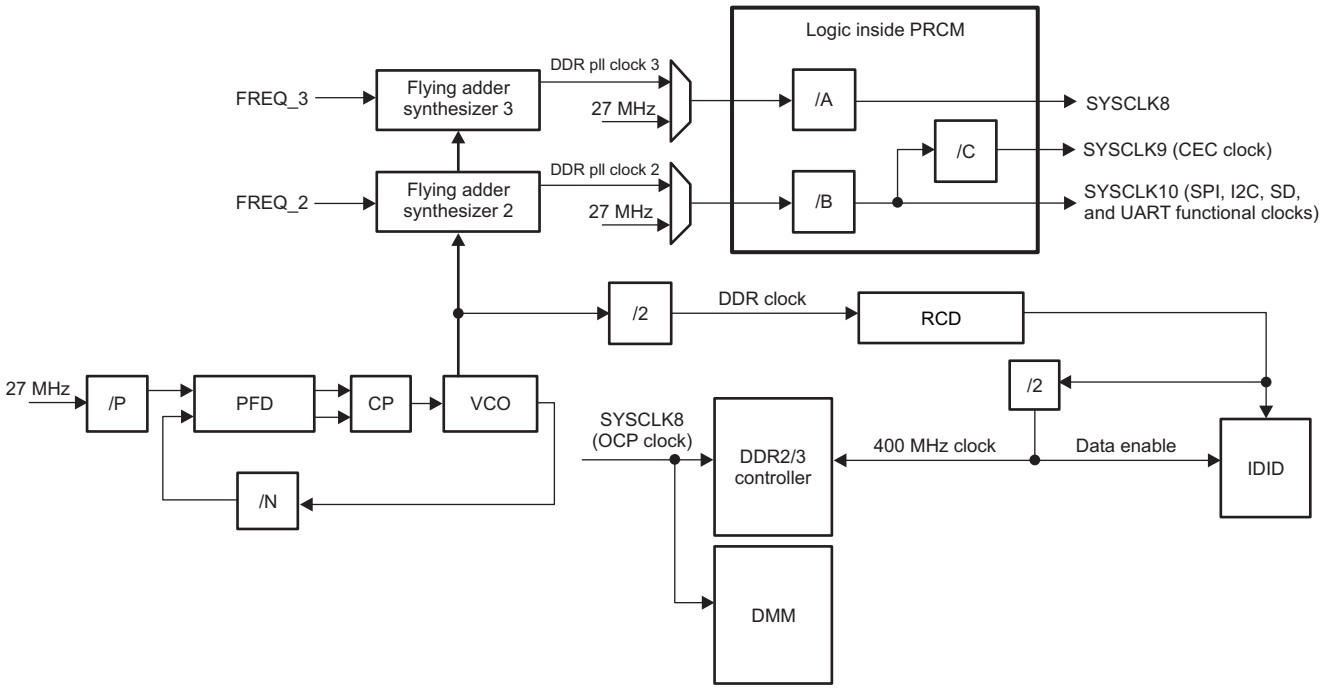
Where x = 1, 2, 3, 4, 5, 6, 7 Flying Adder Synthesizer.

1.10.3.1.2 DDR PLL

Figure 1-71 shows the structure of the DDR PLL. An 800-MHz DDR clock is derived directly from the PLL's VCO output (divided by 2, Post Divider). This clock passes through the RCD(Reset Clock Distribution) to the IDID (DDR Macro). The IDID clock is also divided by 2 to create DDR2/3 controller clock which connects to the IDID to serve as a data enable. The DDR PLL has 2 flying adder synthesizers. One is to generate the 400-MHz OCP clock for the DDR2/3 controller and 364 MHz for DMM and the other is the 48-MHz SYSCLK10 for SPI, I2C, UART, HDMI CEC, and SD/SDIO functional clocks. SYSCLK9 is dividable clock derived from SYSCLK10 which goes to the VTP controller as the VTP clock. The outputs of both synthesizers are muxed with the 27-MHz reference clock to allow its selection during PLL bypass mode.

The L3 interconnect probe also requires a 400-MHz clock synchronous to the DDR2/3 controller OCP interface clock for capturing DDR2/3 probe data. This clock must be free running to keep alive the host service network within the L3. The DDR PLL Clock 3 output directly from the FA-PLL rather than the SYSCLK8 gated clock is used for this purpose. Additionally the SYSCLK8 divider (/A) is tied to 1/1 to ensure that the DDR2/3 controller OCP and L3 interconnect probe remain frequency locked.

Figure 1-71. DDR PLL Structure



A good set of frequencies for DDR2/3 can be generated by playing with FREQ and post divider values. Table 1-81 shows supported divide ratios in PRCM module for dividers.

Table 1-81. DDR PLL Dividers

Divider	Supported Divide Ratio	Default Value
A	1/1	1/1
B	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
C	1/3	1/3

Table 1-82 lists the IPs that are clocked from DDR PLL flying adder synthesizers.

Table 1-82. DDR PLL SYSCLK Frequencies and Destination

SYSCLK	Device Speed Range[1]	Maximum Frequency (MHz)[2]	Destination
SYSCLK8[3]	Blank	364	DMM, DDR OCP clock
	2	364	
	4	425	
SYSCLK9	Blank	16	CEC clock and VTP
	2		
	4		
SYSCLK10	Blank	48	SPI, I2C, SD/SDIO, and UART
	2		
	4		
DDR2/DDR3	Blank	400	DDR2/DDR3
	2		
	4		

(1) For more information on the available device speed ranges for each part number, see the device-specific data manual

(2) Maximum frequency of PLL out clocks should meet minimum cycle limits. Refer to the device-specific data manual for PLL Programming Limits.

(3) SYSCLK8 is applied to the 128-bit interface and the EMIF DDR3 is a 32-bit interface; therefore, the SYSCLK8 364 MHz can work with an 800 MHz DDR3 clock speed without any system issue.

Table 1-83 and Table 1-84 show examples for DDR PLL System Clock generation for speed grade blank and grade 2, and grade 4, respectively. Table 1-85 shows an example for DDR PLL System Clock generation for all speed grades at lower DDR clock speed.

NOTE: Software must configure the desired FREQ values in DDRPLL_FREQ3 register (see Section 1.16.1.2.20) to obtain 364 MHz clock for DMM or 400 MHz clock for DDR2/3.

Table 1-83. Example for DDR PLL Frequencies for Speed Grade Blank and Grade 2

Input Ref Freq	Pre-Divider	Mult	VCO Output Freq	4 Bits Integer	24 Bits Fract	FAPLL Output	Post Divider	Post Divider Output		PRCM Divider	System Clock Domain	SYSCLK Freq (MHz)
								Mean[1]	Max[2]			
f_r (MHz)	P[3]	N[3]	f_{vco} (MHz)	FREQ[3]		f_s (MHz)	M[3]	f_o (MHz)

				NA	NA	NA	2	675	675	NA	DDR External Clock	675
				NA	NA	NA	4	338	338	NA	DDR Clock	338

(1) Mean frequency is an average FAPLL output frequency over time when P, N, M, and FREQ are tuned.
(2) Maximum frequency is an instantaneous frequency when FAPLL generates clock at minimum clock cycle.
(3) The values of Pre-Divider (P), Multiplier (N), FREQ, and Post Divider (M) can be tuned in order to obtain different frequencies; however, the software must respect the limitations (and requirements) described in the device-specific data manual for PLL Programming Limits.

1.10.3.1.2.1 Steps for Changing DDRPLL Frequency

Refer to the appropriate subsection on how to program the DDRPLL clocks:

- If the DDRPLL is powered down (DDR_PLLEN bit in DDRPLL_CTRL is cleared to 0), follow the procedure in Section 1.10.3.1.2.1.1 to initialize the DDRPLL.
- If the DDRPLL is not powered down (DDR_PLLEN bit in VIDEOPLL_CTRL is set to 1), follow the procedure in Section 1.10.3.1.2.1.2 to initialize the DDRPLL multiplier.
- If the DDRPLL is already running at a desired frequency and you only want to change the SYSCLK FREQ and post dividers, follow the procedure in Section 1.10.3.1.2.1.3 to change the SYSCLK dividers.

1.10.3.1.2.1.1 Initializing and Enabling DDRPLL from Power Down Mode

If the DDRPLL is powered down (DDR_PLLEN bit in DDRPLL_CTRL is cleared to 0), perform the following procedure to initialize the DDRPLL:

1. Clear DDR_BP bit in DDRPLL_CTRL to 0 to put DDRPLL in bypass mode.
2. Set DDR_PLLEN bit in DDRPLL_CTRL to 1 to bring DDRPLL out of power-down mode.
3. Clear PWD_CLK1 to PWD_CLK5 bits in DDRPLL_PWD to 0 to bring individual output clocks of DDRPLL out of power-down mode.
4. Set or clear DDR_LOC_CTL bit in DDRPLL_CTRL to select Digital lock or Analog lock detector.
5. Program the required pre-divider and multiplier values in DDR_P and DDR_N bit fields of DDRPLL_CTRL.
6. If necessary, program DDR_INTFREQx and DDR_FRACFREQx bit fields and set DDR_LDFREQx bit to 1 in DDRPLL_FREQx to load integer and fraction values into DDR Synthesizer x.
7. If necessary, program DDR_MDIVx bit field and set DDR_LDMDIVx bit to 1 in DDRPLL_DIVx to load the Post Divider into DDR Synthesizer x.
8. Wait for PLL to Lock: Poll for DDR_LOCK bit in DDRPLL_CTRL to become 1.
9. If DDRPLL is locked in step 8, then set the DDR_BP bit in DDRPLL_CTRL to 1 to bring DDRPLL out of bypass mode.
10. Set PWRDN bit in DDR_RCD to 1 to bring the Reset Clock Distribution module of DDR out of power-down mode.

Where x = 2, 3 Flying Adder Synthesizer.

1.10.3.1.2.1.2 Changing DDRPLL Multiplier

If the DDRPLL is not powered down (DDR_PLLEN bit in DDRPLL_CTRL is set to 1), perform the following procedure to initialize the DDRPLL:

1. Clear DDR_BP bit in DDRPLL_CTRL to 0 to put DDRPLL in bypass mode.
2. Clear PWD_CLK1 to PWD_CLK5 bits in DDRPLL_PWD to 0 to bring individual output clocks of DDRPLL out of power-down mode.
3. Set or clear DDR_LOC_CTL bit in DDRPLL_CTRL to select Digital lock or Analog lock detector.
4. Program the required pre-divider and multiplier values in DDR_P and DDR_N bit fields of DDRPLL_CTRL.
5. If necessary, program DDR_INTFREQx and DDR_FRACFREQx bit fields and set DDR_LDFREQx bit to 1 in DDRPLL_FREQx to load integer and fraction values into DDR Synthesizer x.
6. If necessary, program DDR_MDIVx bit field and set DDR_LDMDIVx bit to 1 in DDRPLL_DIVx to load the Post Divider into DDR Synthesizer x.
7. Wait for PLL to Lock: Poll for DDR_LOCK bit in DDRPLL_CTRL to become 1.
8. If DDRPLL is locked in step 7, then set the DDR_BP bit in DDRPLL_CTRL to 1 to bring DDRPLL out of bypass mode.
9. Set PWRDN bit in DDR_RCD to 1 to bring the Reset Clock Distribution module of DDR out of power-down mode.

Where x = 2, 3 Flying Adder Synthesizer.

1.10.3.1.2.1.3 Changing DDRPLL SYSCLK Dividers

This section discusses the software sequence to change the SYSCLK dividers.

1. If necessary, program DDR_INTFREQx and DDR_FRACFREQx bit fields and set DDR_LDFREQx bit to 1 in DDRPLL_FREQx to load integer and fraction values into DDR Synthesizer x.
2. If necessary, program DDR_MDIVx bit field and set DDR_LDMDIVx bit to 1 in DDRPLL_DIVx to load the Post Divider into DDR Synthesizer x.
3. If necessary, further divide down the SYSCLKs by programming the respective PRCM registers to get the desired SYSCLK frequencies (see Table 1-81 for supported PRCM divider values).

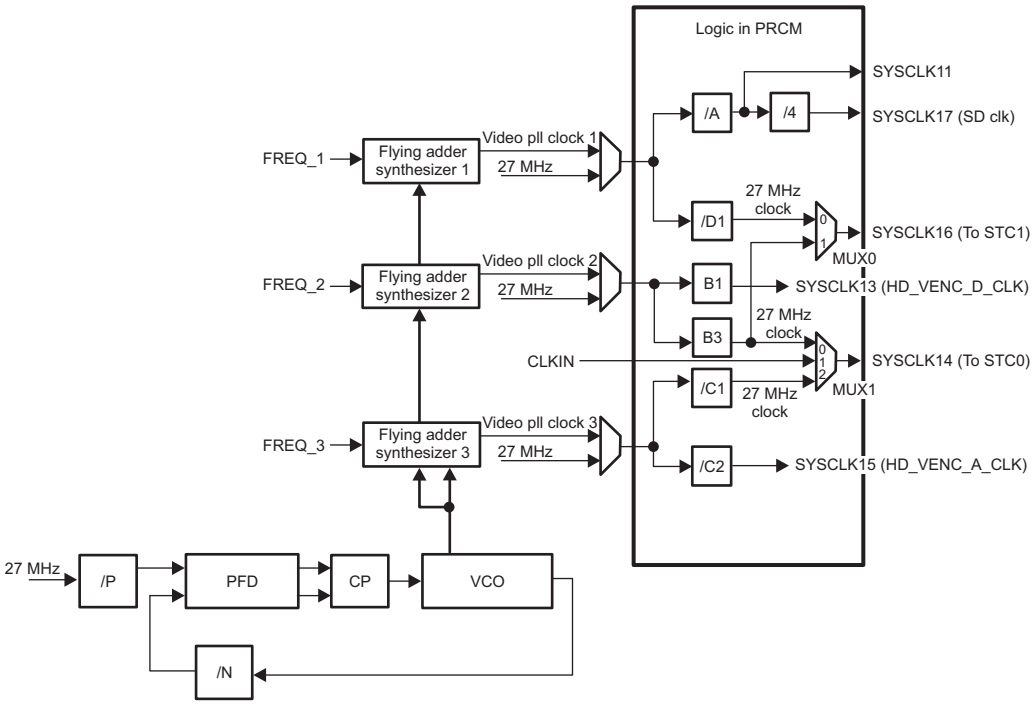
Where x = 2, 3 Flying Adder Synthesizer.

1.10.3.1.3 Video PLL

Figure 1-72 shows the Video PLL structure. There are 3 flying adder synthesizers. The outputs of these synthesizers are muxed with the 27-MHz reference clock to allow its selection during PLL bypass mode. The first synthesizer provides the SYSCLK17 (VENC SD clock) to HDVPSS; this clock is always 54 MHz. The second one provides SYSCLK13 (HD_VENC_D_CLK) for the display subsystem. HD_VENC_D_CLK needs to support 13.5 MHz, 27 MHz, 54 MHz, 74.25 MHz, 148.5 MHz, and 161 MHz frequencies. The third flying adder synthesizer supplies SYSCLK15 (HD_VENC_A_CLK). This clock has similar frequency requirements as HD_VENC_D_CLK.

This devices uses on-chip DCXO using the FA-PLL. Flying adder synthesizer 1, 2, and 3 will be used for this. Software will control the FREQ_1, FREQ_2, and FREQ_3 to track the frequency.

Figure 1-72. Video PLL Structure



Mux0 and Mux1 selects will default to 0.

Table 1-86 shows the supported divide ratios in PRCM module for all dividers in the Video PLL.

Table 1-86. Video PLL Dividers

Divider	Supported Divide Ratios	Default Values
A	1/1, 1/2	1/1
D1	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/8
B1	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/8
B3	1/1,1/2, 1/22	1/22
C1	1/1,1/2, 1/22	1/22
C2	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/4

Table 1-87 lists the IPs that are clocked from Video PLL flying adder synthesizers.

Table 1-87. Video PLL SYSCLK Frequencies and Destination

SYSCLK	Device Speed Range[1]	Maximum Frequency (MHz)[2]	Destination
SYSCLK13	Blank	165	HDVPSS

1.10.3.1.3.1 Steps for Changing VIDEOPLL Frequency

Refer to the appropriate subsection on how to program the VIDEOPLL clocks:

- If the VIDEOPLL is powered down (VIDEO_PLLEN bit in VIDEOPLL_CTRL is cleared to 0), follow the procedure in Section 1.10.3.1.3.1.1 to initialize the VIDEOPLL.
- If the VIDEOPLL is not powered down (VIDEO_PLLEN bit in VIDEOPLL_CTRL is set to 1), follow the procedure in Section 1.10.3.1.3.1.2 to initialize the VIDEOPLL multiplier.
- If the VIDEOPLL is already running at a desired frequency and you only want to change the SYSCLK FREQ and post dividers, follow the procedure in Section 1.10.3.1.3.1.3 to change the SYSCLK dividers.

1.10.3.1.3.1.1 Initializing and Enabling VIDEOPLL from Power Down Mode

If the VIDEOPLL is powered down (VIDEO_PLLEN bit in VIDEOPLL_CTRL is cleared to 0), perform the following procedure to initialize the VIDEOPLL:

1. Set VIDEO_BP bit in VIDEOPLL_CTRL to 1 to put VIDEOPLL in bypass mode.
2. Set VIDEO_PLLEN bit in VIDEOPLL_CTRL to 1 to bring VIDEOPLL out of power-down mode.
3. Clear PWD_CLK1 to PWD_CLK3 bits in VIDEOPLL_PWD to 0 to bring individual output clocks of VIDEOPLL out of power-down mode.
4. Set or clear VIDEO_LOC_CTL bit in VIDEOPLL_CTRL to select Digital lock or Analog lock detector.
5. Program the required pre-divider and multiplier values in VIDEO_P and VIDEO_N bit fields of VIDEOPLL_CTRL.
6. If necessary, program VIDEO_INTFREQx and VIDEO_FRACFREQx bit fields and set VIDEO_LDFREQx bit to 1 in VIDEOPLL_FREQx to load integer and fraction values into VIDEO Synthesizer x.
7. If necessary, program VIDEO_MDIVx bit field and set VIDEO_LDMDIVx bit to 1 in VIDEOPLL_DIVx to load the Post Divider into VIDEO Synthesizer x.
8. Wait for PLL to Lock: Poll for VIDEO_LOCK bit in VIDEOPLL_CTRL to become 1.
9. If VIDEOPLL is locked in step 8, then clear the VIDEO_BP bit in VIDEOPLL_CTRL to 0 to bring VIDEOPLL out of bypass mode.

Where x = 1, 2, 3 Flying Adder Synthesizer.

1.10.3.1.3.1.2 Changing VIDEOPLL Multiplier

If the VIDEOPLL is not powered down (VIDEO_PLLEN bit in VIDEOPLL_CTRL is set to 1), perform the following procedure to initialize the VIDEOPLL:

1. Set VIDEO_BP bit in VIDEOPLL_CTRL to 1 to put VIDEOPLL in bypass mode.
2. Clear PWD_CLK1 to PWD_CLK3 bits in VIDEOPLL_PWD to 0 to bring individual output clocks of VIDEOPLL out of power-down mode.
3. Set or clear VIDEO_LOC_CTL bit in VIDEOPLL_CTRL to select Digital lock or Analog lock detector.
4. Program the required pre-divider and multiplier values in VIDEO_P and VIDEO_N bit fields of VIDEOPLL_CTRL.
5. If necessary, program VIDEO_INTFREQx and VIDEO_FRACFREQx bit fields and set VIDEO_LDFREQx bit to 1 in VIDEOPLL_FREQx to load integer and fraction values into VIDEO Synthesizer x.
6. If necessary, program VIDEO_MDIVx bit field and set VIDEO_LDMDIVx bit to 1 in VIDEOPLL_DIVx to load the Post Divider into VIDEO Synthesizer x.
7. Wait for PLL to Lock: Poll for VIDEO_LOCK bit in VIDEOPLL_CTRL to become 1.
8. If VIDEOPLL is locked in step 7, then clear the VIDEO_BP bit in VIDEOPLL_CTRL to 0 to bring VIDEOPLL out of bypass mode.

Where x = 1, 2, 3 Flying Adder Synthesizer.

1.10.3.1.3.1.3 Changing VIDEOPLL SYSCLK Dividers

This section discusses the software sequence to change the SYSCLK dividers.

1. If necessary, program VIDEO_INTFREQx and VIDEO_FRACFREQx bit fields and set VIDEO_LDFREQx bit to 1 in VIDEOPLL_FREQx to load integer and fraction values into VIDEO Synthesizer x.
2. If necessary, program VIDEO_MDIVx bit field and set VIDEO_LDMDIVx bit to 1 in VIDEOPLL_DIVx to load the Post Divider into VIDEO Synthesizer x.
3. If necessary, further divide down the SYSCLKs by programming the respective PRCM registers to get the desired SYSCLK frequencies (see Table 1-86 for supported PRCM divider values).

Where x = 1, 2, 3 Flying Adder Synthesizer.

1.10.3.1.4 Audio PLL

Figure 1-73 shows the structure of the Audio PLL. The Audio PLL has 5 flying adder synthesizers. The outputs of these synthesizers are muxed with the 27-MHz reference clock to allow its selection during PLL bypass mode. The first synthesizer uses the 27-MHz reference clock as a source and provides a 32.768 kHz clock (SYSCLK18) for the SD/SDIO peripheral. A 32.768 kHz clock for the RTC is sourced from the Control Module. This clock has two sources, SYSCLK18 and the 32768 Hz clock from the primary input pin. The Mux2 select defaults to 0 which selects clock generated from FA synthesizer. This clock is also supplied to the watchdog timer. The DMTIMERS (1-7) have the following muxing for the input clock. Select for this mux will default to 1.

Figure 1-73 shows the connection of audio clocks to McASP, McBSP, and HDMI modules. The default select value for these muxes is “0x0”, which selects SYSCLK20.

Figure 1-73. Audio PLL Structure

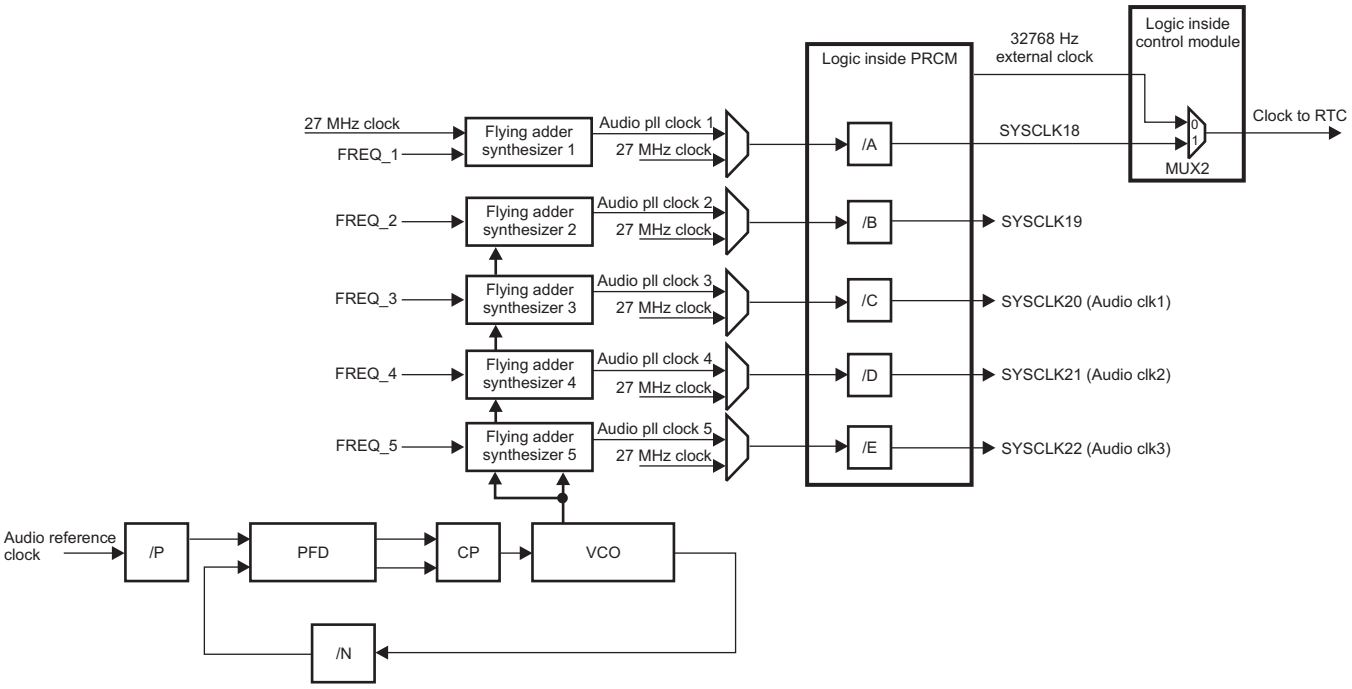

Table 1-89 shows the supported divide ratios in PRCM module for all dividers in the Audio PLL.

Table 1-89. Audio PLL Dividers

Divider	Supported Divider Ratios	Default Value
A	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
B	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
C	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
D	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
E	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1

Table 1-90 lists the IPs that are clocked from Audio PLL flying adder synthesizers.

Table 1-90. Audio PLL SYSCLK Frequencies and Destination

SYSCLK	Device Speed Range[1]	Maximum Frequency[2]	Destination
SYSCLK18	Blank	32 KHz	RTC
	2		
	4		
SYSCLK20	Blank	196 MHz	Audio clock 1
	2		
	4		
SYSCLK21	Blank	196 MHz	Audio clock 2

1.10.3.1.4.1 Steps for Changing AUDIOPLL Frequency

Refer to the appropriate subsection on how to program the AUDIOPLL clocks:

- If the AUDIOPLL is powered down (AUDIO_PLLEN bit in AUDIOPLL_CTRL is cleared to 0), follow the procedure in Section 1.10.3.1.4.1.1 to initialize the AUDIOPLL.
- If the AUDIOPLL is not powered down (AUDIO_PLLEN bit in AUDIOPLL_CTRL is set to 1), follow the procedure in Section 1.10.3.1.4.1.2 to initialize the AUDIOPLL multiplier.
- If the AUDIOPLL is already running at a desired frequency and you only want to change the SYSCLK FREQ and post dividers, follow the procedure in Section 1.10.3.1.4.1.3 to change the SYSCLK dividers.

1.10.3.1.4.1.1 Initializing and Enabling AUDIOPLL from Power Down Mode

If the AUDIOPLL is powered down (AUDIO_PLLEN bit in AUDIOPLL_CTRL is cleared to 0), perform the following procedure to initialize the AUDIOPLL:

1. Set AUDIO_BP bit in AUDIOPLL_CTRL to 1 to put AUDIOPLL in bypass mode.
2. Set AUDIO_PLLEN bit in AUDIOPLL_CTRL to 1 to bring AUDIOPLL out of power-down mode.
3. Clear PWD_CLK2 to PWD_CLK5 bits in AUDIOPLL_PWD to 0 to bring individual output clocks of AUDIOPLL out of power-down mode.
4. Set or clear AUDIO_LOC_CTL bit in AUDIOPLL_CTRL to select Digital lock or Analog lock detector.
5. Program the required pre-divider and multiplier values in AUDIO_P and AUDIO_N bit fields of AUDIOPLL_CTRL.
6. If necessary, program AUDIO_INTFREQx and AUDIO_FRACFREQx bit fields and set AUDIO_LDFREQx bit to 1 in AUDIOPLL_FREQx to load integer and fraction values into AUDIO Synthesizer x.
7. If necessary, program AUDIO_MDIVx bit field and set AUDIO_LDMDIVx bit to 1 in AUDIOPLL_DIVx to load the Post Divider into AUDIO Synthesizer x.
8. Wait for PLL to Lock: Poll for AUDIO_LOCK bit in AUDIOPLL_CTRL to become 1.
9. If AUDIOPLL is locked in step 8, then clear the AUDIO_BP bit in AUDIOPLL_CTRL to 0 to bring AUDIOPLL out of bypass mode.

Where x = 1, 2, 3, 4, 5 Flying Adder Synthesizer.

1.10.3.1.4.1.2 Changing AUDIOPLL Multiplier

If the AUDIOPLL is not powered down (AUDIO_PLLEN bit in AUDIOPLL_CTRL is set to 1), perform the following procedure to initialize the AUDIOPLL:

1. Set AUDIO_BP bit in AUDIOPLL_CTRL to 1 to put AUDIOPLL in bypass mode.
2. Clear PWD_CLK2 to PWD_CLK5 bits in AUDIOPLL_PWD to 0 to bring individual output clocks of AUDIOPLL out of power-down mode.
3. Set or clear AUDIO_LOC_CTL bit in AUDIOPLL_CTRL to select Digital lock or Analog lock detector.
4. Program the required pre-divider and multiplier values in AUDIO_P and AUDIO_N bit fields of AUDIOPLL_CTRL.
5. If necessary, program AUDIO_INTFREQx and AUDIO_FRACFREQx bit fields and set AUDIO_LDFREQx bit to 1 in AUDIOPLL_FREQx to load integer and fraction values into AUDIO Synthesizer x.
6. If necessary, program AUDIO_MDIVx bit field and set AUDIO_LDMDIVx bit to 1 in AUDIOPLL_DIVx to load the Post Divider into AUDIO Synthesizer x.
7. Wait for PLL to Lock: Poll for AUDIO_LOCK bit in AUDIOPLL_CTRL to become 1.
8. If AUDIOPLL is locked in step 7, then clear the AUDIO_BP bit in AUDIOPLL_CTRL to 0 to bring AUDIOPLL out of bypass mode.

Where x = 1, 2, 3, 4, 5 Flying Adder Synthesizer.

1.10.3.1.4.1.3 Changing AUDIOPLL SYSCLK Dividers

This section discusses the software sequence to change the SYSCLK dividers.

1. If necessary, program AUDIO_INTFREQx and AUDIO_FRACFREQx bit fields and set AUDIO_LDFREQx bit to 1 in AUDIOPLL_FREQx to load integer and fraction values into AUDIO Synthesizer x.
2. If necessary, program AUDIO_MDIVx bit field and set AUDIO_LDMDIVx bit to 1 in AUDIOPLL_DIVx to load the Post Divider into AUDIO Synthesizer x.
3. If necessary, further divide down the SYSCLKs by programming the respective PRCM registers to get the desired SYSCLK frequencies (see Table 1-89 for supported PRCM divider values).

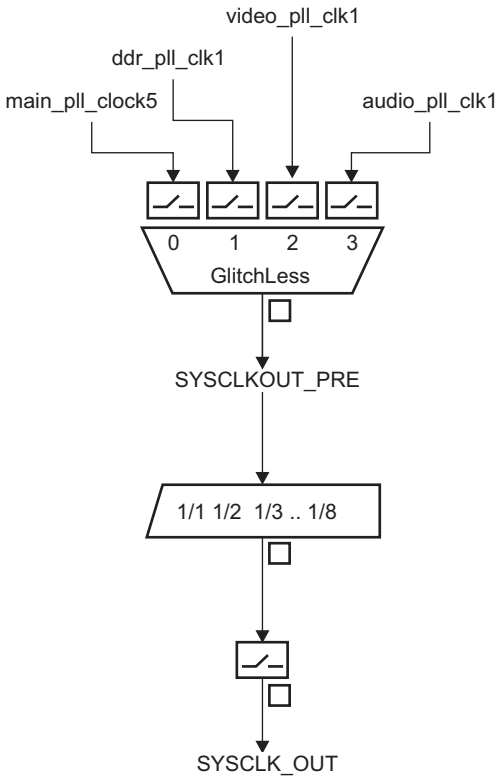
Where x = 1, 2, 3, 4, 5 Flying Adder Synthesizer.

1.10.4 Clock Out

This device has one clockout output pin. Figure 1-74 shows which clocks can be exported out on this pin. The clock sources are muxed, divided and then passed through a clock gate.

As shown in Figure 1-74, there are 4 possible sources for clkout, one clock from each of the 4 PLLs. The selected clock can be further divided by any ratio from 1 to 1/8 before going out on clkout pin. The default selection is to select Main pll clock5, divider set to 1/1 and clock disabled. Refer to the CM_CLKOUT_CTRL register in the *Power, Reset, and Clock Management (PRCM) Module* chapter for more details.

Figure 1-74. Clocks



CAUTION

Glitch-free muxes have an output which is free from any glitches. It requires the previously selected clock and the newly selected clock to both be free-running for switch-over to occur. Switch-over could take 1-2 clock cycles of previously selected and newly selected clock to complete. If newly selected clock is idle a switchover never occurs (previously selected clock continues to pass through the mux). Do not switch to a non existent clock.

1.11 Bus Interconnect

The SoC interconnect is based on a 2-level hierarchical architecture (L3, L4) driven by system performance.

L4 interconnect is based on a fully native OCP infrastructure, directly complying with the OCPIP2.2 reference standard.

1.11.1 Terminology

The following is a brief explanation of some terms used in this document:

Initiator — Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).

Target— Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

Note: A module can have several separate ports; therefore, a module can be an initiator and a target.

Agent— Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).

Interconnect— The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it.

Register target (RT)— Special TA used to access the interconnect internal configuration registers.

Data-flow signal— Any signal that is part of a clearly identified transfer or data flow (typically: command, address, byte enables, etc.). Signal behavior is defined by the protocol semantics.

Sideband signal— Any signal whose behavior is not associated to a precise transaction or data flow.

Command Slot— A command slot is a subset of the command list. It is the memory buffer for a single command. A total of 32 command slots exist.

Out-of-band error— Any signal whose behavior is associated to a device error-reporting scheme, as opposed to in-band errors.

Note: Interrupt requests and DMA requests are not routed by the interconnect in the device.

ConnID— Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted in band with the request and is used for error-logging mechanism.

1.11.2 L3 Interconnect

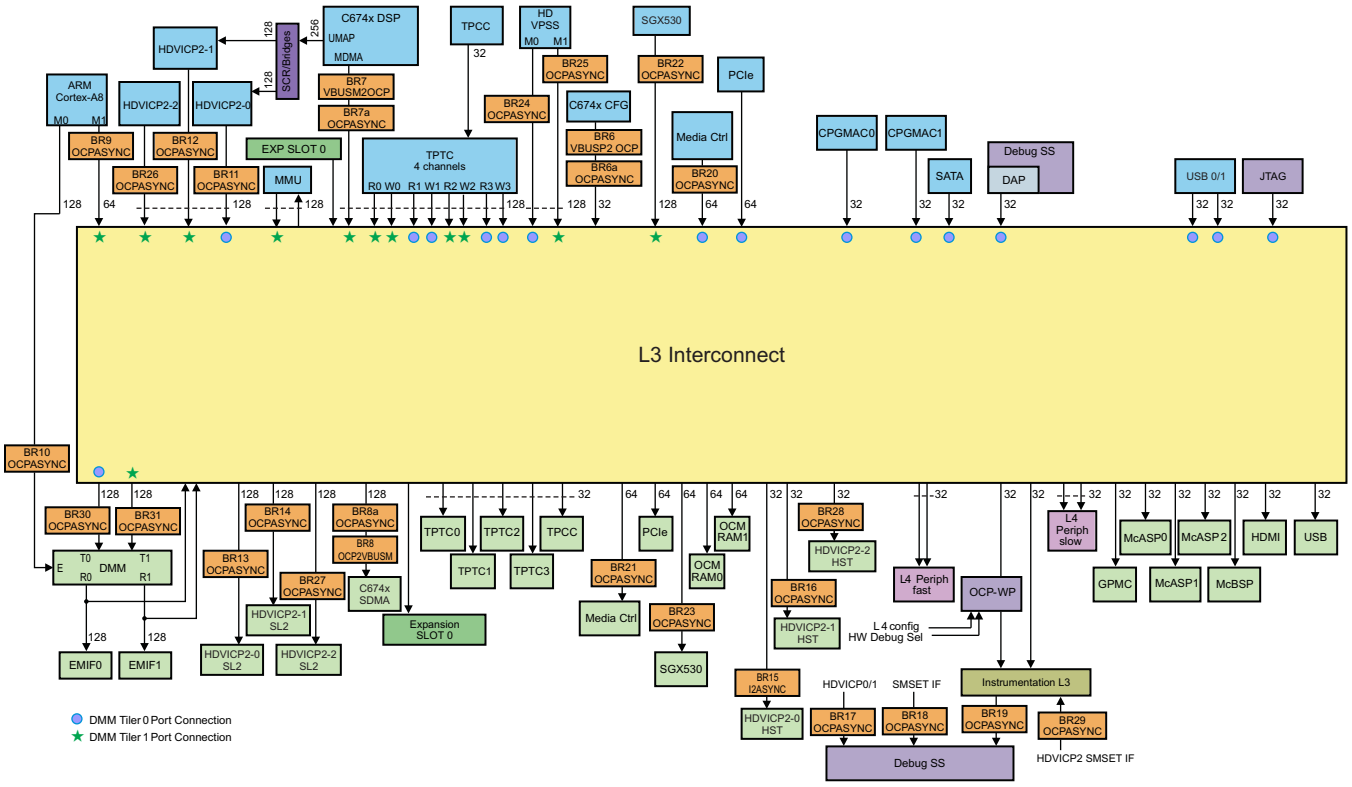
The L3 high-performance interconnect is based on a Network On Chip (NoC) interconnect infrastructure. The NoC uses an internal packet-based protocol for forward (read command, write command with data payload) and backward (read response with data payload, write response) transactions. All exposed interfaces of this NoC interconnect, both for Targets and Initiators; comply with the OCPIP2.2 reference standard.

1.11.2.1 Topology

The L3 topology is driven by performance requirements, bus types, and clocking structure. The main L3 paths are shown in Figure 1-75. Arrows indicate the master/slave relationship not data flow.

As Figure 1-75 shows, there are four clock domains in the NOC corresponding to fast (L3F), median (L3M), and slow (L3S) initiator and target port speeds and a special domain (L3P) for EMIF probes.

Figure 1-75. L3 Interconnect Block Diagram



1.11.2.2 L3 Port Mapping

Each initiator and target core is connected to the L3 interconnect through an NIU. The NIUs act as entry and exit points to the L3 Network on Chip – converting between the IP's OCP protocol and the NOC's internal protocol, and also include various programming registers. All ports are single threaded with tags used to enable pipelined transactions. The SoC interconnect includes:

Initiator Ports:

- Host ARM Subsystem (HASS) 64-bit initiator Port 1 (HASS Port 0 is a special case 128-bit initiator which bypasses the L3.)
- C674x DSP Subsystem MDMA 128-bit initiator port.
- C674x DSP Subsystem CFG 32-bit initiator port.
- HD Video Processing Subsystem (HD-VPSS) 128-bit initiator Port 0 and Port 1.
- HDVICP2-0 128-bit initiator port.
- HDVICP2-1 128-bit initiator port.
- HDVICP2-2 128-bit initiator port.
- MMU 128-bit initiator port.
- 4 TPTC 128-bit read initiator ports.
- 4 TPTC 128-bit write initiator ports.
- Expansion Slot 0 128-bit initiator port.
- CPGMAC0 32-bit initiator port.
- CPGMAC1 32-bit initiator port.
- SATA 32-bit initiator port.
- PCIe 64-bit initiator port.
- Debug Subsystem (DAP) 32-bit initiator port.
- Graphics accelerator (SGX530) 128-bit initiator port.
- USB 32-bit CPPI DMA initiator port.
- USB 32-bit Queue Manager initiator port.
- JTAG Interface 32-bit initiator port.

Target Ports:

- DMM Tiler0 128-bit target port.
- DMM Tiler1 128-bit target port.
- HDVICP2-0 SL2 128-bit target port.
- HDVICP2-1 SL2 128-bit target port.
- HDVICP2-2 SL2 128-bit target port.
- C674x DSP Subsystem SDMA 128-bit target port.
- 4 TPTC CFG 32-bit target ports.
- TPCC CFG 32-bit target port.
- Expansion Slot 0 128-bit target port.
- System MMU 128-bit target port.
- Graphics accelerator (SGX530) 64-bit target port.
- PCIe 64-bit target port.
- OCM RAM0 64-bit target port.
- OCM RAM1 64-bit target port.
- 2 L4_Fast peripheral 32-bit target ports.
- HDVICP2-0 Host1 Control 32-bit target port.
- HDVICP2-1 Host1 Control 32-bit target port.
- HDVICP2-2 Host1 Control 32-bit target port.

- Instrumentation L3 32-bit target port.
- 2 L4_Slow peripheral 32-bit target ports.
- GPMC 32-bit target port.
- McASP0 32-bit target port.
- McASP1 32-bit target port.
- McASP2 32-bit target port.
- McBSP 32-bit target port.
- HDMI 32-bit target port.
- USB 32-bit target port.

1.11.2.3 Connection Identification

Each L3 initiator includes a unique 6-bit master connection identifier (MConnID) that is used to identify the source of a transfer request. The full 6-bit MConnID is used for debug purposes, otherwise only the 4 MSBs are used to distinguish unique masters.

Table 1-92. Device MConnID Assignment

Initiator	4-bit MConnID	6-bit MConnID	Instrumentation	Comment

1.12 Inter-Processor Communication

This SoC is a heterogeneous multi-core device, which requires software to efficiently manage and communicate between the cores. The following are the main features that need to be implemented by any such software:

1. Device management of the slave processors from the host processor.
2. Inter-processor communication between the cores for transfer and exchange of information between them.

In this SoC, the host processor is usually the Cortex-A8. This processor is responsible for boot-loading the slave processors (Video-Media Controller, VPSS-Media Controller, C674x DSP).

The HDVICP2 cores are managed by the Video-Media Controller.

Boot-loading includes power management of the slaves (power-up/down and other power management), reset control (reset/release of the slave processor) and setting the entry point of the slave executable into the appropriate register.

For implementing efficient Inter-Processor Communication between the multiple cores on the device, certain hardware features are provided:

- Mailbox interrupts
- Hardware Spinlocks

1.12.1 Reset Requirements

This SoC has a power on reset (POR) and warm reset. For the POR reset, the A8 is taken out of reset and it boots from its boot ROM. Once booted, the A8 will boot load the C674x DSP, VPSS-Media Controller and Video-Media Controller. The Video-Media Controller will be responsible to boot the 3 HDVICP2s when needed.

1.12.2 Features

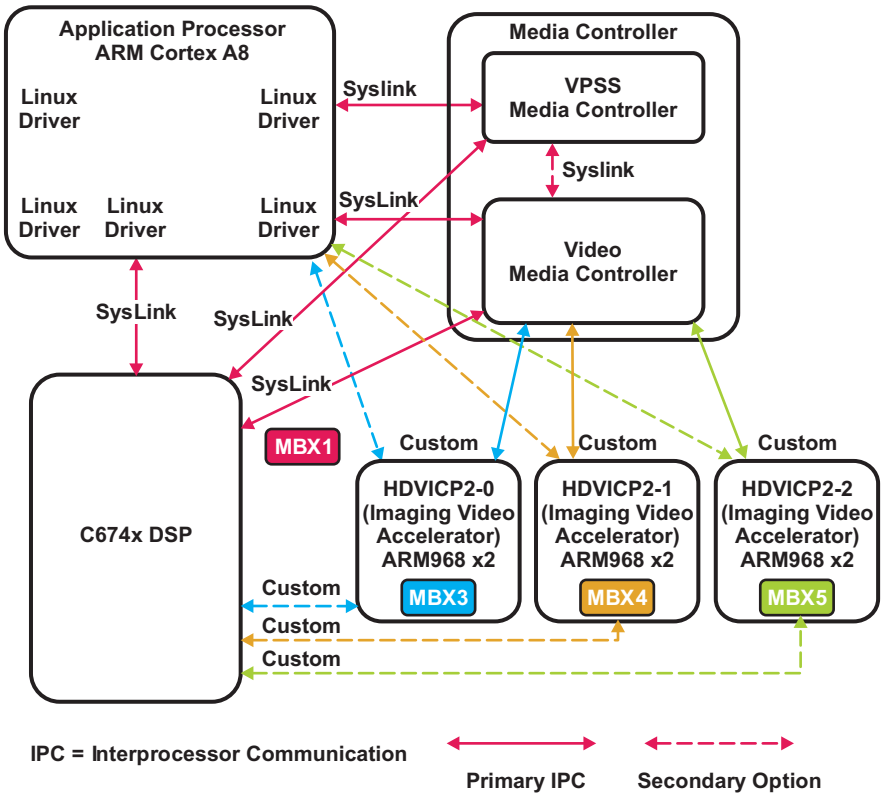
Different methods of IPC are used between the various processing elements in the SoC:

- Custom IPC – This is an IPC that doesn't use any standard IPC software.
- SysLink – This is a new implementation of DSP/BIOS Link that allows communication between the processors in the SoC. SysLink includes ProcMgr module for device management of the slave cores (Video-Media Controller, VPSS-Media Controller, C674x DSP). The Notify method is the API for responding to interrupts. SysLink also incorporates full IPC features including MessageQ, RingIO, and FrameQ.

1.12.3 Overview and Strategy

Figure 1-76 shows the processing elements that are part of the SoC.

Figure 1-76. IPC Overview Diagram



The SoC contains Mailbox and Spinlock hardware to facilitate the IPC mechanism.

Mailboxes provide a mechanism for one processor to write a value to a register and send an interrupt to another processor. One system level mailbox is provided for the IPCs between the A8, the C674x DSP, and the media controllers. The HDVICP2s each have their own mailbox within their IP module.

The SoC shall provide Spinlocks to facilitate Mutexes for access to shared resources in the system.

Mailboxes and Spinlocks will be discussed in more detail later in this document.

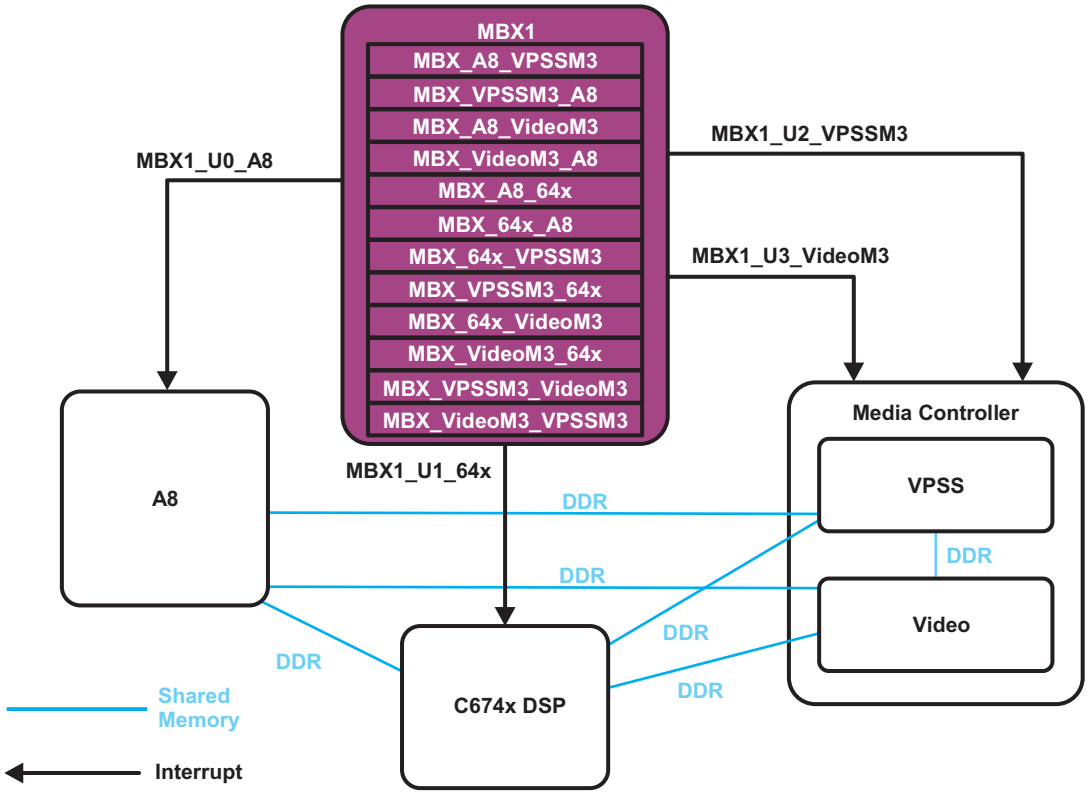
It is intended that the following IPC mechanisms shall be used between various processors:

- SysLink / IPC
  - A8 to C674x DSP
  - A8 to Video-Media Controller
  - A8 to VPSS-Media Controller
  - Video-Media Controller to VPSS-Media Controller
  - C674x DSP to Video-Media Controller
  - C674x DSP to VPSS-Media Controller
- Custom
  - Video-Media Controller to HDVICP2s

1.12.3.1 System IPCs

Figure 1-77 depicts how Mailbox 1 (MBX1) will be used for system IPCs. 4 interrupts are generated from the mailbox that allows the A8, C674x DSP, VPSS-Media Controller, and Video-Media Controller to communicate. DDR is used as the shared memory interface. An IPC can be created between any of the processors listed. The A8 will communicate to the C674x DSP, Video-Media Controller and VPSS-Media Controller using SysLink.

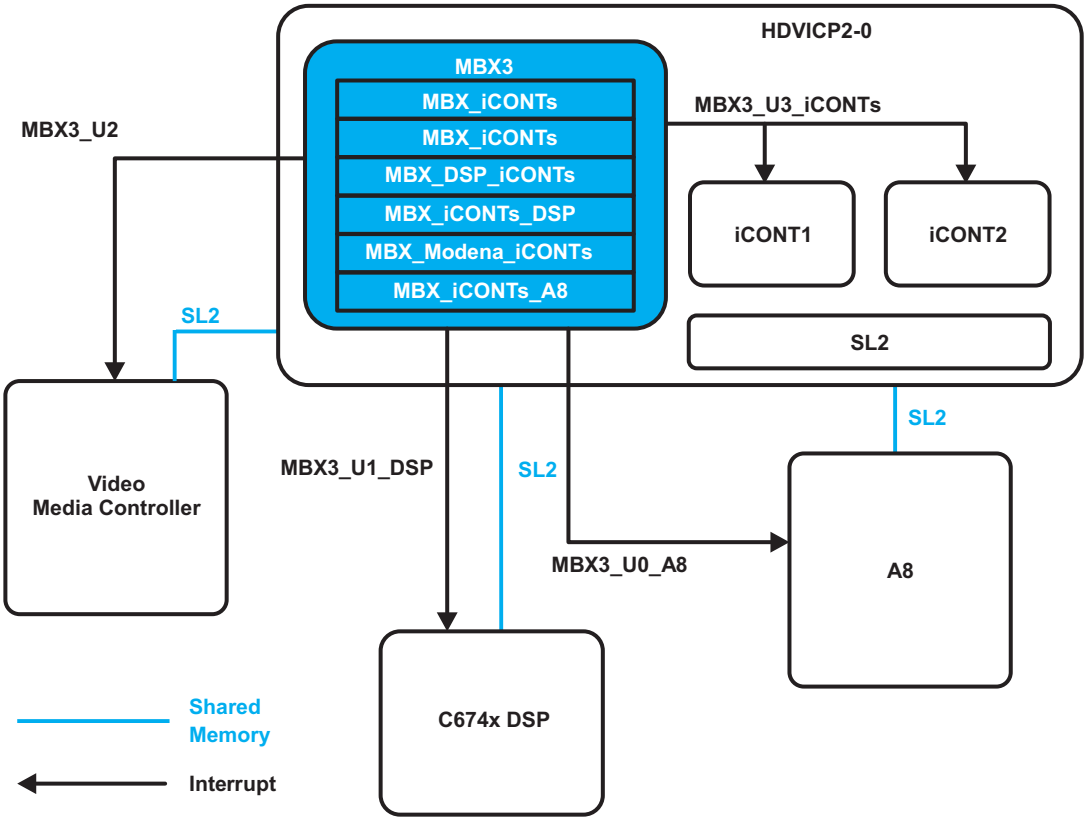
Figure 1-77. System IPCs



1.12.3.2 HDVICP2-0 IPC

Figure 1-78 shows how Mailbox 3 (MBX3) is used for the IPC between HDVICP2-0 and the other processors that may control HDVICP2-0. Only one processor is chosen to control the HDVICP2 at a time. The Video-Media Controller is the primary processor that controls the HDVICP2s. Interrupts from the mailbox are provided as shown in Figure 1-78. IPCs use the Shared Level 2 (SL2) memory that is part of the HDVICP2-0 module. This is necessary since the HDVICP2 processors cannot access DDR or the L3/L4 switch fabric. The HDVICP2 software resides beneath the xDM API.

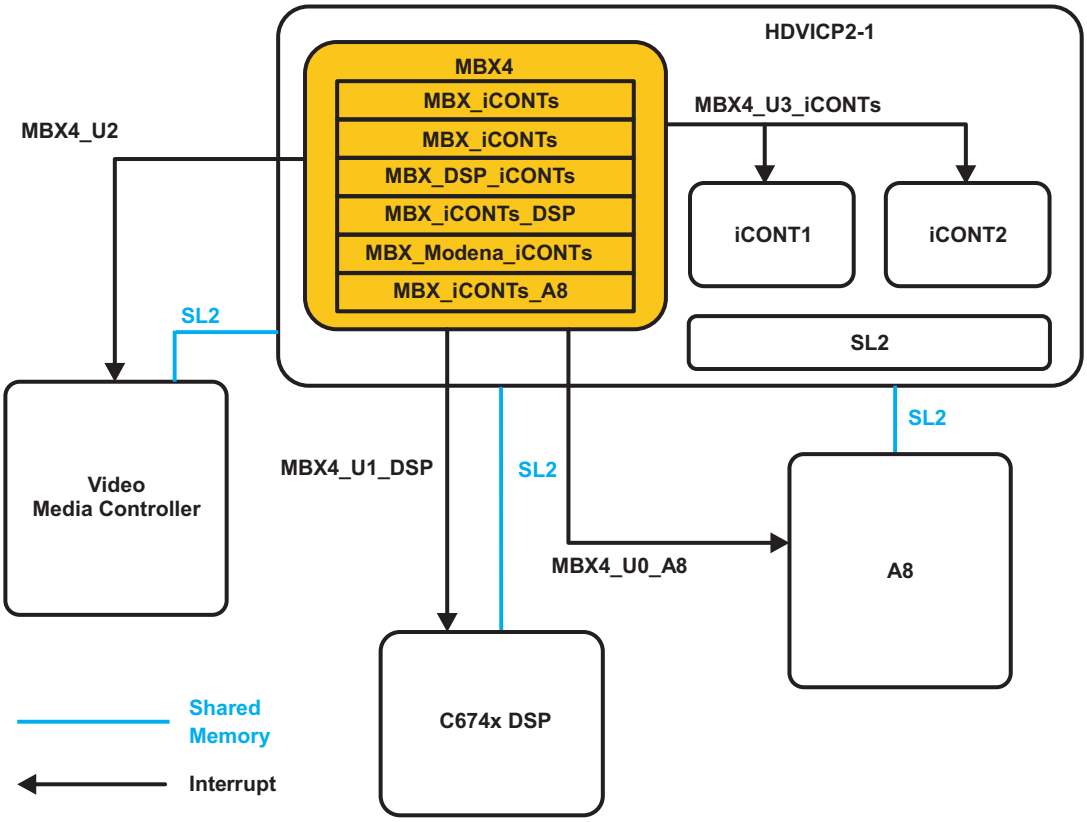
Figure 1-78. HDVICP2-0 IPC



1.12.3.3 HDVICP2-1 IPC

Figure 1-79 shows how Mailbox 4 (MBX4) is used for the IPC between HDVICP2-1 and the other processors that may control HDVICP2-1. HDVICP2-1 is controlled in the same way as HDVICP2.-0

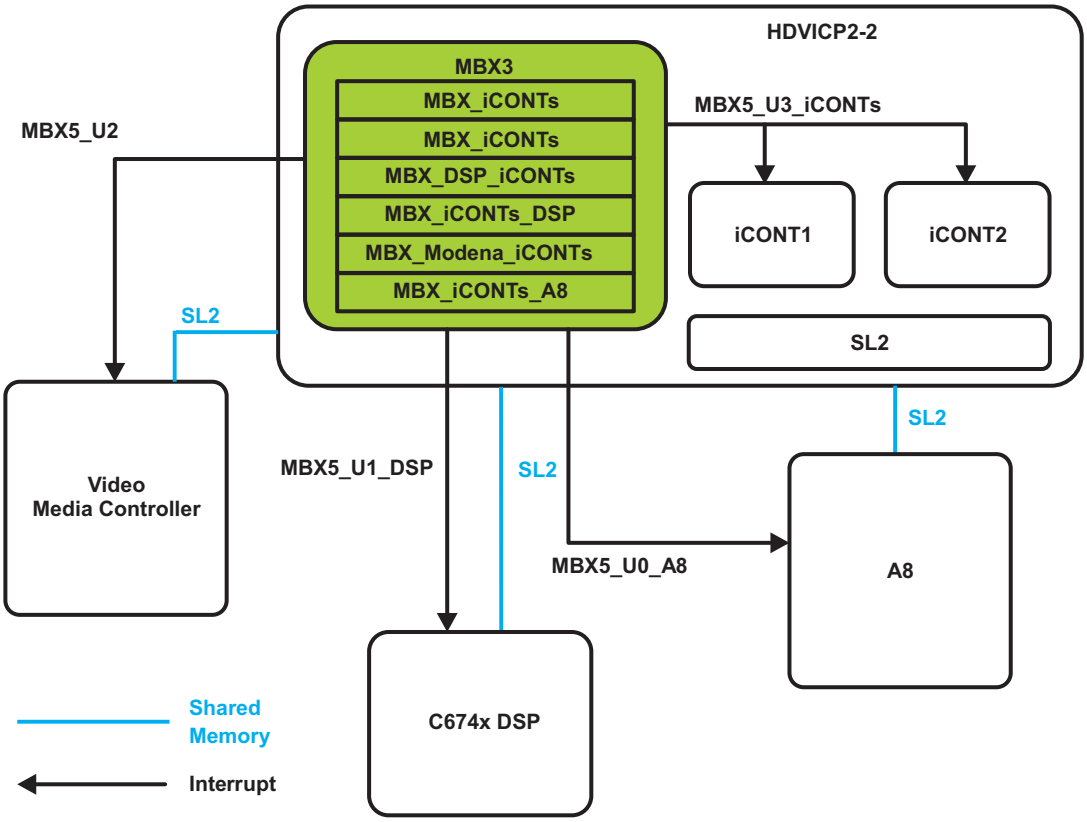
Figure 1-79. HDVICP2-1 IPC



1.12.3.4 HDVICP2-2 IPC

Figure 1-80 shows how Mailbox 5 (MBX5) is used for the IPC between HDVICP2-2 and the other processors that may control HDVICP2-2. HDVICP2-2 is controlled in the same way as HDVICP2-0.

Figure 1-80. HDVICP2-2 IPC



1.12.4 IPC Component Configuration

1.12.4.1 Shared Memory

Shared memory will be used as necessary for the IPCs of the system. Care must be taken to ensure that cache coherency is maintained.

1.12.4.2 IPC Interrupt Module - Mailboxes

Interrupts used by IPCs are generated from Mailbox modules.

All mailboxes use interrupts with both an active high level and active low level. The appropriate type of interrupt is connected to each processor based on the characteristics of that processor.

Each mailbox shall provide 2 messages per mailbox submodule.

1.12.4.3 Hardware Spinlocks

Spinlocks are pared down semaphores designed to provide direct access mutex support without the need for interrupt generator or queues. Spinlocks can be used very effectively as a mechanism to protect data structures in shared memory space that might be accessed by multiple processing cores simultaneously. They can be utilized if the following conditions apply:

1. The time to hold the lock is predictable and small. (How small is a hardware/software system design consideration. For example a maximum hold time of less than 200 CPU cycles may be acceptable.)
2. The locking task cannot be preempted or suspended or interrupted while holding the lock. (This would make the hold time large and unpredictable.)
3. The lock is lightly contended, that is, the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions hold, then the locking code can retry a failed attempt to acquire the lock until success.

The spin lock unit is responsible for providing hardware assistance for synchronizing the processes running on multiple processors in the device:

- The application processor (ARM Cortex-A8)
- C674x DSP

Note that the HDVICP2s can not access the L3/L4 switch fabric, so IPCs to the HDVICP2s can not use spinlocks.

Hardware spinlocks are used by SysLink and IPC products to provide multi-core mutual-exclusion between the processors on this SoC. This is used to protect access to control structures in shared memory. In addition spinlocks can provide a mutual exclusion mechanism that could be used in a system level resource manager.

This SoC has 64 spinlocks for the system.

Table 1-96. Hardware Spinlock Configuration

Hardware Spinlocks	Name	Configuration
0..63	SPINLOCK_0 .. SPINLOCK_63	No configurable options

1.13 Mailbox

1.13.1 Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

There are two mailbox module instances in the device:

- System mailbox - used for Cortex-A8 microprocessor unit (Cortex-A8 MPU) and digital signal processor (DSP) communications.
- HDVICP2 mailbox - used for communication between one internal to the HDVICP2 subsystem user (imaging controller 1 - iCont1, or imaging controller 2 - iCont2) and three external to the HDVICP2 subsystem users (Cortex-A8 MPU, DSP, and Video-Media Controller). This communication is insured through three pairs of mailboxes.

The mailbox module includes the following features:

- Four users for the system mailbox instance (Cortex-A8 MPU, DSP and Media Controller Subsystem)/four users for the HDVICP2 mailbox instance (iCont1/iCont2, Cortex-A8 MPU, DSP, and Video-Media Controller MPU)
- Four mailbox message queues for the system mailbox instance/six mailbox message queues for the HDVICP2 mailbox instance
- Flexible assignment of receiver and sender for each mailbox through interrupt configuration
- Four interrupts (one per user) for the system mailbox instance/four interrupts (one per user) for the HDVICP2 mailbox instance
- 32-bit message width
- Four-message FIFO depth for each message queue
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

1.13.2 System Mailbox Integration

This section describes the system mailbox integration in the device, including information about clocks, resets, and hardware requests. Figure 1-81 shows the system mailbox integration.

Table 1-97 through Table 1-99 summarize the system mailbox integration in the device.

Figure 1-81. System Mailbox Integration

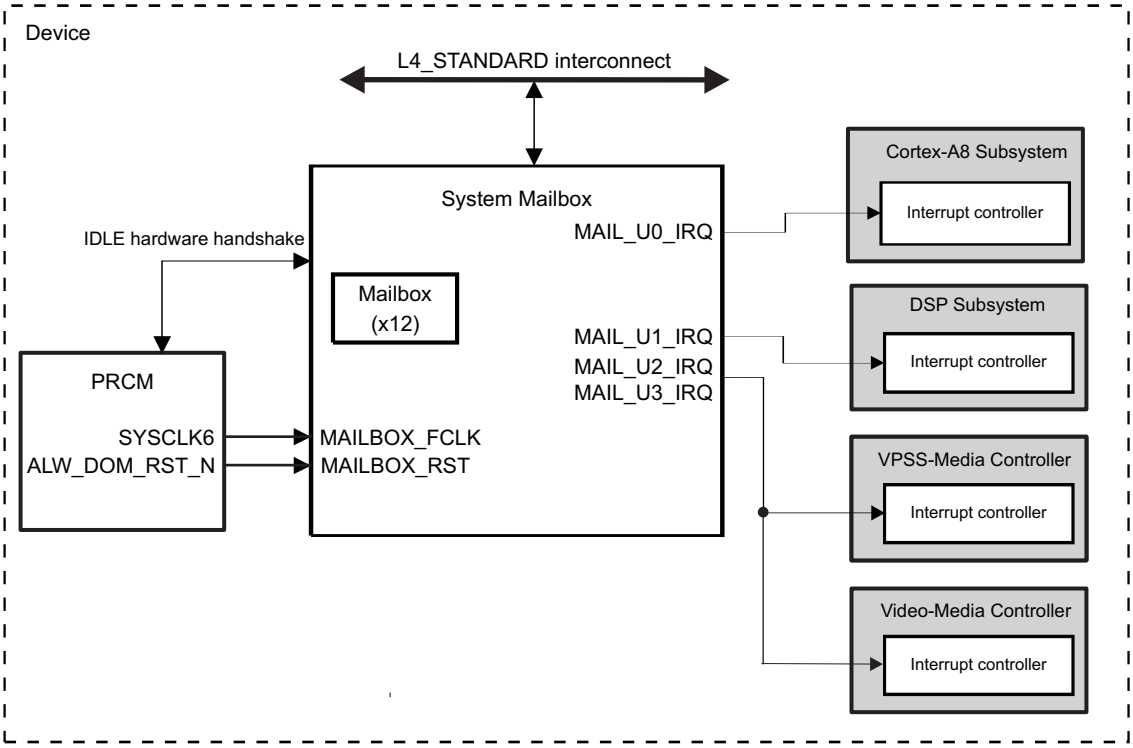


Table 1-97. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SYSTEM_MAILBOX	PD_ALWAYS_ON	L4_STANDARD

Table 1-98. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal**	**Source**	**Description**
SYSTEM_MAILBOX	MAILBOX_FCLK	SYSCLK6	PRCM	Mailbox interface clock. This clock is used for all interface and functional operations.
Resets				
SYTEM_MAILBOX	MAILBOX_RST	ALW_DOM_RST_N	PRCM	Mailbox hardware reset. This reset is asynchronously applied to the Mailbox registers

Table 1-99. Hardware Requests

Module Instance	Source Signal Name	Destination Signal	Destination	Description
SYSTEM_MAILBOX	MAIL_U0_IRQ	A_IRQ_77	Cortex-A8	System Mailbox user 0 interrupt
	MAIL_U1_IRQ	D_IRQ_56	DSP	System Mailbox user 1 interrupt

1.13.3 Functional Description

This device has the following Mailbox instances:

- System Mailbox
- HDVICP2-0 Mailbox
- HDVICP2-1 Mailbox
- HDVICP2-2 Mailbox

Table 1-100 shows Mailbox Implementation in this device, where u is the user number and m is the mailbox number.

Table 1-100. Mailbox Implementation

Mailbox Type	User Number(u)	Mailbox Number(m)	Messages per Mailbox
System Mailbox	0 to 3	0 to 11	4
HDVICP2-0 Mailbox	0 to 3	0 to 5	4
HDVICP2-1Mailbox	0 to 3	0 to 5	4
HDVICP2-2 Mailbox	0 to 3	0 to 5	4

The mailbox module provides a means of communication through message queues among the users (depending on the mailbox module instance). The individual mailbox modules (12 for the system mailbox instance, 6 for each HDVICP2 mailbox instance), or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQENABLE_SET_u (or MAILBOX_IRQENABLE_CLR_u) register.

CAUTION

For each HDVICP2 mailbox instance, communication is possible only if one of the users is iCont1 or iCont2.

The system mailbox module includes the following user subsystems:

- User 0: Cortex-A8 MPU subsystem (u = 0)
- User 1: DSP subsystem (u = 1)

Each HDVICP2 mailbox module includes the following user subsystems, where x=0,1,2.:

- User 0: Cortex-A8 MPU subsystem (u = 0)
- User 1: DSP subsystem (u = 1)
- User 3: HDVICP2 subsystem - only available to the HDVICP2 mailbox instance (u = 3)

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers. Each MAILBOX_IRQSTATUS_RAW_u/MAILBOX_IRQSTATUS_CLR_u interrupt status register corresponds to a particular user.

For the system mailbox instance, a user can query its interrupt status register through the L4_STANDARD (L4 STD) interconnect.

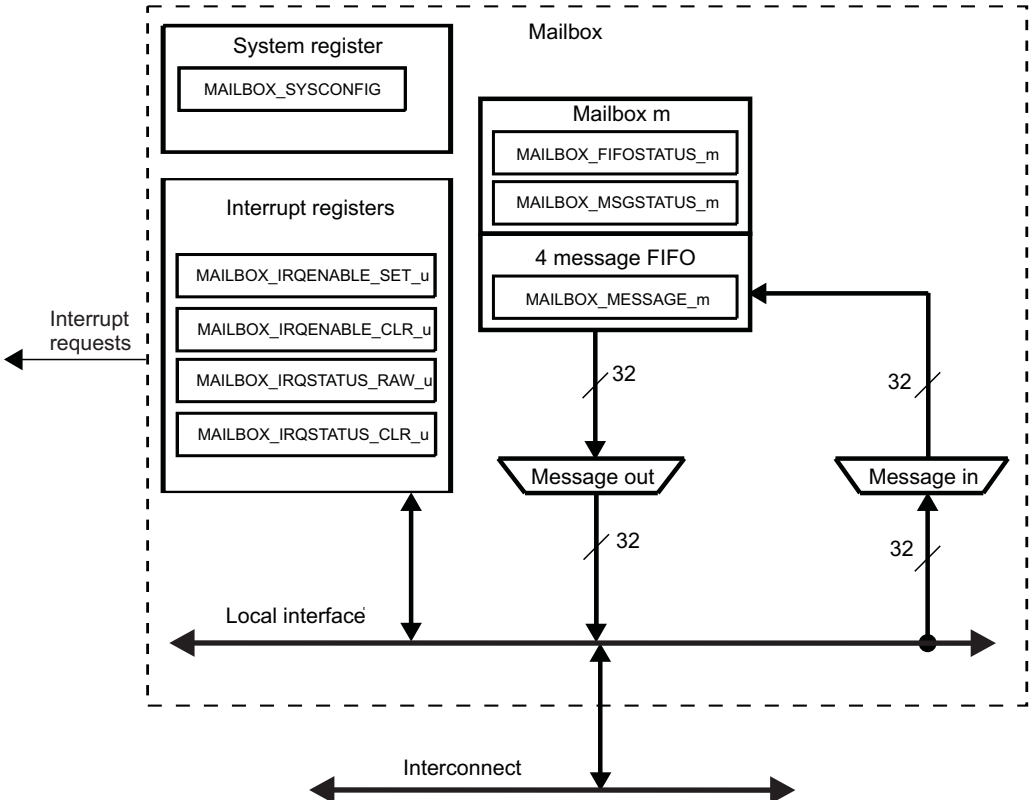
For each HDVICP2 mailbox instance, a user can query its interrupt status register as follows:

- Cortex-A8 MPU and DSP - through the L3 interconnect
- iCont1/iCont2 and DSP - private access (directly through the HDVICP2 and DSP local interconnect respectively)

1.13.3.1 Block Diagram

Figure 1-82 shows the mailbox block diagram.

Figure 1-82. Mailbox Block Diagram



1.13.3.2 Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0].SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

1.13.3.3 Power Management

Table 1-101 describes power-management features available for the mailbox module.

Table 1-101. Local Power Management Features

Feature	Registers	Description
Clock autogating	NA	Feature not available
Slave idle modes	MAILBOX_SYSCONFIG[3:2].SIDLEMODE	Force-idle, no-idle and smart-idle modes are available
Clock activity	NA	Feature not available
Master standby modes	NA	Feature not available
Global wake-up enable	NA	Feature not available
Wake-up sources enable	NA	Feature not available

The mailbox module can be configured using the MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

1.13.3.4 Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user. Table 1-102 lists the event flags, and their mask, that can cause module interrupts.

Table 1-102. Interrupt Events

Non-Maskable Event Flag[1]	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2].		
MAILBOX_IRQSTATUS_RAW_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[0+m*2].NEWMSGSTATUSUUMBm	Mailbox m receives a new message
MAILBOX_IRQSTATUS_RAW_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQSTATUS_CLR_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQENABLE_CLR_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQENABLE_SET_u[1+m*2].NOTFULLSTATUSUMBm	Mailbox m message queue is not full

(1) MAILBOX.MAILBOX_IRQSTATUS_RAW_u register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQSTATUS_CLR_u register. Writing a logical 1 in a bit of the MAILBOX_IRQSTATUS_CLR_u register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQENABLE_SET_u register. Events are reported in the appropriate MAILBOX_IRQSTATUS_CLR_u and MAILBOX_IRQSTATUS_RAW_u registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQENABLE_CLR_u register. Events are only reported in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

In case of the MAILBOX_IRQSTATUS_RAW_u register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

1.13.3.5 Assignment

1.13.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQENABLE_SET_u register. The receiver reads the MAILBOX_MESSAGE_m register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFOSTATUS_m and/or MAILBOX_MSGSTATUS_m registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQENABLE_SET_u register, where u is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFOSTATUS_m or MAILBOX_MSGSTATUS_m registers
- Write the message to the corresponding MAILBOX_MESSAGE_m register, if space is available

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQENABLE_SET_u register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQSTATUS_CLR_u register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQSTATUS_CLR_u register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

1.13.3.6 Sending and Receiving Messages

1.13.3.6.1 Description

When a 32-bit message is written to the MAILBOX_MESSAGE_m register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded. Queue overflow can be avoided by first reading the MAILBOX_FIFOSTATUS_m register to check that the mailbox message queue is not full before writing a new message to it. Reading the MAILBOX_MESSAGE_m register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_m register is read, the value 0 is returned. The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSGSTATUS_m register.

1.13.3.7 16-Bit Register Access

1.13.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the MAILBOX_MESSAGE_m registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02). All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX_MESSAGE_m registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

CAUTION

When using 16-bit accesses to the MAILBOX_MESSAGE_m registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the MAILBOX_MSGSTATUS_m registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX_MESSAGE_m are accessed.

1.13.4 Programming Guide

1.13.4.1 Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

1.13.4.1.1 Global Initialization

1.13.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See Section 1.13.2 for further information.

Table 1-103. Global Initialization of Surrounding Modules for System Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled.
Interrupt Controllers	Cortex-A8 MPU or DSP interrupt controller must be configured to enable the interrupt request generation to the Cortex-A8 MPU or DSP subsystem.

Table 1-104. Global Initialization of Surrounding Modules for HDVICP2-0 Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled.
Interrupt Controllers	Cortex-A8 MPU or DSP or iCont1/iCont2 of HDVICP2-0 Subsystem interrupt controller must be configured to enable the interrupt request generation to the Cortex-A8 MPU or DSP subsystem or HDVICP2-0 Subsystem

Table 1-105. Global Initialization of Surrounding Modules for HDVICP2-1 Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled.
Interrupt Controllers	Cortex-A8 MPU or DSP or iCont1/iCont2 of HDVICP2-1 Subsystem interrupt controller must be configured to enable the interrupt request generation to the Cortex-A8 MPU or DSP subsystem or HDVICP2-1 Subsystem

Table 1-106. Global Initialization of Surrounding Modules for HDVICP2-2 Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled.
Interrupt Controllers	Cortex-A8 MPU or DSP or iCont1/iCont2 of HDVICP2-2 Subsystem interrupt controller must be configured to enable the interrupt request generation to the Cortex-A8 MPU or DSP subsystem or HDVICP2-2 Subsystem

1.13.4.1.1.2 Mailbox Global Initialization

1.13.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 1-107. Mailbox Global Initialization

	Register/Bitfield/Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0].SOFTRESET	1
Wait until reset is complete	MAILBOX_SYSCONFIG[0].SOFTRESET	0
Set idle mode configuration	MAILBOX_SYSCONFIG[3:2].SIDLEMODE	0x-

1.13.4.1.2 Operational Modes Configuration

1.13.4.1.2.1 Main Sequence - Sending a Message (Polling Method)

Table 1-108. Sending a Message (Polling Method)

Step	Register/Bitfield/Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB	=1h
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB	=0h
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUE MBM	----h
ENDIF		

1.13.4.1.2.2 Main Sequence - Sending a Message (Interrupt Method)

Table 1-109. Sending a Message (Interrupt Method)

Step	Register/Bitfield/Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB	=1h
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	1h
User(processor) can perform another task until interrupt occurs		
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUE MBM	----h
ENDIF		

1.13.4.1.2.3 Main Sequence - Receiving a Message (Polling Method)

Table 1-110. Receiving a Message (Polling Method)

Step	Register/Bitfield/Programming Model	Value
IF : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0].NBOFMSGMB	!=0h
Read message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUE MBM	----h
ENDIF		

1.13.4.1.2.4 Main Sequence - Receiving a Message (Interrupt Method)

Table 1-111. Receiving a Message (Interrupt Method)

Step	Register/Bitfield/Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	1h
User(processor) can perform another task until interrupt occurs		

1.13.4.1.3 Events Servicing

1.13.4.1.3.1 Sending Mode

Table 1-112 describes the events servicing in sending mode.

Table 1-112. Events Servicing in Sending Mode

Step	Register/Bitfield/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	1
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUE MBM	----h
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	1

1.13.4.1.3.2 Receiving Mode

Table 1-113 describes the events servicing in receiving mode.

Table 1-113. Events Servicing in Receiving Mode

Step	Register/Bitfield/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	1
IF : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0].NBOFMSGMB	!=0h
Read message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUE MBM	----h
ELSE		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	1
ENDIF		

1.13.5 Mailbox Registers

Table 1-114 lists the mailboxes. The previous register set is applicable to these mailboxes. See the device-specific data manual for the memory address of these mailboxes.

Table 1-114. Mailboxes

Mailbox Type	User Number(u)	Mailbox Number(m)	Messages per Mailbox
System Mailbox	0 to 3	0 to 11	4
HDVICP2-0 Mailbox	0 to 3	0 to 5	4
HDVICP2-1Mailbox	0 to 3	0 to 5	4
HDVICP2-2 Mailbox	0 to 3	0 to 5	4

Table 1-115 lists the mailbox registers. For the base address of these registers, see Table 1-12.

Table 1-115. Mailbox Registers

Offset	Acronym	Register Description	Section
0h	MAILBOX_REVISION	Mailbox Revision Register	Section 1.13.5.1
10h	MAILBOX_SYSCONFIG	Mailbox System Configuration Register	Section 1.13.5.2
40h + (4h × m)	MAILBOX_MESSAGE_m	Mailbox Message Register	Section 1.13.5.3
80h + (4h × m)	MAILBOX_FIFOSTATUS_m	Mailbox FIFO Status Register	Section 1.13.5.4
C0h + (4h × m)	MAILBOX_MSGSTATUS_m	Mailbox Message Status Register	Section 1.13.5.5
100h + (10h × u)	MAILBOX_IRQSTATUS_RAW_u	Mailbox IRQ RAW Status Register	Section 1.13.5.6
104h + (10h × u)	MAILBOX_IRQSTATUS_CLR_u	Mailbox IRQ Clear Status Register	Section 1.13.5.7
108h + (10h × u)	MAILBOX_IRQENABLE_SET_u	Mailbox IRQ Enable Set Register	Section 1.13.5.8
10Ch + (10h × u)	MAILBOX_IRQENABLE_CLR_u	Mailbox IRQ Enable Clear Register	Section 1.13.5.9

1.13.5.1 Revision Register (MAILBOX_REVISION)

This register contains the IP revision code. The Mailbox Revision Register (MAILBOX_REVISION) is shown in Figure 1-83 described in Table 1-116.

Figure 1-83. Revision Register (MAILBOX_REVISION)

31	4	3 2	1	0
REVISION		SIDLEMODE	Reserved	SOFTRESET
R-0		R/W-0	R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-116. Revision Register (MAILBOX_REVISION) Field Descriptions

Bit	Field	Value	Description
31-4	REVISION	0	Reserved
3-2	SIDLEMODE	0	Force-idle. An idle request is acknowledged unconditionally
		1	No-idle. An idle request is never acknowledged
		2	Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module based on the internal activity of the module
		3	Reserved
1	Reserved	0	Reserved
0	SOFTRESET	0	Soft/Hard reset is done.
		1	Reset is ongoing.
		0	No action.
		1	Start the soft reset sequence.

1.13.5.2 System Configuration Register (MAILBOX_SYSCONFIG)

This register controls the various parameters of the communication interface. The Mailbox System Configuration Register (MAILBOX_SYSCONFIG) is shown in Figure 1-84 and described in Table 1-117.

Figure 1-84. System Configuration Register (MAILBOX_SYSCONFIG)

31	0
REVISION	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 1-117. System Configuration Register (MAILBOX_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-0	REVISION	0-FFFF FFFFh	IP Revision

1.13.5.3 Message Register (MAILBOX_MESSAGE_m)

The message register stores the next to be read message of the mailbox. Reads remove the message from the FIFO queue. The Mailbox Message Register (MAILBOX_MESSAGE_m) is shown in Figure 1-85 and described in Table 1-118.

Figure 1-85. Message Register (MAILBOX_MESSAGE_m)

31	0
MESSAGEVALUEMBM	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 1-118. Message Register (MAILBOX_MESSAGE_m) Field Descriptions

Bit	Field	Value	Description
31-0	MESSAGEVALUEMBM	0-FFFF FFFFh	Message in Mailbox. The message register stores the next to be read message of the mailbox. Reads remove the message from the FIFO queue.

1.13.5.4 FIFO Status Register (MAILBOX_FIFOSTATUS_m)

The FIFO status register has the status related to the mailbox internal FIFO. The Mailbox FIFO Status Register (MAILBOX_FIFOSTATUS_m) is shown in Figure 1-86 and described in Table 1-119.

Figure 1-86. FIFO Status Register (MAILBOX_FIFOSTATUS_m)

31	1	0
MESSAGEVALUEMBM		FIFOFULLMBM
R/W-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

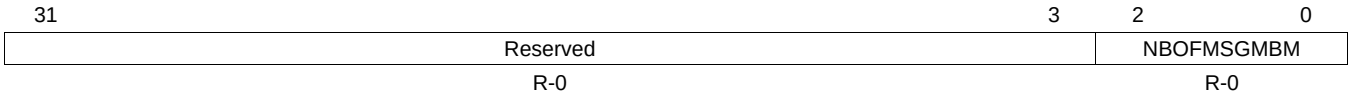
Table 1-119. FIFO Status Register (MAILBOX_FIFOSTATUS_m) Field Descriptions

Bit	Field	Value	Description
31-1	MESSAGEVALUEMBM	0-7FFFF FFFFh	Message in Mailbox. The message register stores the next to be read message of the mailbox. Reads remove the message from the FIFO queue.
0	FIFOFULLMBM		Full flag for Mailbox
		0	Mailbox FIFO is not full
		1	Mailbox FIFO is full

1.13.5.5 Message Status Register (MAILBOX_MSGSTATUS_m)

The message status register has the status of the messages in the mailbox. The Mailbox Message Status Register (MAILBOX_MSGSTATUS_m) is shown in Figure 1-87 and described in Table 1-120.

Figure 1-87. Message Status Register (MAILBOX_MSGSTATUS_m)



LEGEND: R = Read only; -*n* = value after reset

Table 1-120. Message Status Register (MAILBOX_MSGSTATUS_m) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved.
2-0	NBOFMSGMBM	0-7h	Number of unread messages in Mailbox. Limited to four messages per mailbox.

1.13.5.6 IRQ RAW Status Register (MAILBOX_IRQSTATUS_RAW_u)

The interrupt status register has the raw status for each event that may be responsible for the generation of an interrupt to the corresponding user - write 1 to a given bit sets this bit. This register is mainly used for debug purpose. The Mailbox IRQ RAW Status Register (MAILBOX_IRQSTATUS_RAW_u) is shown in Figure 1-88 and described in Table 1-121.

Figure 1-88. IRQ RAW Status Register (MAILBOX_IRQSTATUS_RAW_u)

		0	Write: No action
		1	Write: Set the event (for debug)

1.13.5.7 IRQ Clear Status Register (MAILBOX_IRQSTATUS_CLR_u)

The interrupt status register has the status combined with irq-enable for each event that may be responsible for the generation of an interrupt to the corresponding user - write 1 to a given bit resets this bit. The Mailbox IRQ Clear Status Register (MAILBOX_IRQSTATUS_CLR_u) is shown in Figure 1-89 and described in Table 1-122.

1.14 Spinlock

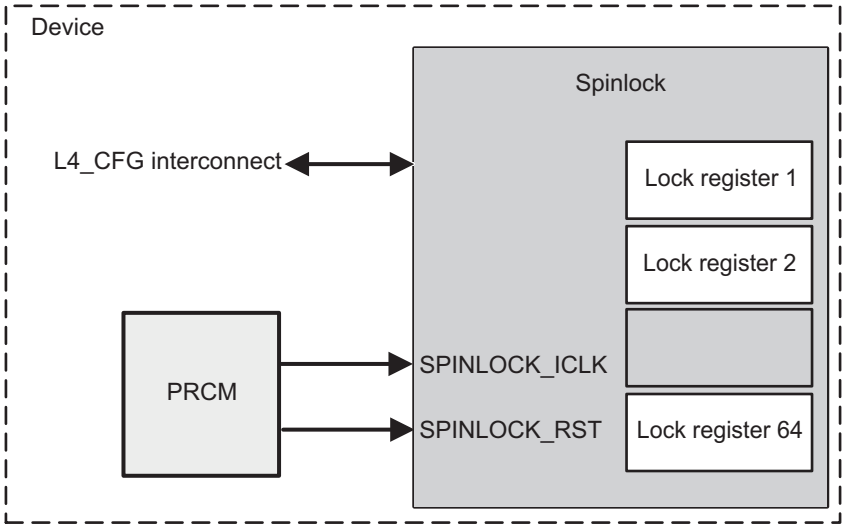
1.14.1 Overview

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Cortex-A8 microprocessor unit (MPU) subsystem
- Digital signal processor (DSP) subsystem
- Media Controller subsystem

The Spinlock module implements 64 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 1-92. Spinlock Module



1.14.2 Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 1-93 shows the Spinlock integration.

Figure 1-93. Spinlock Integration

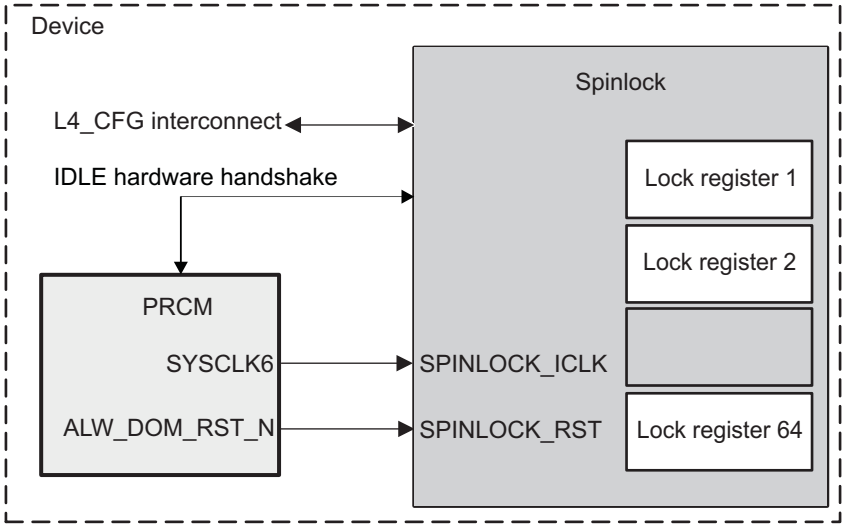


Table 1-125 and Table 1-126 summarize the integration of the module in the device.

Table 1-125. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_ALWAYS_ON	L4_STANDARD

Table 1-126. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SPINLOCK	SPINLOCK_ICLK	SYSCLK6	PRCM	Spinlock interface clock. This clock is used for all interface and functional operations.
Resets				
SPINLOCK	SPINLOCK_RST	ALW_DOM_RST_N	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock registers.

The Spinlock module does not support any interrupt and DMA requests.

1.14.3 Functional Description

1.14.3.1 Software Reset

The Spinlock module can be reset by software through the SPINLOCK_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. This bit also indicates that the software reset is complete when its value is reset to 0. The software must ensure that the software reset completes before doing Spinlock operations.

1.14.3.2 Power Management

Table 1-127 describes power-management features available to the Spinlock module.

Table 1-127. Local Power Management Features

Feature	Registers	Description
Clock auto gating	[0] AUTOGATING bit	This bit indicates that the module uses an automatic internal interface clock gating strategy, based on interface activity.
Slave idle modes	[4:3] SIDLEMODE bit field	This bit field indicates that the module uses smart-idle mode.
Clock activity	[8] CLOCKACTIVITY bit	This bit indicates that the interface clock is not required by the module during idle mode and may be switched off.
Global wake-up enable	[2] ENAWAKEUP bit	This bit indicates that the wake-up generation feature (at module level) is disabled.

NOTE: All the local power management features are non-configurable (that is, their respective bits or bit fields are read-only).

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY bit and Spinlock clock PRCM control bits.

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM module only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

The Spinlock module uses retention flops to retain state including the Taken state of each lock register. This means that the module can be placed in retention at any time when it is not processing a request and it is known that the system will not need to access the module.

Software must ensure to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

- Check that all masters which might use the Spinlock module are either:
  - Already powered off
  - Notified that Spinlock is not available and the notification is acknowledged
- If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 64 locks can be read from the register. If any locks are held, they are orphaned because they are not held by any master that is still active. Alternatively, you may decide to wait a timeout period to allow any active master to clean up its locks before powering down.
- The Spinlock module can now be powered off by writing the appropriate status to the PRCM module.

In the case of powering off the whole system, these steps are unnecessary.

1.14.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

- The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
- The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
- The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

1.14.3.4 Functional Operation

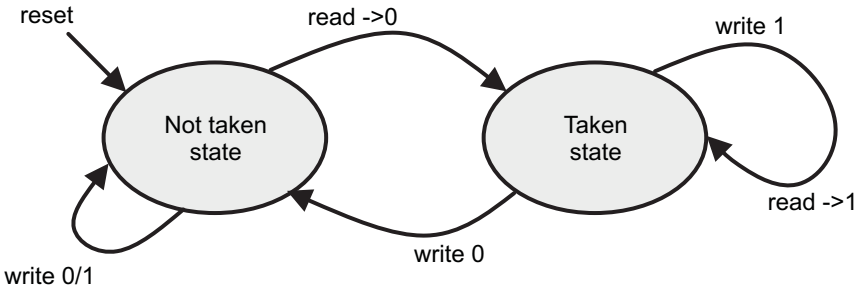
The Spinlock module supports 64 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK_LOCK_REG_i[0] TAKEN bit. There are two states: Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 1) or Not Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 0).

When the status of lock i (where i = 0 to 63) is Not Taken (free), a read from the SPINLOCK_LOCK_REG_i register returns 0 and sets the lock to Taken (locked). When the status of lock i is Taken, a read returns 1 and does not change the state of the lock. A write to the SPINLOCK_LOCK_REG_i register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

CAUTION

Only 32-bit reads and writes are supported.

Figure 1-94. SPINLOCK_LOCK_REG_i Register State Diagram



1.14.4 Programming Guide

1.14.4.1 Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

1.14.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

1.14.4.1.2 Global Initialization of Surrounding Modules

Table 1-128. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, Refer to the *Power, Reset, and Clock Management (PRCM) Module* chapter.
Interconnect	For more information about the L4-Standard interconnect configuration, Refer to the *Bus Interconnect* section.

1.14.4.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

1.14.4.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK_LOCK_REG_i registers at system startup to insure that all locks are initialized to Not Taken.

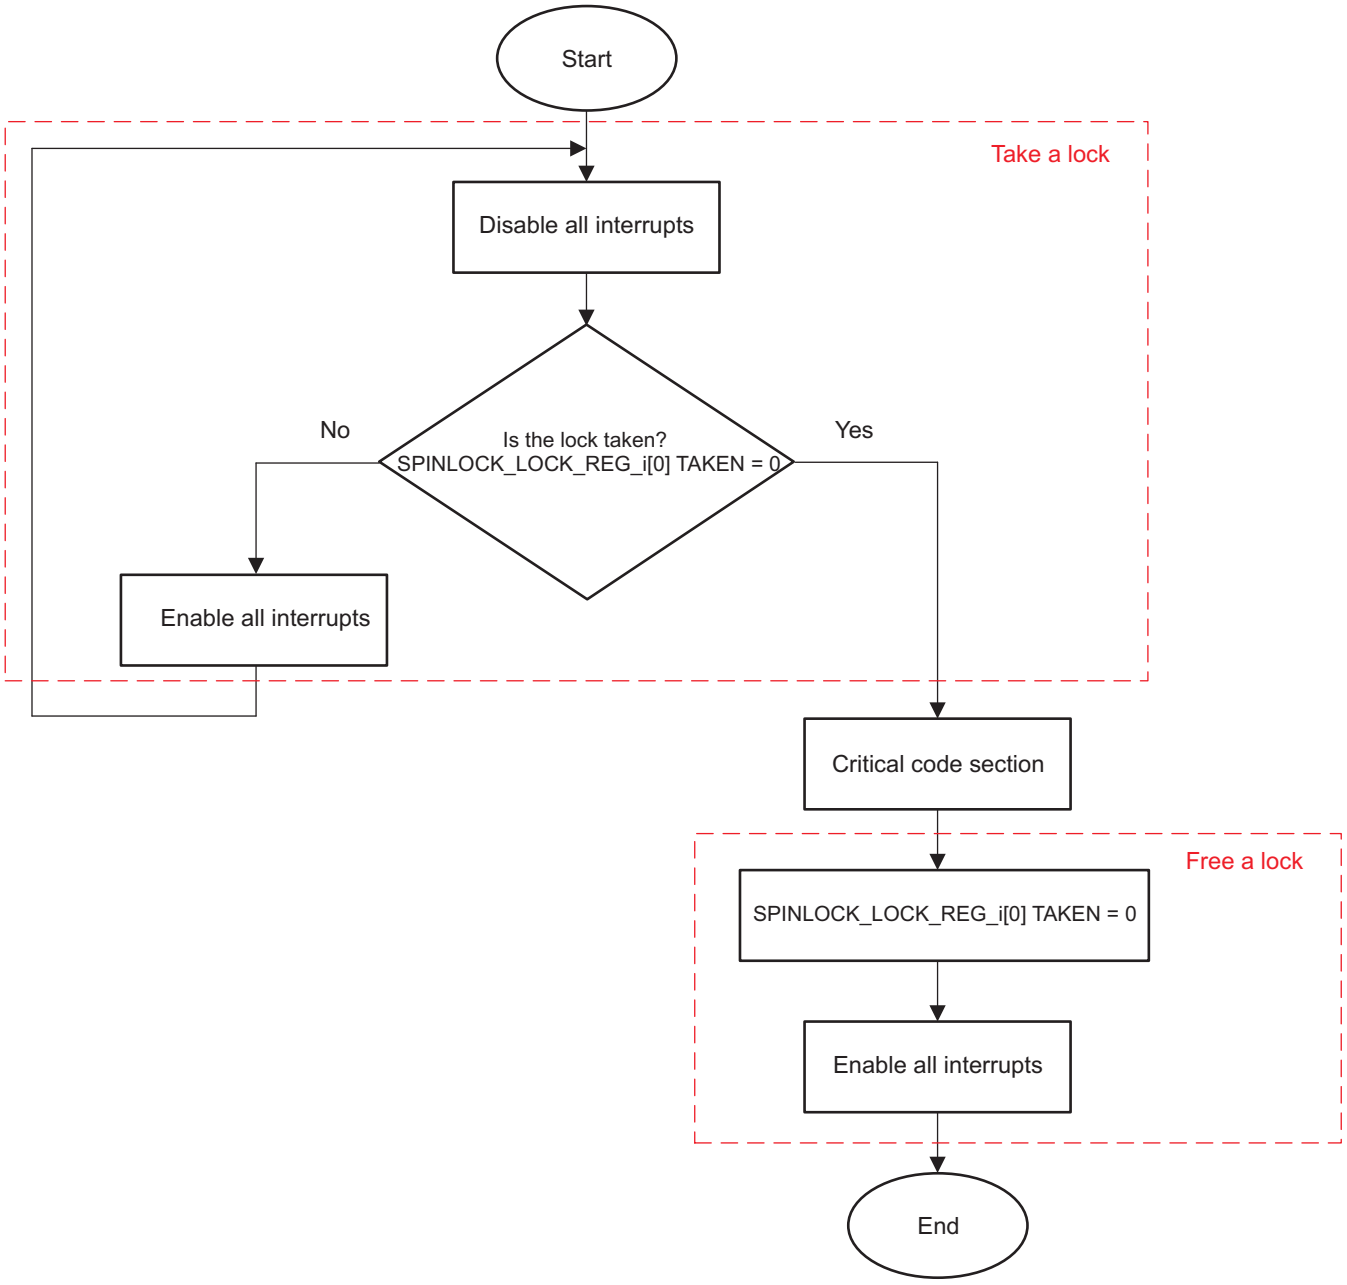
Table 1-129. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = = 1?	SPINLOCK_SYSTATUS[0] IU0	
Free the 64 locks	SPINLOCK_LOCK_REG_i[0] TAKEN (i=0 to 63)	0
END		

1.14.4.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the SPINLOCK_LOCK_REG_i[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be re-attempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before re-attempting to acquire the lock. Figure 1-95 shows the described above procedure.

Figure 1-95. Take and Release Spinlock



1.14.5 Spinlock Registers

Table 1-130 lists the spinlock module registers. For the base address of these registers, see Table 1-12.

Table 1-130. Spinlock Module Registers

Address Offset	Acronym	Description	Section
00h	SPINLOCK_REV	Revision Register	Section 1.14.5.1
010h	SPINLOCK_SYSCFG	System Configuration Register	Section 1.14.5.2
014h	SPINLOCK_SYSSTAT	System Status Register	Section 1.14.5.3
800h + (4h × i)	SPINLOCK_LOCK_REG_i	Lock Register	Section 1.14.5.4

1.14.5.1 Revision Register (SPINLOCK_REV)

The Spin Lock Revision Register (SPINLOCK_REV) is shown in Figure 1-96 and described in Table 1-131.

Bit	Field	Value	Description
31-9	Reserved	0	Reserved
8	CLOCKACTIVITY		Indicates whether the module requires the interface clock when in IDLE mode.
		0	Interface clock is not required by the module during IDLE mode and may be switched off.
		1	Interface clock is required by the module, even during idle mode.
7-5	Reserved	0	Reserved
4-3	SIDLEMODE		Slave interface power management (IDLE request/acknowledgment control)
		0	Force-idle. IDLE request is acknowledged unconditionally and immediately.
		1h	No-idle. IDLE request is never acknowledged.
		2h	Smart-idle. IDLE request acknowledgment is based on the internal module activity.
		3h	Reserved
2	ENWAKEUP		Asynchronous wakeup generation
		0	Wakeup generation is disabled.
		1	Wakeup generation is enabled.
1	SOFTRESET		Module software reset
		0	No action
		1	Start soft reset sequence
0	AUTOGATING		Internal interface clock gating strategy.
		0	Interface clock is not gated when the L4-STANDARD interface is idle.
		1	Automatic internal interface clock gating strategy is applied, based on the L4-CFG interface activity.

1.14.5.3 System Status Register (SPINLOCK_SYSSTAT)

The Spin Lock System Status Register (SPINLOCK_SYSSTAT) is shown in Figure 1-98 and described in Table 1-133.

Figure 1-98. System Status Register (SPINLOCK_SYSSTAT)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 1-134. Lock Register (SPINLOCK_LOCK_REG_i) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	TAKEN		Lock State
		0	Read: Lock was previously Not Taken (free). The requester is granted the lock.
		1	Read: Lock was previously Taken. The requester is not granted the lock and must retry.
		0	Write: Set the lock to Not Taken (free).
		1	Write: No update to the lock value.

1.15 Error Location Module

1.15.1 Error Location Module Overview

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-ChaudhurI-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

1.15.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

1.15.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 1-100 shows the integration of the ELM subsystem in the device.

Figure 1-100. ELM Integration

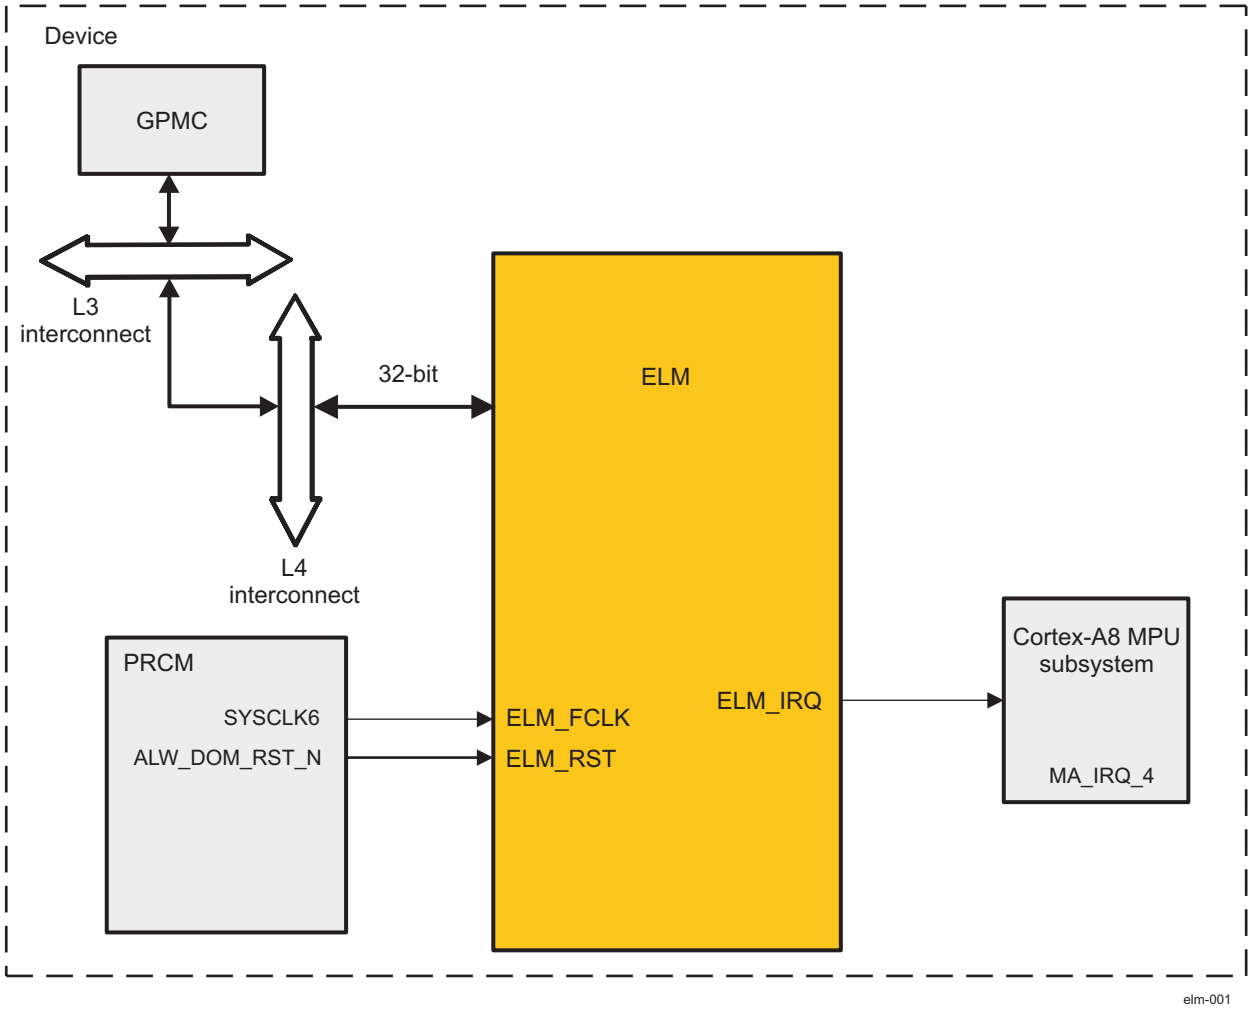

Table 1-135. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ELM	PD_ALWAYS_ON	No	NA

Table 1-137. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
ELM	ELM_IRQ	MA_IRQ_4	Cortex-A8	BCH error-location module interrupt

1.15.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

1.15.3.1 ELM Software Reset

To perform a software reset, write a 1 to the ELM_SYSCONFIG[1] SOFTRESET bit. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

1.15.3.2 ELM Power Management

Table 1-138 describes the power-management features available to the ELM module.

Table 1-138. Local Power Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING bit	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, No-idle, and Smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY bit	The clock can be switched-off or maintained during the wake-up period.
Master Standby modes	N/A	
Global Wake-up Enable	N/A	
Wake-up Sources Enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits.

1.15.3.3 ELM Interrupt Requests

Table 1-139 lists the event flags, and their masks, that can cause module interrupts.

Table 1-139. Events

Event Flag	Event Mask	Map to	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	ELM_IRQ	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	ELM_IRQ	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	ELM_IRQ	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	ELM_IRQ	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	ELM_IRQ	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	ELM_IRQ	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	ELM_IRQ	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	ELM_IRQ	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	ELM_IRQ	Error-location interrupt for syndrome polynomial 0

1.15.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit defines the error-correction level used (4-,8-, or 16-bit error-correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, with i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers are not reset (i = 0 to 7). The software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

1.15.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i are not updated (i = 0 to 7).

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

Table 1-140. ELM_LOCATION_STATUS_i Value Decoding Table

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependant

1.15.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (i = 0 to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set (i = 0 to 7). The processing-exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION fields. The software must only read valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. The CPU must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, the CPU must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bit fields. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bit fields (i = 0 to 7) are processed as usual, but are essentially ignored. The CPU must manually poll the ELM_IRQSTATUS bits to check for their status.

1.15.4 ELM Basic Programming Model

1.15.4.1 ELM Low Level Programming Model

1.15.4.1.1 Processing Initialization

Table 1-141. ELM Processing Initialization

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management.	ELM_SYSCONFIG[4:3] SIDLEMODE	Set value
Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value
If continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
else (page mode is used)	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value
endif		Set value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

1.15.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 1-142 and Table 1-143 describe the processing completion for continuous and page modes, respectively.

Table 1-142. ELM Processing Completion for Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. It is the software responsibility to correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 1-143. ELM Processing Completion for Page Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

1.15.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 1-144. Use Case: Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2x528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (i=0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (i=0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (i=0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (i=0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (i=0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (i=0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (i=0)	0x1AF
	ELM_ERROR_LOCATION_1_i (i=0)	0x426
	ELM_ERROR_LOCATION_2_i (i=0)	0x775
	ELM_ERROR_LOCATION_3_i (i=0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 1-145 are given in decimal format.

Table 1-145. 16-bit NAND Sector Buffer Address Map

NAND Memory Address	Message bit addresses in the memory word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

1.15.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

Table 1-146. Use Case: Page Mode

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 16 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x2
Defines the maximum buffer length: 528 bytes	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in page mode (4 blocks in a page)	ELM_PAGE_CTRL[0] SECTOR_0	0x1
	ELM_PAGE_CTRL[1] SECTOR_1	0x1
	ELM_PAGE_CTRL[2] SECTOR_2	0x1
	ELM_PAGE_CTRL[3] SECTOR_3	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	ELM_IRQENABLE	0x100
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (i=0)	0xE0B718EF
	ELM_SYNDROME_FRAGMENT_1_i (i=0)	0xA329AA05
	ELM_SYNDROME_FRAGMENT_2_i (i=0)	0x8330B5CC

	ELM_SYNDROME_FRAGMENT_4_i (i=1)	0xC22E6669
	ELM_SYNDROME_FRAGMENT_5_i (i=1)	0x49A0D932
	ELM_SYNDROME_FRAGMENT_6_i (i=1)	0xBAD0
Set the input syndrome polynomial 2.	ELM_SYNDROME_FRAGMENT_0_i (i=2)	0x60BA3189
	ELM_SYNDROME_FRAGMENT_1_i (i=2)	0x1579EF7D
	ELM_SYNDROME_FRAGMENT_2_i (i=2)	0x54556EA0
	ELM_SYNDROME_FRAGMENT_3_i (i=2)	0xA6498FEE
	ELM_SYNDROME_FRAGMENT_4_i (i=2)	0xEC3697FA
	ELM_SYNDROME_FRAGMENT_5_i (i=2)	0xB86ABCD5
	ELM_SYNDROME_FRAGMENT_6_i (i=2)	0x69D9

Table 1-146. Use Case: Page Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Set the input syndrome polynomial 3.	ELM_SYNDROME_FRAGMENT_0_i (i=3)	0x0
	ELM_SYNDROME_FRAGMENT_1_i (i=3)	0x0
	ELM_SYNDROME_FRAGMENT_2_i (i=3)	0x0
	ELM_SYNDROME_FRAGMENT_3_i (i=3)	0x0
	ELM_SYNDROME_FRAGMENT_4_i (i=3)	0x0
	ELM_SYNDROME_FRAGMENT_5_i (i=3)	0x0
	ELM_SYNDROME_FRAGMENT_6_i (i=3)	0x0
Initiates the computation process for syndrome polynomial 0	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=0)	0x1
Initiates the computation process for syndrome polynomial 1	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=1)	0x1
Initiates the computation process for syndrome polynomial 2	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=2)	0x1
Initiates the computation process for syndrome polynomial 3	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=3)	0x1
Wait until process is complete for syndrome polynomial 0, 1, 2, and 3: Wait until the ELM_IRQ interrupt is generated or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Read the process exit status for syndrome polynomial 0: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (i=0)	0x1
Read the process exit status for syndrome polynomial 1: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (i=1)	0x1
Read the process exit status for syndrome polynomial 2: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (i=2)	0x1
Read the process exit status for syndrome polynomial 3: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (i=3)	0x1
Read the number of errors for syndrome polynomial 0: 4 errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (i=0)	0x4
Read the number of errors for syndrome polynomial 1: 2 errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (i=1)	0x2
Read the number of errors for syndrome polynomial 2: 1 error detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (i=2)	0x1
Read the number of errors for syndrome polynomial 3: 0 errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (i=3)	0x0
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers:	ELM_ERROR_LOCATION_0_i (i=0)	0x1FE
	ELM_ERROR_LOCATION_1_i (i=0)	0x617
	ELM_ERROR_LOCATION_2_i (i=0)	0x650
	ELM_ERROR_LOCATION_3_i (i=0)	0xA83
Read the error-location bit addresses for syndrome polynomial 1 of the 2 first registers:	ELM_ERROR_LOCATION_0_i (i=1)	0x4
	ELM_ERROR_LOCATION_1_i (i=1)	0x1036
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	ELM_ERROR_LOCATION_0_i (i=1)	0x3E8
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

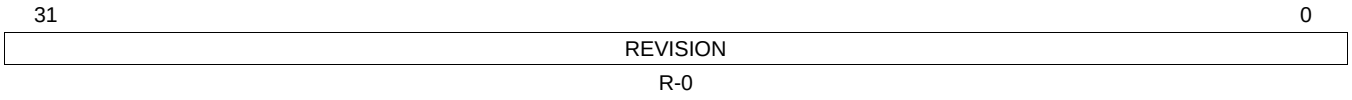
(1) i = 0 to 8

1.15.5.1 ELM Revision Register (ELM_REVISION)

This register contains the IP revision code. The ELM Revision Register (ELM_REVISION) is shown in Figure 1-101 and described in Table 1-148.

Figure 1-101. ELM Revision Register (ELM_REVISION)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

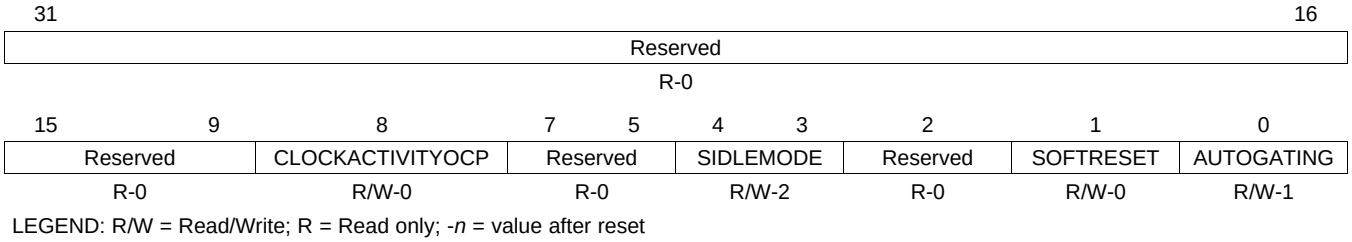
Table 1-148. ELM Revision Register (ELM_REVISION) Field Descriptions

Bit	Field	Value	Description
31-0	REVISION	0-FFFF FFFFh	IP Revision

1.15.5.2 ELM System Configuration Register (ELM_SYSCONFIG)

This register allows controlling various parameters of the OCP interface. The ELM System Configuration Register (ELM_SYSCONFIG) is shown in Figure 1-102 and described in Table 1-149.

Figure 1-102. ELM System Configuration Register (ELM_SYSCONFIG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-149. ELM System Configuration Register (ELM_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved
8	CLOCKACTIVITY OCP		OCP Clock activity when module is in IDLE mode (during wake up mode period).
		0	OCP Clock can be switch-off
		1	OCP Clock is maintained during wake up period
7-5	Reserved	0	Reserved
4-3	SIDLEMODE		Slave interface power management (IDLE req/ack control).
		0	FORCE Idle. IDLE request is acknowledged unconditionally and immediately. (Default *Dumb* mode for safety)
		1h	NO idle. IDLE request is never acknowledged.
		2h	SMART Idle. The acknowledgment to an IDLE request is given based on the internal activity.
		3h	Reserved - do not use
2	Reserved	0	Reserved
1	SOFTRESET		Module software reset. This bit is automatically reset by hardware (During reads, it always returns 0.). It has same effect as the OCP hardware reset.
		0	Normal mode.
		1	Start soft reset sequence.
0	AUTOGATING		Internal OCP clock gating strategy. (No module visible impact other than saving power.)
		0	OCP clock is free-running.
		1	Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.

1.15.5.3 ELM System Status Register (ELM_SYSSTATUS)

The ELM System Status Register (ELM_SYSSTATUS) is shown in Figure 1-103 and described in Table 1-150.

Figure 1-103. ELM System Status Register (ELM_SYSSTATUS)

31	1	0
Reserved		RESETDONE
R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-150. ELM System Status Register (ELM_SYSSTATUS) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	RESETDONE		Internal reset monitoring (OCP domain). Undefined since: From hardware perspective, the reset state is 0. From software user perspective, when the accessible module is 1.
		0	Reset is on-going
		1	Reset is done (completed)

1.15.5.4 ELM Interrupt Status Register (ELM_IRQSTATUS)

This register doubles as a status register for the error-location processes. The ELM Interrupt Status Register (ELM_IRQSTATUS) is shown in Figure 1-104 and described in Table 1-151.

Figure 1-104. ELM Interrupt Status Register (ELM_IRQSTATUS)

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 1-151. ELM Interrupt Status Register (ELM_IRQSTATUS) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved
8	PAGE_VALID		Error-location status for a full page, based on the mask definition.
		0	Read: Error locations invalid for all polynomials enabled in the ECC_INTERRUPT_MASK register.
		1	Read: All error locations valid.
		0	Write: No effect.
		1	Write: Clear interrupt.
7	LOC_VALID_7		Error-location status for syndrome polynomial 7.
		0	Read: No syndrome processed or process in progress.
		1	Read: Error-location process completed.
		0	Write: No effect.
		1	Write: Clear interrupt.
6	LOC_VALID_6		Error-location status for syndrome polynomial 6.
		0	Read: No syndrome processed or process in progress.
		1	Read: Error-location process completed.
		0	Write: No effect.
		1	Write: Clear interrupt.
5	LOC_VALID_5		Error-location status for syndrome polynomial 5.
		0	Read: No syndrome processed or process in progress.
		1	Read: Error-location process completed.
		0	Write: No effect.
		1	Write: Clear interrupt.
4	LOC_VALID_4		Error-location status for syndrome polynomial 4.
		0	Read: No syndrome processed or process in progress.
		1	Read: Error-location process completed.
		0	Write: No effect.
		1	Write: Clear interrupt.
3	LOC_VALID_3		Error-location status for syndrome polynomial 3.
		0	Read: No syndrome processed or process in progress.
		1	Read: Error-location process completed.
		0	Write: No effect.
		1	Write: Clear interrupt.

Table 1-151. ELM Interrupt Status Register (ELM_IRQSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
2	LOC_VALID_2		Error-location status for syndrome polynomial 2.
		0	Read: No syndrome processed or process in progress.
		1	Read: Error-location process completed.
		0	Write: No effect.
		1	Write: Clear interrupt.
1	LOC_VALID_1		Error-location status for syndrome polynomial 1.
		0	Read: No syndrome processed or process in progress.
		1	Read: Error-location process completed.
		0	Write: No effect.
		1	Write: Clear interrupt.
0	LOC_VALID_0		Error-location status for syndrome polynomial 0.
		0	Read: No syndrome processed or process in progress.
		1	Read: Error-location process completed.
		0	Write: No effect.
		1	Write: Clear interrupt.

1.15.5.5 ELM Interrupt Enable Register (ELM_IRQENABLE)

The ELM Interrupt Enable Register (ELM_IRQENABLE) is shown in Figure 1-105 and described in Table 1-152.

Figure 1-105. ELM Interrupt Enable Register (ELM_IRQENABLE)

Table 1-162. ELM_LOCATION_STATUS_i Register Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved
8	ECC_CORRECTABL		Error-location process exit status.
		0	ECC error-location process failed. Number of errors and error locations are invalid.
		1	All errors were successfully located. Number of errors and error locations are valid.
7-5	Reserved	0	Reserved
4-0	ECC_NB_ERRORS	0-1Fh	Number of errors detected and located.

1.15.5.16 ELM_ERROR_LOCATION_0-15_i Registers

The ELM_ERROR_LOCATION_0-15_i Registers is shown in Figure 1-116 and described in Table 1-163.

Figure 1-116. ELM_ERROR_LOCATION_0-15_i Registers

31	13	12	0
Reserved		ECC_ERROR_LOCATION	
R-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 1-163. ELM_ERROR_LOCATION_0-15_i Registers Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved
12-0	ECC_ERROR_LOCATION	0-1FFFh	Error-location bit address.

1.16 Control Module

The Control module complies to the industry standard - OCP Specification Revision 2.2. It includes within it all chip-level registers, which are common to all interfaces whose functionality is general purpose configuration, control and status.

NOTE: Be advised that DSP, GEM, and C674x are used interchangeably throughout this section.

The registers can be classified into the following groups:

Device BOOT Registers
These include the boot control, status and boot address registers.

PLL Control Registers
These include the control and configuration registers for main PLL, Audio PLL, video PLL and DDR PLLs.

Device Configuration Registers
These registers are used to for general purpose configuration, control and status information. Some of the functionality of these registers include - clock and oscillator control, initiator priorities, system MMU configuration, DDR control register, C674x DSP state management, USB control and USB PHY control, Ethernet MAC 48-bit ID, PCIe configuration, RTC control, Audio mute control, HD DACs control, SD DAC control, and HW Event select registers.

PAD Configuration Registers
These set of registers control pin multiplexing and pull up/pull down control per pin of the device.

1.16.1 Control Module Registers

1.16.1.1 Device BOOT Registers

Table 1-164 lists registers that control various boot aspects of the device. For the base address of these registers, see Table 1-12.

Table 1-164. PLL BOOT Registers

Offset	Acronym	Register Description	Section
40h	CONTROL_STATUS	Control Status Register	Section 1.16.1.1.1
44h	BOOTSTAT	Boot Status Register	Section 1.16.1.1.2
48h	DSPBOOTADDR	DSP Boot Address Vector	Section 1.16.1.1.3

1.16.1.1.1 Control Status Register (CONTROL_STATUS)

The CONTROL_STATUS register reflects the system boot and the device type configuration values as sampled when the power-on reset (PORz) or warm reset (RESETz) signal goes high.

The Control Status Register (CONTROL_STATUS) is shown in Figure 1-117 and described in Table 1-165.

Figure 1-117. Control Status Register (CONTROL_STATUS)

31	20	19	18	17	16
Reserved		ADMUX		WAITEN	BW
R-0		R-L		R-L	R-L

15	5	4	0
Reserved		SYSBOOT	
R-0		R-L	

LEGEND: R = Read only; L = Latched pin value; -*n* = value after reset

Table 1-165. Control Status Register (CONTROL_STATUS) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	Reserved.
19-18	ADMUX		GPMC CS0 Default Address Muxing, from CS0MUX[0] and CS0MUX[1] pins.
		0	No Addr/Data Muxing
		1h	Addr/Data Muxing
		2h	Addr/Addr/Data Muxing
		3h	Reserved
17	WAITEN		GPMC CS0 Default Wait Enable, from CS0WAIT pin.
		0	Ignore WAIT input.
		1	Use WAIT input.
16	BW		GPMC CS0 Default Bus Width, from CS0BW pin.
		0	8-bit data bus.
		1	16-bit data bus.
15-5	Reserved	0	Reserved
4-0	SYSBOOT		System Boot Type, from BTMODE pins. These pins determine the primary bootmode.

1.16.1.1.2 Boot Status Register (BOOTSTAT)

The Boot Status (BOOTSTAT) register indicates the status of the device boot process.

The Boot Status Register (BOOTSTAT) is shown in Figure 1-118 and described in Table 1-166.

Figure 1-118. Boot Status Register (BOOTSTAT)

31	20	19	16	15	1	0
Reserved		BOOTERR		Reserved		BC
R-0		R/W-0		R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-166. Boot Status Register (BOOTSTAT) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	Reserved.
19-16	BOOTERR		Boot Error. The exact meaning of the various error codes will be determined by the bootloader software.
		0	No Boot Error
		Other	Bootloader detected boot error.
15-1	Reserved	0	Reserved.
0	BC		Boot Complete bit. This bit may be optionally set by a host boot device to indicate that it has finished loading code. The Host ARM can poll this bit to determine whether to continue the boot process
		0	Host has not complete boot sequence.
		1	Host boot sequence is complete.

1.16.1.1.3 DSP Boot Address Register (DSPBOOTADDR)

The DSP boot address defaults to 0800 0000h (C674x DSP L2 space). The Host ARM must place DSP boot code into C674x DSP L2 prior to releasing GEM reset or change the DSPBOOTADDR to point to the code location. The DSPBOOTADDR register is reset to its default value by a hard reset only and retains its current value over a soft reset.

The DSP Boot Address Register (DSPBOOTADDR) is shown in Figure 1-119 and described in Table 1-167.

Figure 1-119. DSP Boot Address Register (DSPBOOTADDR)

31	10	9	1	0
BOOTADDR		Reserved		RSTDONE
R/W-0		R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-167. DSP Boot Address Register (DSPBOOTADDR) Field Descriptions

Bit	Field	Value	Description
31-10	BOOTADDR	0-3F FFFFh	DSP Boot Address (upper 22 bits)
9-1	Reserved	0	Reserved.
0	RSTDONE	0-1	DSP Reset Done.

1.16.1.2 PLL Control Registers

Table 1-168 lists the registers of the PLL control registers. For the base address of these registers, see Table 1-12.

Table 1-168. PLL Control Registers

Offset	Acronym	Register Description	Section

1.16.1.2.1 Main PLL Control Register (MAINPLL_CTRL)

The MAINPLL_CTRL register is used to enable and control the base frequency of the main PLL. The default values set the frequency at 1728 MHz.

The Main PLL Control Register (MAINPLL_CTRL) is shown in Figure 1-120 and described in Table 1-169.

Figure 1-120. Main PLL Control Register (MAINPLL_CTRL)

Table 1-169. Main PLL Control Register (MAINPLL_CTRL) Field Descriptions

Bit	Field	Value	Description
31-16	MAIN_N	0-FFFFh	Main PLL N multiplier value.
15-8	MAIN_P	0-FFh	Main PLL P divider value.
7	MAIN_LOCK	0-1	Main PLL lock status bit.
6-4	Reserved	0	Reserved. Reads returns 0.
3	MAIN_PLLEN		Main PLL enable.
		0	PLL is disabled (power down state).
		1	PLL is enabled (normal operation).
2	MAIN_BP		Main PLL bypass enable.
		0	Normal operation.
		1	PLL in bypass mode, reference clock driven at output.
1	Reserved	0	Reserved. Reads returns 0.
0	MAIN_LOC_CTL		Select the source to detect PLL lock. Value of 0 is recommended to use the more reliable Analog circuit.
		0	Analog lock
		1	Digital lock

1.16.1.2.2 Main PLL Powerdown Register (MAINPLL_PWD)

The MAINPLL_PWD register is used to power down the individual output clocks of the main PLL.

The Main PLL Powerdown Register (MAINPLL_PWD) is shown in Figure 1-121 and described in Table 1-170.

Figure 1-121. Main PLL Powerdown Register (MAINPLL_PWD)

Table 1-170. Main PLL Powerdown Register (MAINPLL_PWD) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Reads returns 0.
7	PWD_CLK7	1-0	Main PLL Clock7 Powerdown. Setting this bit powers down clock 7 (Audio PLL Reference clock).
6	PWD_CLK6	1-0	Main PLL Clock6 Powerdown. Setting this bit powers down clock 6 (USB Reference clock).
5	PWD_CLK5	1-0	Main PLL Clock5 Powerdown. Setting this bit powers down clock 5 (SYSCLK24).
4	PWD_CLK4	1-0	Main PLL Clock4 Powerdown. Setting this bit powers down clock 4 (SYSCLK4).
3	PWD_CLK3	1-0	Main PLL Clock3 Powerdown. Setting this bit powers down clock 3 (SYSCLK3).
2	PWD_CLK2	1-0	Main PLL Clock2 Powerdown. Setting this bit powers down clock 2 (SYSCLK2).
1	PWD_CLK1	1-0	Main PLL Clock1 Powerdown. Setting this bit powers down clock 1 (SYSCLK1).
0	Reserved	0	Reserved. Reads returns 0.

1.16.1.2.3 Main PLL Frequency 1 Register (MAINPLL_FREQ1)

The MAINPLL_FREQ1 register is used to control the Main PLL Clock 1 pre-divider frequency of the SYSCLK1 (C674x DSP) clock. The default FREQ1 value is 8.5 to generate an 800 MHz (813.1765 MHz) SYSCLK1.

The Main PLL Frequency 1 Register (MAINPLL_FREQ1) is shown in Figure 1-122 and described in Table 1-171.

Figure 1-122. Main PLL Frequency 1 Register (MAINPLL_FREQ1)

Table 1-171. Main PLL Frequency 1 Register (MAINPLL_FREQ1) Field Descriptions

Bit	Field	Value	Description
31	MAIN_LDFREQ1	1-0	Load Synth1 FREQ value. Setting this bit to 1 causes the INTFREQ and FRACFREQ values to be loaded into Main Synthesizer1.
30-29	Reserved	0	Reserved. Reads returns 0.
28	MAIN_TRUNC1	1-0	Synth1 Enable Truncate Correction.
27-24	MAIN_INTFREQ1	8h-Fh	Synth1 Frequency integer divider.
23-0	MAIN_FRACFREQ1	0-FF FFFFh	Synth1 Frequency fractional divider.

1.16.1.2.4 Main PLL Divider 1 Register (MAINPLL_DIV1)

The MAINPLL_DIV1 register is used to control the Main PLL Clock 1 post-divider frequency of the SYSCLK1 (GEM is changed to C674x DSP) clock. The default DIV1 value is 2 to generate an 800 MHz SYSCLK1.

The Main PLL Divider 1 Register (MAINPLL_DIV1) is shown in Figure 1-123 and described in Table 1-172.

Figure 1-123. Main PLL Divider 1 Register (MAINPLL_DIV1)

31	9	8	7	0

Table 1-172. Main PLL Divider 1 Register (MAINPLL_DIV1) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. Reads returns 0.
8	MAIN_LDMDIV1	1-0	Load Synth1 M Divider value. Setting this bit to 1 causes the M Divider value to be loaded into Main Synthesizer1.
7-0	MAIN_MDIV1	0-FFh	Synth1 Frequency M Post Divider.

1.16.1.2.5 Main PLL Frequency 2 Register (MAINPLL_FREQ2)

The MAINPLL_FREQ2 register is used to control the Main PLL Clock 2 pre-divider frequency of the SYSCLK2 (Cortex-A8) clock. The default FREQ2 value is 14 to generate a 1GHz (987.42) clock.

The Main PLL Frequency 2 Register (MAINPLL_FREQ2) is shown in Figure 1-124 and described in Table 1-173.

Figure 1-124. Main PLL Frequency 2 Register (MAINPLL_FREQ2)

Table 1-173. Main PLL Frequency 2 Register (MAINPLL_FREQ2) Field Descriptions

Bit	Field	Value	Description
31	MAIN_LDFREQ2	1-0	Load Synth2 FREQ value. Setting this bit to 1 causes the INTFREQ and FRACFREQ values to be loaded into Main Synthesizer2.
30-29	Reserved	0	Reserved. Reads returns 0.
28	MAIN_TRUNC2	1-0	Synth2 Enable Truncate Correction.
27-24	MAIN_INTFREQ2	8h-Fh	Synth2 Frequency integer divider.
23-0	MAIN_FRACFREQ2	0-FF FFFFh	Synth2 Frequency fractional divider.

1.16.1.2.6 Main PLL Divider 2 Register (MAINPLL_DIV2)

The MAINPLL_DIV2 register is used to control the Main PLL Clock 2 post-divider frequency of the SYSCLK2 (Cortex-A8) clock. The default DIV2 value is 1 for a ~1 GHz SYSCLK2.

The Main PLL Divider 2 Register (MAINPLL_DIV2) is shown in Figure 1-125 and described in Table 1-174.

Figure 1-125. Main PLL Divider 2 Register (MAINPLL_DIV2)

31 9	8	7 0

Table 1-174. Main PLL Divider 2 Register (MAINPLL_DIV2) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. Reads returns 0.
8	MAIN_LDMDIV2	1-0	Load Synth2 M Divider value. Setting this bit to 1 causes the M Divider value to be loaded into Main Synthesizer2.
7-0	MAIN_MDIV2	0-FFh	Synth2 Frequency M Post Divider.

1.16.1.2.7 Main PLL Frequency 3 Register (MAINPLL_FREQ3)

The MAINPLL_FREQ3 register is used to control the Main PLL Clock 3 pre-divider frequency of the SYSCLK3 (IVA HD is changed to HDVICP2) clock. The default FREQ3 value is 8.666667 to generate a 533 MHz SYSCLK3.

The Main PLL Frequency 3 Register (MAINPLL_FREQ3) is shown in Figure 1-126 and described in Table 1-175.

Figure 1-126. Main PLL Frequency 3 Register (MAINPLL_FREQ3)

8	MAIN_LDMDIV3	1-0	Load Synth3 M Divider value. Setting this bit to 1 causes the M Divider value to be loaded into Main Synthesizer3. Bit is cleared by hardware after load is complete.
7-0	MAIN_MDIV3	0-FFh	Synth3 Frequency M Post Divider.

1.16.1.2.9 Main PLL Frequency 4 Register (MAINPLL_FREQ4)

The MAINPLL_FREQ4 register is used to control the Main PLL Clock 4 pre-divider frequency of the SYSCLK4, SYSCLK5, SYSCLK6, and SYSCLK7 clocks. The default FREQ4 value is 9.333333 to generate a 500 MHz SYSCLK4.

The Main PLL Frequency 4 Register (MAINPLL_FREQ4) is shown in Figure 1-128 and described in Table 1-177.

Figure 1-128. Main PLL Frequency 4 Register (MAINPLL_FREQ4)

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. Reads returns 0.
8	MAIN_LDMDIV4	1-0	Load Synth4 M Divider value. Setting this bit to 1 causes the M Divider value to be loaded into Main Synthesizer4.
7-0	MAIN_MDIV4	0-FFh	Synth4 Frequency M Post Divider.

1.16.1.2.11 Main PLL Frequency 5 Register (MAINPLL_FREQ5)

The MAINPLL_FREQ5 register is used to control the Main PLL Clock 5 pre-divider frequency of the CPGMAC rft_clk (SYSCLK24) clock. The default FREQ5 value is 9.216 to generate a 125 MHz SYSCLK24.

The Main PLL Frequency 5 Register (MAINPLL_FREQ5) is shown in Figure 1-130 and described in Table 1-179.

Figure 1-130. Main PLL Frequency 5 Register (MAINPLL_FREQ5)

Table 1-179. Main PLL Frequency 5 Register (MAINPLL_FREQ5) Field Descriptions

Bit	Field	Value	Description
31	MAIN_LDFREQ5	1-0	Load Synth5 FREQ value. Setting this bit to 1 causes the INTFREQ and FRACFREQ values to be loaded into Main Synthesizer5.
30-29	Reserved	0	Reserved. Reads returns 0.
28	MAIN_TRUNC5	1-0	Synth5 Enable Truncate Correction.
27-24	MAIN_INTFREQ5	8h-Fh	Synth5 Frequency integer divider.
23-0	MAIN_FRACFREQ5	0-FF FFFFh	Synth5 Frequency fractional divider.

1.16.1.2.12 Main PLL Divider 5 Register (MAINPLL_DIV5)

The MAINPLL_DIV5 register is used to control the Main PLL Clock 5 post-divider frequency of the CPGMAC rft_clk clock. The default DIV5 value is 12.

The Main PLL Divider 5 Register (MAINPLL_DIV5) is shown in Figure 1-131 and described in Table 1-180.

Figure 1-131. Main PLL Divider 5 Register (MAINPLL_DIV5)

7-0	MAIN_MDIV5	0-FFh	Synth5 Frequency M Post Divider.

1.16.1.2.13 Main PLL Divider 6 Register (MAINPLL_DIV6)

The MAINPLL_DIV6 register is used to control the Main PLL Clock 6 post-divider frequency of the USB Reference clock. The default DIV6 value is 72 to select 24 MHz.

The Main PLL Divider 6 Register (MAINPLL_DIV6) is shown in Figure 1-132 and described in Table 1-181.

Figure 1-132. Main PLL Divider 6 Register (MAINPLL_DIV6)

7-0	MAIN_MDIV6	0-FFh	Frequency M Post Divider6.

1.16.1.2.14 Main PLL Divider 7 Register (MAINPLL_DIV7)

The MAINPLL_DIV7 register is used to control the Main PLL Clock 7 post-divider frequency of the Audio PLL reference clock. The default DIV7 value is 4 to select 432 MHz.

The Main PLL Divider 7 Register (MAINPLL_DIV7) is shown in Figure 1-133 and described in Table 1-182.

Figure 1-133. Main PLL Divider 7 Register (MAINPLL_DIV7)

7-0	MAIN_MDIV7	0-FFh	Frequency M Post Divider7.

1.16.1.2.15 DDR PLL Control Register (DDRPLL_CTRL)

The DDRPLL_CTRL register is used to control the base frequency of the DDR PLL. The default values set the base frequency at 800 MHz (796.5 MHz).

The DDR PLL Control Register (DDRPLL_CTRL) is shown in Figure 1-134 and described in Table 1-183.

Figure 1-134. DDR PLL Control Register (DDRPLL_CTRL)

1.16.1.2.18 DDR PLL Frequency 2 Register (DDRPLL_FREQ2)

The DDRPLL_FREQ2 register is used to control the DDR PLL Clock 2 pre-divider frequency of the SYSCLK9 (16 MHz - VTP) and SYSCLK10 (48 MHz - UART, SPI, CEC, etc.) clock. The default FREQ2 value is 8.85.

The DDR PLL Frequency 2 Register (DDRPLL_FREQ2) is shown in Figure 1-137 and described in Table 1-186.

28	DDR_TRUNC2	1-0	Synth2 Enable Truncate Correction
27-24	DDR_INTFREQ2	8h-Fh	Synth2 Frequency integer divider.
23-0	DDR_FRACFREQ2	0-FF FFFFh	Synth2 Frequency fractional divider.

1.16.1.2.19 DDR PLL Divider 2 Register (DDRPLL_DIV2)

The DDRPLL_DIV2 register is used to control the DDR PLL Clock 2 post-divider frequency of the SYSCLK9 (VTP), and SYSCLK10 (UART, SPI, CEC, etc.) clocks. The default DIV2 value is 30.

The DDR PLL Divider 2 Register (DDRPLL_DIV2) is shown in Figure 1-138 and described in Table 1-187.

1.16.1.2.20 DDR PLL Frequency 3 Register (DDRPLL_FREQ3)

The DDRPLL_FREQ3 register is used to control the DDR PLL Clock 3 pre-divider frequency of SYSCLK8 (364 MHz DMM, EMIF clock; 400 MHz DDR2/3 clock).

The DDR PLL Frequency 3 Register (DDRPLL_FREQ3) is shown in Figure 1-139 and described in Table 1-188.

1.16.1.2.22 DDR PLL Frequency 4 Register (DDRPLL_FREQ4)

The DDRPLL_FREQ4 register is used to control the expansion DDR PLL Clock 4 pre-divider frequency. The default FREQ4 value is 14.

The DDR PLL Frequency 4 Register (DDRPLL_FREQ4) is shown in Figure 1-141 and described in Table 1-190.

Figure 1-141. DDR PLL Frequency 4 Register (DDRPLL_FREQ4)

7-0	VID_MDIV1	0-FFh	Synth1 Frequency M Post Divider.

1.16.1.2.30 Video PLL Frequency 2 Register (VIDEOPLL_FREQ2)

The VIDEOPLL_FREQ2 register is used to control the Video PLL Clock 2 pre-divider frequency of the SYSCLK13 (HD_VENC_D clock) and STC0/STC1 source clocks. If the Video PLL Clock 2 is locked to a transport stream System Time Clock (STC), the FREQ2 value will be modified by software to push or pull the clock frequency as part of the clock recovery process. The default FREQ2 value is 10.0 to generate a 74.25 MHz SYSCLK13.

The Video PLL Frequency 2 Register (VIDEOPLL_FREQ2) is shown in Figure 1-149 and described in Table 1-198.

Table 1-199. Video PLL Divider 2 Register (VIDEOPLL_DIV2) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. Reads returns 0.
8	VID_LDMDIV2	1-0	Load Synth2 M Divider value. Setting this bit to 1 causes the M Divider value to be loaded into VIDEO Synthesizer2.
7-0	VID_MDIV2	0-FFh	Synth2 Frequency M Post Divider.

1.16.1.2.32 Video PLL Frequency 3 Register (VIDEOPLL_FREQ3)

The VIDEOPLL_FREQ3 register is used to control the Video PLL Clock 3 pre-divider frequency of the SYSCLK15 (HD_VENC_A clock) and STC0 source clock. If the Video PLL Clock 3 is locked to a transport stream System Time Clock (STC), the FREQ3 value will be modified by software to push or pull the clock frequency as part of the clock recovery process. The default FREQ3 value is 10.0 to generate a 74.25 MHz SYSCLK15.

The Video PLL Frequency 3 Register (VIDEOPLL_FREQ3) is shown in Figure 1-151 and described in Table 1-200.

Figure 1-151. Video PLL Frequency 3 Register (VIDEOPLL_FREQ3)

31	30 29	28	27 24	23 0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-200. Video PLL Frequency 3 Register (VIDEOPLL_FREQ3) Field Descriptions

Bit	Field	Value	Description
31	VID_LDFREQ3	1-0	Load Synth3 FREQ value. Setting this bit to 1 causes the INTFREQ and FRACFREQ values to be loaded into VIDEO Synthesizer3.
30-29	Reserved	0	Reserved. Reads returns 0.
28	VID_TRUNC3	1-0	Synth3 Enable Truncate Correction.
27-24	VID_INTFREQ3	8h-Fh	Synth3 Frequency integer divider.
23-0	VID_FRACFREQ3	0-FF FFFFh	Synth3 Frequency fractional divider.

1.16.1.2.33 Video PLL Divider 3 Register (VIDEOPLL_DIV3)

The VIDEOPLL_DIV3 register is used to control the VIDEO PLL Clock 3 post-divider frequency of the SYSCLK15 and STC0 source clocks. The default DIV3 value is 2.

The Video PLL Divider 3 Register (VIDEOPLL_DIV3) is shown in Figure 1-152 and described in Table 1-201.

Figure 1-152. Video PLL Divider 3 Register (VIDEOPLL_DIV3)

Table 1-201. Video PLL Divider 3 Register (VIDEOPLL_DIV3) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. Reads returns 0.
8	VID_LDMDIV5	1-0	Load Synth3 M Divider value. Setting this bit to 1 causes the M Divider value to be loaded into VIDEO Synthesizer3.
7-0	VID_MDIV5	0-FFh	Synth3 Frequency M Post Divider.

1.16.1.2.34 Audio PLL Control Register (AUDIOPLL_CTRL)

The AUDIOPLL_CTRL register is used to control the base frequency of the Audio PLL. The PLL is sourced by the audio reference clock from the Main PLL. The default frequency of the Audio PLL is 1105.92 MHz.

The Audio PLL Control Register (AUDIOPLL_CTRL) is shown in Figure 1-153 and described in Table 1-202.

Figure 1-153. Audio PLL Control Register (AUDIOPLL_CTRL)

Table 1-202. Audio PLL Control Register (AUDIOPLL_CTRL) Field Descriptions

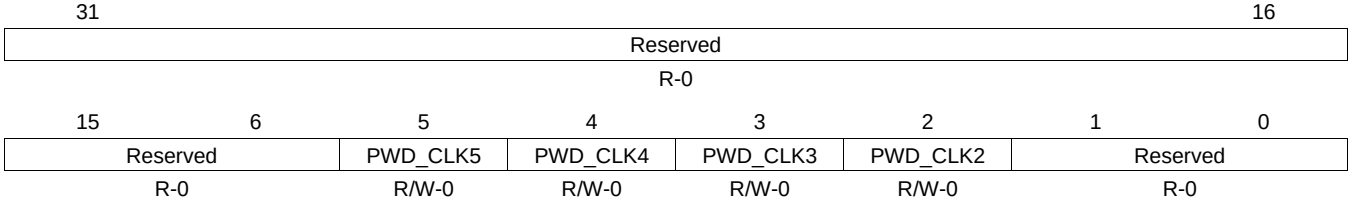
Bit	Field	Value	Description
31-16	AUDIO_N	0-FFFFh	AUDIO PLL N multiplier value.
15-8	AUDIO_P	0-FFh	AUDIO PLL P divider value.
7	AUDIO_LOCK	1-0	AUDIO PLL lock status bit.
6-4	Reserved	0	Reserved. Reads returns 0.
3	AUDIO_PLLEN		AUDIO PLL enable.
		0	PLL is disabled (power down state).
		1	PLL is enabled (normal operation).
2	AUDIO_BP		AUDIO PLL bypass enable.
		0	Normal operation.
		1	PLL in bypass mode, reference clock driven at output.
1	Reserved	0	Reserved. Reads returns 0.
0	AUDIO_LOC_CTL		AUDIO PLL lock output select.
		0	Analog lock
		1	Digital lock

1.16.1.2.35 Audio PLL Powerdown Register (AUDIOPLL_PWD)

The AUDIOPLL_PWD register is used to powerdown the individual output clocks of the Audio PLL.

The Audio PLL Powerdown Register (AUDIOPLL_PWD) is shown in Figure 1-154 and described in Table 1-203.

Figure 1-154. Audio PLL Powerdown Register (AUDIOPLL_PWD)



LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 1-203. Audio PLL Powerdown Register (AUDIOPLL_PWD) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved. Reads returns 0.
5	PWD_CLK5	1-0	AUDIO PLL Clock5 Powerdown. Setting this bit powers down clock 5 (source clock for SYSCLK22).
4	PWD_CLK4	1-0	AUDIO PLL Clock4 Powerdown. Setting this bit powers down clock 4 (source clock for SYSCLK21).
3	PWD_CLK3	1-0	AUDIO PLL Clock3 Powerdown. Setting this bit powers down clock 3 (source clock for SYSCLK20).
2	PWD_CLK2	1-0	AUDIO PLL Clock2 Powerdown. Setting this bit powers down clock 2 (source clock for SYSCLK19).
1-0	Reserved	0	Reserved. Reads returns 0.

1.16.1.2.36 Audio PLL Frequency 2 Register (AUDIOPLL_FREQ2)

The AUDIOPLL_FREQ2 register is used to control the Audio PLL Clock 2 pre-divider frequency of the SYSCLK19 (Transport Out) clock. The default FREQ2 value is 14.0 to generate a SYSCLK19 of approximately 160 MHz.

The Audio PLL Frequency 2 Register (AUDIOPLL_FREQ2) is shown in Figure 1-155 and described in Table 1-204.

Figure 1-155. Audio PLL Frequency 2 Register (AUDIOPLL_FREQ2)

Table 1-204. Audio PLL Frequency 2 Register (AUDIOPLL_FREQ2) Field Descriptions

Bit	Field	Value	Description
31	AUD_LDFREQ2	1-0	Load Synth2 FREQ value. Setting this bit to 1 causes the INTFREQ and FRACFREQ values to be loaded into AUDIO Synthesizer2.
30-29	Reserved	0	Reserved. Reads returns 0.
28	AUD_TRUNC2	1-0	Synth2 Enable Truncate Correction.
27-24	AUD_INTFREQ2	8h-Fh	Synth2 Frequency integer divider.
23-0	AUD_FRACFREQ2	0-FF FFFFh	Synth2 Frequency fractional divider.

1.16.1.2.37 Audio PLL Divider 2 Register (AUDIOPLL_DIV2)

The AUDIOPLL_DIV2 register is used to control the AUDIO PLL Clock 2 post-divider frequency of the SYSCLK19 clock. The default DIV2 value is 4 that results in an Audio PLL CLK2 of approximately160 MHz.

The Audio PLL Divider 2 Register (AUDIOPLL_DIV2) is shown in Figure 1-156 and described in Table 1-205.

Figure 1-156. Audio PLL Divider 2 Register (AUDIOPLL_DIV2)

8	AUD_LDMDIV2	1-0	Load Synth2 M Divider value. Setting this bit to 1 causes the M Divider value to be loaded into AUDIO Synthesizer2.
7-0	AUD_MDIV2	0-FFh	Synth2 Frequency M Post Divider.

1.16.1.2.38 Audio PLL Frequency 3 Register (AUDIOPLL_FREQ3)

The AUDIOPLL_FREQ3 register is used to control the Audio PLL Clock 3 pre-divider frequency of the SYSCLK20 (Audio1) clock. The default FREQ3 value is 9.0 for a SYSCLK20 frequency of 196.608 MHz.

The Audio PLL Frequency 3 Register (AUDIOPLL_FREQ3) is shown in Figure 1-157 and described in Table 1-206.

Figure 1-157. Audio PLL Frequency 3 Register (AUDIOPLL_FREQ3)

30-29	Reserved	0	Reserved. Reads returns 0.
28	AUD_TRUNC3	1-0	Synth3 Enable Truncate Correction.
27-24	AUD_INTFREQ3	8h-Fh	Synth3 Frequency integer divider.
23-0	AUD_FRACFREQ3	0-FF FFFFh	Synth3 Frequency fractional divider.

1.16.1.2.39 Audio PLL Divider 3 Register (AUDIOPLL_DIV3)

The AUDIOPLL_DIV3 register is used to control the AUDIO PLL Clock 3 post-divider frequency of the SYSCLK20 clock. The default DIV3 value is 5 which results in an Audio PLL CLK3 of 196.6080 MHz.

The Audio PLL Divider 3 Register (AUDIOPLL_DIV3) is shown in Figure 1-158 and described in Table 1-207.

Figure 1-158. Audio PLL Divider 3 Register (AUDIOPLL_DIV3)

8	AUD_LDMDIV3	1-0	Load Synth3 M Divider value. Setting this bit to 1 causes the M Divider value to be loaded into AUDIO Synthesizer3.
7-0	AUD_MDIV3	0-FFh	Synth3 Frequency M Post Divider.

1.16.1.2.40 Audio PLL Frequency 4 Register (AUDIOPLL_FREQ4)

The AUDIOPLL_FREQ4 register is used to control the Audio PLL Clock 4 pre-divider frequency of the SYSCLK21 (Audio2) clock. The default FREQ4 value is 9.795918.

The Audio PLL Frequency 4 Register (AUDIOPLL_FREQ4) is shown in Figure 1-159 and described in Table 1-208.

Figure 1-159. Audio PLL Frequency 4 Register (AUDIOPLL_FREQ4)

30-29	Reserved	0	Reserved. Reads returns 0.
28	AUD_TRUNC4	1-0	Synth4 Enable Truncate Correction.
27-24	AUD_INTFREQ4	8h-Fh	Synth4 Frequency integer divider.
23-0	AUD_FRACFREQ4	0-FF FFFFh	Synth4 Frequency fractional divider.

1.16.1.2.41 Audio PLL Divider 4 Register (AUDIOPLL_DIV4)

The AUDIOPLL_DIV4 register is used to control the AUDIO PLL Clock 4 post-divider frequency of the SYSCLK21 clock. The default DIV4 value is 20. which results in an Audio PLL CLK4 of 45.1584 MHz.

The Audio PLL Divider 4 Register (AUDIOPLL_DIV4) is shown in Figure 1-160 and described in Table 1-209.

Figure 1-160. Audio PLL Divider 4 Register (AUDIOPLL_DIV4)

7-0	AUD_MDIV4	0-FFh	Synth4 Frequency M Post Divider.

1.16.1.2.42 Audio PLL Frequency 5 Register (AUDIOPLL_FREQ5)

The AUDIOPLL_FREQ5 register is used to control the Audio PLL Clock 5 pre-divider frequency of the SYSCLK22 (Audio3) clock. The default FREQ5 value is 13.5.

The Audio PLL Frequency 5 Register (AUDIOPLL_FREQ5) is shown in Figure 1-161 and described in Table 1-210.

Figure 1-161. Audio PLL Frequency 5 Register (AUDIOPLL_FREQ5)

Bit	Field	Value	Description
31	AUD_LDFREQ5	1-0	Load Synth5 FREQ value. Setting this bit to 1 causes the INTFREQ and FRACFREQ values to be loaded into AUDIO Synthesizer5.
30-29	Reserved	0	Reserved. Reads returns 0.
28	AUD_TRUNC5	1-0	Synth5 Enable Truncate Correction.
27-24	AUD_INTFREQ5	8h-Fh	Synth5 Frequency integer divider.
23-0	AUD_FRACFREQ5	0-FF FFFFh	Synth5 Frequency fractional divider.

1.16.1.2.43 Audio PLL Divider 5 Register (AUDIOPLL_DIV5)

The AUDIOPLL_DIV5 register is used to control the AUDIO PLL Clock 5 post-divider frequency of the SYSCLK22 clock. The default DIV5 value is 20 which results in an Audio PLL CLK5 of 32.768 MHz.

The Audio PLL Divider Register (AUDIOPLL_DIV5) is shown in Figure 1-162 and described in Table 1-211.

1.16.1.3.1 Device Identification Register (DEVICE_ID)

The DEVICE_ID register contains a software readable version of the device JTAG ID. Software can use this register to determine the version of the device on which it is executing.

The Device Identification Register (DEVICE_ID) is shown in Figure 1-163 and described in Table 1-213.

Figure 1-163. Device Identification Register (DEVICE_ID)

31 28	27 12	11 1	0
DEVREV	PARTNUM	MFGR	Reserved
R-eFuse	R-B81Eh	R-017h	R-1

LEGEND: R = Read only; -*n* = value after reset

Table 1-213. Device Identification Register (DEVICE_ID) Field Descriptions

Bit	Field	Value	Description
31-28	DEVREV	0-Fh	Device revision.
27-12	PARTNUM	0-FFFFh	Device part number (unique JTAG ID).
11-1	MFGR	0-7FFh	Manufacturer's JTAG ID.
0	Reserved	0	Reserved. Always 1.

1.16.1.3.2 Initiator Pressure 0 Register (INIT_PRESSURE_0)

The INIT_PRESSURE_0 register configures the infrastructure “pressure” input for L3 initiators to provide dynamic pressure escalation.

Pressure value of 2h is reserved. Pressure value of 3h wins arbitration over a pressure of 1h which wins over a pressure of 0h.

The Initiator Pressure 0 Register (INIT_PRESSURE_0) is shown in Figure 1-164 and described in Table 1-214.

Figure 1-164. Initiator Pressure 0 Register (INIT_PRESSURE_0)

21-20	GRFX	0-3h	3D Graphics (SGX530) initiator pressure.
19-18	Reserved	0	Reserved.
17-16	PCIE	0-3h	PCIe initiator pressure.
15-14	DSS_CTLR	0-3h	HDVPSS Controller initiator pressure
13-10	Reserved	0	Reserved. Reads returns 0.
9-8	SATA	0-3h	SATA initiator pressure.
7-6	USB_QMGR	0-3h	USB Queue Manager initiator pressure.
5-4	USB_DMA	0-3h	USB DMA port initiator pressure.
3-2	CPGMAC1	0-3h	CPGMAC1 initiator pressure.
1-0	CPGMAC0	0-3h	CPGMAC0 initiator pressure.

1.16.1.3.4 MMU Configuration Register (MMU_CFG)

The MMU_CFG register is used to optionally route certain initiators through the System MMU. The C674x DSP MDMA port accesses will always be routed through the System MMU so no configuration bit is instantiated for C674x DSP. Note that when TPTC0 is routed through the MMU accesses to the C674x DSP SDMA port will still by-pass the MMU for increased performance.

The MMU Configuration Register (MMU_CFG) is shown in Figure 1-166 and described in Table 1-216.

Figure 1-166. MMU Configuration Register (MMU_CFG)

31	16
Reserved

15	14 8	7	6 2	1	0
MMU_ABORT	Reserved	MMU_EN	Reserved	EXPMMU	TC0MMU
R/W-0	R-0	R/W-0	R-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-216. MMU Configuration Register (MMU_CFG) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. Reads returns 0.
15	MMU_ABORT	1-0	MMU abort operation. This bit causes the MMU to abort the current operation in case of lockup.
14-8	Reserved	0	Reserved. Reads returns 0.
7	MMU_EN	1-0	MMU Enable. Clearing this bit disables MMU table lookup and causes accesses to use the non-translated address. This bit defaults to enabled but an identical bit within an MMU configuration register defaults to disabled and must be set after the page tables are programmed for MMU operation.
6-2	Reserved	0	Reserved. Reads returns 0.
1	EXPMMU	1-0	Expansion Slot uses MMU.
0	TC0MMU	1-0	TPTC0 Uses MMU.

1.16.1.3.5 TPTC Configuration Register (TPTC_CFG)

The TPTC_CFG register configures the default burst size for TPTC0, 1, 2, and 3.

The TPTC Configuration Register (TPTC_CFG) is shown in Figure 1-167 and described in Table 1-217.

Figure 1-167. TPTC Configuration Register (TPTC_CFG)

1.16.1.3.6 DDR Control Register (DDR_CTRL)

The DDR_CTRL register reflects the DDR I/O timing as programmed in the device eFuse and controls DDR self-refresh operation.

The DDR Control Register (DDR_CTRL) is shown in Figure 1-168 and described in Table 1-218.

Figure 1-168. DDR Control Register (DDR_CTRL)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-218. DDR Control Register (DDR_CTRL) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reserved. Reads returns 0.
29	FORCE_PHY_RST	1-0	Force DDR Phy Reset. When set, this bit forces a reset of the DDR Phys to allow DDR clock frequency to be changed.
28	DIS_DEV_RST	1-0	Disable DDR Device Reset. Setting this bit cause the RESETn outputs for the DDR0 and DDR1 interfaces to be held high. This allows power-down and subsequent power-up of EMIFs without resetting DDR devices.
27-26	Reserved	0	Reserved. Reads returns 0.
25	KEEPSREF1	1-0	Keep DDR1 Self Refreshed. Setting this bit keeps the DDR1 CLKEN driven to maintain self refresh when the Active power domain is disabled.
24	SREF1	1-0	Enable DDR1 Self Refresh.
23-20	Reserved	0	Reserved. Reads returns 0.
19-18	DDRDATA_SLEW1	0-3h	DDR1 Data Slew. Reflects the DDR1 Data Macro slew adjustment programmed in eFuse.
17-16	DDRCMD_SLEW1	0-3h	DDR1 CMD Slew. Reflects the DDR1 CMD Macro slew adjustment programmed in eFuse.
15-10	Reserved	0	Reserved. Reads returns 0.
9	KEEPSREF0	1-0	Keep DDR0 Self Refreshed. Setting this bit keeps the DDR0 CLKEN driven to maintain self refresh when the Active power domain is disabled.
8	SREF0	1-0	Enable DDR0 Self Refresh.
7-4	Reserved	0	Reserved. Reads returns 0.
3-2	DDRDATA_SLEW0	0-3h	DDR0 Data Slew. Reflects the DDR0 Data Macro slew adjustment programmed in eFuse.
1-0	DDRCMD_SLEW0	0-3h	DDR0 CMD Slew. Reflects the DDR0 CMD Macro slew adjustment programmed in eFuse.

1.16.1.3.7 DSP Standby/Idle Management Register (DSP_IDLE_CFG)

The DSP_IDLE_CFG register controls the state management of the C674x DSP initiator and target port interfaces.

The DSP Standby/Idle Management Register (DSP_IDLE_CFG) is shown in Figure 1-169 and described in Table 1-219.

Figure 1-169. DSP Standby/Idle Management Register (DSP_IDLE_CFG)

31-16	Reserved	0	Reserved. Reads returns 0.
15	DSPSTBY	1-0	Setting this bit will initiate the standby for DSP.
14-6	Reserved	0	Reserved. Reads returns 0.
5-4	STBYMODE		Initiator state management mode
		0	Force-standby mode: Initiator is unconditionally placed in standby state. (for debug only)
		1h	No-standby mode: Initiator is unconditionally removed from standby state. (for debug only)
		2h	Smart-standby mode: Initiator standby status depends on local condition (module functional requirements of initiator). No initiator related wake-up events.
		3h	Smart-standby wakeup-capable mode. : Initiator standby status depends on local condition (module functional requirements of initiator). Initiator related wake-up events may be generated when in standby.
3-2	IDLEMODE		Target state management mode.
		0	Force-idle mode: Target acknowledges idle requests unconditionally (debug only)
		1h	No-idle mode: Target never enters idle state. (for debug only)
		2h	Smart-idle mode: Target acknowledges idle requests after fulfilling IP internal requirements. No IRQ/DMA related wake-up events.
		3h	Smart-idle wakeup-capable mode: Target acknowledges idle requests after fulfilling IP internal requirements. IRQ/DMA related wake-up events may be generated when in standby.
1-0	Reserved	0	Reserved. Reads returns 0.

1.16.1.3.8 USB Control Register (USB_CTRL)

The USB_CTRL register controls various features of the USB subsystem.

The USB Control Register (USB_CTRL) is shown in Figure 1-170 and described in Table 1-220.

Figure 1-170. USB Control Register (USB_CTRL)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-227. PCIE Configuration Register (PCIE_CFG) Field Descriptions

Bit	Field	Value	Description
31-16	PCIE_CFGPLL	0-FFFFh	PCIe PLL Configuration. Enables 25× multiplier. **Bit [31]** is **Reserved** and must be kept at 0. **Bit [30:29] CLKBYP** Clock bypass. Facilitates bypassing of the PLL with **refclkp / n**. 0: The transmitter operates normally from PLL. 1h-2h: Reserved 3h: The PLL clock is bypassed by **refclkp / n**. **Bit [28:27] LB** Keep these bits at 0 (default). **Bit [26] SLEEP_PLL** Puts the PLL into low power sleep state when written to '1'. In this mode, the core of PLL remains locked to refclkp/n, but all clock distribution and associated circuits are powered down. 0: Normal mode 1: Sleep mode **Bit [25] VRANGE** Write this bit to : 0 : If **PLL Output Clock Frequency >= 2.17 GHz.** 1 : If **PLL Output Clock Frequency < 2.17 GHz** **Bit [24] ENDIVCLK** Enable DIVCLK output : 0: Disables output of a divide-by-5 of PLL clock. 1 : Enables output of a divide-by-5 of PLL clock. **Bit [23:17] MPY** Select PLL Multiply factors between 4 and 25. MPY bits default value **(0b1100100)** can be used to enable a 25× multiplier considering a 100 MHz clock source at PLL input. 0b0010000: multiply by 4 0b0010100: multiply by 5 0b0011000: multiply by 6 0b0100000: multiply by 8 0b0100001: multiply by 8.25 0b0101000: multiply by 10 0b0110000: multiply by 12 0b0110010: multiply by 12.5 0b0111100: multiply by 15 0b1000000: multiply by 16 0b1000010: multiply by 16.5 0b1010000: multiply by 20 0b1011000: multiply by 22 0b1100100: multiply by 25 (default) **Bit [16] ENPLL** Enables the PLL. After setting this bit, it is necessary to allow 350 ns for the regulator to stabilize. Thereafter, the PLL will take no longer than 200 cycles (of **refclkp / n**) to lock to the required frequency, provided refclkp / n are stable. The LOCK bit of PCIE_STSPLL bitfield will be driven high by the digital lock detector. 0: Disable PLL. The PLL is fully powered down. 1: Enable PLL
15-12	Reserved	0	Reserved. Reads returns 0.

Table 1-227. PCIE Configuration Register (PCIE_CFG) Field Descriptions (continued)

Bit	Field	Value	Description
11-8	PCIE_STSPLL	0-Fh	PCIe PLL Status. **Bits [11:10]** are Reserved and always read as 0. **Bit[9] DIVCLK** : This bit indicates if divided-by-5 PLL clock is running. DIVCLK bit is held low (divided clock is NOT running) unless both the ENPLL and ENDIVCLK bits of the bitfield PCIE_CFGPLL are set high. Note that the "divide-by-5" clock is synchronous to the refclkp / n and NOT to the recovered recive clocks. Furthermore it will be subject to frequency overshoot of < 5% until the PLL has indicated lock in LOCK status bit. 0: DIVCLK is NOT running 1: DIVCLK is running **Bit[8] LOCK** : PLL Lock status bit. Driven high asynchronously between 2048 - 3071 **refclkp / n** cycles after the PLL has locked, which will occur within 200 **refclkp / n** cycles. Whilst LOCK is low, the PLL output frequency may overshoot by no more than <5 %, provided **MPY** is NOT changed to select a lower multiplicaiton factor. The same percentage overshoot will be mirrored by the bus clocks originating from the SerDes. 0: PLL has NOT locked 1 : PLL has locked
7-2	Reserved	0	Reserved. Reads returns 0.
1-0	PCIE_DEVTYPE		PCIe Module Device Type.
		0	Endpoint (EP) operation.
		1h	Legacy Endpoint operation.
		2h	Root Complex (RC) operation.
		3h	Reserved.

1.16.1.3.16 Clock Control Register (CLK_CTL)

The CLKIN oscillator and the clock source of the CLKOUT output are controlled by the CLKCTL register. The Clock Control Register (CLK_CTL) is shown in Figure 1-178 and described in Table 1-228.

Figure 1-178. Clock Control Register (CLK_CTL)

		3h	40-50 MHz
0	Reserved	0	Reserved. Reads returns 0.

1.16.1.3.17 Audio Interface Control Register (AUD_CTRL)

The AUD_CTRL Register controls features of the McASP and McBSP serial audio interfaces. It determines how the AMUTEIN input of McASP1 and McAPS2 will be driven. This allows all McASPs to share a common hardware mute input (MCA0_AMUTEIN) or have unique mute input controls. McASP0 always uses MCA0_AMUTEIN. The register also controls loopback of McBSP data for testing purposes.

The Audio Interface Control Register (AUD_CTRL) is shown in Figure 1-179 and described in Table 1-229.

Figure 1-179. Audio Interface Control Register (AUD_CTRL)

2	ASP2MUTESRC		McASP2 AMUTEIN source select.
		0	Use MCA2_AMUTEIN
		1	Use MCA0_AMUTEIN
1	ASP1MUTESRC		McASP1 AMUTEIN source select.
		0	Use MCA1_AMUTEIN.
		1	Use MCA0_AMUTEIN.
0	Reserved	0	Reserved. Reads returns 0.

1.16.1.3.18 DSP L2 Memory Sleep Mode Register (DSPMEM_SLEEP)

The DSPMEM_SLEEP Register determines the sleep behavior of the DSP L2 memories. The DSP L2 sleep mode may only be modified by Supervisor access.

The DSP L2 Memory Sleep Mode Register (DSPMEM_SLEEP) is shown in Figure 1-180 and described in Table 1-230.

Figure 1-180. DSP L2 Memory Sleep Mode Register (DSPMEM_SLEEP)

0	DSPMEM_LS	1-0	DSP L2 Memory in Light Sleep Mode. Memory contents are preserved.

1.16.1.3.19 On-Chip Memory Sleep Mode Register (OCMEM_SLEEP)

The OCMEM_SLEEP Register determines the sleep behavior of the on-chip memories.

The On-Chip Memory Sleep Mode Register (OCMEM_SLEEP) is shown in Figure 1-181 and described in Table 1-231.

Figure 1-181. On-Chip Memory Sleep Mode Register (OCMEM_SLEEP)

1.16.1.3.20 HD DAC Control Register (HD_DAC_CTRL)

The HD_DAC_CTRL Register controls operation of the High Definition video DACs.

The HD DAC Control Register (HD_DAC_CTRL) is shown in Figure 1-182 and described in Table 1-232.

Figure 1-182. HD DAC Control Register (HD_DAC_CTRL)

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. Reads returns 0.
3	HD_CALSEL		HD DAC Calibration Select. Controls the video path mux between the Display Subsystem HD output and calibration register values.
		0	Normal operation (DSS output).
		1	Output calibration value.
2-1	HD_MIDRND		HD DAC MID randomizer mode.
		0	Bypass mode.
		1h	Swap 1.
		2h	Swap 2.
		3h	Bit shift.
0	RESET_HD	1-0	Reset HD DACs

1.16.1.3.21 HD DAC A Calibration Register (HD_DACA_CAL)

The HD_DACA_CAL Register is used to calibrate the output level of HD DAC A (HD Red/Y). Users can use this register to drive a known value to the DAC input for performing system video level calibration.

The HD DAC A Calibration Register (HD_DACA_CAL) is shown in Figure 1-183 and described in Table 1-233.

Figure 1-183. HD DAC A Calibration Register (HD_DACA_CAL)

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 1-245. HDMI Observe Clock Control (HDMI_OBSCLK_CTRL) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved. Reads returns 0.
9	SUBLVDS_EN		Sub-LVDS Mode Enable. Allows LVDS transmitter to operate in sub-LVDS mode.
		0	Common mode voltage is 1.2 V
		1	Common mode voltage is 0.9 V
8	BIAS_TRIM1	1-0	Badgap Reference Trimming bits.
7	BIAS_TRIM0		The BIAS_TRIM bits allow the Bandgap voltage to be adjusted when BIAS_TRIMEN is high.
		00	1.2 V – 3%
		01	1.2V
		10	1.2V + 3%
		11	1.2V – 1%
6	BIAS_TRIMEN		Bandgap Bias eFuse Trim Enable.
		0	Trimming is disabled.
		1	Trimming is enabled.
5	BIAS_EFUSESET		Bandgap Reference eFuse Set.
		0	Trimming is enabled by BIAS_TRIMEN.
		1	Trimming is disabled (1.2V NOM output).
4	BIAS_PWRDN		Bandgap Reference Powerdown.
		0	Bias voltage outputs are valid.
		1	Bias voltage outputs are at Vss.
3	PWRDN		Buffer Powerdown
		0	PAD and $\overline{\text{PAD}}$ outputs are driven.
		1	PAD and$\overline{\text{PAD}}$ outputs are low.
2	LPSEL		LPSEL selects internal termination between PAD and $\overline{\text{PAD}}$ of 100 Ω when low and 200 Ω when high to enable low power operation. When used in conjunction with LOPWRA and LOPWRB, the output current is selected as follows:
1	LOPWRB		LPSEL = 0 / LPSEL = 1
			11 - 4.0 mA / 11 - 4.0 mA
0	LOPWRA		10 - 3.5 mA / 10 - 3.33 mA
			01 - 3.0 mA / 01 - 2.66 mA
			00 - 2.5 mA / 00 - 2.00 mA

1.16.1.3.34 Serdes Control Register (SERDES_CTRL)

The SERDES_CTRL Register controls the SERDES reference clock input buffer and distribution.

The Serdes Control Register (SERDES_CTRL) is shown in Figure 1-196 and described in Table 1-246.

Figure 1-196. Serdes Control Register (SERDES_CTRL)

31	2	1	0
Reserved		SERDES_PWRDN	RCD_PWRDN
R-0		R/W-0	R/W-0

1	CML_PWRDN	1-0	PLL Observe clock CML driver powerdown.
0	RCD_PWRDN	1-0	PLL Observe clock Reference Clock Distribution powerdown.

1.16.1.3.37 DDR RCD Register (DDR_RCD)

The DDR_RCD Register controls power to RCD.

The DDR RCD Register (DDR_RCD) is shown in Figure 1-199 and described in Table 1-249.

Figure 1-199. DDR RCD Register (DDR_RCD)

31	1	0
Reserved		PWRDN
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-249. DDR RCD Register (DDR_RCD) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. Reads returns 0.
0	PWRDN		Power enable/disable for RCD.
		0	Power down.
		1	Normal mode.

1.17 Pin Multiplexing Control

Device-level pin multiplexing is controlled on a pin-by-pin basis by the MUXMODE bits of the PINCTRL1-PINCTRL321 registers in the SYSCFG module. The default state for each multiplexed pin is MUXMODE = 000.

Pin multiplexing selects which of several peripheral pin functions control the pin's IO buffer output data values. The input from each pin is routed to all of the peripherals that share the pin, regardless of the MUXMODE setting.

The PINCTRL*n* register is shown in Figure 1-200 and described in Table 1-250.

Figure 1-200. PINCTRL*n* Register

1.18 Interrupt Controller

The device provides two interrupt controller (INTC) modules that controls interrupts at the device level: the Cortex-A8 MPU subsystem interrupt controller and the DSP subsystem (DSPSS) interrupt controller.

Figure 1-201 shows the top level block diagram of interrupt controller in device.

1.18.1 Cortex-A8 MPU Subsystem Interrupt Controller

This INTC module is a single functional unit that is integrated in the Cortex-A8 multiprocessor core alongside Cortex-A8 processors. It provides:

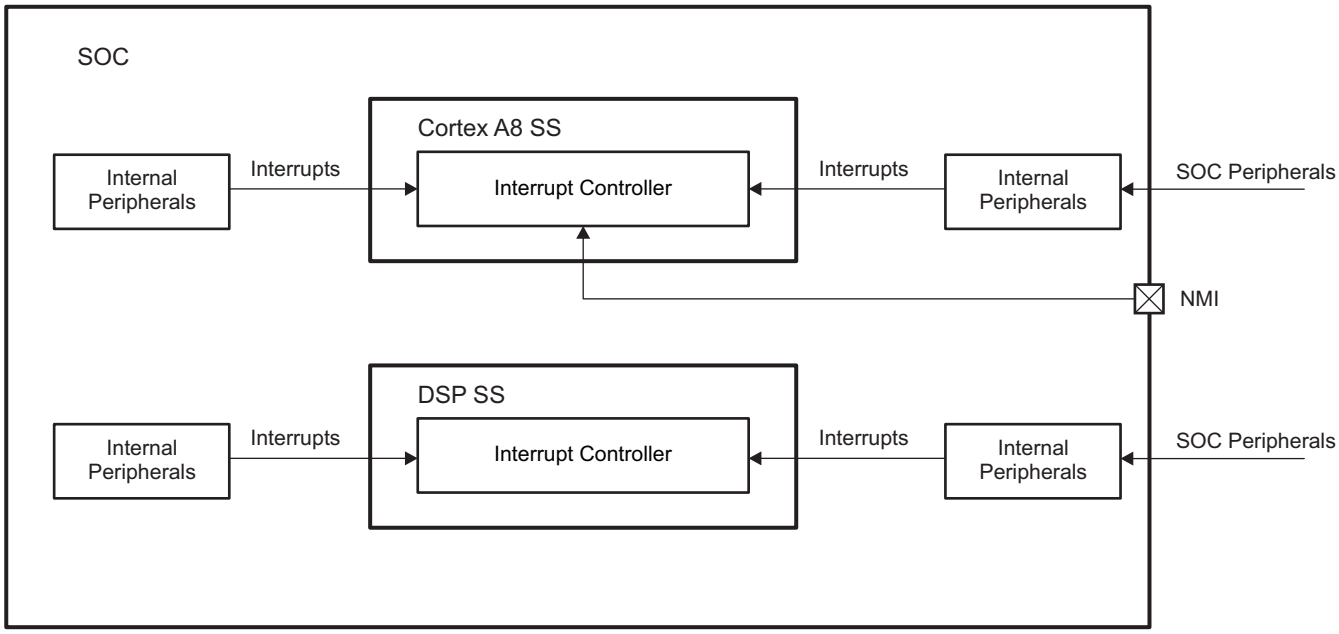
- 128 hardware interrupt inputs.
- Generation of interrupts by software.
- Prioritization of interrupts.
- Masking of any interrupts.
- Distribution of the interrupts to the target Cortex-A8 processor(s).
- Tracking the status of interrupts.

For detailed information about this module, see the *ARM Interrupt Controller (AINTC)* chapter.

1.18.2 DSP Subsystem (DSPSS) Interrupt Controller

This module is used for the DSP, but is not described in this section. For detailed information about this module, see Section 1.3.

Figure 1-201. Interrupt Controller in Device



1.19 Resets

The device has several types of system-level resets. The reset types differ by how they are initiated and by their effect on the device. Table 1-252 lists these reset types, along with the reset initiator and the effects of each reset on the device. Each type is further described in the Reset section of the device-specific data manual and the *Power, Reset, and Clock Management (PRCM) Module* chapter.

Table 1-252. System-Level Reset Sources

Type	Initiator	Resets All Modules,Excluding Emulation	Resets Emulation	Latches Boot Pins	Asserts RSTOUT*n* pin
Power-on Reset (POR)	$\overline{\text{POR}}$ pin	Yes	Yes	Yes	Yes
External Warm Reset	$\overline{\text{RESET}}$ pin	Yes	No	Yes	Yes
Emulation Warm Reset	On-chip Emulation Logic	Yes	No	No	Yes
Watchdog Reset	Watchdog Timer	Yes	No	No	Yes
Software Global Cold Reset	Software	Yes	Yes	No	Yes
Software Global Warm Reset	Software	Yes	No	No	Yes
Test Reset	$\overline{\text{TRST}}$ pin	No	Yes	No	No

The $\overline{\text{RSTOUT}}$ pin on the device reflects the device reset status. The $\overline{\text{RSTOUT}}$ pin remains asserted until the PRCM module releases the host ARM Cortex-A8 processor for reset. This output is always asserted when any of the following resets occur:

- Power-On Reset ($\overline{\text{POR}}$)
- External Warm Reset
- Emulation Warm Reset ($\overline{\text{RESET}}$)
- Software Global Cold/Warm Reset
- Watchdog Timer Reset

If any of the previous reset sources occur simultaneously, the device only processes the highest-priority reset request. The reset request priorities, from high to low, are as follows:

1. Power-On Reset ($\overline{\text{POR}}$)
2. Test Reset ($\overline{\text{TRST}}$)
3. External Warm Reset ($\overline{\text{RESET}}$)
4. Emulation Cold/Warm Resets
5. Watchdog Reset
6. Software Global Cold/Warm Resets

Reset Sources and Reset Sequences are described in detail in the Reset Management section of the *Power, Reset, and Clock Management (PRCM) Module* chapter.

Refer to the device-specific data manual for Pin Behaviors at Reset. Internal pull-up/down resistors are enabled during and immediately after reset as described in the Terminal Functions section of the data manual.

High-Definition Video Processing Subsystem (HDVPSS)

This chapter describes the High-Definition Video Processing Subsystem (HDVPSS).

Topic **Page**

2.1 Introduction

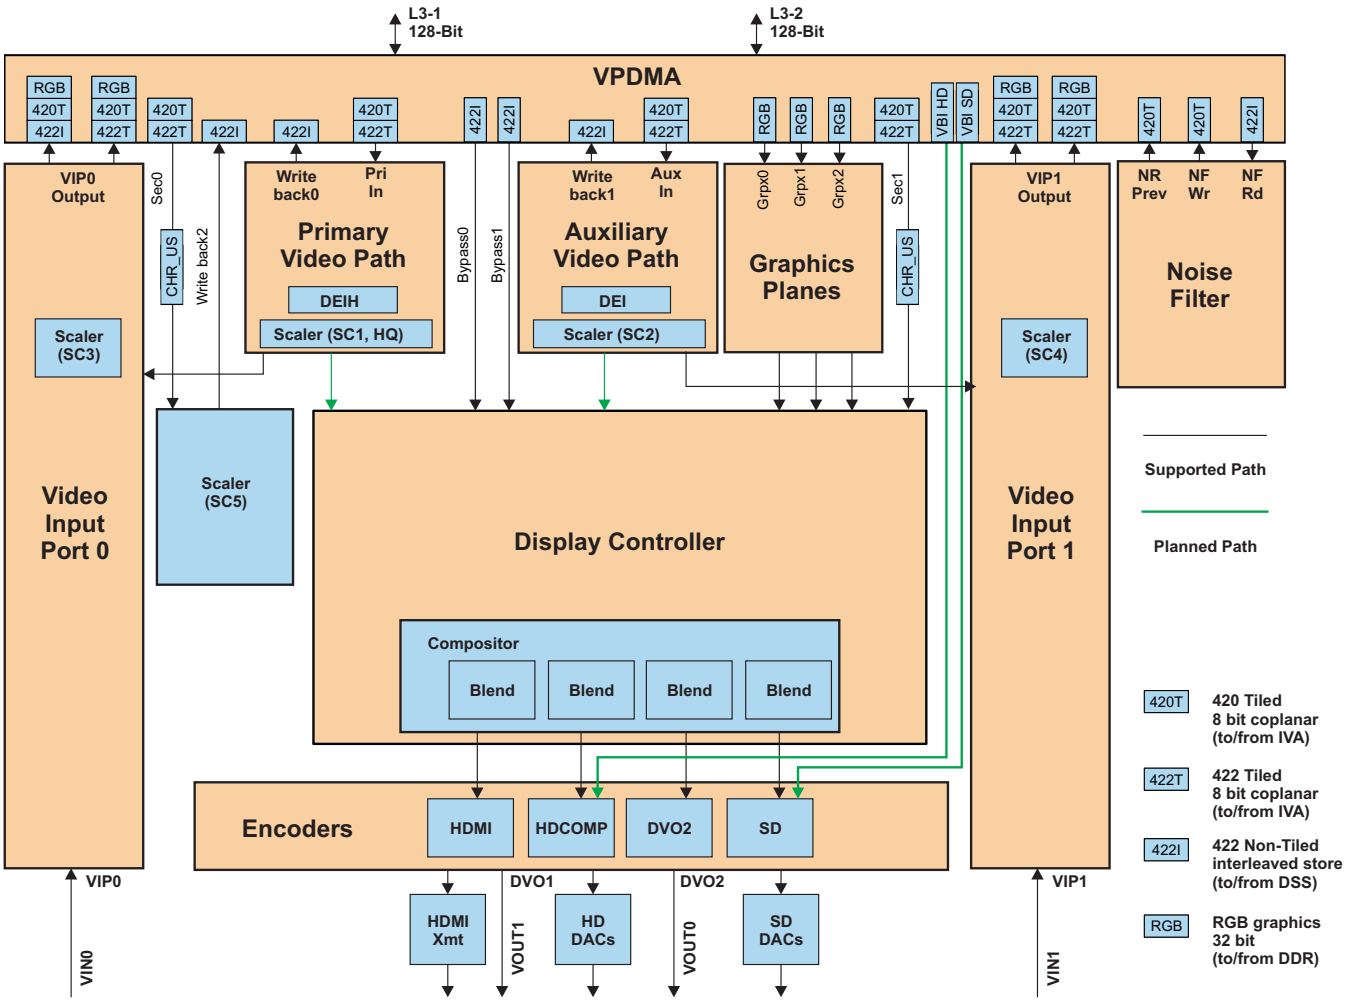
2.1.1 Overview

The high-definition video processing subsystem (HDVPSS) includes video/graphics display and capture processing using the latest TI developed algorithms, flexible compositing and blending engine, full range of external video interfaces in order to deliver a high quality video contents to the end devices.

2.1.2 Functional Block Diagram

Figure 2-1 shows a block diagram of the HDVPSS.

Figure 2-1. HDVPSS Detailed Block Diagram



2.1.3 Terminology Used in this Document

The following is a brief explanation of some terms used in this document:

COMP— Compositor

DEI— De-Interlacer

DEIH— High quality De-Interlacer

DVO— Digital Video Output

GRPX— Graphics Pipeline

HD— High Definition

HDCOMP— High Definition Component

HDMI— High Definition Multimedia Interface

HDVPSS— High Definition Video Processing Subsystem

NF— Noise Filter

NTSC— National Television System Committee

PAL— Phase Alternating Line

SC— Scaler

SD— Standard Definition

SDK— Software Development Kit

TILER— Tiling and Isometric Lightweight Engine for Rotation

VENC— Video Encoder

VIP— Video Input Port

VPDMA— Video Port Direct Memory Access

2.1.4 Data Format

Table 2-1 lists the data formats for the HDVPSS. Note that for the 422T input port, the maximum input width is 960 pixels if the data format is YUV422I_YUYV.

Table 2-1. Data Format

Name	Data Format	Arrangement	TILER Support
422I	YUV422I_YUYV	Single buffer: Y U Y V Y U Y V	No
420T	YUV420SP_UV	Y buffer: Y Y Y Y UV buffer: U V U V	Y: 8-bit container UV: 16-bit container
422T	YUV422SP_UV	Y buffer: Y Y Y Y UV buffer: U V U V	Y: 8-bit container UV: 16-bit container
422T	YUV422I_YUYV	Single buffer: Y U Y V Y U Y V	No

2.1.5 HDVPSS Features

2.1.5.1 Overall Features

- Two independent video capture input ports up to 165 MHz, each VIP instance supports scaling, pixel

format conversion, and up to one 1080P60 or 8-channel multiplexed D1 data.

- Two video processing engines with de-interlacing, scaling, noise reduction, format conversion (aspect-ratio, and pixel format).
- The HDVPSS is able to accept the HDVICP2 video decoder output formats and adjust to several video formats. This includes (but not limited to) tiled and raster data formats, scan format conversion, aspect-ratio conversion, and frame-size conversion.
- Three independent graphics processing engines with scaling capability, alpha-blending, chroma keying.
- Four independent compositors (3 HD + 1 SD) supports composition of video and graphics overlays to provide various display combinations, each compositor support up to 5 display overlays (2 video + 3 graphics), alpha-blending, chroma keying and display order reshuffling.
- Four VENCs (2 HD Digital, 1 HD analog, and 1 SD analog) supports up to 3 HD (up to 1080P60) + 1 SD display simultaneously.
- The HDVPSS handles both video and graphics efficiently to create high-quality user interfaces. This includes (but not limited to) de-interlacing, scaling, noise reduction, alpha blending, chroma keying, flicker filtering, and pixel format conversion.
- HDMI 1.3a compliant transmitter up to 162 MHz.

2.1.5.2 Video Processing Features

- Two parallel video processing pipelines (primary and auxiliary) for concurrent video stream processing are supported.
- The primary video pipeline is used for processing video for the full-size HD display. The primary video pipeline employs highest-quality image processing, per pixel motion adaptive temporal and spatial noise reduction, motion-adaptive de-interlacer, edge-directed scaler, and spatial edge enhancement.
- The auxiliary video pipeline is used for processing the video for the full HD/SD video output. The pipeline employs an area-efficient algorithm that includes a motion-adaptive 3D de-interlacer and a non-edge adaptive scaler.
- The noise filter (NF) performs a memory to memory spatial/temporal noise filter algorithm on a 422 raster input source and produces a 420 tiled output source.
- Supported video input formats are 4:2:0 (aligned-chroma, semi-planar, frame/field), and 4:2:2 (planar, semi-planar, frame/field). YUV420, the output formats of the HDVICP2 and video formats of captured external digital video data, is supported.
- Scan format conversion (interlaced to progressive and conversely) is supported. Especially the interlaced to progressive conversion employs a high quality motion-adaptive 3D de-interlacer to properly render both static and dynamic objections in scenes.
- The output of the video processing is sent to either compositor or external memory. When the output is sent to external memory, context switching between multiple inputs is handled efficiently, that is, multi-CH mode of operation.
- Both the main and auxiliary video pipelines include a write-back path to the external memory to support memory to memory scaling of video frames independently from the display output frame timing.
- Color keying (transparency) is supported.

2.1.5.3 Graphics Features

- Three independently generated graphics layers are supported.
- Each graphic layer supports full-screen resolution graphics.
- Each of the graphics pipelines includes an up/down scaler optimized for graphics application. The scaler supports scaling ratios from 0.25× to 4× with 0.01 scaling step size.
- Supported graphics formats are:
  - 32-bit: ARGB8888, RGBA8888
  - 24-bit: RGB888, ARGB6666,RGBA6666
  - 16-bit: ARGB1555, RGB565, ARGB4444, RGBA5551, RGB4444

  - Bitmap: 1, 2, 4, 8-bit CLUT table
- Global and pixel-level alpha blending value is supported (256 levels). For pixel-level blending, the alpha value can come from either source or CLUT table.
- Color keying (transparency) is supported.
- Stenciling (pixel masking with a separate 1-bit mask plane) is supported independently for each graphics layer.

2.1.5.4 High Definition/Standard Definition (HD/SD) Compositor Features

- Four independently controlled compositors (HDMI/DVO1, HDComp, DVO2, SD) are supported to drive the corresponding display encoder outputs.
- The HD compositor supports composition of video and graphics layers to provide full-size video display, graphics overlay, and video-in-graphics for HD video outputs.
- The SD compositor supports video display, graphics overlay, and video-in-graphics for SD video outputs.
- Each input layer is given a display order priority that determines the display and blending orders.
- Each output supports independent layer visibility control.
- The compositor supports 256-level alpha blending of two overlapping layers.

2.1.5.5 High Definition/Standard Definition (HD/SD) Video Signal Encoding Features (Video Displays)

- A single HDMI 1.3 compliant interface
- Two DVO (VOUT) interfaces that support up to 1080p@60 Hz, 8/16/24 YCbCr/RGB formats are included.
- VOUT0 supports up to 10/20/30-bit and VOUT1 supports only 20-bit.
- Each VOUT port supports both embedded and separated sync outputs.
- HD Component: meets all requirements defined in CEA 770.3-D.
- SD Composite/S-video (NTSC/PAL): meets all requirements defined in ITU-R BT.470-6 (TBD: SECAM support).
- Supported VESA resolutions up to 165 MHz. Note that the maximum supported line width is 1920 pixels. Furthermore, width and height values must always be an even number.
- Support Simultaneous HD and SD output.
- 2 video clocks to support two independent HD displays, the clock of third HD display will be tied to one of the other two.

2.1.5.6 Video Capture Features

- The HDVPSS supports two independently configurable external video input capture ports with up to 165 MHz.
- Each video input capture port can be operated as one 16-bit input channel (with separate Y and Cb/Cr inputs) or two clock independent 8-bit input channels (with interleaved Y/C data input). Further one of the VIP ports can operate in 24-bit mode to support RGB capture.
- Supports both embedded sync and discrete sync.
- The video capture port channel supports de-multiplexing of both pixel-to-pixel and line-to-line multiplexed streams.
- Up to 1920 × 1200@60 Hz (165 MHz) input data rate supports 16-bit mode input port.
- Each video capture port supports one scaler capable of both up and down scaling of one non-multiplexed input stream (one of two 8-bit channel inputs or 16-bit channel input data). Note that if the source is from external video decoder/camera, only down scaling is supported.
- Each video capture port supports one programmable color space conversion to convert between 24-bit RGB data and YCbCr data.
- The VIP supports data storage in RGB, 422, and 420 formats.
- Each video capture port channel supports chroma down-sampling (422 to 420) for any non-multiplexed

input data. The chroma down-sampling for multiplexed streams is done as memory to memory operations outside of the HDVPSS on an individual frame data.

2.1.5.7 Other Features

- The HDVPSS supports 2 secondary video input sources in 420 or 422 tiled format used for memory-memory operations and SD output display.
- The HDVPSS supports 2 bypass video input sources in YUV422 YUYV interleaved non-tiled format for display.
- The HDVPSS supports video data display for the following; there is no processing performed, that is, no scaler, de-interlacing, format conversion.
  1. Secondary 1 video input source in the SD display only.
  2. 2 bypass video input sources in YUV422 YUYV interleaved format for display.
- The HDVPSS supports video data write back paths (memory-to-memory) for the following:
  1. Scaled video from secondary 0 video input sources - saved as YUV422 YUYV interleaved format video.
  2. Scaled video from auxiliary DEI video channel saved as YUV422 YUYV interleaved format video.
  3. Independent scaled video from primary DEIH output - saved as a 420 video using the scaler and chroma_downsampler resources in VIN0 port
  4. Scaled video from primary DEIH video channel saved as YUV422 YUYV interleaved format video.
  5. Independent scaled video from auxiliary DEI output – saved as a 420 video using the scaler and chroma_downsampler resources in the VIN1 port.

2.2 Chroma Up-Sampler (CHR_US) Module

The chroma up-sampler (CHR_US) module is used to convert from YCbCr 4:2:0 data format input to YCbCr 4:2:2 format output.

2.2.1 Features

- Input:
  - YUV420 Semi-planar Tiled Memory
  - YUV422 Semi-planar Tiled Memory
  - YUV420 Semi-planar Non-Tiled Memory
  - YUV422 Semi-planar Non-Tiled Memory
  - YUV422 YUYV Interleaved Non-Tiled Memory
- Output:
  - YUV422 YUYV Interleave non-Tiled Memory
- Supports both interlaced and progressive inputs
- Support bypass mode for 4:2:2 input

2.2.2 Functional Description

The up-sampling is performed by an interpolation filter that uses Catmull-Rom algorithm.

2.3 De-Interlacer (DEI) Module

The de-interlacer (DEI) module is used to generate progressive data output from interlaced input format (also known as, de-interlacing).

2.3.1 Features

- Input:
  - YUV420 Semi-planar Tiled Memory

  - YUV422 Semi-planar Tiled Memory
  - YUV420 Semi-planar Non-Tiled Memory
  - YUV422 Semi-planar Non-Tiled Memory
  - YUV422 YUYV interleaved Non-Tiled Memory
- Output:
  - Output is always tied to the Scalar input
- Motion-adaptive de-interlacing
- Edge-Directed Interpolation (EDI)
- Bad Edit Detection (BED)
- Interlace Bypass:
  - For Interlaced Input, the module can pass the inputs data directly to the outputs in a bypass configuration. No internal processing is performed.

2.3.2 Functional Description

The DEI is primarily used to convert interlaced video source material to progressive form. This particular module is a reduced feature set of the DEIH module, it does not perform Temporal Noise Reduction and is limited to 4 field motion detection. It performs edge directed interpolation, but utilizes a simpler (and smaller) algorithm compared to the DEIH module. It can perform de-interlacing on up to 1080i video input source, producing 1080p video output.

2.3.3 Modes of Operation

The DEI can be operated in three modes:

- Interlace bypass mode
- Progressive bypass mode
- De-interlacer mode

2.3.3.1 Interlace Bypass Mode

In the interlace bypass mode, input luma and chroma are buffered and sent to the stage after DEI without processing.

2.3.3.2 Progressive Bypass Mode

In the progressive bypass mode, the top and bottom YUV streams are combined into a continuous frame and are sent to the following stage as a frame without any processing.

2.3.3.3 Interlace Mode

In the interlace mode, DEI takes in alternative field YUV data and sends out a sequential frame YUV data by interpolation techniques. DEI supports four interpolation modes when converting interlaced pictures to progressive pictures.

2.3.4 Modes of Interpolation

2.3.4.1 Interpolation Mode 0

In mode 0, the interpolated field is created by simple line averaging from the original YUV data. That is, the interpolated line is created by averaging its top and bottom line. Setting of MDT mode has no effect on output pictures.

2.3.4.2 Interpolation Mode 1

In mode 1, the interpolated field is created by averaging pixels from fields before and after the current field. In other words, if the current field is a top field, the interpolated bottom field picture is created by averaging pixels from bottom field pictures before and after the current field. MDT setting has no effect on the result.

2.3.4.3 Interpolation Mode 2 (EDI)

Mode 2 is an edge assisted interlace mode with edges detected from the luma information of a 2 × 7 (H × W) frame window. It detects seven possible edges between 45 and 135 degrees. Edges with slopes greater than 135 degrees are treated as 135 degree lines, and edges with slopes less than 45 degrees are treated as 45 degree lines.

Luma for missing lines are interpolated using original luma along the detected edge.

Motion value (MV) from the MDT module is used to select coefficients from a look up table on how 2D interpolation from the current field and 3D interpolation from two fields adjacent to the current fields are blended. The way to perform blending for chroma is slightly different than for luma, because the MV is based on luma and extra care needs to be taken when blending is applied to chroma.

At this mode, edge-directed interpolation is applied to luma only. Vertical interpolation is performed for chroma data.

2.3.4.4 Interpolation Mode 3 (EDI)

The edge detection method used in this mode is similar to interpolation mode 2. The only difference is that the edge-directed interpolation is performed on both luma and chroma. Chroma is interpolated similarly according to the edge vectors obtained based on luma information. The reason chroma is interpolated slightly different is because of the down-sampled chroma data.

2.3.5 Motion Detection (MDT)

Motion values from the MDT module are calculated only based on luma information. The motion value is used to determine how 2D and 3D interpolated results should be blended. The motion detection module in DEI supports 4-field mode.

2.4 High-Quality De-Interlacer (DEIH) Module

The high quality de-interlacer (DEI_H) module is used to generate progressive data output from interlaced input format (also known as, de-interlacing).

2.4.1 Features

- Input:
  - YUV420 Semi-planar Tiled Memory
  - YUV422 Semi-planar Tiled Memory
  - YUV420 Semi-planar Non-Tiled Memory
  - YUV422 Semi-planar Non-Tiled Memory
  - YUV422 YUY`V interleaved Non-Tiled Memory
- Output:
  - Output is always tied to the Scalar input
- Motion-adaptive de-interlacing:
  - Motion detection (MDT) based on both luma and chroma
  - Two modes of motion detection: 4-field, 5-field
- Temporal Noise Reduction (TNR):
  - Motion directed 3D noise reduction. Performed before EDI.
  - Allows noise reduction for both luma and chroma

- Edge-Directed Interpolation (EDI)
- Spatial Nose Reduction (SNR)
- Bad Edit Detection (BED)
- TNR support on progressive input Interlace Bypass
  - For Interlaced Input, the module can pass the inputs data directly to the outputs in a bypass configuration. No internal processing is performed.

2.4.2 Functional Description

The DEIH is primarily used to convert interlaced video source material to progressive form. This particular module incorporates features such as Temporal Noise Reduction, 4- and 5-field motion detection and very fine edge detection capabilities to produce a very high-quality de-interlaced output. It can perform de-interlacing on up to 1080i video input source, producing 1080p video output.

2.4.3 Modes of Operation

The DEIH can be operated in four modes:

- Interlace bypass mode
- Progressive bypass mode
- Progressive mode
- De-interlace mode

2.4.3.1 Interlace Bypass Mode

In the interlace mode, data are buffered and sent to the stage after DEIH without processing.

2.4.3.2 Progressive Bypass Mode

In the progressive mode, the top and bottom YUV streams are combined into a continuous frame and are sent to the following stage as a frame.

2.4.3.3 Progressive Mode

The only available data processing in the progressive mode are 2D (spatial) and 3D (temporal) noise reduction. Those two noise reduction modes can be independently enabled. If 3D noise reduction is turned on, the top and bottom YTNR and UVTNR (filtered Y and UV) are sent to external memory and should be returned to the DEIH after 1 field delay. The top and bottom YUV streams are treated as two separate streams and are combined into a frame before being sent out.

2.4.3.4 Interlace Mode

In the Interlace mode, DEIH takes in alternative field YUV data and sends out a sequential frame YUV data by interpolation techniques mentioned below. DEIH supports 4 interpolation modes, 3 motion detection (MDT) modes, 3D temporal noise reduction (TNR) and 2D spatial noise reduction (SNR) when converting interlaced pictures to progressive pictures.

2.4.4 Modes of Interpolation

2.4.4.1 Interpolation Mode 0

In mode 0, the interpolated field is created by simple line averaging from the original YUV data. That is, the interpolated line is created by averaging its top and bottom line. MDT setting has no effect on the result. TNR and SNR can be independently applied.

2.4.4.2 Interpolation Mode 1

In mode 1, the interpolated field is created by averaging pixels from fields before and after the current field. In other words, if current field is a top field, the interpolated bottom field picture is created by averaging pixels from bottom field pictures before and after the current field. TNR and SNR can be independently applied.

2.4.4.3 Interpolation Mode 2 (EDI)

Mode 2 is an edge assisted interlace mode with edges detected from the luma information of a 7 × 2 (W × H) frame window. It detects seven possible edges between 45 and 135 degrees. Edges with slopes greater than 135 degrees are treated as 135 degree lines, and edges with slopes less than 45 degrees are treated as 45 degree lines.

Luma for missing lines are interpolated using original luma along the detected edge. Chroma is interpolated similarly according to the edge vectors obtained based on luma information.

2.4.4.4 Interpolation Mode 3 (EDI)

Mode 3 is an edge assisted interlace mode with edges detected from a 17 × 2 (W × H) frame window. It detects edges between 11.3 and 168.7 degrees with 1/8 pixel resolution.

Luma for missing lines are interpolated from 2 methods: 4-tap vertical interpolation and 2-tap interpolation along detected edges.

Chroma is interpolated using the pixel resolution edge vectors obtained based on luma information.

2.4.5 Motion Detection (MDT)

Motion values from the MDT module are calculated only based on luma information. The motion value is used to determine how 2D and 3D interpolated results should be blended.

The TNR module needs a motion value to determine the mixing coefficient of YUV from current field and YTNR/UVTNR from previous frame. MV from both luma and chroma data are calculated within the TNR module and the larger MV from Y or UV is used to determine the blending factor.

The SNR module also needs MV to decide how data are blended in the sigma filter. MV for SNR sigma filters is provided by the TNR. The MDT modes discussed in the following sections apply only to the MDT module and has no effect on how MV is determined in the TNR.

2.4.5.1 MDT Modes

There are 2 modes of motion detections in the DEIH:

- 4-field
- 5-field

2.4.5.1.1 4-Field Mode

Motion value (MV) is first estimated from y_f0 and y_f2 (current and two field delayed Y). The maximum value of MV and one field delayed data of MV, MV_f1, is used to create the overall MV per pixel. In addition to y_f0 and y_f2, y_f1 is used to detect scene change. It is also used to detect slow motion in the advanced mode. Since this motion detection method utilizes three fields of luma data and one field delayed MV, it is called 4-field mode as MVs come from four fields of luma data.

There is one field delay between the YUV inputs and the YUV outputs. The “current_field” that the interpolator works on is the YUV_f1 data.

2.4.5.1.2 5-Field Mode

Motion value (MV) is first calculated from yuv_f0 and yuv_f2, like the 4-field mode, but the overall MV per pixel is calculated using both MV_f1 and MV_f2 as the inputs. Instead of yuv_f1, yuv_f3 is used in the scene change detection. It is called 5-field mode since MVs come from five fields of luma data.

There are two fields delay between the YUV inputs from the VPI and the YUV outputs. The “current_field” interpolator works on is yuv_f2.

2.4.6 Temporal Noise Reduction (TNR)

Temporal nose filter is a 3D noise filter that does IIR filtering temporarily. For an interlaced picture, pixels delayed by two fields, pixels of two neighboring top fields or two neighboring bottom fields are used in the IIR filtering. When DEIH is at the progressive mode, a picture frame is broken into top and bottom fields. TNR is performed on top and bottom fields, simultaneously. TNR data only needs to be delayed by one field instead of two fields at progressive mode.

2.4.7 Spatial Noise Reduction (SNR)

The spatial noise filter does 2D noise filtering on a ‘frame’ picture after the interpolation step. It does not differentiate if DEIH is in the progressive mode or the interlace mode. The SNR contains two filter algorithms: Impulse noise filter and Sigma filter.

The impulse noise filter aims at removing isolated speckles. A set of median filters is adaptively selected to achieve this goal depending on the amount of impulse noise detected. The Gaussian noise filter is targeting removing Gaussian noise.

The sigma filter is an edge-friendly filter by including only neighboring pixels that have a value not deviating from the current pixel by a given range.

2.5 Video Compositor (COMP) Module

The video compositor (COMP) module is used to blend the input video and graphics sources into a single stream to drive video encoders (VENCs).

2.5.1 Features

- Four independently controlled compositors
- Supports four displays: 3 HD and 1 SD
- Supports up to 5 input layers for each display: 2 videos and 3 graphics
- Supports 256-level cascade alpha blending for up to 2 video input layers first and up to 3 graphic input layers later
- Supports programmable display priority for input layers
- Supports programmable background color

2.5.2 Functional Description

The COMP module has four independently controlled blenders (compositors), each of which can take up to five input layers (2 videos and 3 graphics) to generate one composite output layer. Each blender is associated with one of the four video encoders (VENCs) to drive the display data. The accessibility of each blender to the input layer is shown in Table 2-2.

Each of the input layers can be associated to one or more VENCs in the HDVPSS. All the input layers associated with a VENC should have the same size and type (progressive or interlaced) of the display. This implies that if an input layer is shared with multiple VENCs, all those VENCs should have the same size, type and frame rate. For example, if the 1080p HDMI output is desired to have primary video input and auxiliary video input with 1 graphics overlay, then the primary and auxiliary video input must be 1080p, and one of the graphics must be 1080p. If another blender is setup for 480i, it cannot use either the primary or auxiliary video inputs, and must use a different graphics input.

Input layers associated to a VENC are grouped together, reordered according to the user programmable display priority order list, and blended using embedded alpha values between overlapped layers.

Table 2-2. Input Layers and Associated Blenders

Input Layers\Compositor	HDMI	HDCOMP	DVO2	SD
Primary HD video	Yes	No	Yes	No
HDCOMP video	No	Yes	No	No
SD video	No	No	No	Yes
HD auxiliary video	Yes	Yes	Yes	No
GRPX0	Yes	Yes	Yes	Yes
GRPX1	Yes	Yes	Yes	Yes
GRPX2	Yes	Yes	Yes	Yes

2.5.2.1 Input Sources

Each blender in the COMP module receives up to five input sources to blend and sends the composited output to the corresponding VENC.

All the inputs that are connected to a single blender should:

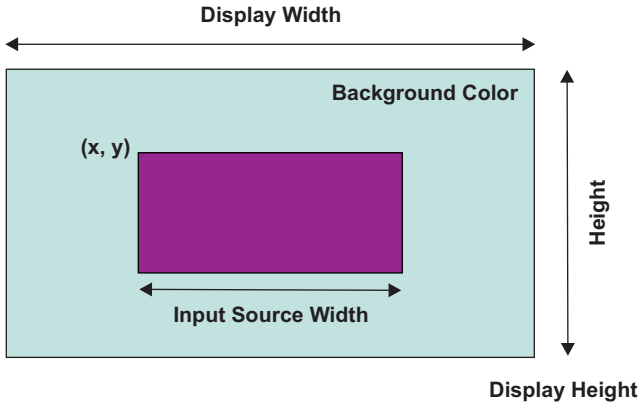
(a) Have the same size of its corresponding VENC display size. This is done by forming a WINDOW (see Figure 2-2) in the upstream modules. Note that it does not imply any restriction on the actual input video sizes in external memory to be the same. For example, Video-0 can be 1920 × 1080 and Video-1 can be 720 × 480 in the memory.

(b) Carry their priority levels to re-order themselves as layers on the final display stream (only for graphic inputs).

(c) Carry alpha values used to blend with each other using the above priority levels.

If the size of any input is not the same as the display size, background color is inserted in the remaining portion as shown in Figure 2-2.

Figure 2-2. Upstream Module Window Coloring



2.5.2.2 Blender

The compositor blends two video input sources together to generate a single video output first, and then reshuffles the video and graphics inputs to allow flexible display order based on programmable display priority, and finally blends all of them together to generate a single display output to the VENC.

When two input sources, input1 and input2, are blended, the resulting source is calculated as follows:

```
Blended Output     = (a)*input1 + (1-a)*input2, if input1 is top layer and input2 is bottom layer
Blended Output     = (1-b)*input1 + (b)*input2, if input2 is top layer and input1 is bottom layer
```

Where a and b are alpha values of input1 and input2 windows, respectively. The layer order (top or bottom) is decided by priority levels of the two video inputs.

2.5.2.3 Background Color

There is a programmable background color in the COMP module. Background color is configured in RGB format with 10-bits in each R, G, and B. Any pixel with an alpha value of 0 is replaced by this color. If the video bottom layer is disabled, the video top layer is blended with background color. If both video layers are disabled, the background color is used as the output of video alpha blending. For SD channel, only one video stream comes in and it is blended with the background color.

2.6 Graphics (GRPX) Module

The graphics module (GRPX) is a graphics processor that composes RGB or Bit Map data to create a display plane input for the video compositor (COMP) module.

2.6.1 Features

- Non-Tiled memory only
- Input:
  - RGB565
  - RGB888
  - ARGB1555
  - ARGB4444
  - ARGB6666
  - ARGB8888
  - RGBA5551
  - RGBA4444
  - RGBA6666
  - RGBA8888
  - Bitmap data (8/4/2/1 bit) with configurable CLUT
  - Non-Tiled memory
  - Supports optional stenciling (1-bit mask) table
- Output:
  - Output data format is ARGB32
- Width, Height, placement (X & Y) parameters
- Display priority
- Scalar enable/disable
- Scaling ratio attributes
- Stenciling enable/disable
- Support for global, color and pixel level Blending
- Configurable Chroma Keying options
- Bounding box enable

2.6.2 Functional Description

The GRPX module takes in RGB or bitmap data, applies attributes, and sends out the data output to the COMP module.

2.6.2.1 Disp_Priority

An inter-graphics-pipeline display priority level may be used to switch the order from two GRPX pipelines. The GRPX module simply passes these values along with each pixel data to the COMP module and the COMP uses it to reorder between two GRPX data. This should only be used when both GRPX outputs are tied to the same display output format and rate.

2.6.2.2 Scaler

The scaler used in the GRPX module consists of a 5-tap/8-phase horizontal and 4-tap/8-phase vertical polyphase filters.

2.6.2.3 Anti-Flicker Filter Implementation

When data is scaled up or down, the poly-phase vertical filter inherently provides anti-flicker filtering. Even when data is not needed to be scaled, the scaler still is enabled to perform low-pass filtering along the vertical direction with scaling ratio = 1.

2.6.2.4 Stenciling

The VPDMA sends 1 bit for each pixel that has the “stenciling” feature enabled. This bit is used to force the alpha value of the pixel to 0, in order to mask-off the pixel (that is, make the pixel transparent). This feature can be used by an application to assign an arbitrary mask shape to a rectangular graphics.

2.6.2.5 Boundary Box Blending

The GRPX module supports overwriting alpha values of pixels that make up a 1-pixel wide boundary box with a semitransparent (alpha) value (default = 80h) so that the flickering around the edges can be minimized. A programmed boundary box alpha value is assigned to each boundary pixel.

2.6.2.6 Blending

The GRPX module supports four blending modes:

- no-blending
- global
- CLUT
- pixel

When no-blending is selected, the GRPX forces each alpha to FFh. In global blending, a programmed alpha value is assigned to each pixel. For color or pixel blending, the alpha value with CLUT mapping or embedded alpha value (argb format source) is used, respectively.

The blending level supported is from 0 (transparent) to 255 (totally opaque).

2.6.2.7 Transparency Handling

The GRPX module supports a transparency mode to determine how an alpha value for each pixel is set. When transparency is enabled, each pixel color is compared against the programmed transparency color (RGB888) to determine whether the pixel is to be transparent or not. If the colors match, the alpha value is forced to 00h. Otherwise, the alpha value remains as programmed. During the comparison, the application can assign LSB bit masking to notify the module which LSBs are masked. The GRPX supports three different LSB bit masks: masking LSB bit0; masking LSB bit[1:0] and masking LSB[2:0]. For example, if masking LSB[2:0] is selected, then the top 5 bits of the R/G/B component data are compared to the corresponding 5 bits of the programmed transparency R/G/B color.

Because the alpha value is also scaled in the same way the color components (RGB) are scaled, all enabled blending/transparency related tasks are performed in the following order:

1. Application of no-blending (force alpha = FFh) or Global blending (force alpha = programmed global blend level)
2. Transparency check to force alpha = 0 for transparent pixels
3. Stenciling application to force masked pixels (stencil data = 1) with alpha = 0
4. Scaling of alpha (if scaling is enabled)
5. Box blending (force alpha = programmed box_blend_level)

2.7 High-Definition Video Encoder (HD_VENC) Module

There are three high-definition video encoders (HD_VENCs) in the HDVPSS. The HD_VENC module encodes the active video data from the COMP module and sends it up to a 30-bit wide DVO (digital video output) port by generating timing signals to control the data flow.

2.7.1 Features

- Two independent digital video output ports (DVO1 and DVO2)
- The DVO ports support output data rates up to 165 MHz
- The DVO1 (VOUT1) port supports 20-bit wide output with embedded sync or discrete sync
- The DVO2 (VOUT0) port supports up to 10/20/30-bit wide output with embedded sync or discrete sync
- Display timing generator: generates the display timing signals VS, HS, FID, HBI, VBI, and ACT_VID for OSD
- Analog output support embedded sync only
- Color Space Conversion

2.7.2 Functional Description

The HD_VENC primarily has two blocks:

- OSD
- encoder

The OSD module is used to get the data from the COMP module using the sync signals generated by the encoder module. In the device, the HD_VENC supports either digital (HDMI/DVO1, DVO2) or analog output (HDCOMP), but not both. Table 2-3 lists the possible display ports and corresponding VENC names.

Table 2-3. Display Ports and VENC Names

Display Port Name	Type	VENC Name	Port Name for PINMUX
HDMI/DVO1	Digital	HDMI	VOUT1
DVO2	Digital	DVO2	VOUT0
HDCOMP	Analog	HDCOMP	Not Applicable
SD	Analog	SD	Not Applicable

2.7.2.1 OSD Interface

The interface between the OSD and the video display encoder consists of a 30-bit data bus, a pixel clock, and five sync signals. By default, 30-bit RGB video data is passed from the OSD to the encoders on every rising edge of the pixel clock during an active video period. Table 2-4 lists all the control signals of the OSD interface.

Table 2-4. OSD Interface Signals

Signal Names	Descriptions
FID	Field ID signal. In interlace mode, this signal toggles between 1 and 0 on every field. In progressive mode, this signal toggles between 1 and 0 on every frame.
VS	Vertical sync signal. This signal is a one-line long pulse. In interlace mode, this pulse indicates the first line of each field. In progressive mode, this pulse indicates the first line of each frame.
VBI	Vertical blank interval signal. This signal goes to 1 during a non-active video period; this signal stays at 0 during an active video period.
HS	Horizontal sync signal. This is the horizontal sync signal.
HBI	This is a 4-pixels wide and active-high signal. It appears once every video line.

Table 2-4. OSD Interface Signals (continued)

Signal Names	Descriptions
ACT_VID	This is an active-video qualification signal. When this signal is high, the encoder is expecting an active video data output from the OSD after 1 clock delay.

2.7.2.2 Digital Video Output (DVO)

Table 2-5 lists all formats that the digital video output supports.

Table 2-5. DVO Formats

Formats	Bits
Single-stream 656	YCbCr-10-bits
Dual-stream 656	Y/CbCr-20-bits
Triple-stream 656	Y/Cb/Cr/R/G/B - 30-bits
YUV422 20-bit output with discrete sync	Y/CbCr - 20-bits
30-bit output with discrete sync	Y/Cb/Cr/R/G/B - 30-bits

The DVO outputs both embedded sync and discrete sync. In embedded sync, the DVO supports single/dual/triple stream. In discrete sync, the following are the sync signals that the DVO outputs:

- HS (horizontal sync signal)
- VS (vertical sync signal)
- ACT_VID (active-video signal)
- FID (field ID signal)

2.7.2.3 Color Space Converter (CSC)

The color space converter (CSC) module is used to convert the input data from one color space to another by 3 × 3 matrix.

2.7.2.4 DAC Interface

There are three 12-bit video DACs inside the device. The active video digital combining with the sync signals is directly synthesized in the digital domain and sent to the DACs.

In component video format, the sync signal is inserted in the Y channel or G (green) channel. In ITU and SMPTE standards, the sync signals are also allowed to be inserted in the R. B, Pb, and Pr channels. The device implements the sync insertion only in Y and G channels.

2.8 Noise Filter (NF) Module

The noise filter (NF) module is used to reduce noise in a video sequence in order to improve video image quality and compression efficiency.

2.8.1 Features

- Input:
  - YUV422 YUYV interleaved Non-Tiled memory
- Output:
  - YUV420 Semi-Planar Tiled Memory YUV420 Semi-Planar Non-Tiled Memory
- Spatial video noise filtering
- Spatial video noise filtering bypass
- Temporal video noise filtering
- Temporal video noise filtering bypass

- Chroma down-sampling

2.8.2 Functional Description

The NF module is a combination of spatial and temporal IIR filters and chroma down-sampling. The spatial filter is performed with neighboring pixels in the current frame; the temporal filter is performed with a past filtered frame to suppress both spatial and temporal noises.

The NF module performs a memory-to-memory spatial/temporal noise filter algorithm on a 422 raster input source and produces a 420 tiled output source. Its primary use mode is part of the video input port processing. In this use mode, the external video source is captured by the video input port and sent to the memory as 422 raster format. It is then brought back into the NF module from memory, filtered, and sent back to the memory as 420 tiled format.

The NF module can be configured to perform spatial-temporal filtering, spatial-only filtering, temporal-only filtering, or at bypass mode. When a filtering function is enabled, the previous NF filtered output is required to use as an additional input to perform the noise reduction. Previous noise filter output is not required if the NF module is in bypass mode, and the NF module performs YUV422 to YUV420 chroma down-sampling only.

2.9 High-Quality Scalar (SC_H) and Scalar (SC)

The SC_H (high-quality scalar) and SC are used for scaling the incoming video stream to other resolutions.

2.9.1 Features

- Input:
  - DEI output, Chroma_up output of VIP output
- Output:
  - YUV422 YUYV Interleaved
- Horizontal/Vertical cropping
- Polyphase filter for horizontal
- Polyphase filter/Running average filter for vertical
- Scaling up to a maximum of 1920 pixels in the horizontal direction and up to 1080 pixels in the vertical direction

2.9.2 Functional Description

The Scaler takes the data from the upstream module. The input image is resized to the desired output size. The module sends the output image to the downstream module. It can scale full HD (1080p) and output full HD (1080p). The SC_H is a high profile version configured for the best quality video scaling and performs edge-directed vertical scaling. It is only used in the primary video data path. The SC is a medium profile version optimally configured for good scaling quality without the edge-directed scaling. This scalar is used in the auxiliary video path and in all other video write-back data paths in the HDVPSS module.

For both of these scalars, the scaling is performed in following three steps:

1. Trimming
2. Vertical Scaling
3. Horizontal scaling

2.9.2.1 Trimmer

The trimmer can be programmed to redefine a new source image within the input video frame sent from an upstream module before it is sent to the scaling submodules. This feature enables small area zoom out, source pan/scan, or removal of unwanted area in the video.

2.9.2.2 Vertical Scaling

The vertical scalar has a polyphase and a running average filter. While the polyphase filter is used for any up-scaling and preferably downscaling to a 3/16 scale factor, the running average filter is used only for downscaling to a ½ or less size. Selection between these two scalars is based on the user setting of "use_rav" parameter, according to the user preference of the tradeoff between sharpness preserving and introduced artifacts.

2.9.2.3 Polyphase Scaler

In both scalars (SC_H and SC), the vertical polyphase scalar is mainly implemented using a 32-phase 5-tap polyphase filter. For SC_H, a 2-tap edge-directed bilinear filter is added to improve quality making use of the edge information in the source image. The bi-linear vertical interpolation is only available in the SC_H, and it uses two source lines to generate missing lines in the output image. Due to the aliasing effects in the downscaling, this scaling is to be used only for up-scaling cases.

2.9.2.4 Running Average Filter

When a polyphase filter is used, usually it has to have many taps in order to achieve acceptable quality for very small downscaling ratio, which requires the use of many line buffers. In the HDVPSS, there is a weighted running average filter for downscaling when the scaling factor is small (for example, when the scaling ratio is less than 0.5). This highly optimized design requires only one line buffer for luma and one for chroma, which still achieves acceptable quality. The output of the running average filter is based on a weighted average of pixels in the current and previous rows in the vertical direction.

2.9.2.5 Horizontal Scaling

The horizontal scalar is implemented using a 32-phase × 7-tap polyphase filter preceded by two sets of 1/2× decimators. The general configuration of the horizontal scalar is performed as follows:

1. For upscaling, the input video is interpolated using the polyphase scalar.
2. For downscaling, input video is decimated by 2 until the modified scale factor falls between ½ and 1. Then, a polyphase filter is configured with coefficients selected based on the scale factor.

2.10 Standard-Definition Video Encoder (SD_VENC) Module

The standard-definition video encoder (SD_VENC) converts digital component YCbCr/RGB video signals to conform to the various TV standard analog video.

2.10.1 Features

- Master Clock Input - 27 MHz
- Support PAL/NTSC Standard
- Composite (CVBS)
- S-Video (Y/C)
- Color Space Conversion

2.10.2 Functional Description

The SD_VENC module operates in synchronization with horizontal/vertical sync signals generated in the built-in sync signal generator. For the analog video output, one of the following TV formats (525i or 625i) needs to be specified. The format setting specifies the format-dependent timing parameters such as sync rise/fall build-up time, active video rise/fall time, vertical sync, and equalizing pulse position.

2.10.2.1 Color Space Converter (CSC)

The 2× interpolated data then comes into a color space converter (CSC) to be converted into the desired color format.

2.10.2.2 Macrovision

The SD_VENC module supports analog copy protection Macrovision Rev7.1 to the SDTV CVBS output. Due to strict security control by Macrovision, any information such as Macrovision register map and usages are not directly distributed to the customers. This information is supplied by Macrovision upon certification.

2.10.2.3 DAC Output

The SD_ VENC module has 4 channel, 12-bit digital outputs for DAC input.

2.11 Video Input Parser (VIP) Module

The video input parser (VIP) module is used to capture the video data into the HDVPSS module.

2.11.1 Features

- Input:
  - YUV422 8-bit embedded sync mode (exclude BT. 1120)
  - YUV422 8-bit discrete sync mode
  - YUV422 16-bit embedded sync mode
  - YUV422 16-bit discrete sync mode
  - YUV422 8-bit 2×/4× pixel multiplexed mode
  - YUV422 8-bit 4× line multiplexed mode
  - RGB 24-bit embedded sync mode
  - RGB 24-bit discrete sync mode
  - YUV444 24-bit embedded sync
  - YUV444 24-bit discrete sync mode
- Output:
  - YUV422 YUYV interleaved format
  - YUV420 Semi-planar format
  - RGB 24-bit interleaved format
  - YUV422 Semi-planer format
- Two 165 Mhz video capture instance of the VIP Subsystem
- VIP instance 0 is 16/24-bit channel, VIP instance 1 is 16 bit channel
- For each VIP instance, two pixel clock input domains are supported (Port A and Port B)
- Pixel clock input domain Port A supports one input data bus up to 24-bit
- Pixel clock input domain Port B supports one 8-bit input data bus
- Each VIP instance can be in dual 8-bit capture channels
- Embedded sync data interface mode supports single or multiplexed sources
- Discrete sync data interface mode supports only single source input
- The two pixel clock input domains can be individually configured in any combination of embedded sync or discrete sync
- Multiplexed data can only appear in embedded sync mode
- Where possible, blanking pixels that may contain embedded vertical ancillary data will be stored in a dedicated buffer per each video source
- Color Space Conversion (CSC)
- Chroma Down-Sampling
- Scaling
- Multiplexed data can not use CSC, Chroma Down-Sampling, and scaling

2.11.2 Functional Description

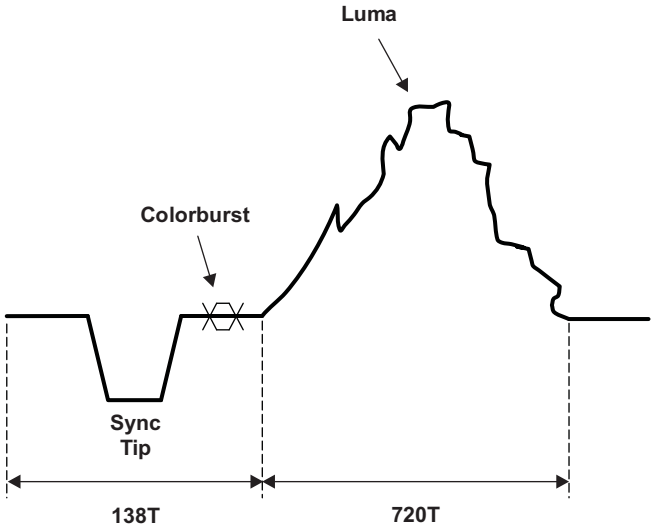
The video data is captured from the external video source by the VIP parser sub-block in the VIP block. The VIP parser then sends the captured data for further processing in the VIP block that includes color space conversion, scaling, chroma down-sampling, and finally writes the video data to external DDR memory. Color space conversion, scaling, and chroma down-sampling are all optional for the incoming stream.

The scaler and chroma down-sample module inside the VIP module is also used for the memory-to-memory operation, if they are not used in the capture mode.

2.11.2.1 Analog Video

A digital interface stream is based on analog video. The waveform for a line of NTSC analog video is shown in Figure 2-3.

Figure 2-3. NTSC Analog Video Waveform for One Horizontal Line



T is a time constant. For NTSC, T = 1/13.5 Mhz = 74 ns

2.11.2.2 Digitized Video

Digitized video is based on scan lines found in analog video. BT.601 uses various sync signals to specify when a new field and a new line starts. BT.656 and BT.1120 use sync words embedded in the data stream to specify the start of a field and the start of a line.

An image can be digitized into regions as shown in Figure 2-4.

With the capability to encode sync words inside the data stream, there is more flexibility for adding non-video related data, called Ancillary Data. Also, code words embedded in the digital stream can be used as a type of identifier for multiplexing several sources of video into one data stream. Such a multi-camera multiplex is useful in the digital security markets.

Figure 2-4. Digitized Video

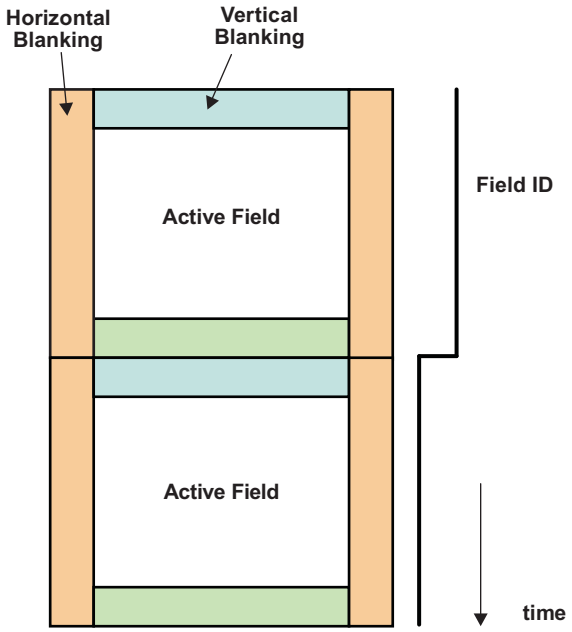


Figure 2-5 shows End-of-Active-Video (EAV) and Start-of-Active-Video (SAV) code words added to a video transmission. The period between the EAV and SAV is equivalent to horizontal blanking. The period between the SAV to the next EAV is active video or vertical blanking.

In the BT.656 or BT.1120 embedded code word scheme, three bits of the EAV/SAV code word are important: F (field), H (horizontal blanking), and V (vertical blanking).

Figure 2-6 shows the values of F, V, and H flags at different locations in the picture. The F flag specifies the state of the field ID for the picture. For progressive frames, F is always 0. The V flag specifies the vertical blanking areas. The H flag specifies the horizontal blanking portions of the picture.

Figure 2-5. Code Word Embedded Video Format

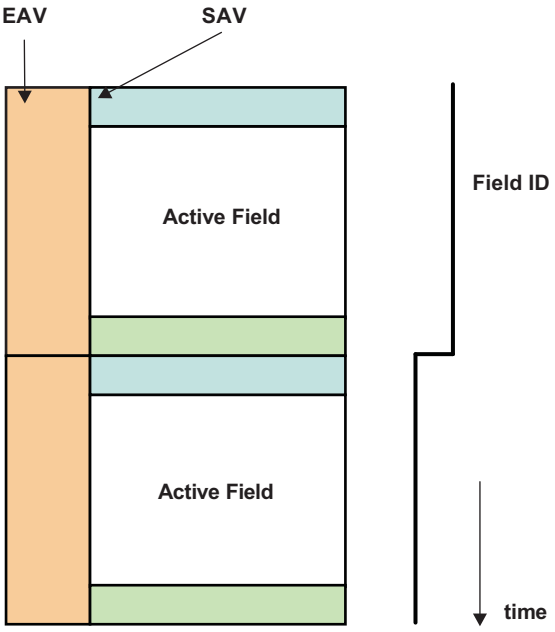

Figure 2-6. Digitized Video with F, V, and H Flags in EAV/SAV

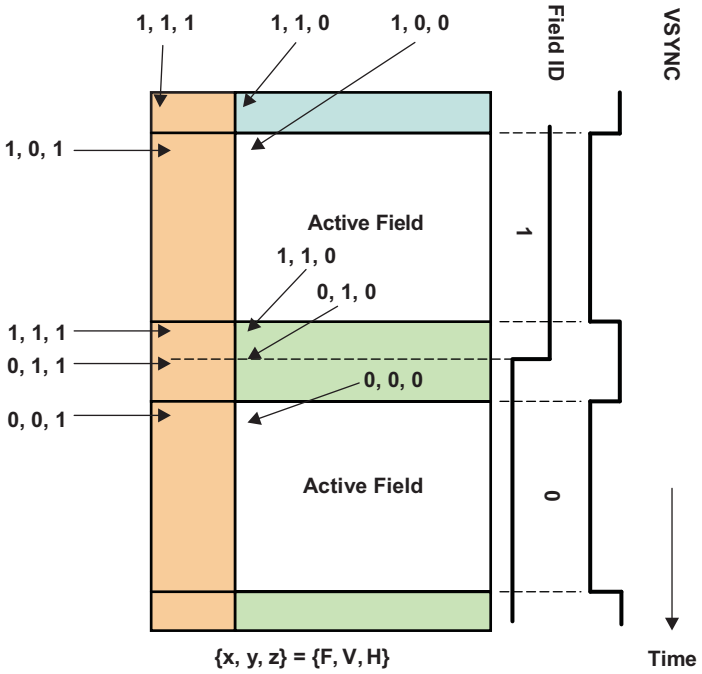


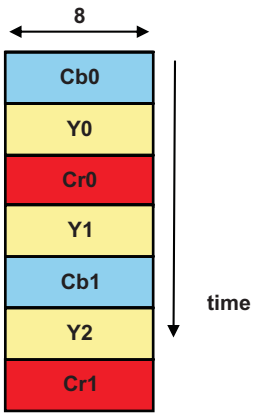
2.11.2.3 Input Data Interface

This section describes how the data (luma and chroma data for YUV422 format capture and R/G/B data for RGB888 format capture) is multiplexed for the interface modes.

2.11.2.3.1 8b Interface Mode

In 8b interface mode, the input pixels are multiplexed according to Figure 2-7. The chroma format is 4:2:2. Sites with Cb/Cr pixels are known as chroma sites. Those sites with Y pixels are known as luma sites.

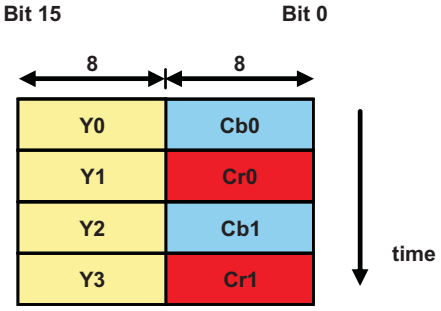
Figure 2-7. 8b Interface Discrete Sync Pixel Multiplexing



2.11.2.3.2 16b Interface Mode

In 16b interface mode, luma is on 8 bits of the data bus and Cb/Cr chroma pixels alternate on the other 8 bits of the data bus, as shown in Figure 2-8.

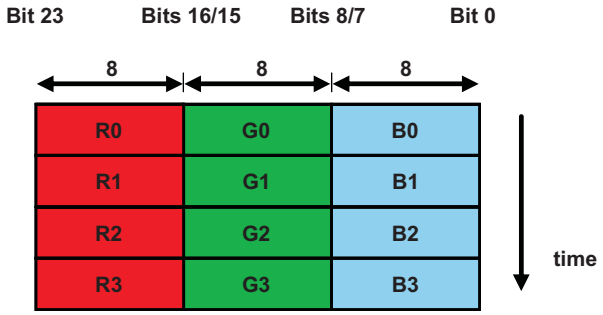
Figure 2-8. 16b Interface Discrete Sync Pixel Multiplexing



2.11.2.3.3 24b Interface Mode

In 24b interface mode, RGB data is sent. The three components are packed into the data bus and sent to the video port direct memory access (VPDMA), as shown in Figure 2-9. The 24-bit luma VPI client to the VPDMA carries all three components. This data is saved to the DDR in packed mode. That is, the three components are not separated by hardware.

Figure 2-9. 24b Interface RGB Discrete Sync



In 24b interface mode YUV4:4:4 data is also supported. The flow for YUV4:4:4 data is the same as RGB data (Figure 2-9). Bits [23:16] of the input data bus are placed on bits [23:16] of the data bus going to VPDMA. Bits [15:8] of the input bus are placed on bits [15:8] of the data bus going to VPDMA. Bits [7:0] of the input data bus, are placed on bits [7:0] on the bus going to VPDMA.

2.11.2.4 Input Ports and Sharing of the 24-Bit Data Bus

The VIP parser supports two independent pixel clock input domains: Port A and Port B. Port A supports a single 24-bit data bus at the instance level. Port B supports a single 8-bit data bus at the instance level. For the device, a single set of 24 device pins are used to drive both Ports A and B.

The two VIP instances are not identical from the chip level. VIP instance 0 is a 24-bit interface and VIP instance 1 is a 16-bit interface. The configuration for each device input port is described in Table 2-6. Each port can individually be configured as Discrete Sync or Embedded Sync.

Table 2-6. Valid Input Port Configurations

Port A	Port B
8 Bit	Off
16 Bit	Off

Table 2-6. Valid Input Port Configurations (continued)

Port A	Port B
24 Bit	Off
8 Bit	8 Bit
Off	8 Bit

2.11.2.5 Frame Buffers

The VIP/VPDMA supports frame buffers in DDR for active video. 4:2:2 data is always saved in packed pixel buffers. 4:2:0 data is saved in planar luma buffers and planar CbCr pair buffers. A luma frame buffer is a planar storage area. Each line is the width in pixels (1Byte/pixel) of the output picture size format. The frame buffer contains the number of active video lines in the output picture size format. A chroma pair frame buffer is planar storage of CbCr pixel pairs, with each pixel being a byte. For 4:2:0 storage, N lines in the output picture active video results in N/2 lines of CbCr pairs being stored.

2.11.2.6 Source Multiplexing

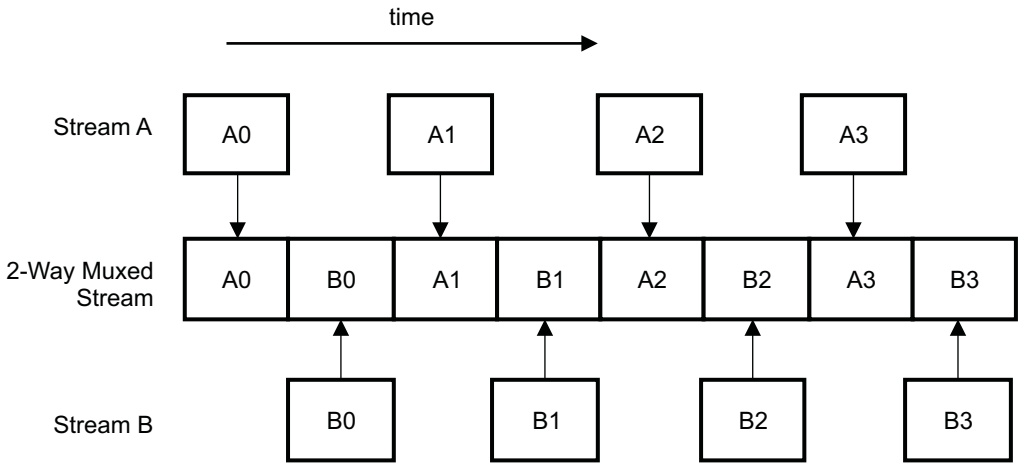
Some applications require multiple camera sources to be used at the same time. For example, video surveillance systems can record and display multiple camera sources. 16 camera sources are limited to be saved to DDR per pixel clock input domain.

2.11.2.6.1 2-Way Multiplexing

For 2-way multiplexing, two embedded sync streams are interleaved a pixel at a time as shown in Figure 2-10.

The sync codeword, FF-00-00-XY, is replicated in both source streams. In 2-way multiplexing, the sizes of both camera sources must be the same. Likewise, the vertical ancillary data size for both sources must be identical. However, the two streams are not necessarily sending the same pixel site in adjacent clock cycles.

Figure 2-10. 2-Way Multiplexing

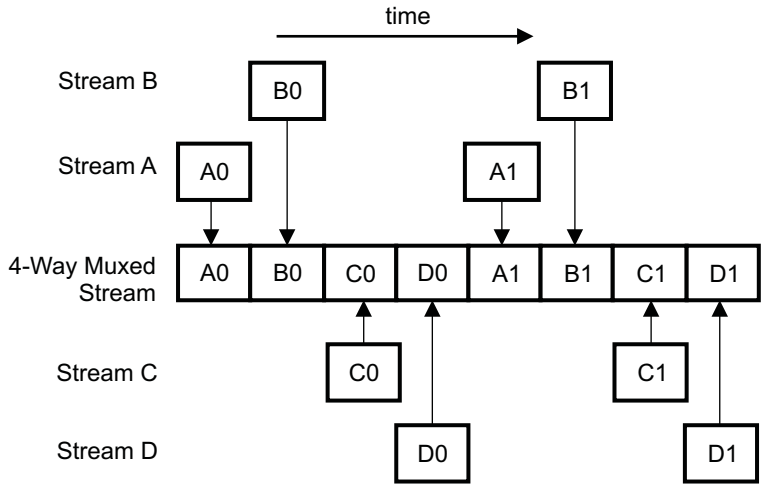


2.11.2.6.2 4-Way Multiplexing

For 4-way multiplexing, four embedded sync streams are multiplexed into one as shown in Figure 2-11.

The sync codeword is replicated in all four sources. Like 2-way multiplexing, the sizes of the four camera sources are the same and the sizes of the vertical ancillary data regions are the same. The four streams are not necessarily sending the same pixel site in adjacent clock cycles.

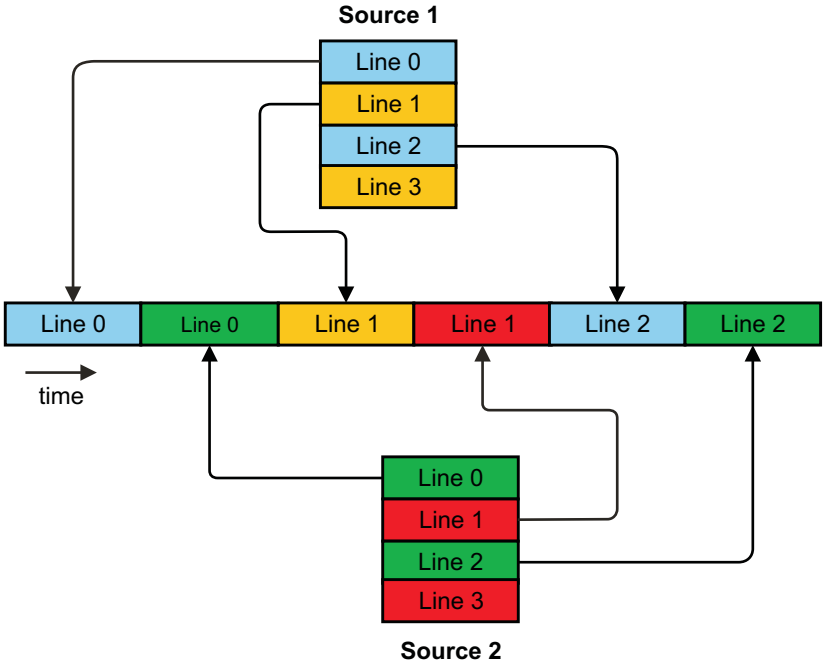
Figure 2-11. Example of 4-Way Multiplexing



2.11.2.6.3 Line Multiplexing

In line multiplexing, *n*-different sources are sent into the VIP a complete line at a time, using a modified version of embedded sync. An example of line multiplexing for two sources is shown in Figure 2-12.

Figure 2-12. Example of Line Multiplexing



2.11.2.7 Embedded Sync Mux Modes and Data Bus Widths

Valid combinations of embedded sync mux modes and data bus widths are listed in Table 2-7.

Table 2-7. Valid Embedded Sync Mux Mode and Data Bus Width Combinations

Data Bus Width	1× Mux	2× Mux	4× Mux	Line Mux
8 bit	Yes	Yes	Yes	Yes
16 bit	Yes	No	No	Yes
24 bit	Yes	No	No	No

2.12 Other Video Input Ports

2.12.1 Bypass Video Input Ports

2.12.1.1 Features

- Input: YUV422 YUYV Interleaved Non-Tiled memory

2.12.1.2 Functional Description

The HDVPSS has two independent bypass video input ports: bypass0 and bypass1. Both ports are used for the display purchase without any processing.

2.12.2 Secondary Video Input Ports

2.12.2.1 Features

- Input:
  - YUV420 Semi-Planar Tiled memory
  - YUV422 Semi-Planar Tiled memory
  - YUV420 Semi-Planar Non-Tiled memory
  - YUV422 Semi-Planar Non-Tiled memory
  - YUV422 YUYV interleaved Non-Tiled memory
- Output: YUV422 YUYV interleaved Non-Tiled memory (memory to memory operations)

2.12.2.2 Functional Description

The HDVPSS has two secondary video input ports: secondary0 and secondary1. Secondary0 is used for the memory-to-memory operations through scaler5. Secondary1 is used for SD display only through the SD_VENC.

Power Management

This chapter describes the power management in the device.

Topic **Page**

3.1 Introduction

Power management is an important aspect for most embedded applications. For several applications and target markets, there may be a specific power budget and requirements to minimize power consumption for both power supply sizing and thermal considerations. Additionally, lower power consumption results in more optimal and efficient designs from cost, design, and energy perspectives. This device has several means of managing the power consumption. This chapter discusses the various power management features.

Power consumed by semiconductor devices has two components: dynamic and static.

- Dynamic power is the power consumed to perform work when the device is in active modes (clocks applied, busses, and I/O switching), that is, analog circuits changing states. There are several features in design as well as user driven software control to reduce dynamic power consumption. The design features (not under user control) include a power optimized clock tree design to reduce overall clock tree power consumption and automatic clock gating in several modules when the logic in the modules is not active.
- Static power is essentially a function of the "leakage", or the power consumed by the logic when it is not switching or is not performing any work. Leakage current is dependent mostly on the manufacturing process used, the size of the die, and so on. Leakage current is unavoidable while power is applied and scales roughly with the operating junction temperatures. Leakage power can only be avoided by removing power completely from a device or power domain.

Refer to the *TMS320DM816x/TMS320C6A816x/AM389x Power Estimation Spreadsheet* (SPRABK3) for details on how to model power consumption for a specific user's application.

3.2 Power Management

The on-chip power, reset, and clock management (PRCM) module manages the switching on and off of the power supply to the device modules. To minimize device power consumption, the power to the modules can be switched off when they are not in use. Independent power control of sections of the device allow the PRCM module to turn on and off specific sections of the device without affecting the others. Software controlled module level clock gating reduces both clock tree and module power by basically disabling the clocks when the modules are not being used. Clock management also allows clocks to be slowed down to reduce the dynamic power.

Table 3-1 describes the static power management features.

3.2.1 Power Domains

A power domain is a section (that is, a group of modules) of the device with an independent and dedicated power manager. A power domain can be turned on and off without affecting the other parts of the device.

The AVS and 1V constant voltage domains have multiple power domains. All other voltage domains have only always-on power domain. Within the 1-V AVS and 1-V constant voltage domains, each power domain, except for the always-on domain, has an internal power switch that can isolate the power supply rail from that domain. At power-up, all domains, except always-on, come-up as power gated. Since there is an always-on power domain in each voltage domain, all power supplies are expected to be ON all the time (as long as the device is in use).

Refer to the Power Management section of the *Power, Reset, and Clock Management (PRCM) Module* chapter for the Power-Down and Power-Up Sequences.

Table 3-1. Static Power Management Features

Power Management	Description	Feature
	Clock Management	
PLL bypass and power-down	PLLs can be powered-down and run in bypass mode when not in use.	Saves power when PLL is in powered down mode.
Module clock ON	Module clocks can be turned on/off without requiring reconfiguring the registers.	When the module clock is turned OFF, this reduces the module's dynamic/switching power consumption down to zero.
	Memory Power Management	
Memory power management modes	The memory in each functional block is assigned to both a voltage domain and a power domain. The modes are ACTIVE and SHUT-DOWN.	In order to reduce SRAM leakage, many SRAM blocks can be switched from ACTIVE mode to SHUT-DOWN mode.
	System/Device Sleep Management	
Standby modes	All switchable power domains are in off state, the Cortex-A8 is in lowest frequency of operation executing in an idle process loop and all functional blocks not needed for a given application are clock gated.	
Deep sleep modes	The mode is enabled to further eliminate active power when memories are not being used.	
	Peripheral I/O Power Management	
Video DACs power down	Video DACs can be powered down.	Video DACs can be powered down; results in power save.
DDR2/DDR3 data and command macros	DDR data and command macros can be powered down to reduce power.	DDR data and command macros can be powered down; results in power save.
USB PHY power down	USB PHY can be powered down.	USB2.0 PHY can be powered down; results in power save.
HDMI PHY power down	HDMI PHY can be powered down.	HDMI PHY can be powered down; results in power save.
PCIe PHY low power	PCIe PHY low-power state	PCIe PHY is in low-power state when PCIe is disabled.
SATA PHY low power	SATA PHY low-power state	SATA PHY is in low-power state when SATA is disabled.

3.2.2 Memory Power Management

The device memories offer three different modes to save power when memories are not being used, see Table 3-2.

Table 3-2. Memory Power Management Modes

Mode	Power Saving	Wakeup Latency	Memory Contents
Light Sleep (LS)	~60%	Low	Preserved
Deep Sleep (DS)	~75%	Medium	Preserved
Shut Down (SD)	~95%	High	Lost

The device provides a feature that allows software to put the chip level memories (C674x L2, OCMC RAMs) in any of the three (LS, DS, or SD) modes. There are control registers in the Control Module to control the power down state of C674x L2, OCMC RAM0, and OCMC RAM1. There are also status registers that are used during power-up to check if memories are powered-up. Status registers are useful when coming out of SD and DS mode as the wakeup latency is significant. Wakeup latency associated with DS and SD mode are longer due to following reasons:

- In SD and DS modes, power to the memory periphery is cut-off and there will be ramp-up time required for the memory supply when memory is coming out of these modes.
- In SD mode, even the array power is cut-off and wakeup latency depends upon the ramp-up time required for the memory supply for array and periphery both.
- To avoid large current sink during memory power-up, hardware sequences the power-up of memory instances in such a way that all instances are not powered-up at the same time. This adds to the wake-up latency.

Memories inside switchable domains go to the SD state whenever the power domain goes to the OFF state. Memories come back to a functional state along with the domain power-up.

3.2.2.1 OCMC RAM Power Down Sequence

1. Software writes to module enable/disable register in PRCM to request disabling of OCMC RAM.
2. PRCM initiates IDLE protocol with OCMC RAM module.
3. OCMC RAM completes pending read/write transactions and enters in IDLE mode and gates-off all internal clocks.
4. OCMC RAM sends acknowledge back to PRCM.
5. Software writes to Control Module registers to put OCMC RAMs in one of the power down modes (LS, DS, or SD).

3.2.2.2 OCMC RAM Power Up Sequence

1. Software writes to Control Module registers to bring out OCMC RAM from the power down state.
2. Software writes to module enable/disable register in PRCM to bring OCMC RAM in functional mode.
3. PRCM de-asserts IDLE request and waits for the ack.
4. OCMC RAM un-gates its internal clocks and sends acknowledge to PRCM.

3.2.2.3 C674x L2 Power Down Sequence

Note that the C674x L2 is powered down only when Active domain is OFF. When Active domain is turned off, the C674x (including L1s) gets power gated automatically, but L2 is still powered. The sequence to power down the C674x L2 is:

1. Software writes to Control Module register to put L2 in one of the power down modes (LS, DS, or SD).

3.2.2.4 C674x L2 Power Up Sequence

The C674x L2 needs to be powered-up before Active domain is powered up. The sequence to power up the C674x L2 is:

1. Software writes to Control Module register to bring the C674x L2 out of power down state.
2. Software can then turn on Active domain.

3.2.3 Voltage Management

The ARM Cortex-A8 in conjunction with the SmartReflex™ sensors control the voltage scaling (that is, switching the voltage in discrete steps or in a continuum within a range of possible values) of the power sources of the device. This allows controlling the device power consumption according to the defined performance criteria.

3.2.3.1 Voltage Domains

A voltage domain is a section of the device supplied by a dedicated voltage source (that is, an internal LDO or external switch mode power supply [SMPS]). When a voltage domain is controlled by the PRCM module, a dedicated voltage manager is associated. The voltage manager allows regulation of the voltage level of the source for the voltage domain, independently of other voltage domains of the device.

3.2.3.2 SmartReflex Adaptive Voltage Scaling

SmartReflex™ power and performance technologies is a power-management technique for control of the operating voltage of a module to reduce both leakage and dynamic power consumption. With SmartReflex, power-supply voltage is dynamically adapted to silicon performance (based on the temperature-induced real-time performance of the device). A comparison of these predefined performance points to the real-time on-chip measured performance determines whether to raise or lower the power-supply voltage. SmartReflex achieves the optimal performance/power trade-off for all devices across the technology process spectrum and across temperature variations.

Adaptive Voltage Scaling (AVS) is a power-management technique based in SmartReflex that is used for automatic control of the operating voltages of the device to reduce active power consumption. Based on the silicon process and temperature, the SmartReflex modules guide software in adjusting the Core Logic Voltage Domain supply voltages within the voltage range. The Vmin to Vmax voltage range is split into equidistant steps (8, 16, or 32 are recommended). The advantage of using more steps is that it enables the system to more closely approach the optimum operating voltage and results in a flatter leakage power curve (see Figure 3-2 and Figure 3-3).

AVS achieves the optimal performance/power trade-off for all devices across the technology process spectrum and across temperature variation. The device voltage is automatically adapted to maintain performance of the device. This ensures optimal power consumption. AVS occurs continuously and in real time, helping to minimize power consumption in response to changing operating conditions. Not using AVS will result in a considerable increase in device power consumption and the voltage applied to the device may be too high for devices from the hot end of the process distribution which can lead to hold timing violations, and hence incorrect operation. Therefore, AVS is required for reliable operation.

TI recommends using a fault-tolerant power supply design to protect against over-current conditions. Refer to the *TMS320DM816x/TMS320C6A816x/AM389x Power Estimation Spreadsheet* (SPRABK3) for AVS Disable data to aid in design of robust power supplies that may withstand momentary AVS control failure.

Figure 3-1, Figure 3-2, and Figure 3-3 show examples of AVS power management as compared to a constant voltage system, and the resulting leakage power curves.

Figure 3-1. Constant Voltage

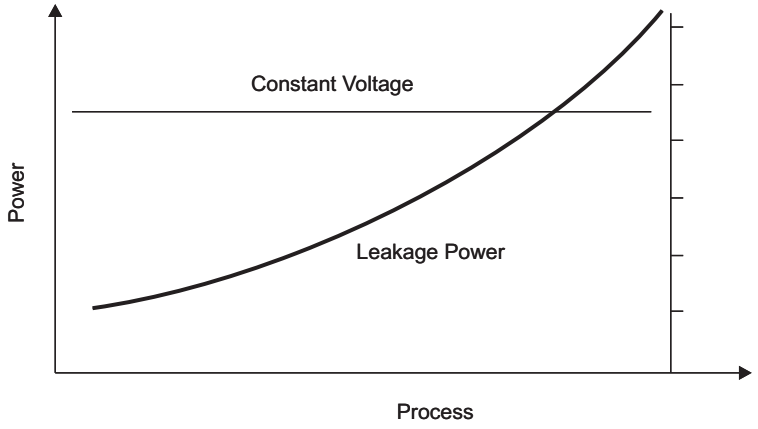


Figure 3-2. AVS Example – 8 Steps

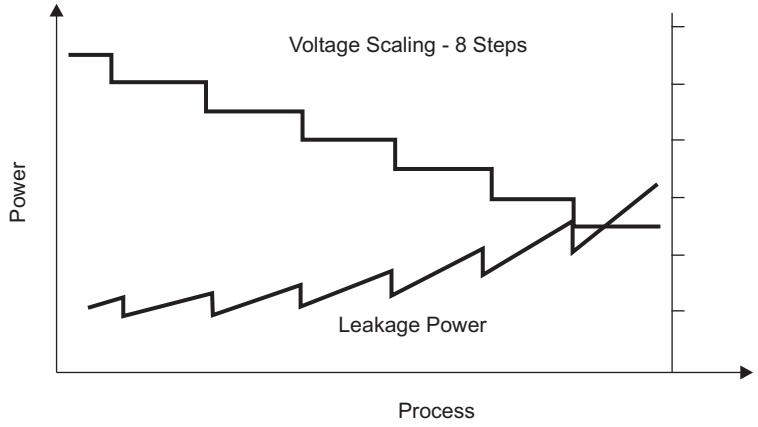

Figure 3-3. AVS Example – 32 Steps

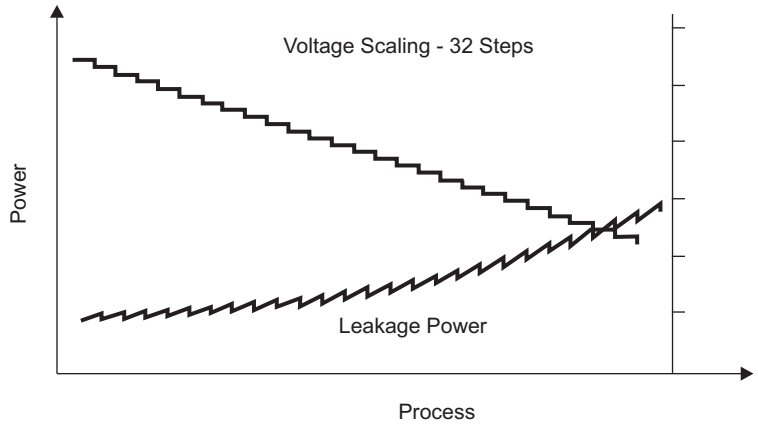


3.2.3.2.1 General SmartReflex Operation

The device supports a class of SmartReflex technologies that enables dynamic voltage adjustments by software. The SmartReflex module provides an interrupt to help the CPU adjust the supply voltage. The SmartReflex module also provides a parameter that can be sampled to know the magnitude and direction of the voltage adjustment required. When an interrupt reaches the CPU, software will service the interrupt and adjust the voltage supply accordingly.

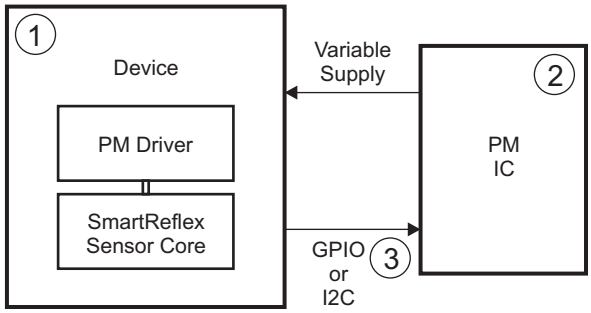
3.2.3.2.2 Device-Specific Software Driver Operation

Texas Instruments provides a SmartReflex driver to insure proper implementation of SmartReflex AVS closed-loop operation. The Power Management (PM) driver basically operates as a performance monitor where environmental changes may require adjustment of the voltage to maintain device performance. The SmartReflex module generates a system interrupt when a measured average performance parameter goes beyond programmed limits. The driver monitors this interrupt and then determines the appropriate corrective action - whether to raise or lower the AVS power supply level. The communication link between the host processor and the external regulators (Power Management IC or PMIC) is a system-level decision and can be accomplished using GPIOs or I2C. The major SmartReflex system components are shown in Figure 3-4 and the basic operation is:

1. The Device PM Driver responds to SmartReflex Sensor interrupts and adjusts power supply up or down via commands to the PMIC.
2. The PMIC is commanded to raise or lower the Device supply voltage. The PMIC driver responds to voltage adjustment commands by setting the PMIC output voltage to the voltage step nearest and above the level requested. The system designer decides how many voltage steps to use (8, 16, or 32 are recommended) and creates a table of voltages in the desired range that includes that number of voltage steps.
3. Communication between the Device and the PMIC is either via GPIO or I2C. The commands sent to the PMIC are continual, not just at startup. This allows compensation for temperature changes over time.

The Power Management driver uses basic API's to exchange information between the device and PMIC for voltage level changes. Refer to the Power Management Software Guide for details on using the Power Management driver.

Figure 3-4. SmartReflex System Block Diagram



3.2.4 Clock Management

3.2.4.1 Module Clock ON/OFF

The module clock on/off feature allows software to disable clocks to module individually, in order to reduce the module's dynamic/switching power consumption down to zero. This device is designed in full static CMOS; thus, when a module clock stops, the module's state is preserved and retained. When the clock is restarted, the module resumes operating from the stopping point.

NOTE: Stopping clocks to a module only affects dynamic power consumption, it does not affect static power consumption of the module or the device.

The power, reset, and clock management (PRCM) module controls module clock gating. If a module's clock(s) is stopped while being accessed, the access may not occur, and it can potentially result in unexpected behavior. The PRCM provides some protection against such erroneous conditions by monitoring the internal bus activity to ensure there are no accesses to the module from the internal bus, before allowing module's internal clock to be gated. However, it is still recommended that software must ensure that all of the transactions to the module are finished prior to disabling the clocks.

NOTE: To preserve the state of the module, the module state in the PRCM must be set to Disable.

In this state, the module reset is not asserted and only the module clock is turned off. Furthermore, special consideration must be given to clock on/off.

Additionally some peripherals implement additional power saving features by automatically shutting off the clock to components within the module, when the logic is not active. This is transparent to the user, but reduces overall dynamic power consumption when modules are not active.

3.2.4.2 Module Clock Frequency Scaling

This device supports static frequency scaling using dividers in the FA-PLL and in the PRCM. Divide ratios supported by these dividers are detailed in the Clocking section. Frequency change should be made when the corresponding clock domain is completely idle. Additionally, some modules might also have internal clock dividers. Reducing the clock frequency reduces the dynamic/switching power consumption, which scales linearly with frequency.

3.2.5 Standby Mode

The lowest power mode of the device is Standby Mode. In Standby Mode, all switchable power domains are in an off state, the Cortex-A8 is in the lowest frequency of operation executing in an idle process loop and all functional blocks not needed for a given application are clock gated.

Exit from standby is performed by Cortex-A8 polling, loop count time out, or responding to an interrupt from a peripheral. The clock must be maintained to those peripherals that generate the interrupt.

3.2.6 Additional Peripheral Power Management Considerations

This section lists additional power management features and considerations that might be part of other chip-level or peripheral logic, apart from the features supported by the core, PLL controller (PLLC), and power, reset, and clock management (PRCM) module.

3.2.6.1 USB PHY Power Down Control

The USB modules can be clock gated using the PRCM; however, this does not power down/clock gate the PHY logic. You can put the USB PHY in the lowest power state, when not in use, by writing to the PWRDN bits in the USB control register (USB_CTRLx) of the Device Configuration Registers.

3.2.6.2 HDMI PHY Power Down Control

The HDMI PHY supports a standby power mode that yields significant power reduction during periods in which the PHY is not used. In applications in which the HDMI is not used at all, the power supply to the HDMI PHY must be connected to 1.0V source.

3.2.6.3 Video DACs Power Down Control

In applications in which the Video DACs are not used at all, the power supply to the Video DACs can be powered down by configuring the HD_DAC_CTRL and SD_DAC_CTRL registers of the Device Configuration Registers.

3.2.6.4 DDR2/DDR3 Memory Controller Clock Gating

The DDR2/DDR3 memory controller supports different methods for reducing its power consumption including clock gating.

Additionally, the DDR2/DDR3 memory controller DLL, PHY, and the receivers at the I/O pins can be disabled.

For details of power management in the DDR2/DDR3 memory controller, see the *DDR2/DDR3 Memory Controller* chapter.

3.2.6.5 Floating Input Pins

In general, you should ensure that all input pins are always pulled to a logic-high or a logic-low voltage level.

A floating input pin can consume a small amount of I/O leakage current. The I/O leakage current can be greatly multiplied in the case of several floating inputs pins. This device includes internal pull-up and pull-down resistors that prevent floating input pins. For unused input pins, the internal pull resistor should be enabled, or an external pull resistor should be used, to prevent floating inputs. For more details, refer to the data manual sections on Pin Multiplexing Control and How to Handle Unused Pins.

3.2.6.6 PCIe PHY Power Down Control

If the PCIe module has not been enabled, the SERDES/PHY will be kept in a low-power state.

3.2.6.7 SATA PHY Power Down Control

If the SATA module has not been enabled, the SERDES/PHY will be kept in a low-power state.

DMM/TILER

This chapter describes the Dynamic Memory Manager (DMM) and its Tiling and Isometric Lightweight Engine for Rotation (TILER) submodule.

Topic **Page**

4.1 Introduction

4.1.1 Overview

This section describes the Dynamic Memory Manager (DMM) and its Tiling and Isometric Lightweight Engine for Rotation (TILER) submodule.

As shown in Figure 4-1, the DMM is located in front to the SDRAM controllers and thus interfaces to the memory accesses generated by all the initiators.

The dynamic memory manager (DMM), is a module aimed at managing – in a broad sense – various aspects of memory accesses such as:

- Initiator-indexed priority generation
- Multizone SDRAM memory interleaving configuration
- Block object transfer optimization – tiling and sub-tiling
- Centralized low-latency page translation – MMU-like feature

The dynamic qualifier for memory management highlights the software configurability – and, hence, the run-time nature – of the four aspects of memory management handled by the DMM.

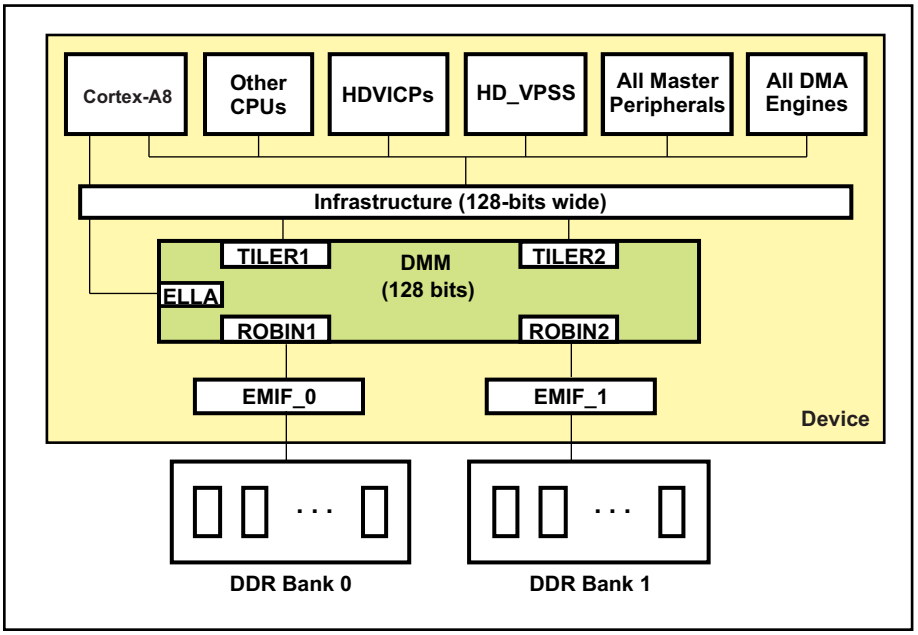
On a functional perspective, the role of the DMM is to:

- add initiator-based priority to any incoming requests
- perform to-and-fro tiling conversions of "tiled" requests
- provide an optional low-latency page-based translation to handle memory fragmentation - MMU
- distribute the traffic on both the attached memory controllers according to the interleaving configuration

The TILER is a submodule within the DMM aimed at efficient handling of two dimensional data, such as video/graphics accesses for HDVICP2, by the use of tiled format.

- optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation
- making on-the-fly, zero overhead transforms, such as 90°, 180°, or 270° rotations, with either a horizontal or vertical reflection

Figure 4-1. DMM Integration



4.1.2 Features

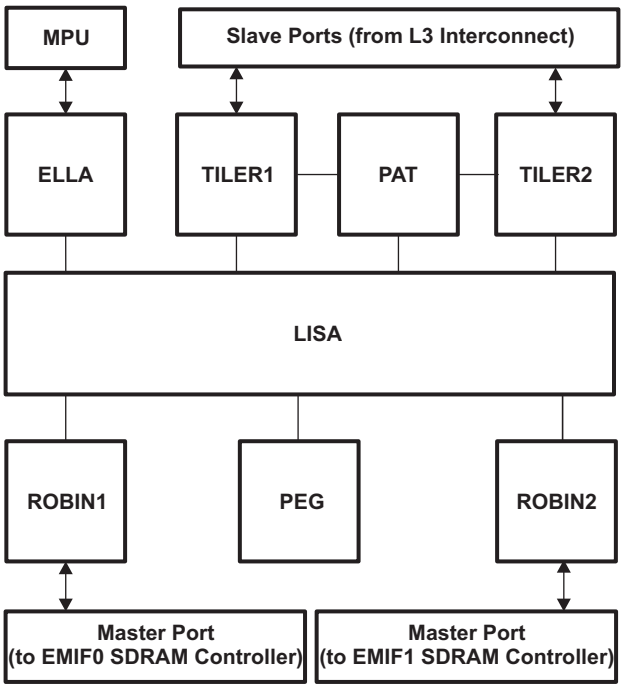
- Special low latency interconnect port. ELLA, only for Cortex-A8 accesses.
- Ability to interleave the DDR data between two EMIF banks, using the programmable multi-zone DRAM memory mapping . This increases the memory throughput by a factor of 2. Up-to four unique memory sections supported.
- Programmable Initiator based request priority extension, for up to 16 Initiator groups.
- Support for address translations of tiled data, on a 4KB page granularity using the PAT. This helps manage memory fragmentation.
- Two internal address lookup tables (LUT), each with 256x128 entries. Four refill engines to program the LUTs, with automatic synchronized reload.
- Supports up to 4 unique PAT views.

4.1.3 Functional Block Diagram

Figure 4-2 shows the DMM macro architecture. The DMM consists of six blocks:

- A Priority Extension Generator (PEG) to generate priorities required by the SDRAM controller, note that these priorities are not used in the DMM
- One Extra Low Latency Access (ELLA), having its own interconnect slave port, for providing lower latency accesses to the memory
- A Local Interconnect and Synchronization Agent (LISA) to synchronize all DMM subsystems and provide access to their configuration registers
- A Physical Address Translator (PAT) for managing the memory fragmentation
- Two Re-Ordering Buffer and Initiator Nodes (ROBIN), having each their own interconnect master port, to initiate requests to the SDRAM controller and allow tiled data, tiled response and split response reconstruction. The ROBIN block is only managing the re-ordering buffer and performing the data re-ordering due to the orientation.
- Two Tiling and Isometric Lightweight Engine for Rotation (TILER), having each their own interconnect slave port, for converting requests to-and-fro between the input virtual addressing mode and the output physical tiled addressing mode. Note that, the tiling conversions of requests, write data and responses is fully performed in the TILER blocks.

Figure 4-2. DMM Block Diagram



4.1.4 Terminologies and Acronyms Used in this Document

The following is a brief explanation of some terms used in this document:

bpp— Bits per pixel

DMM— Dynamic Memory Manager

ELLA— Extra Low Latency Access

GB, GiB— Both imply Giga Byte

Initiator— A node inside the Device and is either a CPU, peripheral or DMA engine, which can be internal bus Master. Each initiator is identified by a ConnID (Connection ID). With a limit of only 16 ConnIDs, some of the Initiators are grouped together with same ConnID.

Interlaced— Qualifier for accesses skipping one line every line

IVA— Image Video Accelerator. Also called HDVICP2, IVA_HD.

LISA— Local Interconnect and Synchronisation Agent

KB, KiB— Both imply Kilo Byte

LUT— Look Up Table

MMU— Memory Management Unit

MPU— Main Processing Unit. For this device, it is Cortex-A8

PAT— Physical Address Translator

PEG— Priority Extension Generator

Progressive— Qualifier for line-by-line accesses

ROBIN— Re-Ordering Buffer and Initiator Node

Tiled access— 1D or 2D Access to the tiled area, where the image data is read and written in two dimensional format, to improve the efficiency of accesses of 2D accesses, example image macro block. TILER Tiling and Isometric Lightweight Engine for Rotation 1D access A simple linear read or write access request. The DMM responds with read/write from/to the contiguous memory starting with address specified in the request.

2D access— HDVICP2 and HD_VPSS, can generate a special access to 2D image buffers, with read/write request, with Height and Width information. The DMM-TILER decodes the access type based on the Height, width and address, and responds with read/write from/to data in the physical memory, which has been co-located, with sub-tile granularity.

4.2 Architecture

4.2.1 DMM Functional Description

4.2.1.1 Priority Extension Generator (PEG)

The priority extension generator (PEG) is a dynamic software-programmable initiator-indexed table of priorities. Its unique role is to generates priorities for each access forwarded by the DMM to the SDRAM controller. For initiators that do not generate their own per-transaction priority, the priority value that is programmed in the table, will be assigned to all SDRAM accesses generated by that initiator. These priorities are not used by the DMM, for internal arbitrations.

The 16 priority entries are software-programmable with DMM_PEG_PRIO0 (for the first eight entries of the ConnID table) and DMM_PEG_PRIO1 (for the last eight entries) registers and set on a 3-bit scale, ranging from values 0-7, with Priority=0, being the highest priority.

When a request is passed to the SDRAM controller, the priority from the corresponding DMM_PEG_PRIOx field for an initiator is passed to SDRAM. For example, an access from the C674x DSP is sent to SDRAM with the priority captured in DMM_PEG_PRIOn. Note that the priority does not impact the behavior in DMM itself. It is passed to the SDRAM controller and the controller may use it in the prioritization of requests. However, for HD_VPSS, the peripheral itself generates a priority. The DMM_PEG_PRIOx field for HD_VPSS is bypassed and the priority indicated by HD_VPSS access is sent to SDRAM controller.

4.2.1.2 ELLA

The Extra Low Latency Access (ELLA) of the DMM is a simple interface port for all accesses made by Cortex-A8. As the name suggests, this interface is simplified to reduce latency to the request from Cortex-A8. In this respect, the ELLA block:

- Is limited to 1D bursts only
- Is not capable of performing tiling conversions
- Does not interact with the PAT block

The ELLA block main role is to split incoming requests at DMM atomic unit boundaries to ensure that requests sent to the SDRAM controller fit in a single SDRAM page. More precisely, the ELLA block is responsible for:

- Allocating an internal response context to timely generate the appropriate responses
- Splitting the incoming requests at DMM atomic section boundaries
- Requesting internal buffer allocation in the appropriate ROBIN
- In case of a write request, allocating and updating an internal write context to subsequently direct the incoming write data into the relevant re-ordering buffer

NOTE: In the device, Cortex-A8 accesses in the system address space of 8000 0000h-FFFF FFFFh, are only routed through ELLA port. Accesses made by Cortex-A8, in the all four tiled modes, including Paged mode, will be routed through the TILER ports, thus not getting benefit of lower latency of the ELLA port.

ELLA sub-module is not software configurable.

4.2.1.3 LISA

The Local Interconnect and Synchronisation Agent (LISA) is a hardware interconnect module, aimed at setting priorities, managing tags and memory mapping. LISA maps the system addresses on the incoming DMM requests to the SDRAM addresses, as per the LISA sections programming.

LISA interconnect routes:

1. ELLA and TILER requests on the ROBIN initiator nodes.
2. ELLA and TILER write data on the ROBIN write buffers.

3. ROBIN read data to the relevant TILER initiators or to ELLA initiator.

The LISA block registers are DMM_LISA_MAP_i (i = 0 to 3) and DMM_LISA_LOCK.

LISA block manages all the incoming requests to ELLA, TILER and PAT and translates then to requests to Registers and ROBIN ports. Highest priority is given to accesses coming to the low-latency port (ELLA). When both DMM-ROBIN ports are in use, LISA module interleaves the two ports at a programmable boundary from 128 Bytes or more, as programmed in the DMM_LISA_MAPn registers. See sub-section on Section Mapping for details about LISA sections programming.

4.2.1.3.1 LISA LOCK

The DMM_LISA_LOCK register is used to lock the configuration once set. If written to one, the LOCK bit prevents further writes to all DMM_LISA_MAP_i registers. The LOCK itself cannot be written back to 0. A reset is required to re-program the sections.

It is expected that LISA MAP is set up once during system configuration and not changed subsequently. The LOCK feature helps accomplish this and is expected to be set once the configuration is done.

4.2.1.4 PAT, Physical Address Translator Engine

The physical address translation engine (PAT) of the DMM is composed of two 32-k entry physical address translation vector table and a set of four refill engines. The refill engine is a specialized DMA aimed at refilling the content of the physical address translation table.

The address translation mechanism is only available when the incoming request is hitting a page mode or tiled mode container, that is, when the incoming address is targeting the TILER or its aliased view in the system addressing space. Otherwise the physical address translation logic is bypassed so that the resulting physical address corresponds to the input address.

The PAT is supporting multiple address translation schemes, called views, which can be bound to one or more initiator through a view mapping mechanism.

The usage of the Refill Engines is described in detail in the later section.

4.2.1.4.1 PAT Views

A PAT view defines the kind of physical address translation to perform for each tiled mode accesses (page, 8-bit, 16-bit and 32-bit). Each mode of each PAT view can be configured to either use PAT Direct Access Translation or PAT In-Direct Access Translation.

The PAT supports up to four unique Views, using the DMM_PAT_VIEW_MAP[0..3] Registers.

4.2.1.4.2 PAT View Mappings

The 16 groups of initiators of the Device, each identified by their ConnID, share a set of 4 PAT views. The connection from an initiator to a PAT view is made through the DMM_PAT_VIEW register. The register DMM_PAT_VIEW0 is used for the first eight initiator groups and DMM_PAT_VIEW1 for the second eight. Thus each initiator can choose one of the four configurable PAT views in the system.

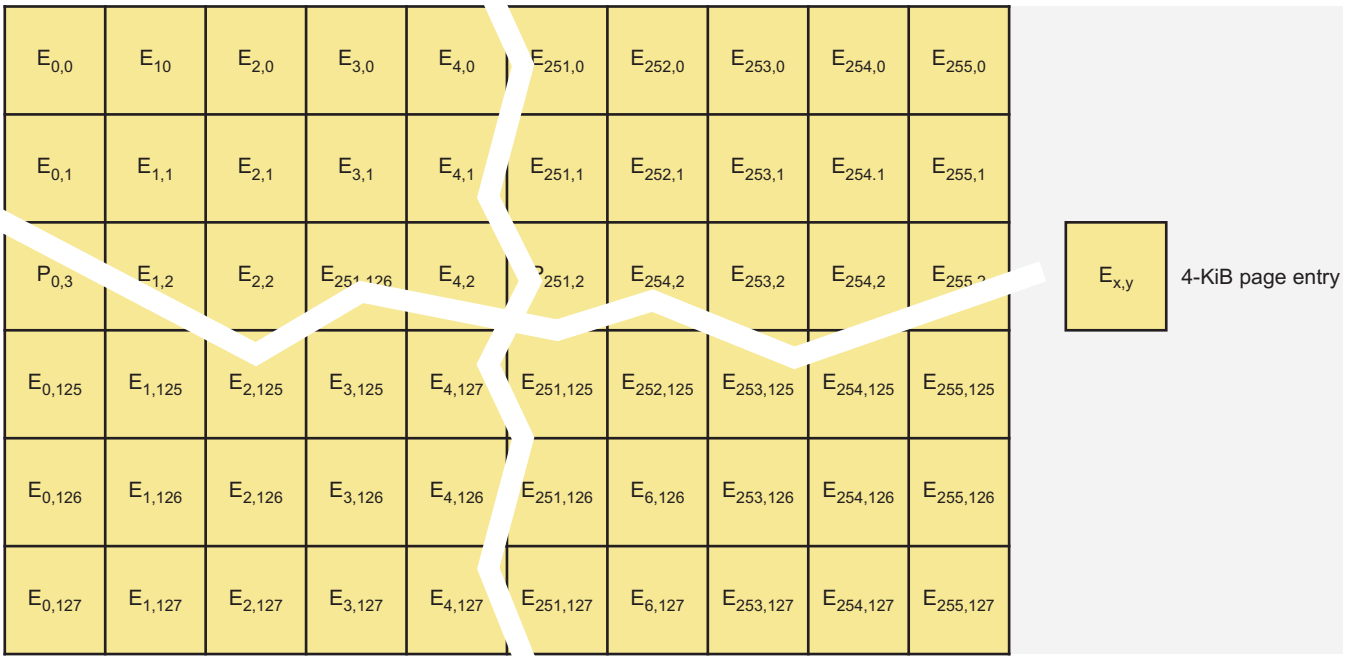
4.2.1.4.3 PAT View Map Base Address

The PAT view map base address is defining the base address of all PAT translated addresses. The bit 31 of all PAT translated address is set to BASE_ADDR. In the Device, the bit 31 should be set to 1, which corresponds top 2GB assigned for external SDRAM in the system memory map. Hence the addresses translated by PAT range in addresses 8000 0000h-FFFF FFFFh.

4.2.1.4.4 PAT - Look Up Tables (LUTs)

The PAT contains two LUTs, each of has 32K (256 × 128) entries. This geometry corresponds to that of the Virtual TILER container. So incoming address maps the actual entry in the LUT. The PAT shall then translate to a physical memory mapped to any 4K page the DDR. Each entry of the PAT address corresponds to the page in the DMM container that has the same location. For example - The entry (74, 42) in the table corresponds to the page (74, 42) in any DMM container.

Figure 4-3. DMM Look-Up Table



Each of this entry points to a 4K page in the memory. Hence a total of 128 MB of tiled memory can be mapped using one LUT. With upto 2G of DDR space, supported in the Device, each LUT entry is 19 bits wide.

The PAT uses the LUTs only in case of PAT In-Direct Access Translation.

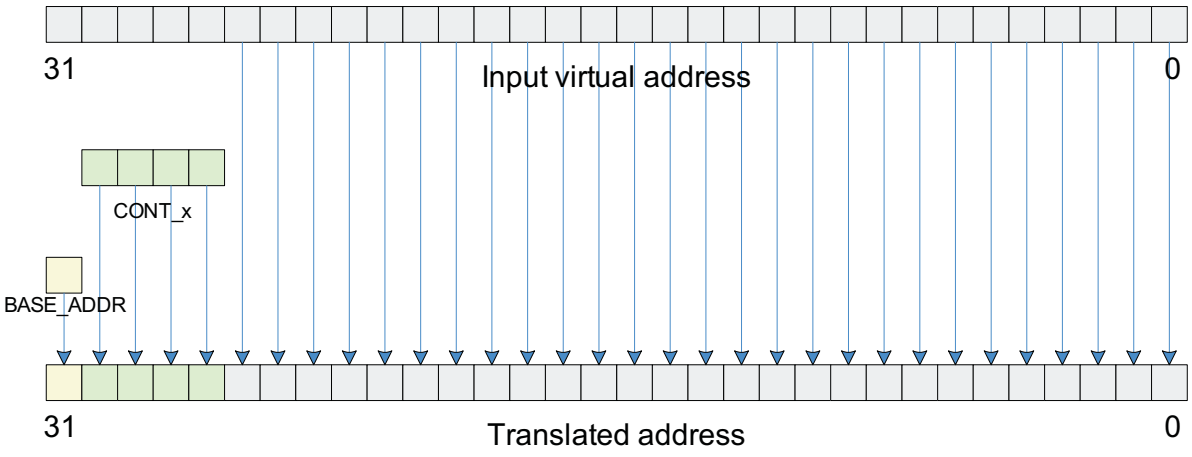
4.2.1.4.5 PAT Direct Access Translation

The container-grained translation is named the direct access. In this mode, the translation vector is directly given by the CONT_x field, in DMM_PAT_VIEW_MAP register, corresponding to the accessed mode(8-bit/16-bit/32-bit/paged mode).

With PAT Direct Access translation, the 128 MB virtual containers for all the four modes, 8-bit, 16-bit, 32-bit, and paged modes can be mapped to their unique System Address, by defining their base addresses.

Figure 4-4 describes the actual translation that happens.

Figure 4-4. DMM PAT Direct Access Translation

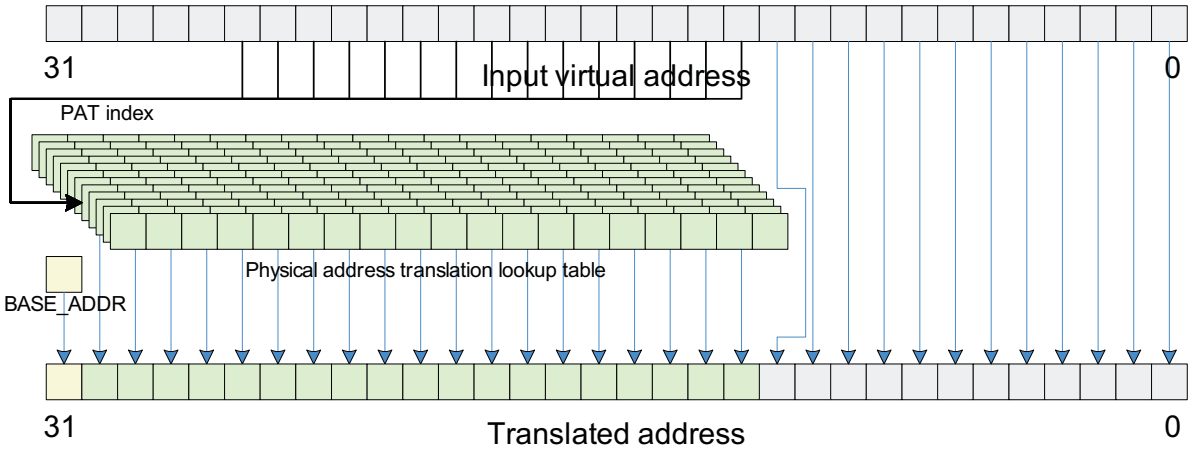


4.2.1.4.6 PAT In-Direct Access Translation - Paged Mode Access

DMM_PAT_VIEW[0..3] specify, whether to do Direct or In-direct access translation. Per each of the 8-bit,16-bit ,32-bit and paged container mode, user specifies which LUT to use for address lookup, by using CONT_x field, in DMM_PAT_VIEW_MAP registers. Then bits [19:12] of input address specify the X co-ordinate and bits [26:20] of input address specify the Y co-ordinate LUT entry. The PAT replaces bits[30:12] of input address, with 19-bit value specified in LUT entry.

This translation happens on the 4K page boundary and hence the lower 12 bits are not translated. Figure 4-5 describes the actual translation that happens.

Figure 4-5. DMM PAT In-Direct Access Translation



4.2.1.4.7 PAT In-Direct Access Translation - 8-bit, 16-bit, 32-bit Mode Access

DMM_PAT_VIEW[0..3] specify, whether to do Direct or In-direct access translation. Per each of the 8-bit,16-bit ,32-bit and paged container mode, user specifies which LUT to use for address lookup, by using CONT_x field, in DMM_PAT_VIEW_MAP registers.

How the 26 LSBs of this incoming virtual address is interpreted by the PAT is different for 8-bit,16-bit ,32-bit mode accesses, as compared to the paged mode access described in the preceding section. Please refer the TILER section describes the rationale behind decoding the address this way.

Virtual address decoding in 8-bit mode access mode is:

- Bits 0:5 - 6 bits offset into the horizontal line of the page
- Bits 6:13 - 8 bits, that select horizontal page in the tiler container as well as the X co-ordinate of the LUT table
- Bits 14:19 - 6 bits offset to select the line inside the page
- Bits 20:26 - 7 bits, that select vertical page in the tiler container and also Y co-ordinate of the LUT table
- Bits 27:31 - In 8 bit mode, their value is binary (01100), that is address in range 6000 0000h-67FF FFFFh

Virtual address decoding in 16-bit mode access mode is:

- Bit 0 - is always 0, as accesses are at-least 16-bit aligned
- Bits 1:6 - 6 bits offset into the horizontal line of the page
- Bits 7:14 - 8 bits, that select horizontal page in the tiler container as well as the X co-ordinate of the LUT table
- Bits 15:19 - 5 bits offset to select the line inside the page
- Bits 20:26 - 7 bits, that select vertical page in the tiler container and also Y co-ordinate of the LUT table

- Bits 27:31 - In 16 bit mode, their value is binary (01101), that is address in range 6800 0000h-6FFF FFFFh

Virtual address decoding in 32-bit mode access mode is:

- Bit 0,1 - are always 0, as accesses are at-least 32-bit aligned
- Bits 2:6 - 5 bits offset into the horizontal line of the page
- Bits 7:14 - 8 bits, that select horizontal page in the tiler container as well as the X co-ordinate of the LUT table
- Bits 15:19 - 5 bits offset to select the line inside the page
- Bits 20:26 - 7 bits, that select vertical page in the tiler container and also Y co-ordinate of the LUT table
- Bits 27:31 - In 32 bit mode, their value is binary (01110), that is address in range 7000 0000h-77FF FFFFh

4.2.1.5 ROBIN

The re-ordering buffer and initiator node (ROBIN) is a block aimed at providing some working buffering for converting data and responses to-and-fro between raster and tiled organizations and a master port to connect to the SDRAM controller.

The ROBIN block does:

- Request Forwarding
- Buffering of Write access data and buffering of Read access Response data
- Keeps write data ordering
- Intra-word tiling and orientation transforms
- Tag handling

NOTE: Both ROBIN sub-modules are not software configurable.

4.2.1.6 Section Mapping

In the device, DMM supports two unique SDRAM controllers, with a software configurable option to interleave data between both banks, at granularity of 128 Bytes, 256 Bytes and 512 Bytes. When accessing tiled data in 8-bit, 16-bit and 32-bit modes, which in the interleaved section of the memory, the interleaving will happen at the tile boundary of 1KB, over-riding the interleaving definition of the section.

For optimal system performance, it is recommended to enable interleaving between the 2 EMIF banks and thus have same sized memory on both the EMIF banks. Example : 512MB of DDR3 on EMIF bank 0 and 512MB of DDR3 on EMIF bank 1, for a total system DDR3 memory of 1GB.

NOTE: This interleaving is supported only if DDRs system connected to both the SDRAM controllers have same electrical characteristics.

If for cost reduction, one chooses to build a system with asymmetrical memory on both EMIF banks, then a few limited configurations can be supported by using the LISA section programming feature of DMM.

The address mapping inside the DMM is configurable through up to four sections. Each section is defined based on:

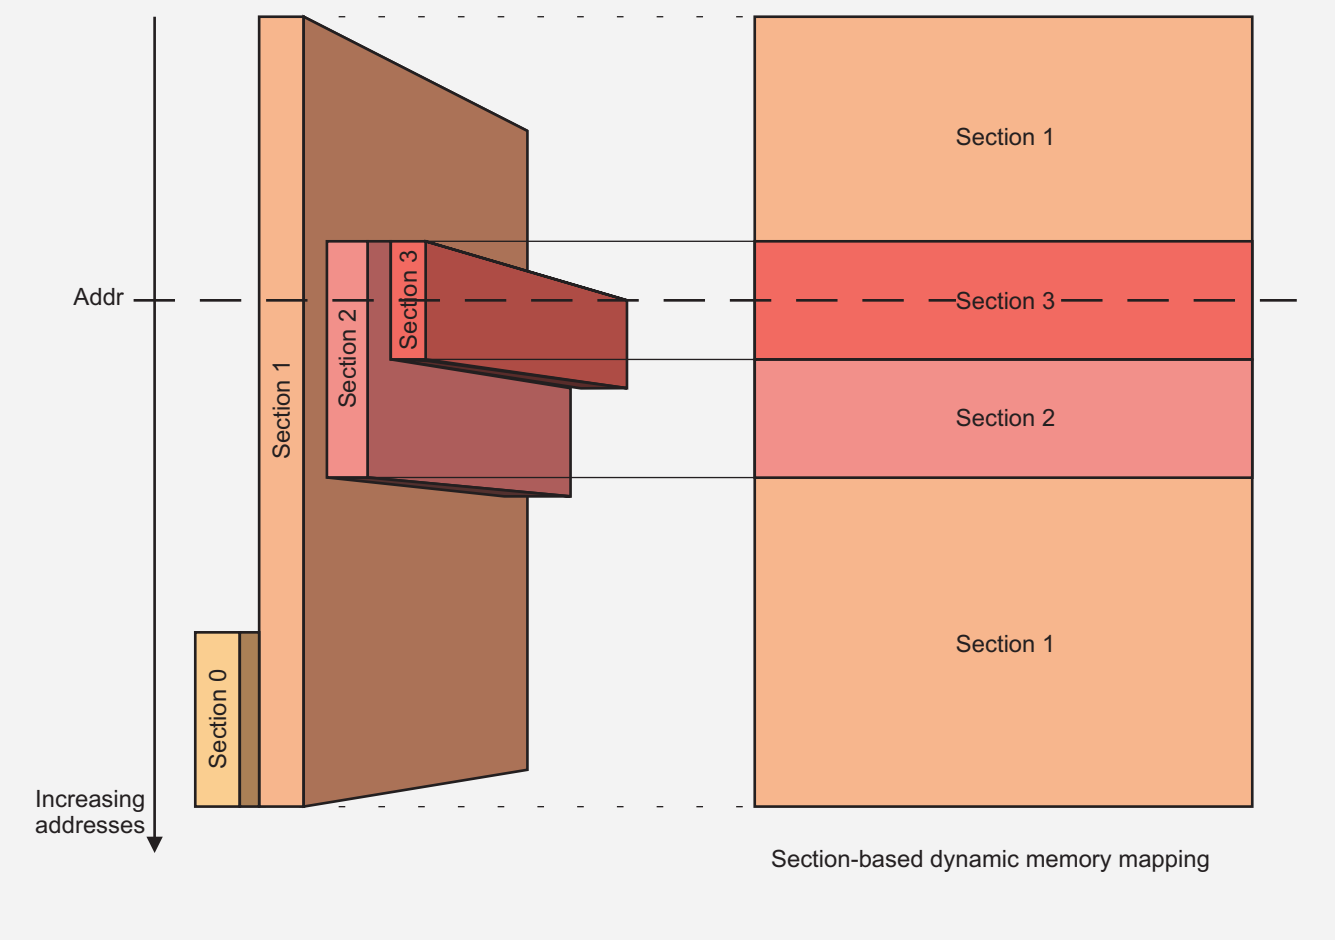
- Its system address: the base address of the decoding range for the section. This is the address of the incoming access to the DMM, also referred to as System Address.
- Its size: the encoding is the number of bits actually used in the upper 8-bits of the incoming system address. Hence the size of the section can be a value 16MB-2GB and power of 2. With interleaving enabled, the minimum size of the section is 32 MB.
- Its physical address: the base address of the memory range access in the external memory controller. It is also referred to as SDRC address.

- The target memory controller: A section may hit either of EMIF banks or both.
- Its interleaving definition : Interleave at 128Bytes, 256 Bytes, 512 Bytes or no interleaving.

A LISA section is:

- a memory segment of size 16MB – 2GB, which is a power of two and aligned to that size in the system map. If the section is configured to interleave data between 2 EMIF, then the minimum section size is 32 MB.
- An area with constant interleaving scheme, with fixed interleaving granularity. Interleaving between 2 EMIF banks can be also disabled, for this section.
- If two sections overlap, then the property of higher section number will be applied, as shown in Figure 4-6. There can be a total of 4 unique section definition in DMM.

Figure 4-6. DMM Section and Memory Mapping



In Figure 4-6, a request at the system address Addr will follow the interleaving scheme of section 3, although hitting sections 1, 2 and 3. Similarly, this DMM configuration also prevents any request to use the interleaving scheme of section 0, since section 0 is fully masked by section 1 – which has a higher priority.

The DMM section specifies the range of incoming (to DMM) System address (granularity of 16 MB) and how it maps to the physical SDRC address of EMIF0 and/or EMIF 1, with similarly aligned granularity.

The interleaving of data between two EMIF banks is transparent to all the initiators of the system and will not require special address conversions. Figure 4-7 and Figure 4-8 give examples of all the interleaving schemes.

Figure 4-7. 128B and 256B Interleaving

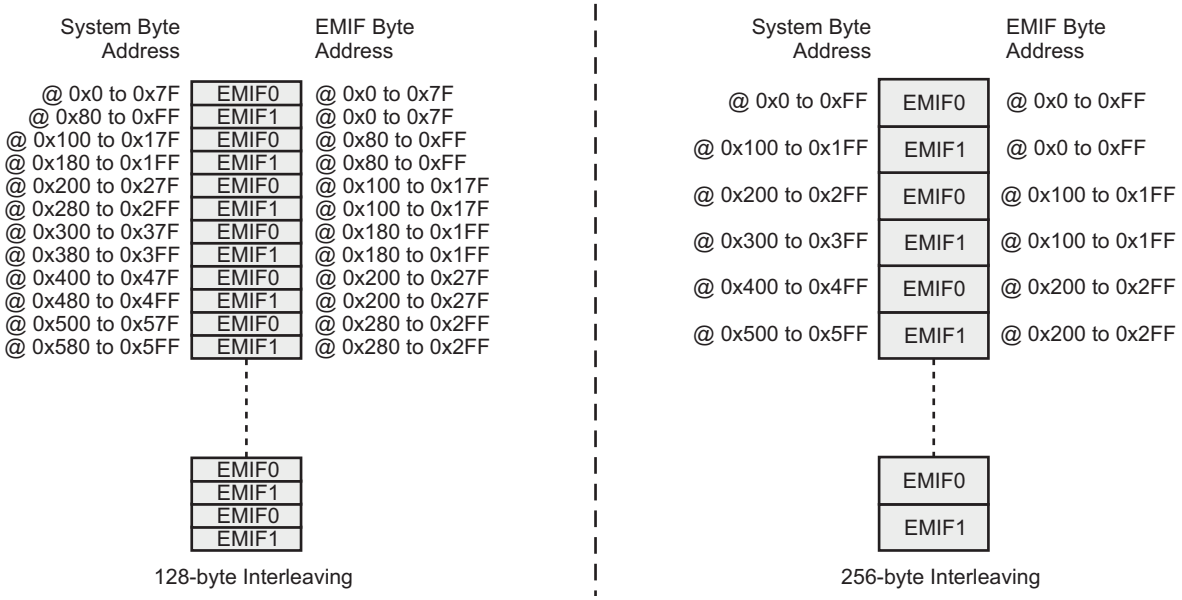


Figure 4-8. 512KB and 1KB Interleaving

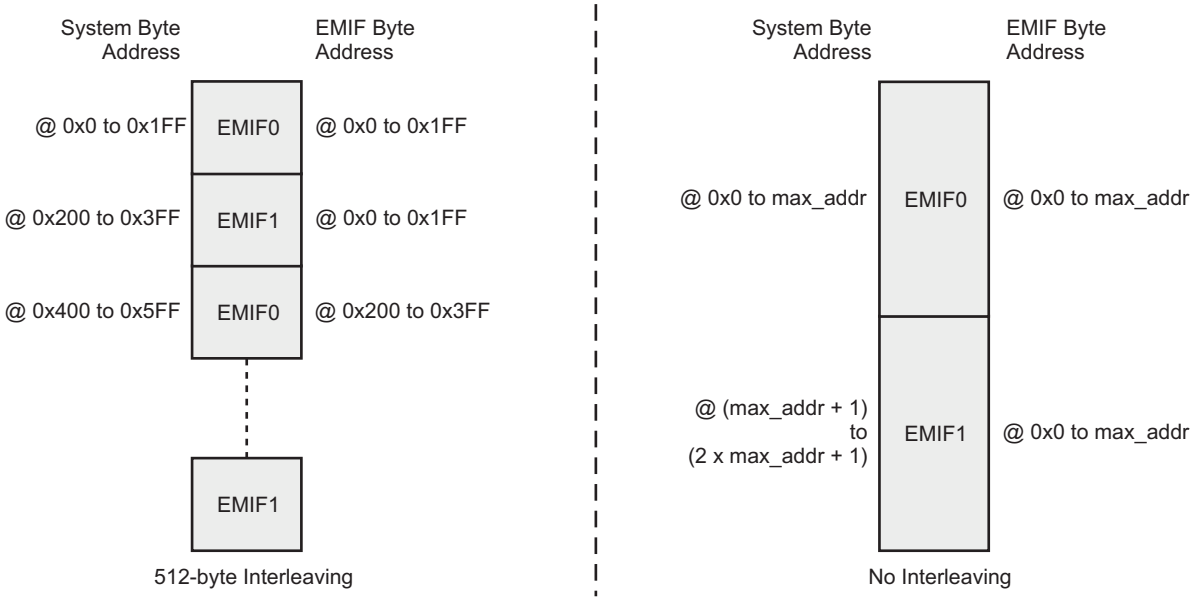


4.2.1.7 TILER

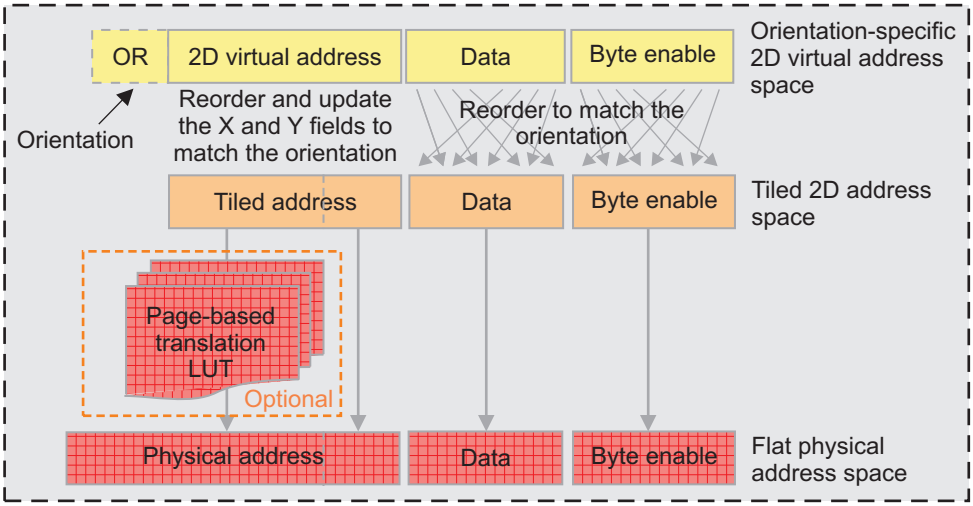
As can be seen in Figure 4-2, the two TILER ports interface to the incoming accesses to DMM. Its primary function is increase efficiency of a 2D Tiled Block access. Mentioned below are the main functions of the TILER module:

1. primary handling efficiently 2 dimensional data mapped in tiles, such as video or graphics macro blocks.
2. optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation, on 4KB page granularity.
3. making isometric – distance preserving – transforms, such as 90°, 180°, or 270° rotations, with either a horizontal or vertical reflection, with no overhead.

Written differently, the functionality of this TILER module is to map a 2D virtually-addressed incoming request into one or more physically-addressed SDRAM requests by:

1. Decoding the incoming access address to qualify whether the request targets the TILER or the memory directly.
2. If the incoming access is a TILER-specific requests, then transforming to the virtual address, data and byte enable to match the requested 0°, 90°, 180°, or 270° orientation in a tiled 2D addressing space.
3. optionally translating the oriented tiled address by a page-specific vector to manage memory fragmentation and physical object aliasing, as shown in Figure 4-9.
4. Splitting tiled requests at tile boundaries and non-tiled requests at DMM atomic section boundaries
5. Requesting the page-based address translation
6. Requesting buffer allocation in the appropriate ROBIN.
7. In case of a write request, allocating and updating an internal write context to subsequently direct the incoming write data into the relevant re-ordering buffer.

Figure 4-9. Overview of Request Conversion

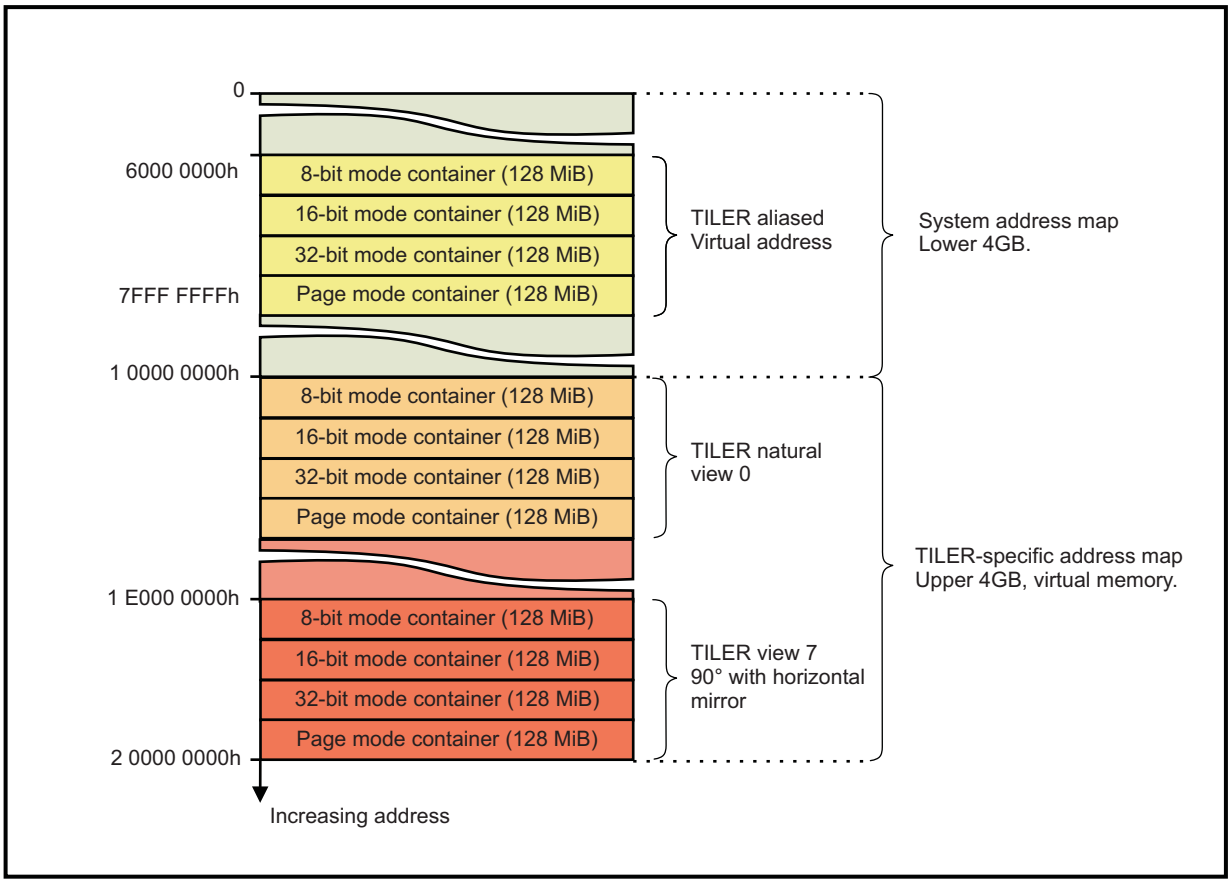


4.2.1.7.1 Device Memory Map - For Tiled Data

In the Device, the initiators read and write tiled data by generating accesses to the tiled space by the one of the two methods:

1. For all initiators except, HD_VPSS, the tiled space is accessed in the 512 MB address range of (6000 0000h to 7FFF FFFFh). These initiators use the access the any of 8 views by using the respective DMM_TILER_OR0 or DMM_TILER_OR1 registers.
2. For HD_VPSS, the TILER module supports its own 4-GB virtual addressing space, from address (1 0000 0000h to 1 FFFF FFFFh), and allows any of the eight 512-MB oriented sub-spaces – or views – to be remapped in the system virtual addressing space.

Figure 4-10. Memory Map



NOTE: Despite the larger virtual address windows, 512 MB in the system memory map and 4GB in the TILER memory map, the maximum size of physical tiled data is only 128MB. This 128MB is co-located in a 128MB aligned space, if using PAT direct access translation. In case of using the optional PAT Indirect access translation, then this 128MB is mapped to any location in the SDRAM, using the LUT tables, at the granularity of 4KB page.

4.2.1.8 Clock

The DMM is a synchronous design and operates from the same clock as the internal L3 interconnect. All timings use this clock as a reference.

4.2.1.9 Interrupts

DMM module generates interrupt to Cortex-A8, for status and error conditions related to PAT refills engines. There 8 different conditions which can be individually enabled or disabled. With 4 Refill engines, there are total 32 unique sources of interrupts.

Refer to Section 4.3.3 for detailed description on using the PAT refill engines.

Per Refill engine, status and error conditions are mentioned below:

1. FILL_DSCn: Refill of any descriptor, for engine n, complete.
2. FILL_LSTn: Refill of the last descriptor, for engine n, complete.
3. ERR_INV_DSCn: Invalid descriptor pointer, for engine n.
4. ERR_INV_DATAn: Invalid data table pointer, for engine n.
5. ERR_UPD_AREAn: Error caused by area register update while refilling, for engine n.
6. ERR_UPD_CTRLn: Error caused by control register update while refilling, for engine n.
7. ERR_UPD_DATAn: Error caused by data register update while refilling, for engine n.
8. ERR_LUT_MISSn: Access to a yet-to-be-filled entry, that is part of the area being refilled, for engine n.

The six error conditions mentioned above are also reported in the respective DMM_PAT_STATUSn register.

4.2.1.10 Address Translations Within DMM, For Tiled Accesses

This section describes address translations that happen at various interfaces within DMM, for tiled accesses.

From a user perspective, the PAT can be seen as an additional step in the process applied to the tiled addresses by the TILER:

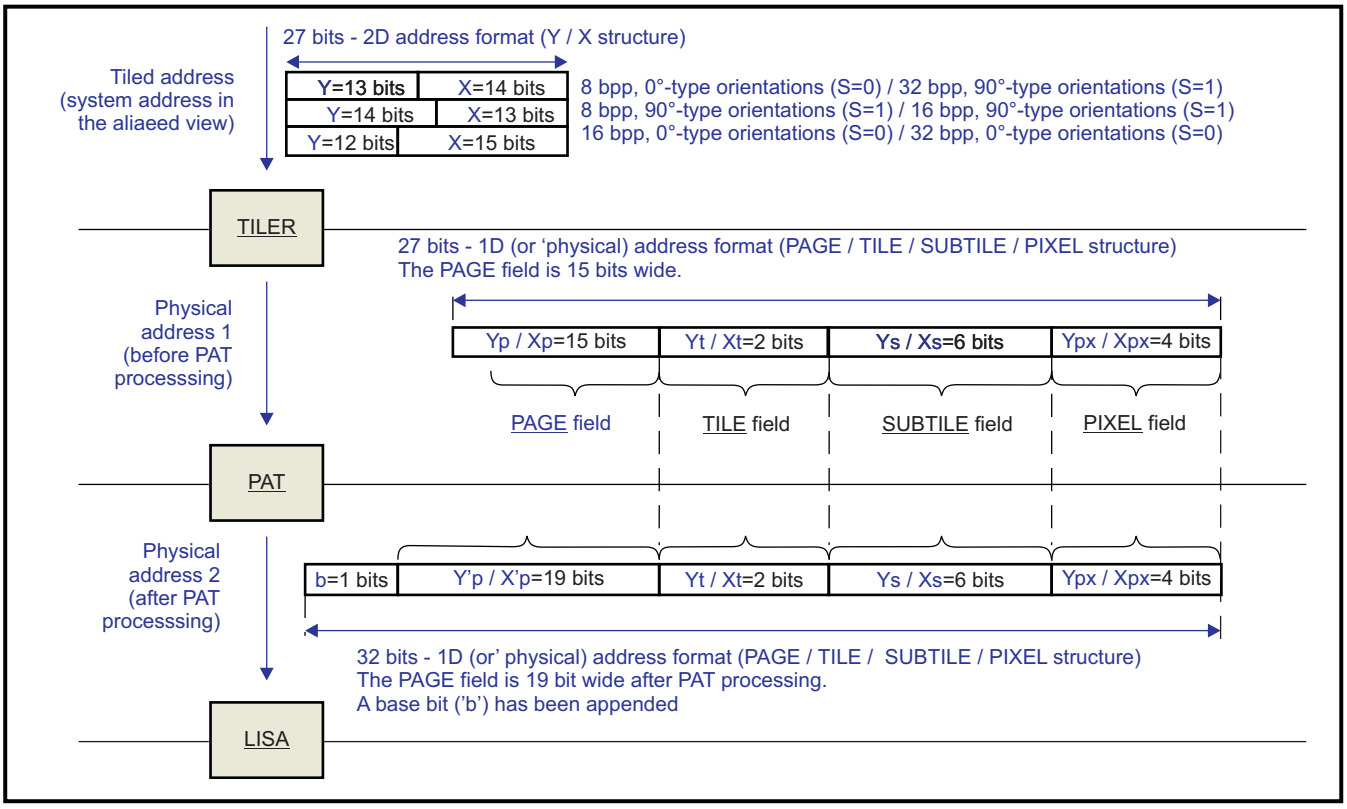
- the TILER first transforms a tiled address into a 27 bit physical address which fits within a 128MB address range.
- the PAT then processes the high order bits of the physical address output by the TILER, and outputs a 32-bit physical address which covers a 4GB address range. Section 4.2.1.4 describes the exact details for this address translation.

The purpose of the PAT is to map the tiled data anywhere in the 4GB physical address range, with a PAGE granularity (The TILER page is the granularity of physical memory allocation in TILER container. Each page is 4KB). This can be summed-up in Figure 4-11 where the PAT process appears in red.

Only the high order bits of the physical address are modified by the PAT: the 12 low-order bits remain unchanged. This means that the data ordering within each 4kB PAGE remains as calculated by the TILER.

A PAT view is defining the kind of physical address translation to perform for each of the page, 8-bit, 16-bit and 32-bit mode accesses. Each mode in each PAT view can be programmed in 2 different modes (direct translation and indirect translation) which will be described in PAT section. Note that indirect mode is the most commonly used. Direct mode is used only for debug or in case of a DMM without PAT module.

Figure 4-11. DMM Address Translations



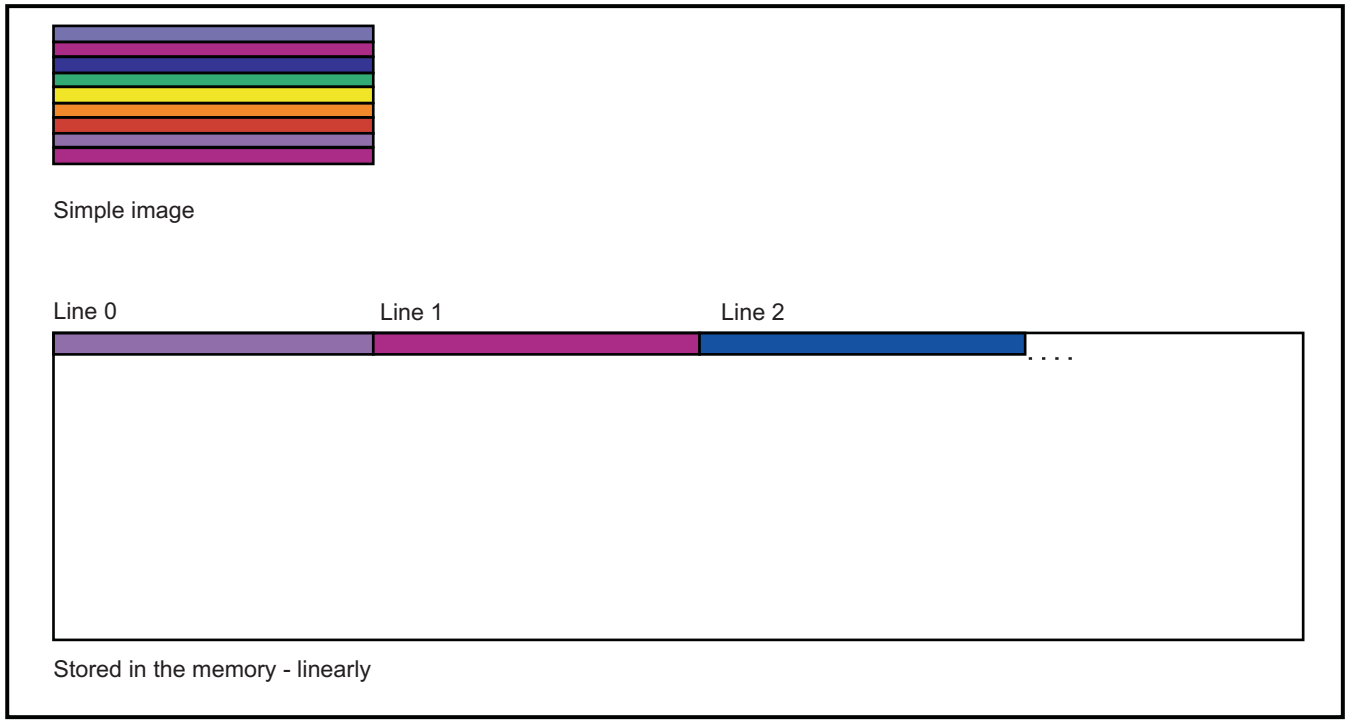
4.2.2 TILER Functional Description

4.2.2.1 Introduction to TILER

4.2.2.1.1 Need for a TILER

Image processing algorithms like H.264 encode and decode, which works on the principle of spatial locality, access the image data in two-dimensional format, for example, 16 pixels wide by 16 pixels high. If the image is stored in the memory in linear format then it would appear as in Figure 4-12. Thus, to access the macroblock, multiple memory accesses would need to be made. In the device, each memory access can be up to 128 bytes large. However, because macroblock is not stored contiguously in the memory, only partial pixels is useful in each memory access and the rest is discarded and a new access is generated to fetch rest of the data.

Figure 4-12. Image Stored in the Memory Linearly

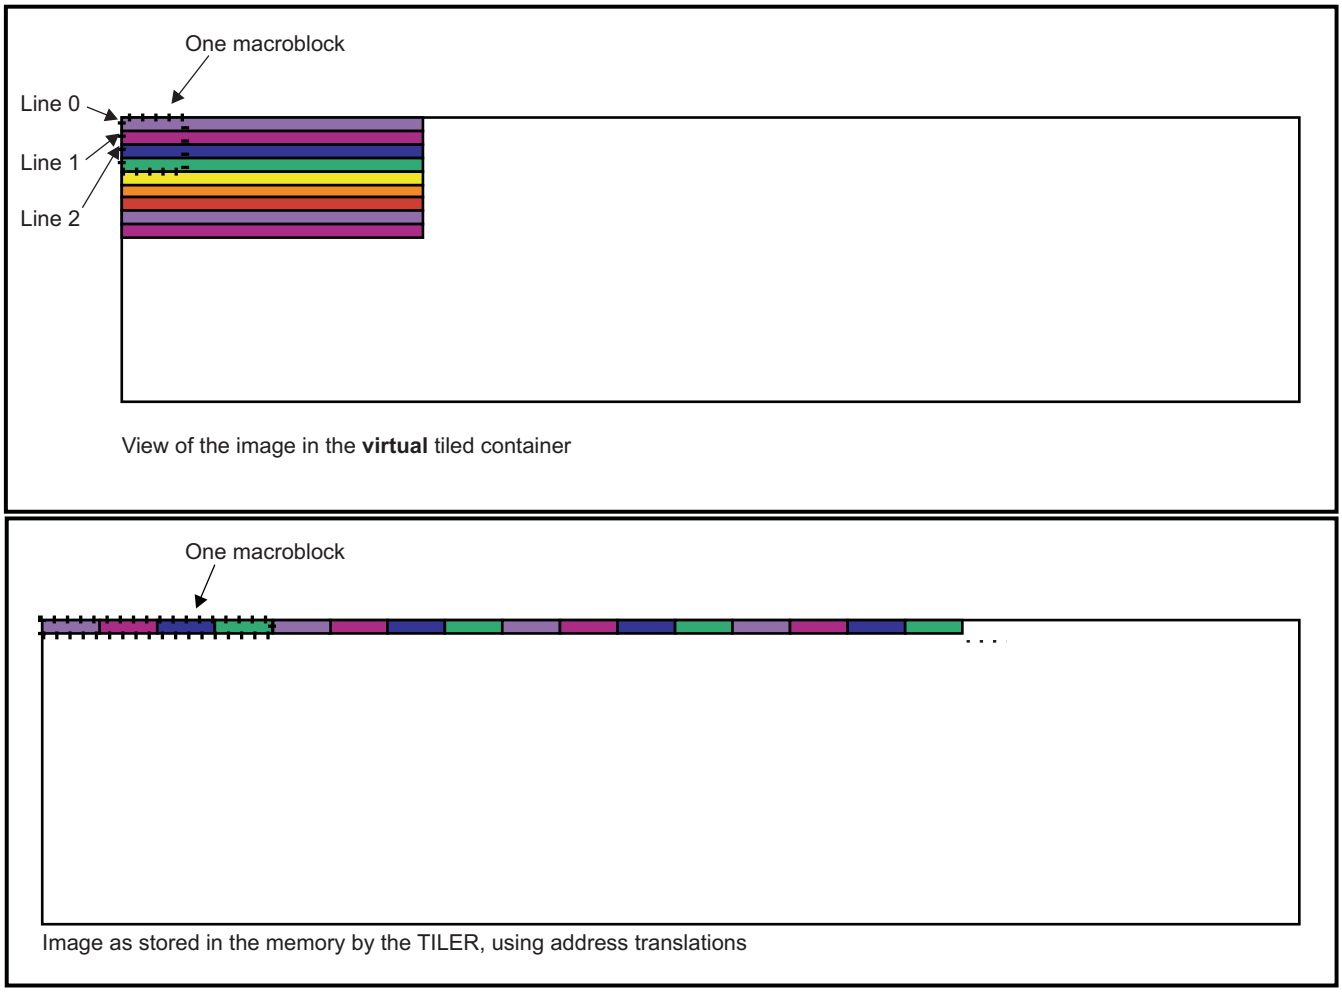


Instead, if the image is stored in bi-dimensional format, much fewer accesses are needed to read the entire macroblock of data, which directly transforms into several advantages:

1. Faster processing of algorithms.
2. Fewer SDRAM page opens.
3. Lesser wastage of memory bandwidth in the system.

This concept is the primary motive for storing the image data in the tiled format.

Figure 4-13. Image Stored in the Memory by TILER



NOTE : This is only a pictorial representation and actual arrangement of the data in the 128-bit subtile may be different.

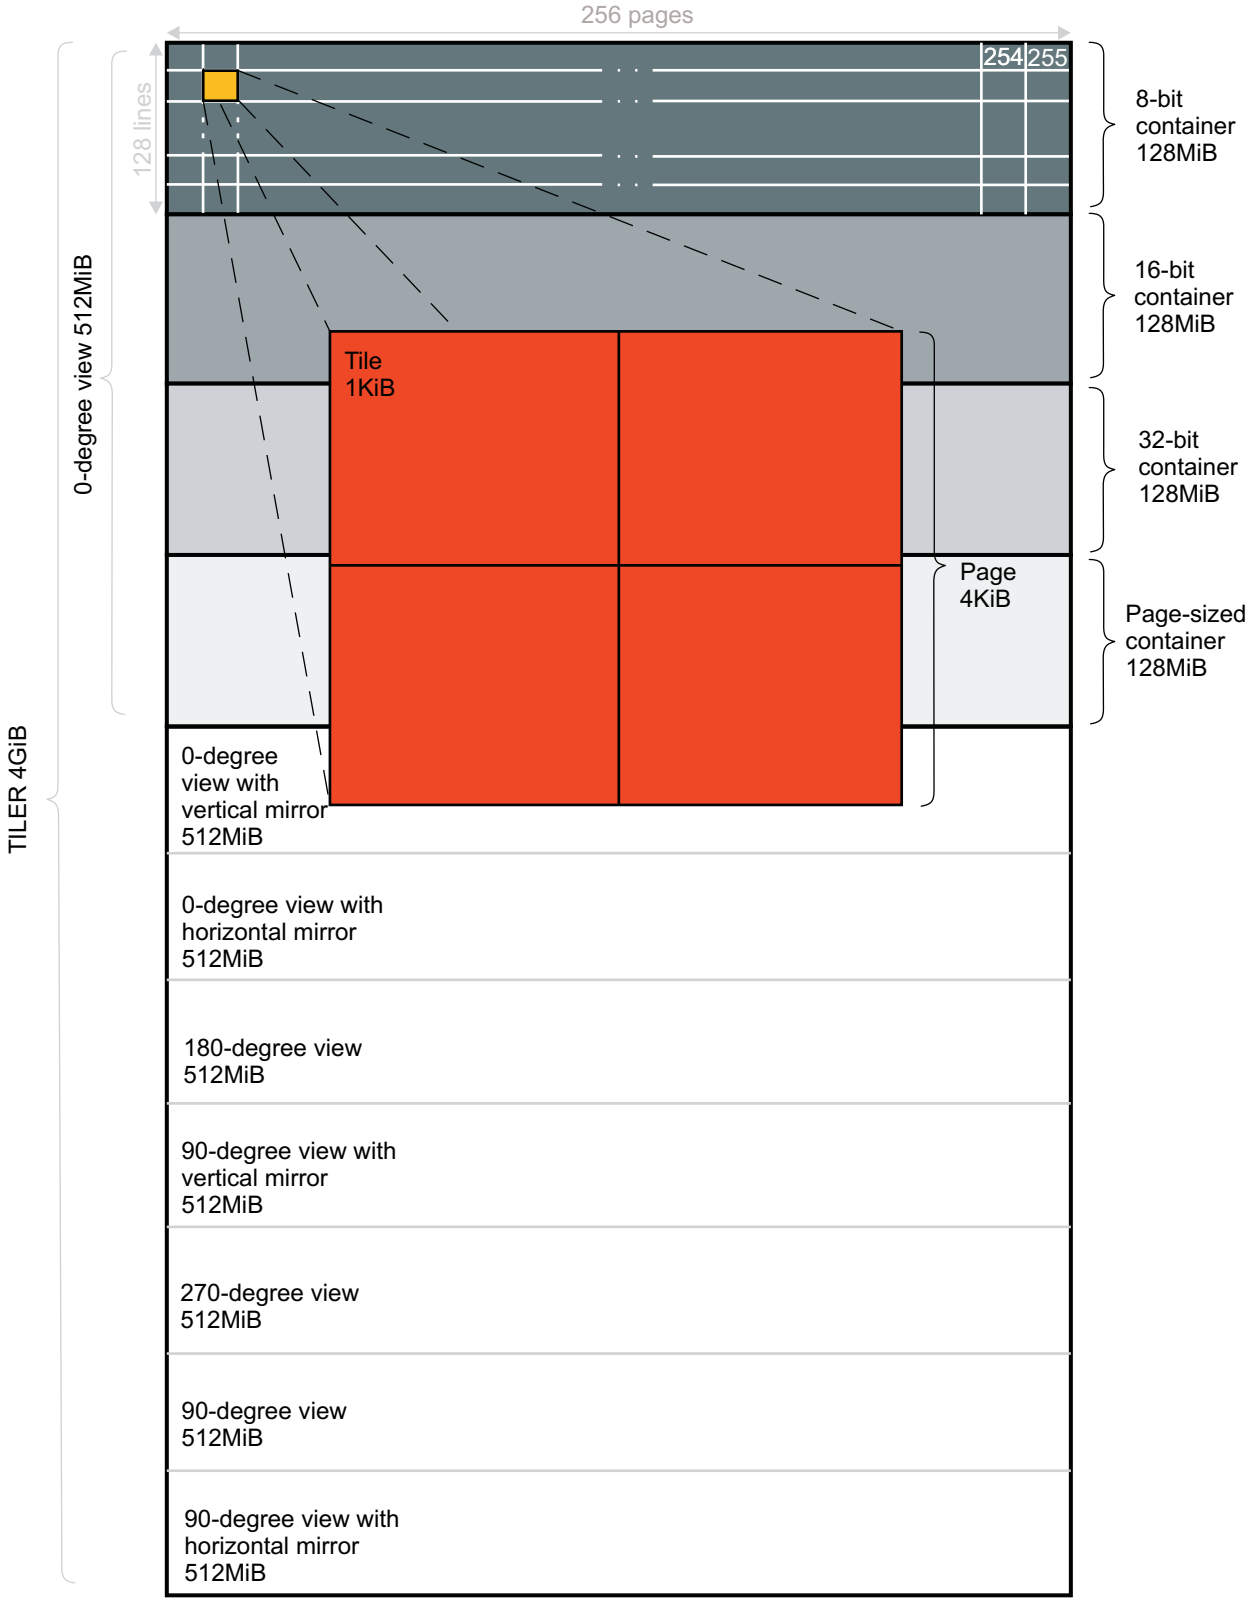
4.2.2.1.2 Consuming Tiled Data

In the device, the DMA engine of HD_VPSS, also known as VPDMA, has internal line buffers of its capture and display paths (called clients). For every tiled access, it is ensured that rastering tiled data has zero overhead, when processing an entire frame, or 2^{2n} number of lines.

4.2.2.2 TILER Rationale - A Top-down Approach

This section is a synthesis of all TILER concepts, through a top-down approach starting from the main object container, giving one rule per TILER structure level. Figure 4-14 shows the TILER address space structure for tiled modes.

Figure 4-14. Address Space Structure for Tiled Modes



4.2.2.2.1 The TILER is a 4-GB Virtual Address Space Composed of Eight Views

A TILER is addressed using a virtual 4 GB address space, containing 8 unique orientation views of 512 MB each. There is one view for each of the eight possible way of scanning a frame-buffer.

1. From left to right then from top to bottom (0 natural orientation)
2. From right to left then from top to bottom
3. From left to right then from bottom to top
4. From right to left then from bottom to top
5. From top to bottom then from left to right
6. From top to bottom then from right to left
7. From bottom to top then from left to right
8. From bottom to top then from right to left

Section 4.2.2.7 summarizes how the view can be visualized on a 128MB TILER container.

4.2.2.2.2 A View is a 512-MB Virtual Address Space Composed of Four Containers

There is one container per element size to allow correct access patterns in any of the eight possible orientations. The container is the entity where all objects of a given element type are allocated. The element is the entity of maximum size - 8 bits, 16 bits, 32 bits or page-sized - which is invariant in any orientation.

4.2.2.2.3 A Container is a 128-MB Virtual Address Space

A 128 MB container can be visualized as an array of 128 x 256 pages of 4 KB each. The page defines the granularity of physical memory allocation through a physical address translation unit - MMU.

4.2.2.2.4 A Page is a 4-KB Virtual Address Space

A page is composed of two lines. Each line consists of two tiles. Figure 4-15, Figure 4-16, and Figure 4-17 illustrate the Page geometry for 8-,16-, and 32-bit views, respectively.

Figure 4-15. 4KB Page, 8-bit Mode

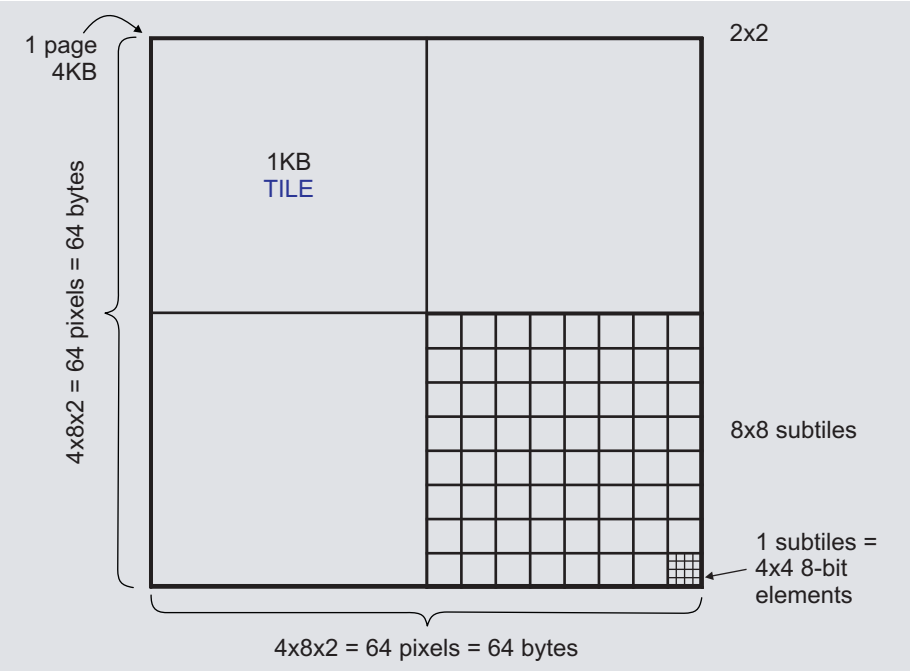


Figure 4-16. 4KB Page, 16-bit Mode

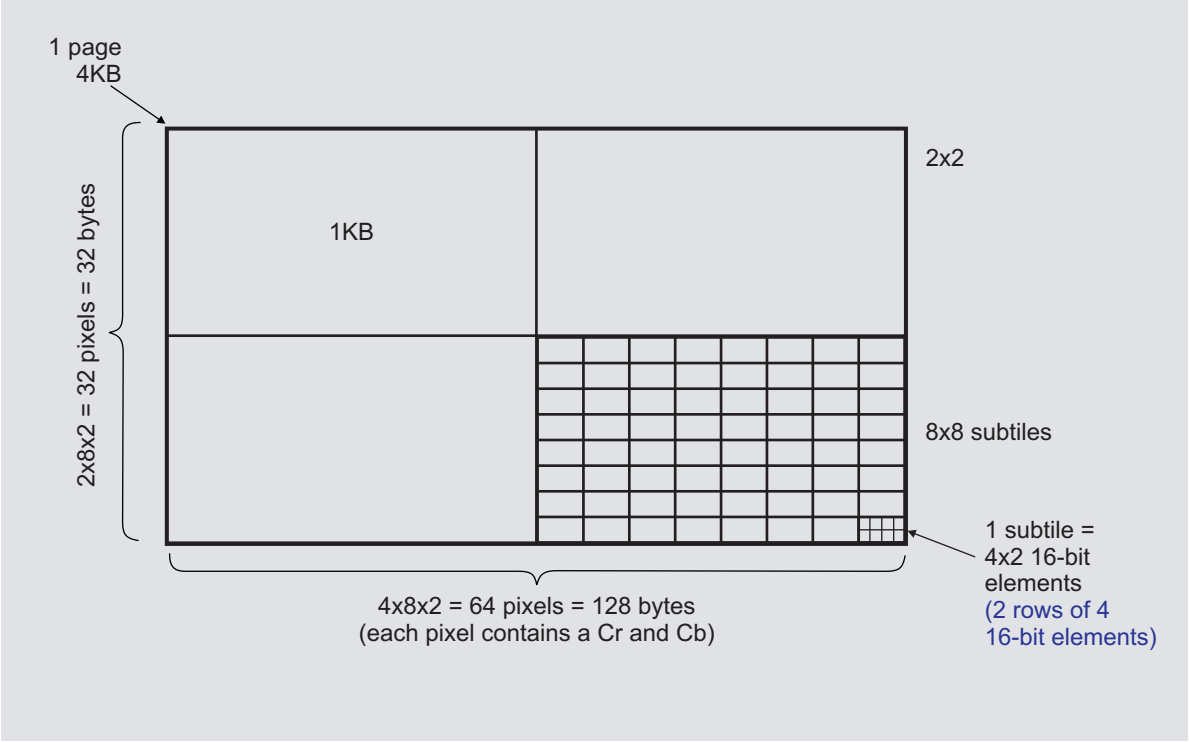

Figure 4-17. 4KB Page, 32-bit Mode

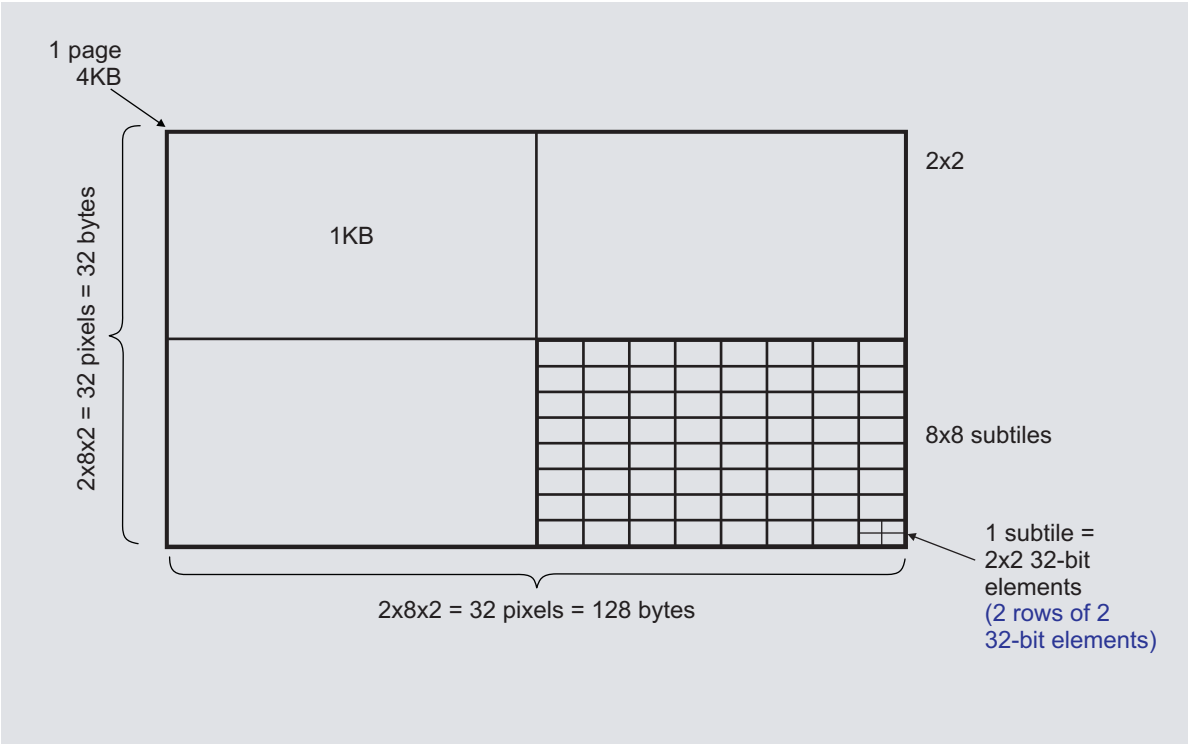
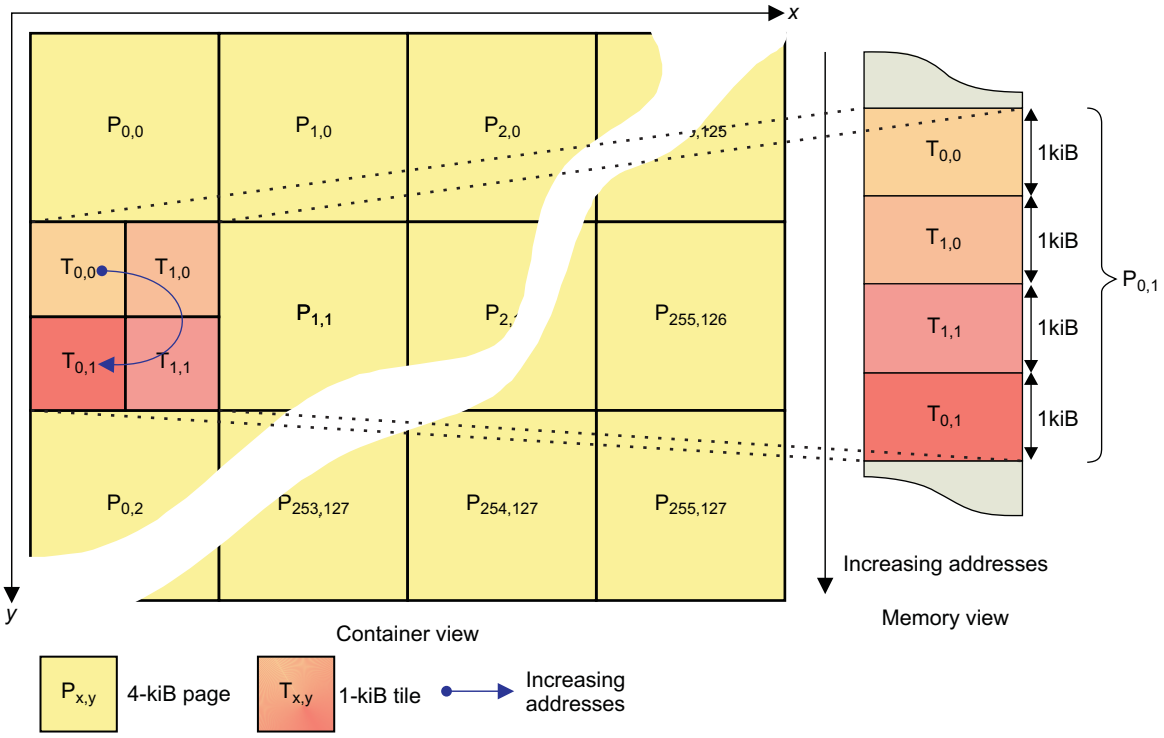


4.2.2.2.5 A Tile is a 1-KB Address Space

The tile is designed to offer bi-dimensional data locality in a single SDRAM page. In this respect, it has been sized to 1 KB (the size of the smallest SDRAM page).

Figure 4-18 shows how 4 tiles are arranged in a page. This arrangement ensures that any two adjacent tiles in a page are not stored on the same EMIF(when interleaving is enabled). Thus a large tiled access will be efficient as it will be evenly spread across both SDRAM controllers.

Figure 4-18. Four 1KB Tiles in One 4KB Page



4.2.2.2.6 A Sub-tile is a 128-bit Address Space

A 1KB tile is further decomposed into 64 sub-tiles, each sized 128 bits. The sub-tile structure is such that it balances accesses in two-dimensional modes, thus improving SDRAM access efficiency.

Furthermore, using Sub-tile pairing, the interlaced accesses to the tiled data can be improved. A Sub-tile is defined as follows:

1. An 8-bit sub-tile (Figure 4-19) is defined as an array of four horizontal lines of four 8-bit data. Thus, in 8-bit tiled mode, the TILER container is a 16384 × 8192 2D array of 8-bit elements.
2. A 16-bit sub-tile (Figure 4-20) is defined as an array of two horizontal lines of four 16-bit data. Thus, in 16-bit tiled mode, the TILER container is a 16384 × 4096 2D array of 16-bit elements.
3. A 32-bit tiled (Figure 4-21) mode as an array of two horizontal lines of two 32-bit data. Thus, in 32-bit tiled mode, the TILER container is an 8192 × 4096 2D array of 32-bit elements.

Figure 4-19. 8-bit Sub-tile

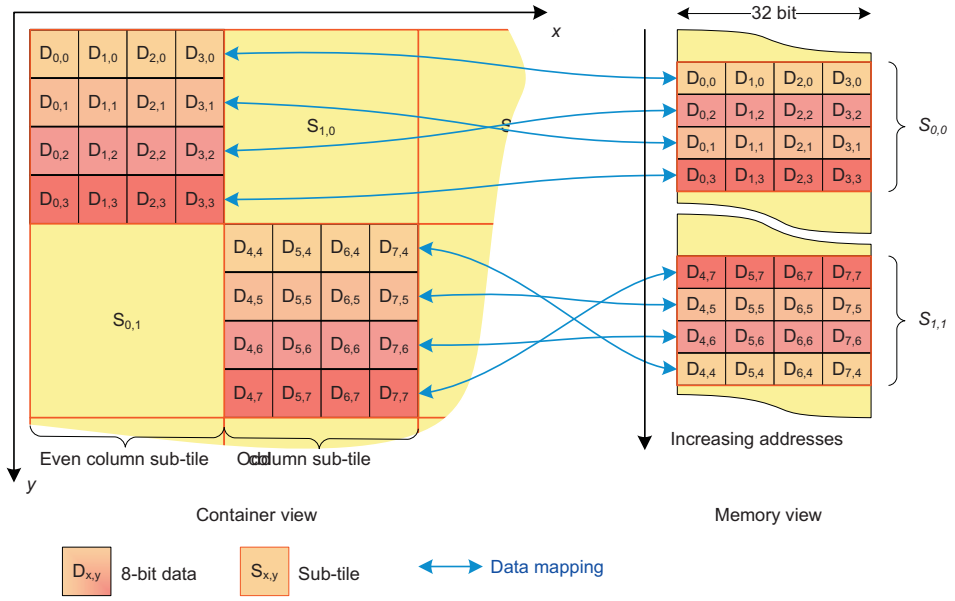


Figure 4-20. 16-bit Sub-tile

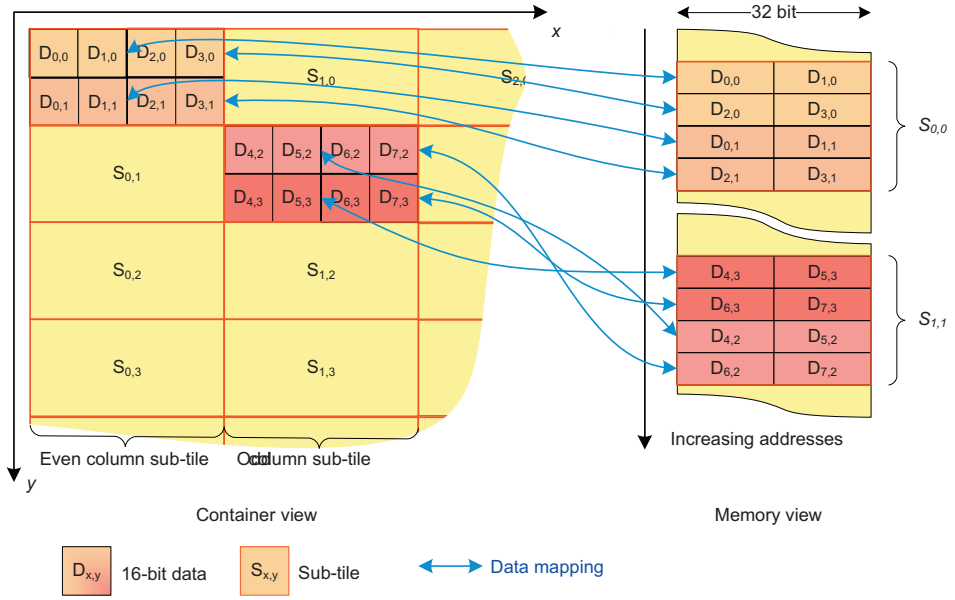

Figure 4-21. 32-bit Sub-tile

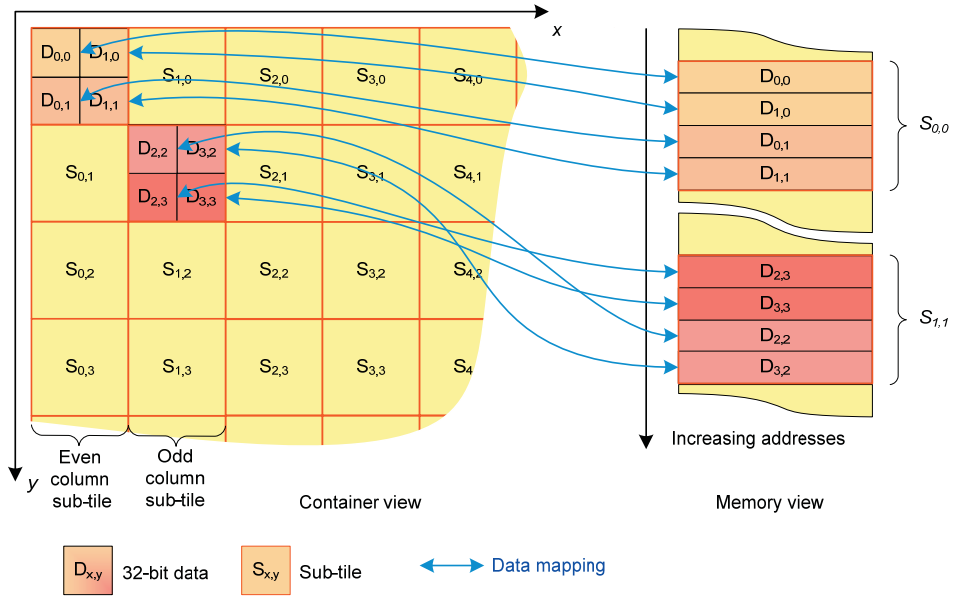


4.2.2.3 TILER Container - Summary

TILER is a 128-MB virtual container arranged in 2 dimensions as 256 × 128 pages, each of 4KB.

Each 4-KB page is has 4 tiles.

Each 1-KB tile has 64 subtiles, each of size 128 bits.

Based on the mode of access, 8/16/32 bit, the data stored can be aligned differently, as explained in the previous section.

4.2.2.3.1 Where Will the Tiled Data Be Stored in Physical Memory?

Using PAT Direct Access Translation:

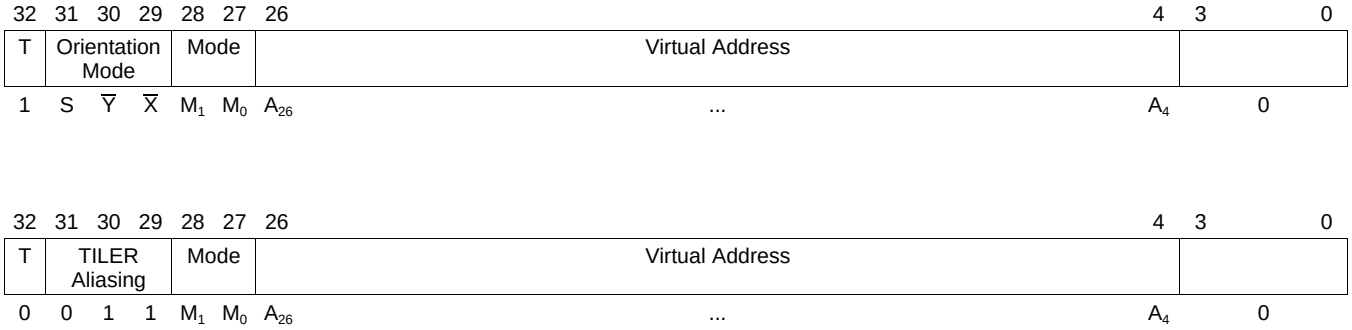
By bypassing the LUT, the entire 128MB space has to be contiguous in the physical memory. Then each of the 8-bit 128 MB virtual container, 16-bit 128 MB virtual container, 32-bit 128 MB virtual container and paged container, can be mapped to either the same physical 128 MB space or at different locations. Refer to the PAT_VIEW_MAP register, which defines the base address of this 128 MB space. As can be seen, this base address is 256 MB aligned.

Using PAT In-Direct Access Translation:

A more common use case would be to use the two LUTs in the DMM to map the virtual data to physical address, at 4KB granularity. Then the physical 128MB need not be contiguous. With two LUTs in the system, only 256 MB of data is possible. Hence, the 8, 16, 32 bit and paged containers may need to be aliased to same pages. For example - use one LUT to map 8-bit, 16-bit, and 32-bit containers; hence, they would all correspond to the same physical memory pages. The other LUT would be used to map the 128 MB contained for paged accesses, as shown in Figure 4-24.

4.2.2.3.2 Addressing Formats

Figure 4-22. Address Format



1. The 33rd bit, noted T, is aimed at distinguishing the standard 4-GB system address map from the 4-GB TILER-specific address map In the Device, only HD_VPSS can generate accesses in the latter space.
2. The orientation bits, noted S, Y, and X, define the request orientation as specified in Section 4.2.2.7.
3. The mode bits, noted M1 and M0, encoded as in Section 4.2.2.8.1.
4. The remaining 27 bits, noted A0 to A26, define the mode and orientation specific virtual address.

4.2.2.4 TILER Modes

The TILER is supporting three major access modes - bypass, page and tiled - each having a specific output request generation.

4.2.2.4.1 Bypass Mode

This mode is transparent at the TILER perspective. Bypass mode is for accesses generated by initiators with System addresses outside the virtual tiled address range, since TILER will bypass PAT. Still, at the DMM perspective:

- 2D block bursts are broken down on a line-basis in a set of incremental bursts
- Incremental bursts - including those issued by a 2D block burst breakdown - are split at the DMM atomic unit of the section hit by the burst at:
  - at the interleaving granularity of the section - 128 byte, 256 byte or 512 byte - in interleaved sections
  - at 1-KB boundary in non-interleaved sections

4.2.2.4.2 Paged Mode

The purpose of this mode is to use the DMM PAT address translation mechanism for non-tiled accesses. In this respect it is similar to the bypass mode:

- 2D block bursts are broken down on a line-basis in a set of incremental bursts
- Incremental bursts - including those issued by a 2D block burst breakdown - are split at:
  - the interleaving granularity of the section - 128 byte, 256 byte or 512 byte - in interleaved sections
  - 1-KB boundary in non-interleaved sections

4.2.2.4.3 Tiled Mode

When the being accessed in tiled mode, it can be either of the following:

- A well formed 2D block requests - conforming to the orientation, mode and stride
- A 1D incremental requests and ill-formed 2D block requests

Table 4-1. Stride for Well-formed Tiled Mode 2D Block Requests

Orientation			Mode		Stride (bytes)	Description
S	Y	X	M1	M0		
0	x	x	0	0	16384	Plain access to an 8-bit progressive frame in 0° or 180°
					32768	Field access to an 8-bit interlaced frame in 0° or 180°
			0	1	32768	Plain access to a 16-bit progressive frame in 0° or 180°
					65536	Field access to a 16-bit interlaced frame in 0° or 180°
			1	0	32768	Plain access to a 32-bit progressive frame in 0° or 180°
					65536	Field access to a 32-bit interlaced frame in 0° or 180°
1	x	x	0	0	8192	Plain access to an 8-bit progressive frame in 90° or 270°
					16384	Field access to an 8-bit interlaced frame in 90° or 270°
			0	1	8192	Plain access to a 16-bit progressive frame in 90° or 270°
					16384	Field access to a 16-bit interlaced frame in 90° or 270°
			1	0	16384	Plain access to a 32-bit progressive frame in 90° or 270°
					32768	Field access to a 32-bit interlaced frame in 90° or 270°

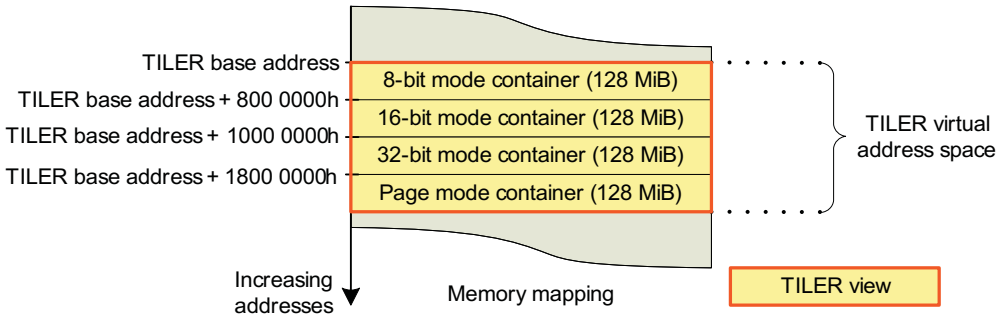
4.2.2.5 Object Container Definition

The object container is the unique addressable entry point of the TILER. It is a 128-MB virtual address space, where all objects of a same kind - and orientation - are allocated. Four main types of containers are present in the TILER, each one being referred by a mode:

- A 8-bit element mode, for efficiently accessing bi-dimensional arrays of 8-bit data, example 8-bits per pixel Luma buffers of image.
- A 16-bit element mode, for efficiently accessing bi-dimensional arrays of 16-bit data, example 16-bits per pixel interleaved-Chroma(CbCr) buffers of image.
- A 32-bit element mode, for efficiently accessing bi-dimensional arrays of 32-bit data, example 32-bits per pixel, ARGB graphics buffers.
- A page mode, for efficient 1D accesses

Figure 4-23 shows the TILER object containers and views.

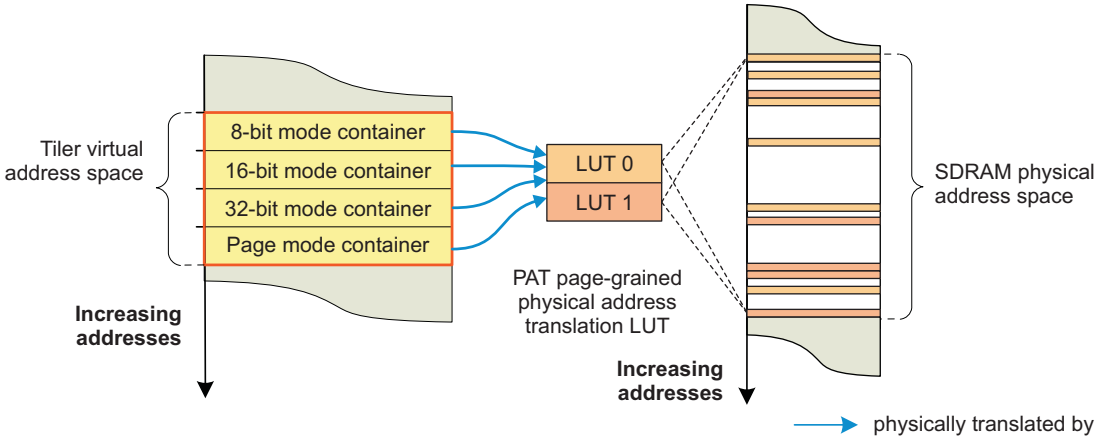
Figure 4-23. TILER Object Containers and Views



In the device, there are two LUTs in the PAT. Each LUT can map up to 128MB of objects at a 4KB page granularity. The four modes share the two LUTs .

One of the recommended usages, as shown in Figure 4-24, is to use one LUT for 8,16, and 32-bit modes and the other LUT for paged mode accesses. With this scheme, up to 128MB of objects can be available simultaneously in 8,16 and 32-bit modes and another 128MB of objects for paged mode accesses.

Figure 4-24. Using LUT to Translate Tiled Virtual Address to Physical SDRC Address



NOTE: You need to ensure that an object allocated in a particular container mode does not physically overlap with any other object either in the same mode or other container modes.

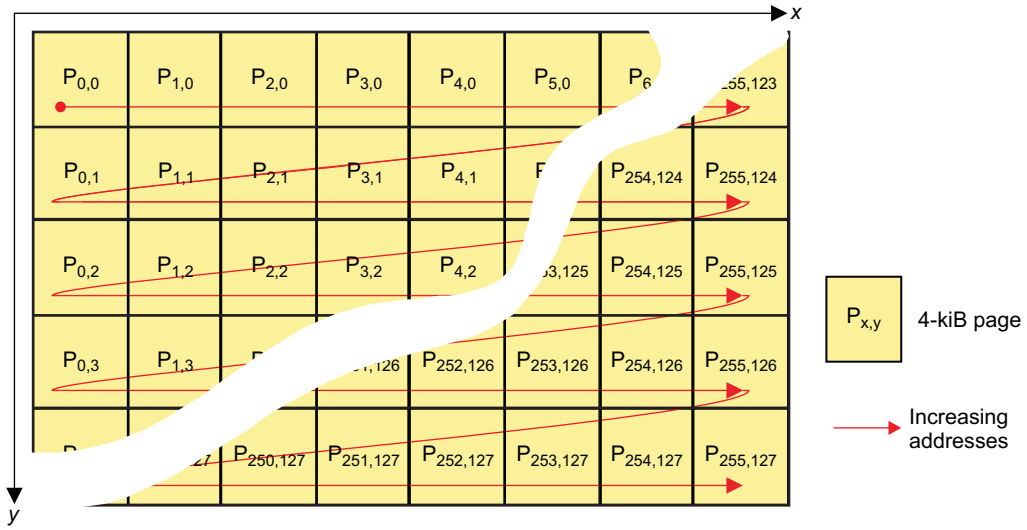
4.2.2.6 Page Definition

A TILER page defines the granularity of object allocation in virtual TILER containers. Given that the sub-page structure is mode specific, the 4KB page is the smallest granularity common to all modes, making it the granularity to consider in the TILER resource manager for object allocation.

4.2.2.6.1 Container Geometry with 4-kiB Pages

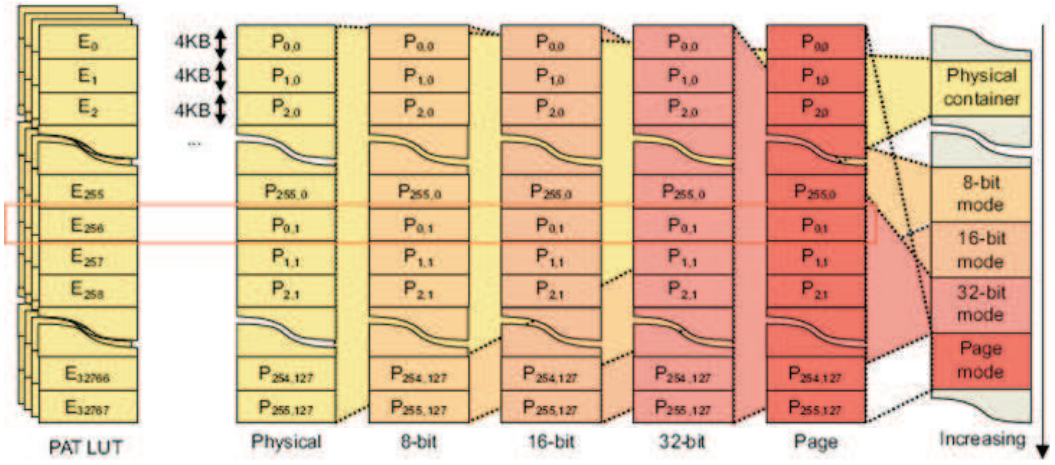
As pages size is 4KB, any 128MB object container is a set of 256 × 128 = 32768 pages, organized in an array of 256 columns and 128 rows, as shown in Figure 4-25.

Figure 4-25. Object Container Geometry with 4KB Pages



This array of pages is mapped to the system address space as shown in Figure 4-26.

Figure 4-26. TILER Page Mapping When Using 4KB Pages



In any 128-MB object container, the 4KB page Px,y at column x (0 ≤ x < 256) and row y (0 ≤ y < 128), is found at an offset of 4096. (x + 256.y) bytes from the base address of the related object container.

Similarly, the page Px,y at column x (0 ≤ x < 256) and row y (0 ≤ y < 128), is translated by the LUT entry Ex + 256.y found at the index x + 256.y.

4.2.2.6.2 Container Geometry and Page Mapping Summary

The TILER has a page size of 4096 bytes. The page Px,y:

- has maxx = 256 and maxy = 128
- is found at an offset of: 4096.(x + maxx.y) bytes from the base address of the related object container
- is translated by the entry found at the index (x + maxx.y) of the LUT table

4.2.2.7 Orientation

This section describes the eight on-the-fly orientation-related isometric transforms, corresponding to all available changes of orthonormal basis in the TILER container bi-dimensional space.

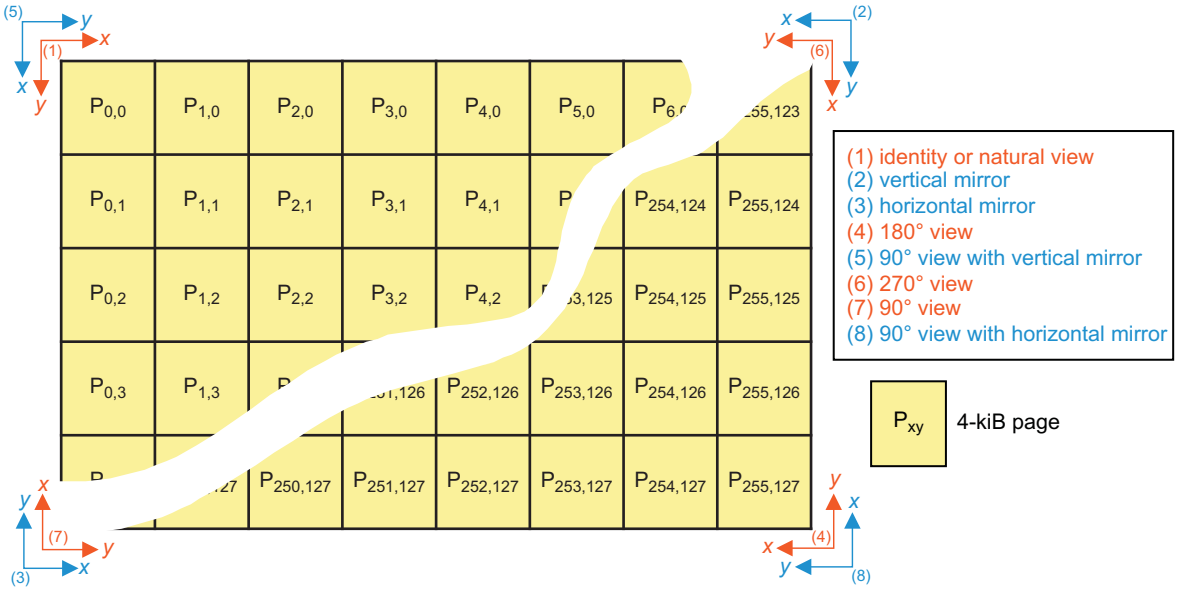
Figure 4-27 shows isometric transforms in the TILER container.

Mathematically speaking, all these transforms correspond to the composition of a 0º, 90º, 180º, or 270º rotation with an optional reflection. The nature of this orientation is based on the three following binary parameters:

- X to change the direction of the x axis of the TILER container
- Y to change the direction of the y axis of the TILER container
- S to swap the modified x and y axis

From now on, and in the rest of this document, the term orientation refers to any composition of a "quadrant" rotation with an optional horizontal - flip-flop - or vertical mirroring.

Figure 4-27. Isometric Transforms in the TILER Container



Selection of orientation:

1. For all initiators except, HD_VPSS, the tiled space is accessed in the 512 MB address range of (6000 0000h to 7FFF FFFFh). These initiators use the access the any of the 8 views by using the respective DMM_TILER_OR0 or DMM_TILER_OR1 registers.
2. For HD_VPSS, the TILER module supports its own 4-GB virtual addressing space, from address (1 0000 0000h to 1 FFFF FFFFh). These eight 512MB spaces correspond to the 8 availables views. With multiple display, capture and transcode path, using the unique 512 MB address space, these ports of HD_VPSS can simultaneously generate access in any of the 8 views.

4.2.2.8 Tile Definition

A tile is a subdivision of a page, aimed at:

- Representing a 2D block to better balance the accesses in both directions
- Ensuring that any "tiled" access that fits within a tile is made atomic in the SDRAM controller, and fits in a single SDRAM memory page
- Minimising the number of SDRAM page openings per 2D block transfer

The tile is defined as a 1KB 2D block, and a 4KB page as an array of 2 lines of 2 tiles each, as described in section detailing a 4KB page.

When the considered page is in an interleaved DMM section, it is necessary that:

- the DMM memory interleaving size of tiled accesses is set to 1 KB - a tile size - so that any tiled request that fits within a tile, fits in a single SDRAM memory page
- any request that spans over 2 or 4 tiles, is distributed on a maximum number of SDRAM memory controllers

4.2.2.8.1 TILER Virtual Addressing

The TILER can be virtually accessed in four different modes, namely 8-bit, 16-bit, 32-bit and page modes. Each mode defines the element granularity to apply isometric transforms, as summarized in Table 4-2.

Table 4-2. TILER Modes

Mode	Name	Granularity (element size)
0	8-bit tiled mode	8 bits
1	16-bit tiled mode	16 bits
2	32-bit tiled mode	32 bits
3	Page mode	4096 bytes

For instance, making a vertical mirroring of a 16-byte horizontal line containing the word 0001 0203 0405 0607 0809 0A0B 0C0D 0E0Fh, leads to:

- 0F0E 0D0C 0B0A 0908 0706 0504 0302 0100h in 8-bit tiled mode
- 0E0F 0C0D 0A0B 0809 0607 0405 0203 0001h in 16-bit tiled mode
- 0C0D 0E0F 0809 0A0B 0405 0607 0001 0203h in 32-bit tiled mode
- 0001 0203 0405 0607 0809 0A0B 0C0D 0E0Fh in page mode - unchanged as the element granularity is 4KB

Besides, as each of the eight orientations is available for any of the four modes, this gives 32 TILER addressing possibilities.

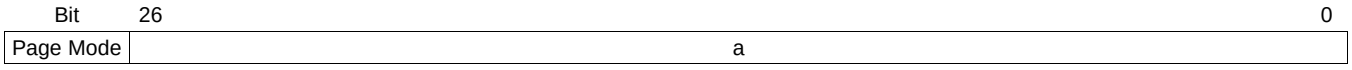
NOTE: The format that the TILER manages the tiled data is dictated by which 4 modes (8-,16-, 32-bit or paged) and which orientation (8 views) is used while accessing (read and write) the data.

As long as the data accessed is written and read in the same mode, it is assured that the response to the access will be correct. While accessing in the same mode, if written in one view and read back in the other view, then the read back data will be rotated and/or mirrored as per the view used.

4.2.2.8.2 Page Mode Virtual Addressing and Characteristics

When used in page mode, the 128-MiB TILER space is seen as an orientation-specific sequence of 32768 pages of 4 kiB each. The access sequence inside a page is left unchanged. Therefore, in page mode, the TILER is accessed similarly to any 128-MiB memory, with a 27-bit byte-based address.

Figure 4-28. Paged Mode Addressing



4.2.2.8.3 Tiled Mode Virtual Addressing and Characteristics

When used in tiled mode, the 128-MiB TILER space is seen as a giant frame-buffer - the container. The addressing and characteristics of this giant frame-buffer depends on:

- The tiled mode, which defines the considered atomic element size
- The orientation, which potentially swaps its x and y axis - and hence the container geometry

Table 4-3 summarizes tiled mode container characteristics.

Table 4-3. Tiled Mode Container Characteristics

Orientation			Element Size (bits)	Width (elements)	Height (elements)	Stride (bytes)	
S	Y	X				Progressive	Interlaced
0	x	x	8	16384	8192	16384	32768
			16	16384	4096	32768	65536
			32	8192	4096	32768	65536
1	x	x	8	8192	16384	8192	16384
			16	4096	16384	8192	16384
			32	4096	8192	16384	32768

As a result, the coordinate (x0, y0) of a pixel in an oriented view is translated in a virtual address as shown in Figure 4-29 and Figure 4-30, for all the four orientations.

Figure 4-29. Tiled Mode Addressing in 0° or 180° Orientations, (S = 0)

Bit	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
8-bit tiled mode	y_0													x_0													
16-bit tiled mode	y_0													x_0													
32-bit tiled mode	y_0													x_0													

Figure 4-30. Tiled Mode Addressing in 90° or 270° Orientations, (S = 1)

Bit	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
8-bit tiled mode	y_0														x_0												
16-bit tiled mode	y_0 x_0														x_0												
32-bit tiled mode	y_0														x_0												

Having understood the characteristic of the tiled container and the how the data is stored in bi-dimensional manner, it is easy to understand how stride is calculated. Stride is calculated as the number bytes between pixel (m,n) and pixel (m,(n+1)), where m = x co-ordinate of the image buffer, n = y co-ordinate of the image buffer.

For S = 0, that is, all views with 0º and 180º:

- 8-bit mode: stride_8bitmode = 4 bytes per sub-tile × 1 byte height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 256 pages = 4 × 1 × 8 × 2 × 256 = 16KB
- 16-bit mode: stride_16bitmode = 4 bytes per sub-tile × 2 bytes height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 256 pages = 4 × 2 × 8 × 2 × 256 = 32KB
- 32-bit mode: stride_32bitmode = 4 bytes per sub-tile × 2 bytes height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 256 pages = 4 × 2 × 8 × 2 × 256 = 32KB

For S = 1, that is, all views with 90º and 270º:

- 8-bit mode: stride_8bitmode = 4 bytes per sub-tile × 1 byte height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 128 pages = 4 × 1 × 8 × 2 × 128 = 8KB
- 16-bit mode: stride_16bitmode = 4 bytes per sub-tile × 1 byte height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 128 pages = 4 × 1 × 8 × 2 × 128 = 16KB
- 32-bit mode: stride_32bitmode = 4 bytes per sub-tile × 2 bytes height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 128 pages = 4 × 2 × 8 × 2 × 128 = 16KB

4.2.2.8.4 Element Ordering in the TILER Container

This section highlights how elements - 8-bit data, 16-bit data, 32-bit data or 4-kiB page - are ordered in the container. In other words, this section highlights how the path of incrementing virtual addresses is mapped in the container.

It is interesting to note that whatever the mode, and hence the element size, the sequence for ordering the elements in their related container is strictly similar and only depends on the related orientation. In other words:

- Mode is about element granularity
- Orientation is about change of orthornormal basis for ordering the elements in the mode-specific container

A corollary to the previous statements is that in a given mode the internal structure of an element is unchanged whatever the orientation. In page mode for instance, the offset of a word inside a page is invariant by orientation; the content of a page is always accessed in the same manner.

In the next sections, the natural container orthonormal basis is referenced as: (Xn , Yn) and the oriented orthonormal basis as: (Xo , Yo).

4.2.2.8.4.1 Natural View or 0º View (Orientation 0)

This orientation defined by S = 0, Y = 0, and X = 0 and means that the operated change of basis is:

X0 = Xn

Y0 = Yn

In any TILER mode, the elements are then ordered from left-to-right and then from top-to-bottom in their container, as shown in Figure 4-31 and Figure 4-32.

Figure 4-31. Tiled Mode Ordering of Elements in Natural View

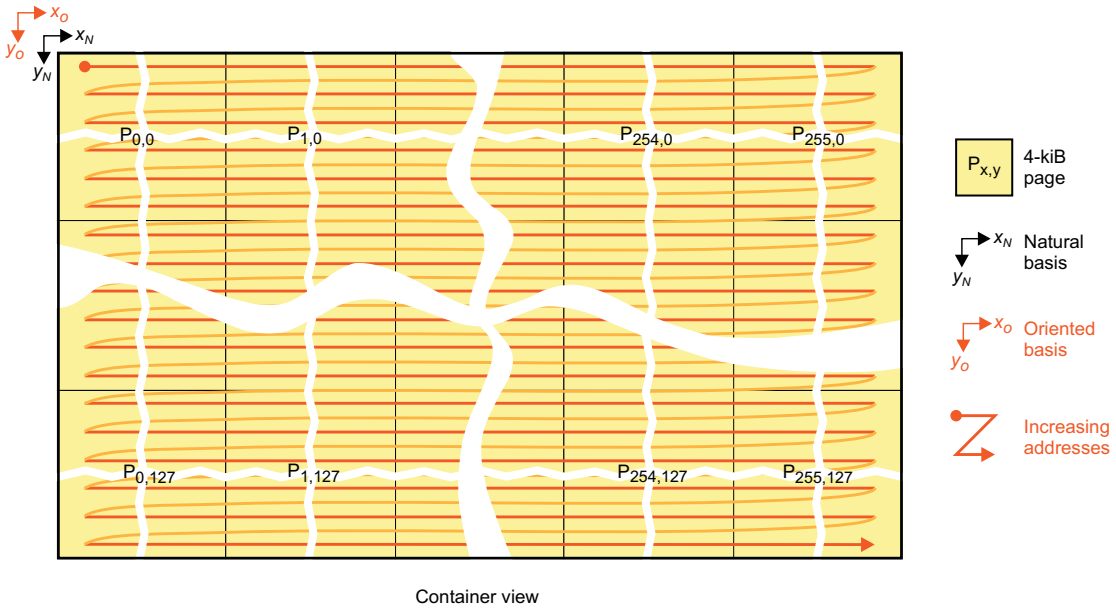


Figure 4-32. Page Mode Ordering of Elements in Natural View

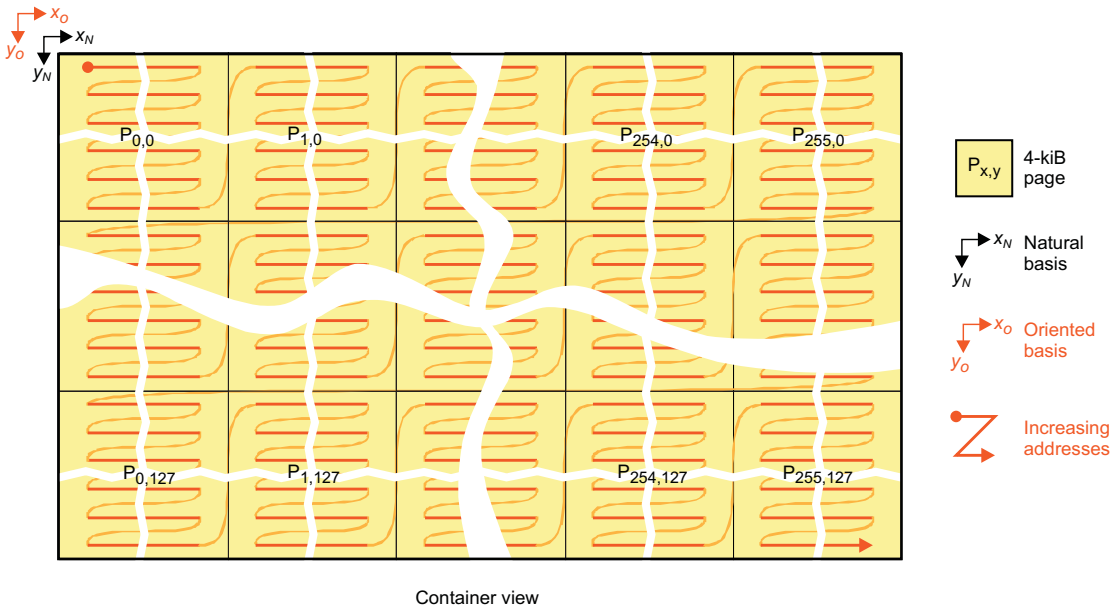


4.2.2.8.4.2 0º View with Vertical Mirror or 180º View with Horizontal Mirror (Orientation 1)

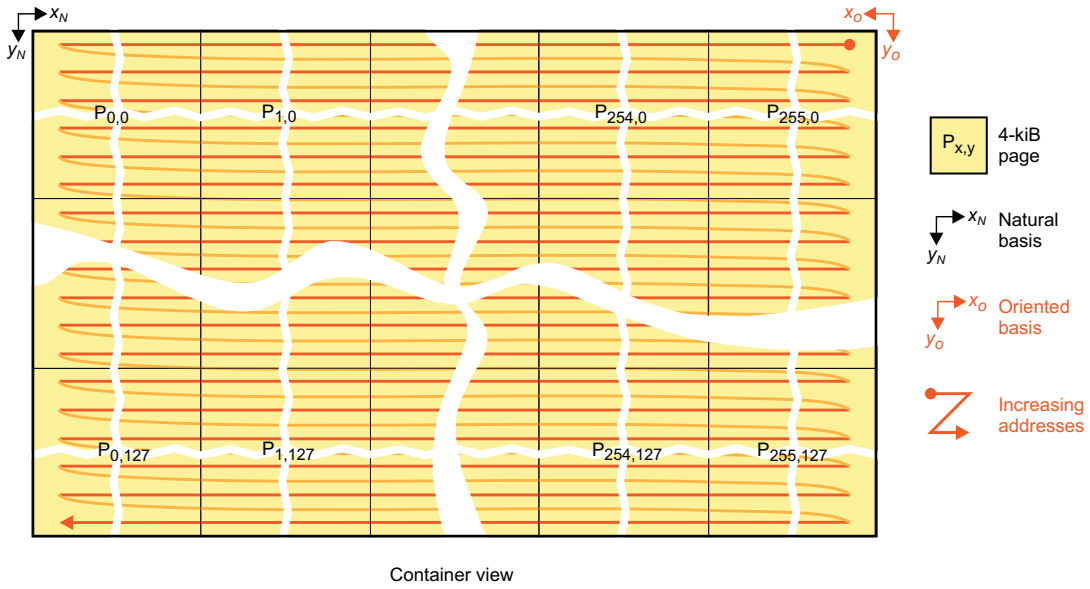
This orientation defined by S = 0, Y = 0, and X = 1 and means that the operated change of basis is:

X0 = -Xn

Y0 = Yn

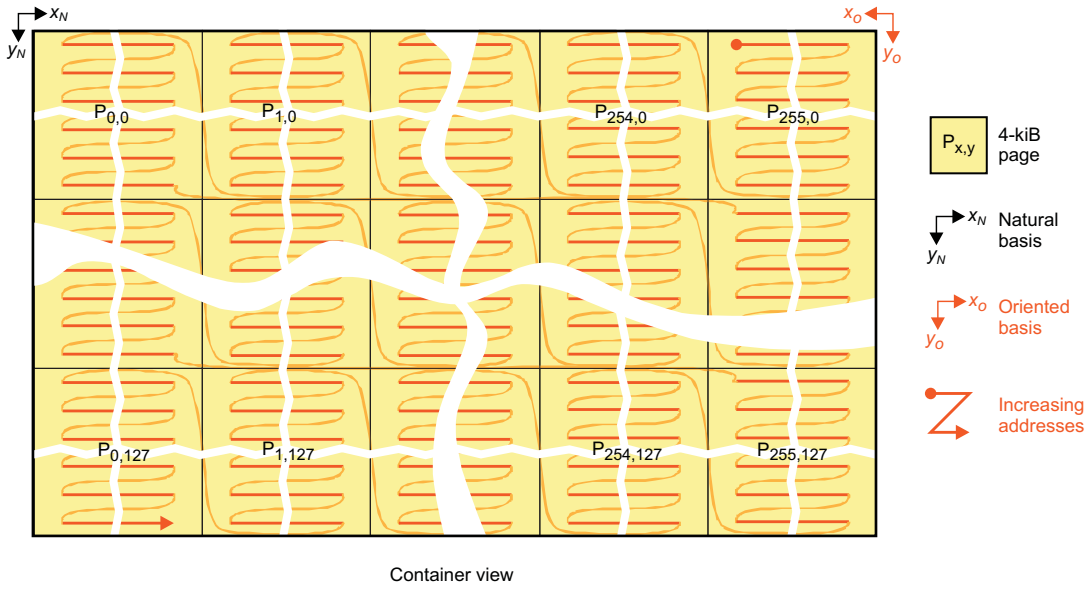
In any TILER mode, the elements are then ordered from right-to-left and then from top-to-bottom in their container, as shown in Figure 4-33 and Figure 4-34.

Figure 4-33. Tiled Mode Ordering of Elements in 0° View with Vertical Mirror



Container view

Figure 4-34. Page Mode Ordering of Elements in 0° View with Vertical Mirror



Container view

4.2.2.8.4.3 0º View with Horizontal Mirror or 180º View with Vertical Mirror (Orientation 2)

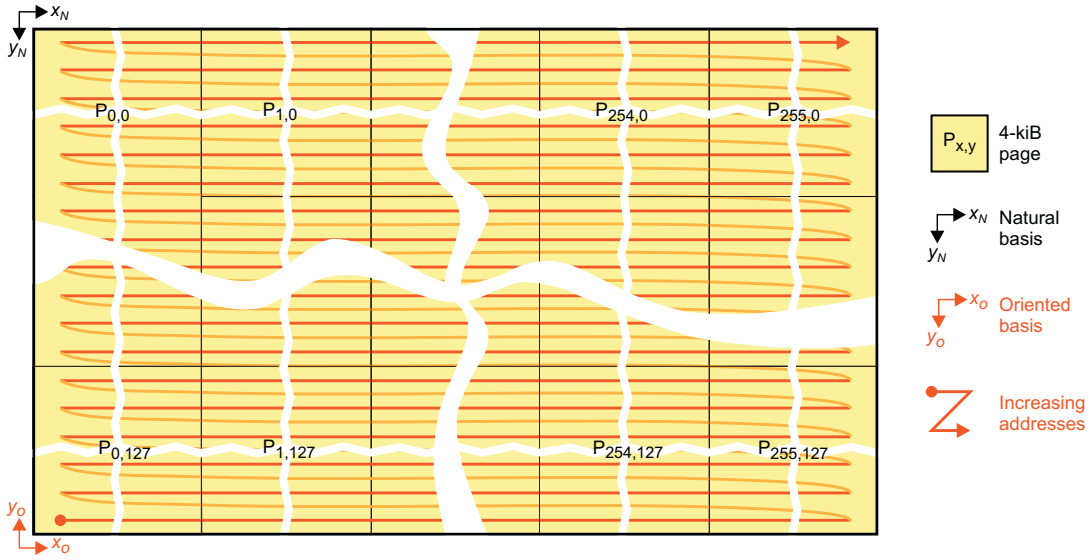
This orientation defined by S = 0, Y = 1, and X = 0 and means that the operated change of basis is:

X0 = Xn

Y0 = -Yn

In any TILER mode, the elements are then ordered from left-to-right and then from bottom-to-top in their container, as shown in Figure 4-35 and Figure 4-36.

Figure 4-35. Tiled Mode Ordering of Elements in 0° View with Horizontal Mirror



Container view

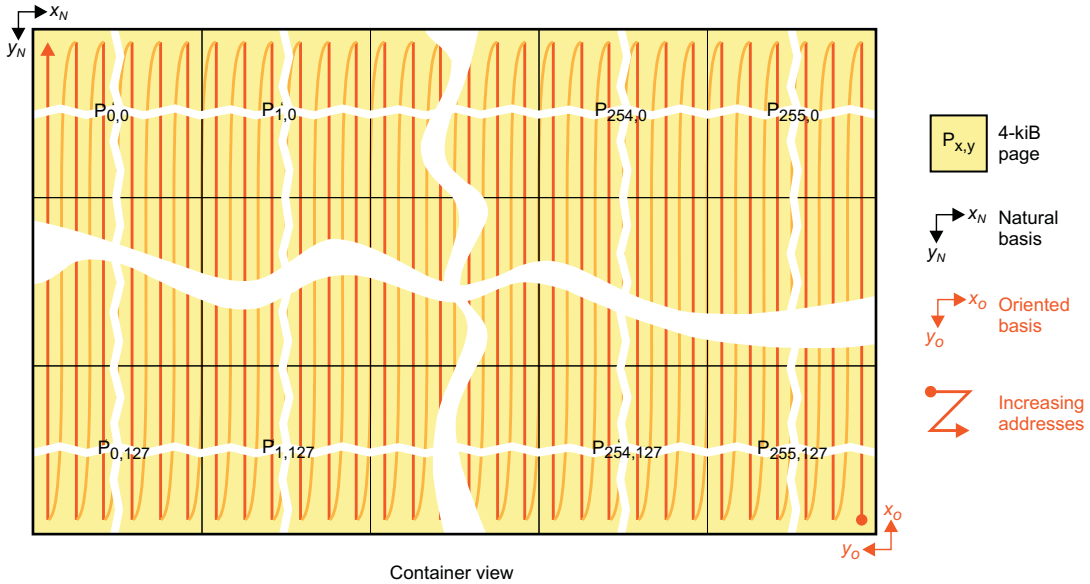

Figure 4-46. Page Mode Ordering of Elements in 90º View with Horizontal Mirror

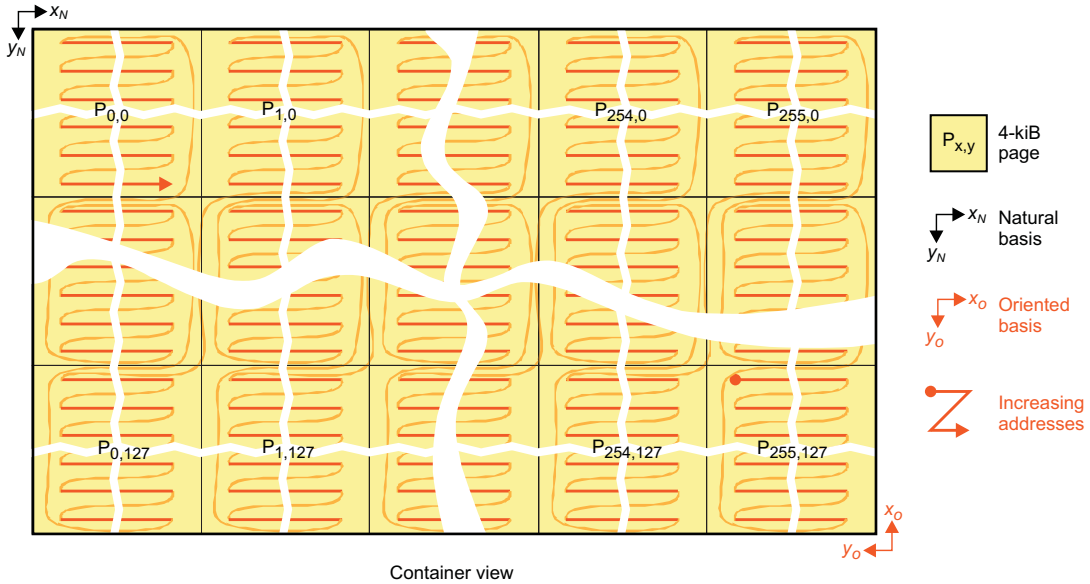


4.2.2.8.5 Tiled and Rotational Efficiency

Because of the distribution of the image data in both direction and co-locating them, using sub-tiling, the Image processing algorithms running on the HDVICPs are more efficient by making fewer accesses to the SDRAM, to fetch Macro-blocks of data.

In the Device, the DMA engine of HD_VPSS, also known as VPDMA, has internal line buffers of its clients. For every tiled access, it is ensured that rastering tiled data has zero overhead, when processing an entire frame, or 2^{2n} number of lines.

4.3 Use Case

4.3.1 DMM Basic Register Setup

This section describes basic steps to initialize the DMM, in the device.

1. Set base address, DMM_PAT_VIEW_MAP_BASE to value 8000 0000h, which corresponds to base SDRAM address in the device memory map.
2. Program the four PAT views, by writing DMM_PAT_VIEW_MAP__0..3 registers. By default, all the four PAT views are having value of 0, which implies Direct access translation for all the four tiled modes of (8,16,32-bit and paged mode) and all the four containers will overlap with their base address mapped to 8000 0000h.
3. Program PAT views for all initiators, indexed by ConnID, by programming the DMM_PAT_VIEW__0..1 registers. There are 4 possible views available in device. Default is for all initiators to use PAT view 0.
4. Program PEG priority for all the initiators. By default - all are having priority = 0.
5. Program the TILER orientation for all the initiators, by writing to DMM_TILER_OR__0..1 registers. By default - all will access tiled data in Orientation = 0, which is the normal view.
6. Program Section mapping, based on the SDRAM configuration of the system, which depends on the size of the SDRAM on one or both the banks.
   - Example 1: Symmetrical DDRs on both EMIF banks. Each size = 512MB to add up to 1GB of total SDRAM memory. In all DMM_LISA_MAP__0..3 registers, program value 8064 0300h, which implies 1GB section starting from System address : 8000 0000h, mapped to 0000 0000h of both EMIF0 and EMIF1, with interleaving of 128 bytes enabled. Note that the above example uses only one DMM section and the three other are identical. There are other ways to define up-to 4 sections and configure each differently

4.3.1.1 PAT Direct Access Translation with Distinct 128 MB Containers for Each of the 4 Modes

Following is a simplistic use case, bypassing the LUTs for address translation and setting aside a chunk of 128MB contiguous memory, with base address 128MB aligned, for each of the 4 modes (8, 16,32-bit and paged mode). The same addresses will be used by all initiators in the system.

Configure PAT view 0:

Program DMM_PAT_VIEW_MAP__0 to a value of 0302 0100h. Here : 8-bit mode container will be mapped to 8000 0000h. 16-bit mode container will be mapped to 8800 0000h. 32-bit mode container will be mapped to 9000 0000h. Paged mode container will be mapped to 9800 0000h.

Configure all initiators to use PAT view 0:

Program DMM_PAT_VIEW__0..1 to a value of 0.

4.3.2 Simple LUT Bypass Use Case: Arrangement of Video Buffers

This section describes one possible arrangement of H.264 video buffers which are in YUV 420 format. Setup is as follows:

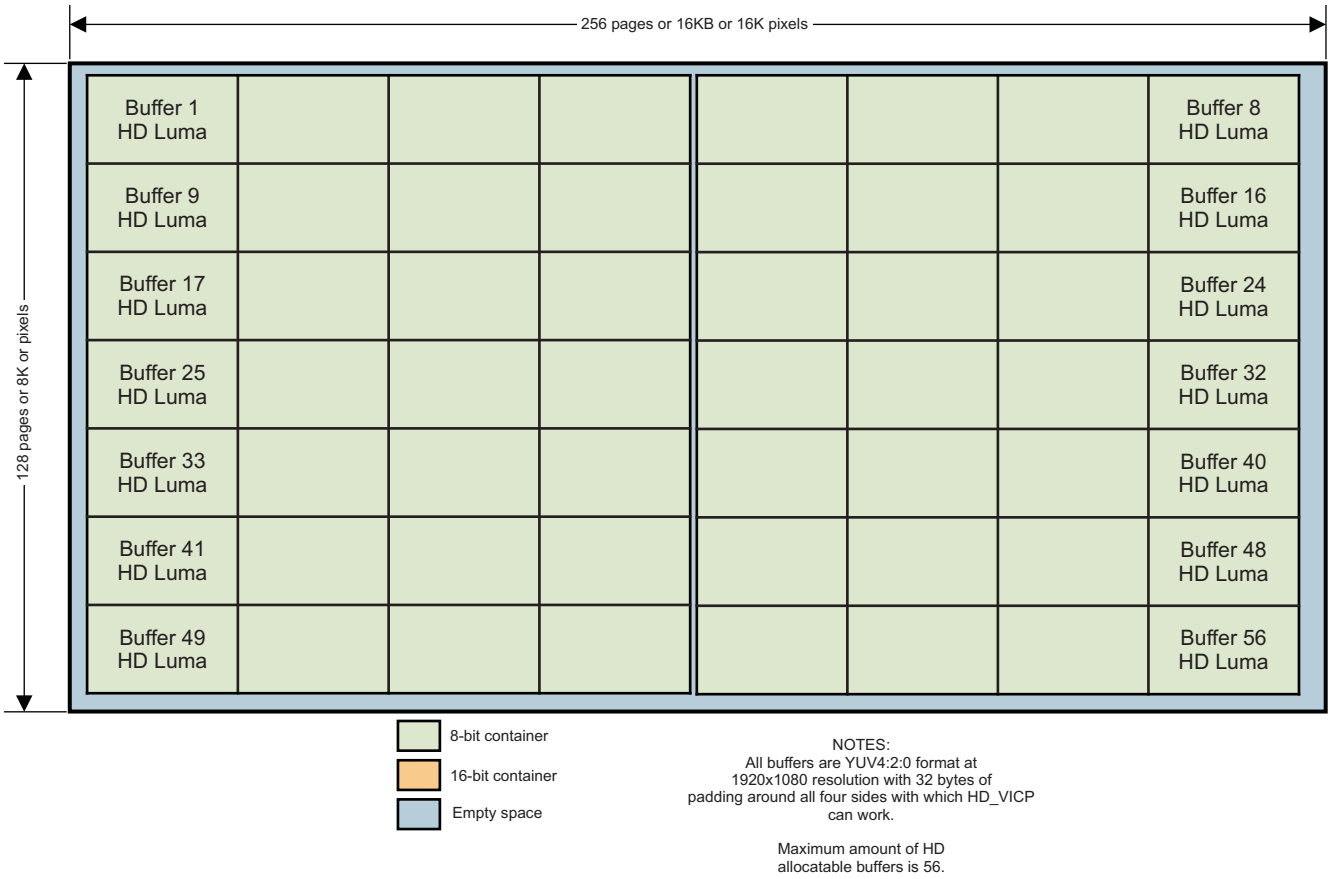
1. The buffers size if 1920 × 1080
2. The Luma buffers are allocated in the 8-bit mode container
3. The Chroma buffers are allocated in the 16-bit mode container
4. The H.264 algorithm needs 32 bytes of padding on each side for Luma buffer and 16 bytes padding in each side for a chroma buffer
5. All buffers are allocated on a 4K aligned address

4.3.2.1 Luma Buffers

In 8-bit tiled mode (Figure 4-47), each 4K page is arranged as 64-pixels wide and 64-pixels high, where each pixel is of size 8-bits. In YUV 420 format, the Luma buffer of the image is 1920 × 1080 and each pixel is 8-bits. Thus, each buffer is 1920 bytes wide. With a pad of 32 bytes on each side, the buffer is (1920 + 64 =) 1984-bytes wide. So one video buffer needs (1984/64 =) 31 pages, along the width of the tiler container. So the tiler container can fit (256/31 ~) 8 buffers, along its width.

Similarly, with a pad of 32 bytes on top and bottom, the buffer is (1080 + 64 =) 1144. Rounding it to (1144 + 8 =) 1152, so that buffer is allocated on page boundary. So one video buffer needs (1152/64 =) 18 pages, along the height of the tiler container. So the tiler container can fit (128/18 ~) 7 buffers, along its height.

Figure 4-47. Buffer Arrangement for HD Luma Buffers in 128MB 8-bit Mode Container

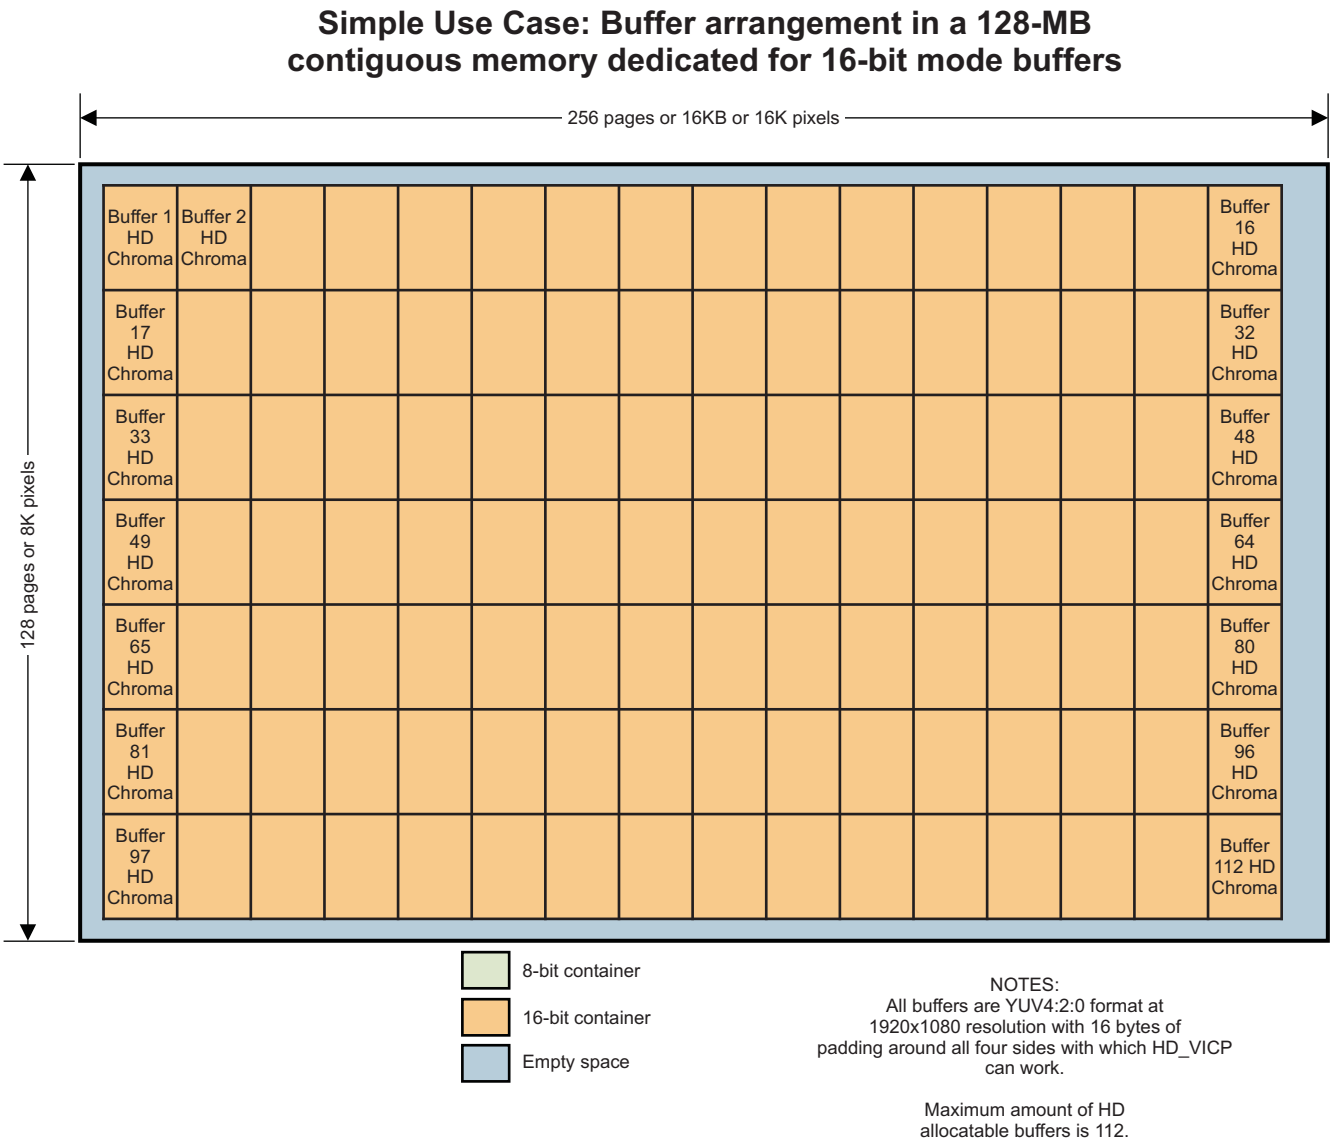


4.3.2.2 Chroma Buffers

In 16-bit tiled mode (Figure 4-48), each 4K page is arranged as 64-pixels wide and only 32-pixels high, where each pixel is of size 16-bits. In YUV 420 format, the Chroma buffer of the image is 960 × 540 and each pixel is 16-bits. Thus, each buffer is 960-bytes wide. With a pad of 16 bytes on each side, the buffer is (960 + 32 =) 992-bytes wide. Rounding it to (992 + 32 =) 1024, so that buffer is allocated on page boundary. So one video buffer needs (1024/64 =) 16 pages, along the width of the tiler container. So the tiler container can fit (256/16 =) 16 buffers, along its width.

Similarly, with a pad of 16 bytes on top and bottom, the buffer is (540 + 32 =) 572. Rounding it to (572 + 4 =) 576, so that buffer is allocated on page boundary. So one video buffer needs (576/32 =) 18 pages, along the height of the tiler container. So the tiler container can fit (128/18 ~) 7 buffers, along its height.

Figure 4-48. Buffer Arrangement for HD Chroma Buffers in 128MB 16-bit Mode Container



NOTE: The above scheme of Luma and Chroma buffer arrangement can be optimized further, by allocating buffers on sub-tile boundary, instead of page boundary (which is required when using LUT for address translation).

4.3.3 LUT Refill Using the PAT Refill Engines

There are two LUTs, each of size 256 × 128 elements, in the device.

There four refill engines, along with their own set of registers, to program the LUTs.

Also in this section are described in five different ways to program the LUT.

1. Simple manual area refill
2. Single auto-configured area refill
3. Chained auto-configured area refill
4. Synchronised auto-configured area refill
5. Cyclic synchronised auto-configured area refill

Some of the guidelines, in programming the LUTs are mentioned below:

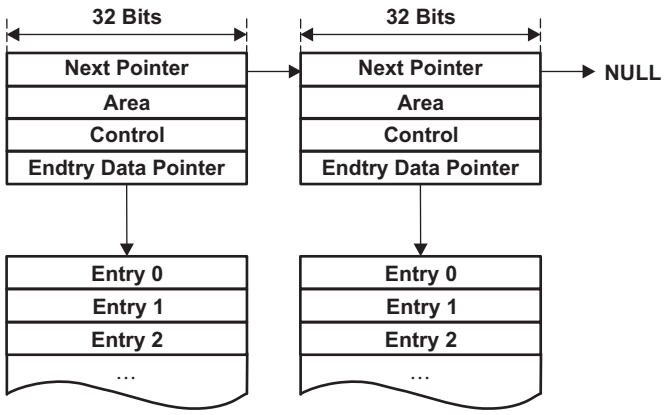
1. Entry table must be in DDR and cannot be split between 2 EMIF banks, when data interleaving enabled.
2. The data table should start from address 16-byte aligned.
3. With one set of descriptor, up to 64 LUT entries can be programmed, in any 2D area dimension.

4.3.3.1 PAT Memory Mapped Refill Descriptors

A PAT descriptor is a singly-linked list node as shown in Figure 4-49, containing:

- a description of the LUT area to reload
- a description of how to reload the defined LUT area
- a pointer to the location where the corresponding LUT entries are stored

Figure 4-49. PAT Descriptor Node



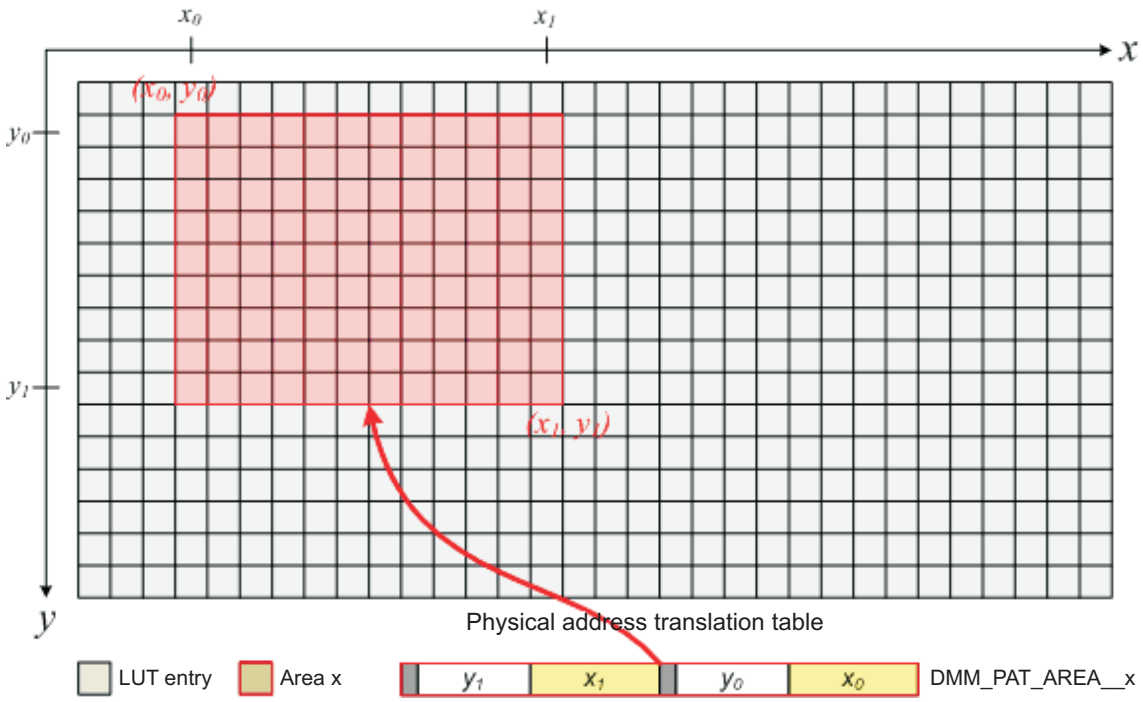
The PAT descriptor node and the entry data pointer must both be 16-byte aligned. A typical 'C' language description of this node is as follows:

```
struct PAT_desc {
         struct PAT_desc *next;
   u32_t            area;
   u32_t            ctrl;
   PAT_data        *data;
} __attribute__ ((aligned(16)));
```

4.3.3.1.1 PAT Area Refill Description

The area refill description is actually describing the top-left and bottom right corner of the PAT vector table as shown in Figure 4-50.

Figure 4-50. PAT Area Description



4.3.3.1.2 PAT Data Description

The pointer to the address in SDRAM, containing the memory based Data table, should be 16 byte aligned. Each field in this table is a 32 bit value, corresponding to the value to be programmed in one LUT entry. Though it is a 32 bit value, only 19 bits [30:12] are relevant. Bit 31 and bits [0:11] are ignored by the PAT refill engine.

4.3.3.1.3 PAT Memory Dump

This section presents how to dump the PAT LUT. This has to be done using the direct access mode of PAT, following the below steps:

1. Set at least one of the refill engine to direct LUT access mode. This has to be done using DMM_PAT_CONFIG register. Only bit 0 to 3 are used for mode of refill engine 0 to 3. (Value 0 is normal mode, value 1 is direct LUT access mode).
2. Set system coordinates we would like to read/write in the LUT. This has to be done using DMM_PAT_AREA__x. x is the refill engine index that has to be coherent with the refill engine used in direct mode (DMM_PAT_CONFIG). Only (x0,y0) is used in direct mode.
3. Select the LUT_ID using DMM_PAT_CTRL__x register.
4. Read (or write) the data in DMM_PAT_DATA__x register. x is the refill engine index.

4.3.3.1.4 PAT Refill Direction

The DMM_PAT_CTRL__x.DIRECTION field gives the “order” of the area refill with the same “SYX” encoding as in the TILER orientations:

- 0: from left to right then from top to bottom
- 1: from right to left then from top to bottom
- 2: from left to right then from bottom to top
- 3: from right to left then from bottom to top
- 4: from top to bottom then from left to right
- 5: from top to bottom then from right to left
- 6: from bottom to top then from left to right
- 7: from bottom to top then from right to left

This feature allows the initiators HD_VPSS and HDVICPs to start an access to an on going refill area. In this case, the direction field is set in accordance with the orientation accesses made by the initiators. The DMM_PAT_STATUS__x.ERROR is asserted to 1 if an access is done to a not yet refilled page.

4.3.3.2 Simple Manual Area Refill

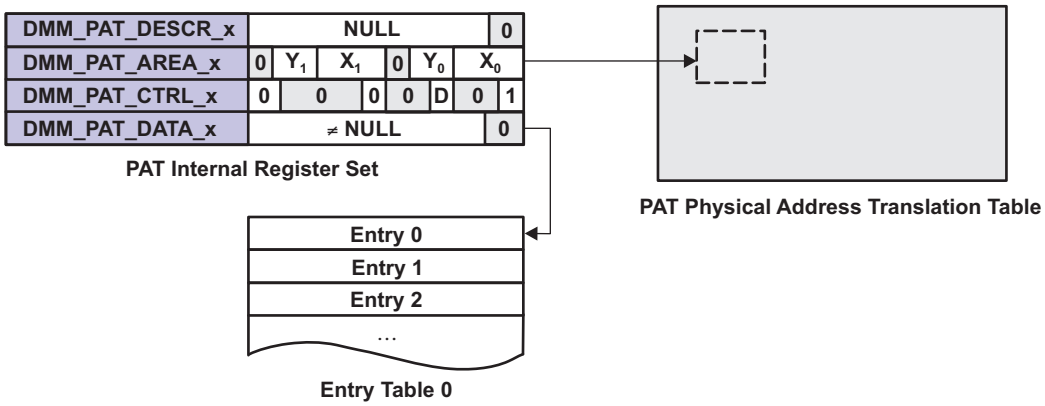
These steps have to be performed to create the 16-byte aligned memory-mapped entry table containing all entries of the defined area, as seen in Figure 4-51.

- Write the DMM_PAT_AREA_i register with the relevant (x0, y0) (x1, y1) area definition
- Write the DMM_PAT_DATA_i register with the physical address of the created entry table
- Write the DMM_PAT_CTRL_i register with the requested refill direction and assert the

DMM_PAT_CTRL_i[0] START bit:

- The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
- A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 4-51. DMM Simple Manual Area Refill

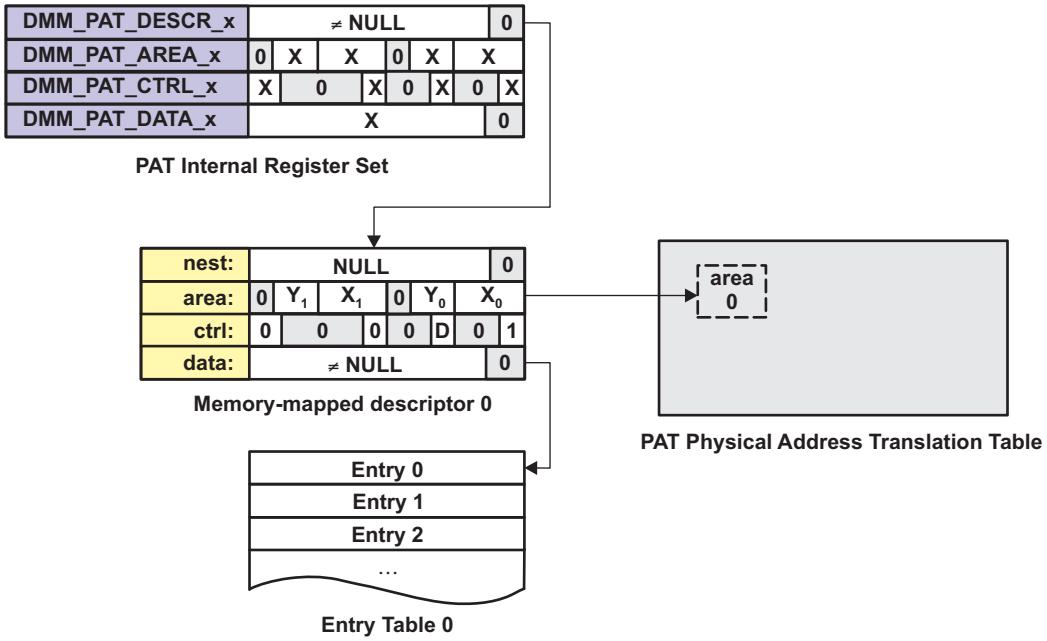


4.3.3.3 Single Auto-Configured Area Refill

These steps have to be performed to create the 16-byte aligned memory-mapped entry table containing all entries of the defined area, as seen in Figure 4-52.

1. Create a 16-byte aligned memory-mapped descriptor structure where:
   (a) the next field is set to NULL
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the requested direction D and the start bit asserted to start refilling as soon as this descriptor enters the PAT refill engine
   (d) the data field is set to the physical address of the created entry table
2. The DMM_PAT_DESCR_i register with the physical address of the created descriptor.
3. The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 4-52. DMM Single Auto-configured Area Refill

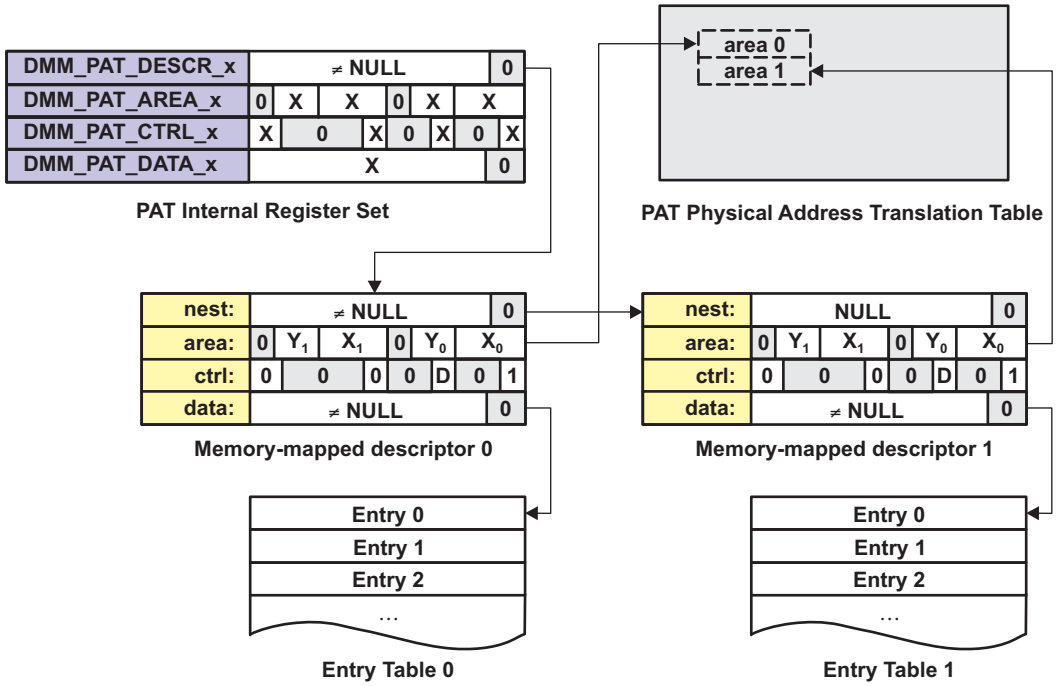


4.3.3.4 Chained Auto-Configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area, as seen in Figure 4-53.

1. Create one 16-byte aligned memory-mapped descriptor structures per area where:
   (a) the next field is set to the physical address of the next descriptor or NULL for the last one
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the requested direction D and the START bit asserted to start refilling as soon as the previous area refill is done
   (d) the data field is set to the physical address of the corresponding entry table
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 4-53. DMM Chained Auto-configured Area Refill

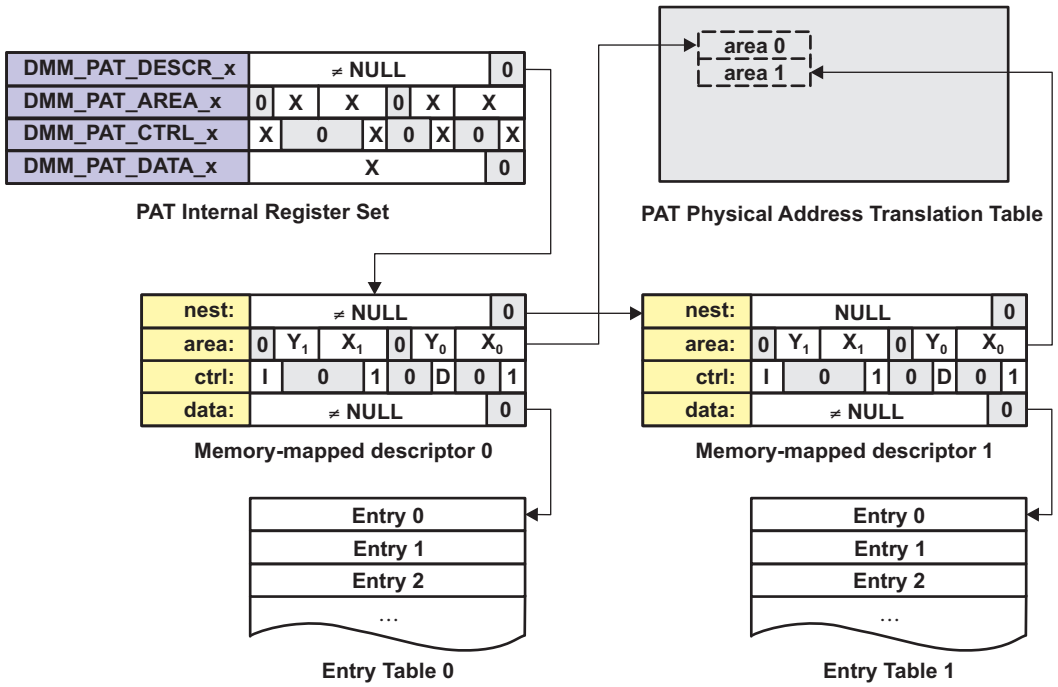


4.3.3.5 Synchronised Auto-configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area, as seen in Figure 4-54.

1. Create one 16-byte aligned memory-mapped descriptor structures per area where:
   (a) the next field is set to the physical address of the next descriptor or NULL for the last one
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the synchronising initiator identifier I, the SYNC bit asserted, the requested direction D, and the START bit asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area
   (d) the data field is set to the physical address of the corresponding entry table
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 4-54. DMM Synchronised Auto-configured Area Refill

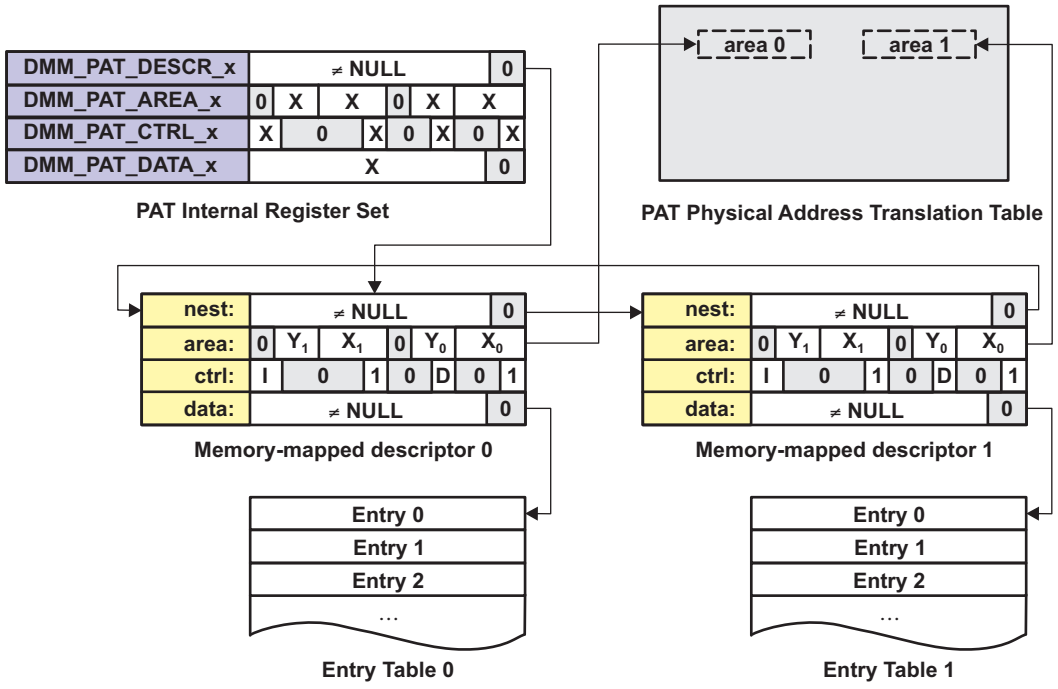


4.3.3.6 Cyclic Snchronised Auto-Configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area, as seen in Figure 4-55.

1. Create one 16-byte aligned memory-mapped descriptor structures per area where:
   (a) the next field is set to the physical address of the next descriptor in the circular list
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the synchronising initiator identifier I, the SYNC bit asserted, the requested direction D, and the START bit asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area
   (d) the data field is set to the physical address of the corresponding entry table
2. Write the DMM_PAT_DESCR_i register with the physical address of the initial descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated by writing any value to the DMM_PAT_DESCR_i to abort the current one.

Figure 4-55. DMM Cyclic Synchronised Auto-configured Area Refill



4.3.4 Address Management Using LISA Sections

In the device, there are either one ot two memory controllers (EMIFs).

4.3.4.1 DMM Sections

The DMM section definition is certainly the very first step in the DMM software configuration, as it is about defining the system address map to be used when accessing the SDRAM controllers.

A DMM section description fits in a single 32-bit register (DMM_LISA_MAP_x), where:

- SYS_ADDR defines the base address of the decoding range for the section
- SYS_SIZE defines the size of the section. Note that the encoding of this parameter is the number of bits actually used in the upper 8-bits of the incoming system address.
- SDRC_ADDR defines the physical base address of the section in the external memory controller
- SDRC_ADDRSPC defines the address space used on the SDRAM controller when hitting this section. The address space feature is not supported.
- SDRC_MAP defines the target memory controllers for this section. A section may hit a one or two controllers. The section is not used if this parameter is set to zero.
- SDRC_INTL defines the granularity of the interleaving if the section is mapped on more than one memory controllers

A couple of examples are given in the next subsections.

4.3.4.1.1 Case 1: Two Memory Controllers, 2GB DDR Symmetrical Distribution

Use Case: In this example we assume 2GB of external memory, spread evenly between 2 SDRAM controllers.

Table 4-4. Case 1 Memory Controllers

System Address Range	Memory Controller	EMIF Address Range
8000 0000-FFFF FFFFh	1 and 2, interleaved at 256 Bytes	0000 0000h-7FFF FFFFh

Configuration:

Table 4-5. Controller Configuration

Bit	Field	Section 0
31-24	SYS_ADDR	80h (incoming System Address MSB)
22-20	SYS_SIZE	7h (2 GB)
19-18	SDRC_INTL	2h (256 bytes interleaving)
17-16	SDRC_ADDRSPC	0 (Unused Reserved field)
8	SDRC_MAP	3h (Map to both EMIF0 and EMIF1
7-0	SDRC_ADDR	0 (SDRC address MSB)

NOTE: Section 1, Section 2 and Section 3 - identical to Section 0.

How DMM decodes and translates:

1. To check if an address hits a section, use the eight upper address bits of the address and mask them with the hit mask (2 8 - 2SYS_SIZE). If the result is equal to SYS_ADDR, the section is hit.
2. To define the physical address to be issued to the memory controller, use the eight upper address of the system address, mask them with the address mask ($2^{SYS\_SIZE} – 1$), and then OR them with SDRC_ADDR. This will give the resulting eight upper physical address bits. All lower address bits are forwarded unchanged.
3. If interleaving enabled, the physical address generation is modified. In case of a 256 bytes interleaving, the first chunk of 256 bytes is mapped to the first controller, the second chunk to the second controller, and so on. This results in system address bit 8 to be decoded as the SDRAM controller ID, 0 for the first controller and 1 for the second one (system address bit 7 would be used for interleaving at 128 bytes boundary, and bit 9 for 512 bytes). This bit is not included in the computed physical address, meaning the upper system address bits 9 to 31 are shifted to bits 8 to 30 when generating the physical address.

Example with above configuration:

1. Incoming access's System address 99AE 37F0h:
2. Hit mask: $2^8 - 2^7 = 80h$
3. Masked upper address bits: 80h AND 80h = 80h (the SYS_ADDR) , thus hits section 0
4. Address mask: $2^7 - 1 = 7Fh$
5. Masked upper address bits: 99h AND 7Fh = 19h
6. Full masked address: 19AE 37F0h
7. Bit 8 is 1 -> targets the second memory controller
8. Full masked shifted address (suppressing bit 8): 0CD7 1BF0h
9. OR upper physical address bits with SDRC_ADDR: 0CD7 1BF0h
10. Physical address: 0CD7 1BF0h

This request will be forwarded to address 0CD7 1BF0h, of the second memory controller, that is, EMIF1.

4.3.4.1.2 Case 2: Two Memory Controllers, 1152 MB (1 GB + 128 MB) DDR Symmetrical Distribution

In this example we assume 2GB of external memory, spread evenly between two EMIF controllers.

Table 4-6. Case 2 Memory Controllers

System Address Range	SDRAM Controller	EMIF Address Range
8000 0000h-C7FF FFFFh	1 and 2, interleaved at 256 Bytes	0000 0000h-47FF FFFFh

Configuration:

Table 4-7. Controller Configuration

Bit	Field	Section 0	Section 1
31-24	SYS_ADDR	80h (incoming System Address MSB)	C0h (incoming System Address MSB)
22-20	SYS_SIZE	6h (1 GB)	3h (128 MB)
19-18	SDRC_INTL	2h (256 bytes interleaving)	1 (128 bytes interleaving)
17-16	SDRC_ADDRSPC	0 (Unused Reserved field)	0 (Unused Reserved field)
8	SDRC_MAP	3h (Map to both EMIF0 and EMIF1)	3h (Map to both EMIF0 and EMIF1)
7-0	SDRC_ADDR	0 (SDRC address MSB)	20h (SDRC address MSB)

NOTE: Section 2 and Section 3 are identical to Section 1.

How DMM decodes and translates:

Identical to Section 4.3.4.1.1.

See Figure 4-56 for System Address Memory Range and its mapping to EMIFs.

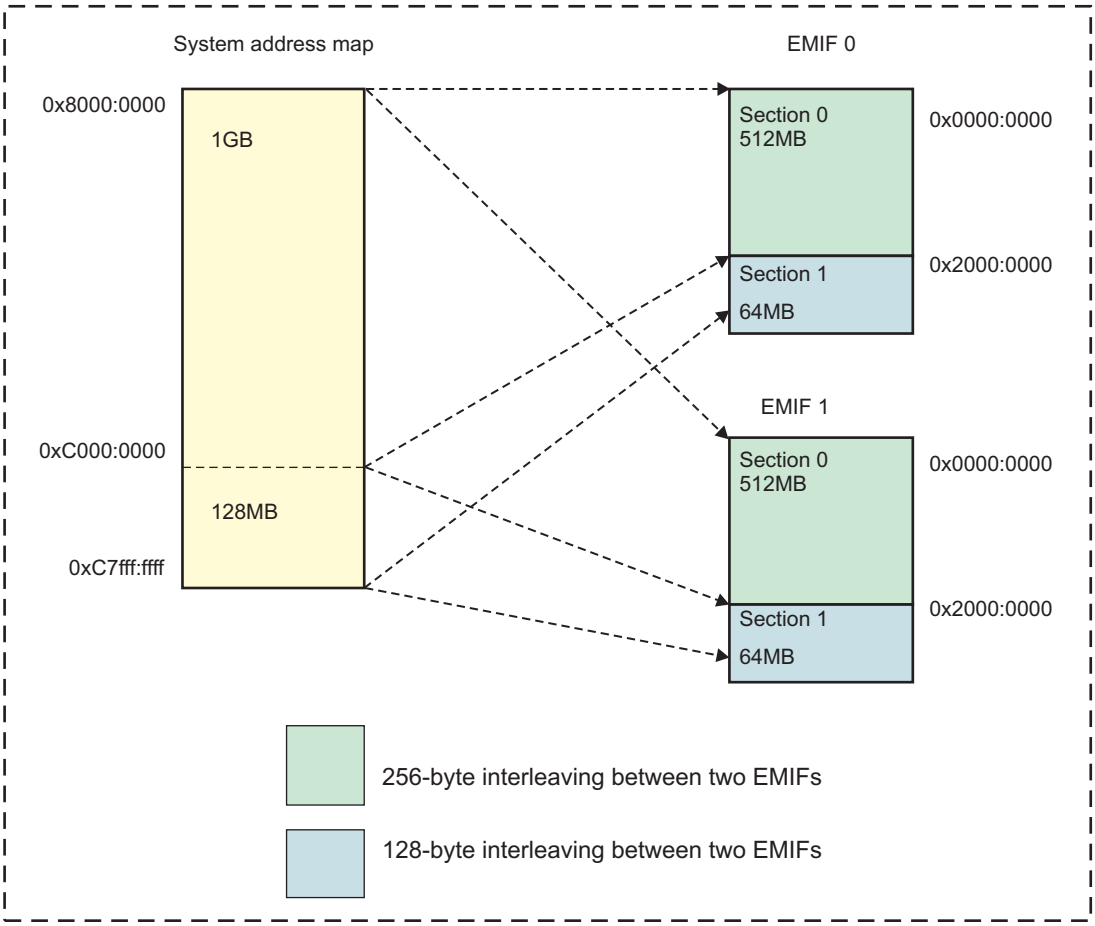
Example with above configuration:

Incoming accesses System address C022 34C0h:

1. Upper address bits: C0h
2. Hit mask: $2^8 - 2^3$ = F8h
3. Masked upper address bits: C0h AND F8h = C0h (the SYS_ADDR) , thus hits section 1
4. Address mask: $2^3 - 1$ = 7h
5. Masked upper address bits: C0h AND 7h = 0
6. Full masked address: 0022 34C0h
7. Bit 7 is 1 -> targets the second memory controller
8. Full masked shifted address (suppressing bit 7): 0011 1A60h
9. OR upper physical address bits with SDRC_ADDR: 0011 1A60h
10. Physical address: 0011 1A60h

This request will be forwarded to address 0011 1A60h, of the second memory controller; that is, EMIF1.

Figure 4-56. DMM Section Use-Case 2



4.3.4.1.3 Case 3: Two SDRAM Controllers, 1152 MB (1 GB + 128 MB) DDR Asymmetrical Distribution

NOTE: For optimal system performance, symmetric configuration is HIGHLY recommended. Unless dictated by system cost and other constraints, Asymmetrical distribution of memory should not be considered.

There are many ways to configure the section mapping in this use case.

Option 1: Asymmetrical section of EMIF0 is mapped to system address C000 0000h-C7FF FFFFh, higher portion of the SDRAM in system memory map.

Table 4-8. Section Mapping Option 1

Bit	Field	Section 0	Section 1
31-24	SYS_ADDR	80h (incoming System Address MSB)	88h (incoming System Address MSB)
22-20	SYS_SIZE	3h (128 MB)	6h (1 GB)
19-18	SDRC_INTL	0 (No interleaving)	2h (256 bytes interleaving)
17-16	SDRC_ADDRSPC	0 (Unused Reserved field)	0 (Unused Reserved field)
8	SDRC_MAP	1 (Map to EMIF0)	3h (Map to both EMIF0 and EMIF1)
7-0	SDRC_ADDR	20h (SDRC address MSB)	0 (SDRC address MSB)

Option 2: Asymmetrical section of EMIF0 is mapped to system address 8000 0000h-87FF FFFFh, Lower portion of the SDRAM in system memory map.

Table 4-9. Section Mapping Option 2

Bit	Field	Section 0	Section 1
31-24	SYS_ADDR	80h (incoming System Address MSB)	C0h (incoming System Address MSB)
22-20	SYS_SIZE	6h (1 GB)	3h (128 MB)
19-18	SDRC_INTL	2h (256 bytes interleaving)	0 (No interleaving)
17-16	SDRC_ADDRSPC	0 (Unused Reserved field)	0 (Unused Reserved field)
8	SDRC_MAP	3h (Map to both EMIF0 and EMIF1)	1 (Map to EMIF0)
7-0	SDRC_ADDR	0 (SDRC address MSB)	20h (SDRC address MSB)

4.4 DMM/TILER Registers

Table 4-10 lists the DMM/TILER registers. For the base address of these registers, see Table 1-11.

Table 4-10. DMM/TILER Registers

Address Offset	Register Name	Section
0	DMM_REVISION	Section 4.4.1
10h	DMM_SYSCONFIG	Section 4.4.2
1Ch	DMM_LISA_LOCK	Section 4.4.3

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 4-18. DMM_PAT_VIEW_MAP Registers Field Descriptions

Bit	Field	Value	Description	Type
31	ACCESS_PAGE		Kind of access for this page mode container	R/W
		0	Direct access, container base address given in CONT_PAGE	
		1	indirect access through the LUT indexed by CONT_PAGE	
30-28	Reserved	0	Reserved	R
27-24	CONT_PAGE	0	Base address of Container for page mode -or - LUT index	R/W
23	ACCESS_32		Kind of access for this 32-bit mode container	R/W
		0	Direct access, container base address given in CONT_32	
		1	indirect access through the LUT indexed by CONT_32	
22-20	Reserved	0	Reserved	R
19-16	CONT_32	0	Base address of Container for 32-bit mode -or - LUT index	R/W
15	ACCESS_16	0	Kind of access for this 16-bit mode container	R/W
		0	Direct access, container base address given in CONT_16	
		1	indirect access through the LUT indexed by CONT_16	
14-12	Reserved	0	Reserved	R
11-8	CONT_16	0	Base address of Container for 16-bit mode -or - LUT index	R/W
7	ACCESS_8		Kind of access for this 8-bit mode container	R/W
		0	Direct access, container base address given in CONT_8	
		1h	indirect access through the LUT indexed by CONT_8	
6-4	Reserved	0	Reserved	R
3-0	CONT_8	0	Base address of Container for 8-bit mode -or - LUT index	R/W

4.4.9 DMM PAT View Mapping Base Address Register: DMM_PAT_VIEW_MAP_BASE

The DMM PAT View Mapping Base Address register is shown in Figure 4-65 and described in Table 4-19.

Figure 4-65. DMM_PAT_VIEW_MAP_BASE Register

31	30	0
BASEADDR	Reserved	
R/W-0	R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 4-19. DMM_PAT_VIEW_MAP_BASE Register Field Descriptions

Bit	Field	Value	Description	Type
31	BASEADDR	0	MSB of the PAT view mapping base address	R/W
30-0	Reserved	0	Reserved	R

4.4.10 DMM PAT End of Interrupt Register: DMM_PAT_IRQ_EOI

The DMM PAT End of Interrupt register is shown in Figure 4-66 and described in Table 4-20. This register is per-event raw interrupt status vector. The purpose is mostly for debug. Raw status is set even if the related event is not enabled. Write 1 to set the (raw) status.

Figure 4-66. DMM_PAT_IRQ_EOI Register

4.4.16 DMM PAT Descriptor Registers: DMM_PAT_DESCR_0-DMM_PAT_DESCR_3

The DMM PAT Descriptor register is shown in Figure 4-72 and described in Table 4-26.

- Physical address of the next table refill descriptor
- Writing to this register aborts the current ongoing area reload
- Write also resets the corresponding DMM_PAT_AREA_x, DMM_PAT_CTRL_x and DMM_PAT_DATA_x registers
- The descriptor address must be in the DDR and not any other internal memory

2-0	P_PAT	4h	Priority for PAT engine.	R/W

Enhanced Direct Memory Access (EDMA3) Controller

This chapter describes the features and operations of the enhanced direct memory access (EDMA3) controller.

Topic **Page**

5.1 Introduction

5.1.1 Overview

The enhanced direct memory access (EDMA3) controller's primary purpose is to service user-programmed data transfers between two memory-mapped slave endpoints on the device.

Typical usage includes, but is not limited to the following:

- Servicing software-driven paging transfers (for example, transfers from external memory, such as DDR2 to internal device memory, such as DSP L2 SRAM).
- Servicing event-driven peripherals, such as a serial port.
- Performing sorting or sub-frame extraction of various data structures.
- Offloading data transfers from the main device CPU(s) or DSP(s) (see the device-specific data manual for specific peripherals that are accessible via the EDMA3 controller.).

The EDMA3 controller has a different architecture from the previous EDMA2 controller on the TMS320C621x/C671x DSPs and TMS320C64x DSPs. (See the *EDMA v3.0 (EDMA3) Migration Guide for TMS320C645x DSP* (SPRAAB9) for more information on new/advanced features.)

The EDMA3 controller consists of two principal blocks:

- EDMA3 channel controller (EDMA3CC).
- EDMA3 transfer controller(s) (EDMA3TC).

The EDMA3 channel controller serves as the user interface for the EDMA3 controller. The EDMA3CC includes parameter RAM (PaRAM), channel control registers, and interrupt control registers. The EDMA3CC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TRs) to the transfer controller.

The EDMA3 transfer controllers are slaves to the EDMA3 channel controller that is responsible for data movement. The transfer controller issues read/write commands to the source and destination addresses that are programmed for a given transfer. The operation is transparent to user.

5.1.2 Features

The EDMA3 channel controller has following features:

- Fully orthogonal transfer description:
  - Three transfer dimensions.
  - A-synchronized transfers: one-dimension serviced per event.
  - AB-synchronized transfers: two-dimensions serviced per event.
  - Independent indexes on source and destination.
  - Chaining feature allows a 3-D transfer based on a single event.
- Flexible transfer definition:
  - Increment or FIFO transfer addressing modes.
  - Linking mechanism allows automatic PaRAM set update.
  - Chaining allows multiple transfers to execute with one event.
- Interrupt generation for the following:
  - Transfer completion.
  - Error conditions.
  - Error conditions routed to Cortex-A8 only.
- Up to 8 interrupt outputs for multi-core support.
- Debug visibility:
  - Queue water marking/threshold.
  - Error and status recording to facilitate debug.

- 64 DMA channels:
  - Event synchronization.
  - Manual synchronization (CPU(s) write to event set register).
  - Chain synchronization (completion of one transfer triggers another transfer).
  - Support for programmable DMA channel to PaRAM mapping.
- Eight QDMA channels:
  - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
  - Support for programmable QDMA channel to PaRAM mapping.
- 512 PaRAM sets:
  - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Four transfer controllers/event queues. You program the system-level priority of these queues. (See the device data manual for the possible system priorities.)
- 16 event entries per event queue.
- Memory protection support:
  - Proxy memory protection for TR submission.
  - Active memory protection for accesses to PaRAM and registers.

The EDMA3 transfer controller has the following features:

- Four transfer controllers (TC0-TC3).
- 128-bit wide read and write ports per TC.
- Up to four in-flight transfer requests (TRs).
- Programmable priority level.
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA3CC manages the 3rd dimension).
- Support for increment or constant addressing mode transfers.
- Interrupt and error support.
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness.

5.1.3 Terminology Used in This Document

The following is a brief explanation of some terms that are used in this document:

A-synchronized transfer— A transfer type where one dimension is serviced per synchronization event.

AB-synchronized transfer— A transfer type where two dimensions are serviced per synchronization event.

Chaining— A trigger mechanism in which a transfer can be initiated at the completion of another transfer or sub-transfer.

CPU(s)— The main processing engine or engines on a device. The CPU is typically a DSP or general-purpose processor (see the device-specific data manual to learn more about the CPU on your system.)

DMA channel— One of the 64 channels that external, manual, or chained events can trigger. All direct memory access (DMA) channels exist in the EDMA3CC.

Dummy set or dummy PaRAM set— A PaRAM set for which at least one of the count fields is equal to 0 and at least one of the count fields is nonzero. All of the count fields are cleared in a null PaRAM set.

Dummy transfer— A dummy set results in the EDMA3CC performing a dummy transfer. This is not an error condition. A null set results in an error condition.

EDMA3 channel controller (EDMA3CC)— The EDMA3CC is the portion of the EDMA3 that you program. The EDMA3CC contains the parameter RAM (PaRAM), event processing logic, DMA/QDMA channels, and event queues. The EDMA3CC service events (external, manual, chained, and QDMA) and is responsible for submitting transfer requests to the transfer controllers (EDMA3TC) that perform the actual transfer.

EDMA3 programmer— Any entity on the chip that has read/write access to the EDMA3 registers and can program an EDMA3 transfer.

EDMA3 transfer controller(s) (EDMA3TC)— Transfer controllers are the transfer engines for the EDMA3 controller. They perform the read/writes, as dictated by the EDMA3CC's transfer requests.

Enhanced direct memory access (EDMA3) controller— EDMA3 consists of the EDMA3 channel controller (EDMA3CC) and the EDMA3 transfer controller(s) (EDMA3TC), referred to as EDMA3 in this document.

L3— System bus infrastructure that arbitrates and decodes bus transactions from multiple masters to multiple slaves.

Link parameter set — A PaRAM set that is used for linking.

Linking— The mechanism of reloading a PaRAM set with new transfer characteristics on completion of the current transfer.

Memory-mapped slave— All on-chip memories, off-chip memories, and slave peripherals. These typically rely on the EDMA3 (or other master peripheral) to perform transfers to and from them.

Master peripherals— All peripherals that are capable of initiating read and write transfers to the system that may not solely rely on the EDMA3 for their data transfers.

Null set or null PaRAM set— A PaRAM set that has all count fields cleared (except for the link field). A dummy PaRAM set has at least one of the count fields nonzero.

Null transfer— A trigger event for a null PaRAM set results in the EDMA3CC performing a null transfer. This is an error condition. A dummy transfer is not an error condition.

Parameter RAM (PaRAM)— Programmable RAM that stores PaRAM sets that DMA channels, QDMA channels, and linking uses.

Parameter RAM (PaRAM) set— The PaRAM set is a 32-byte EDMA3 channel transfer definition. Each parameter set consists of eight words (that are four bytes each) that store the context for a DMA/QDMA/link transfer. A PaRAM set includes source address, destination address, counts, indexes, and options.

Parameter RAM (PaRAM) set entry— A PaRAM set entry occurs when one of the eight four-byte components of the parameter set.

QDMA channel— A QDMA channel is one of the four channels that you can trigger when writing to the trigger word (TRWORD) of a PaRAM set. All QDMA channels exist in the EDMA3CC.

Slave end points— Slave end points are all on-chip memories, off-chip memories, and slave peripherals. Slave end points may rely on the EDMA3 to perform transfers to and from them.

Transfer request (TR)— A command for data movement that is issued from the EDMA3CC to the EDMA3TC. A TR includes source and destination addresses, counts, indexes, and options.

Trigger event— A trigger event is an action that causes the EDMA3CC to service the channel and to submit a transfer request to the EDMA3TC. Trigger events for the DMA channels include events that are triggered manually, externally, and by chain. Trigger events for QDMA channels include events that are triggered automatically and by link.

Trigger word— For QDMA channels, the trigger word specifies the PaRAM set entry that results in a QDMA trigger event when it is written. The trigger word is programmed via the QDMA channel map register (QCHMAP) and can point to any of the PaRAM set entries.

TR synchronization (sync) event— See Trigger event.

5.2 Architecture

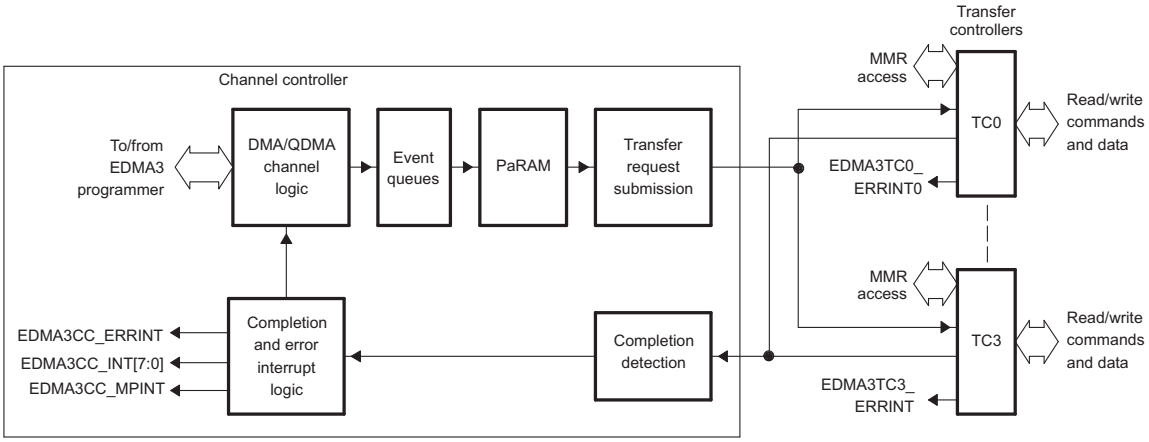
This chapter discusses the architecture of the EDMA3 controller.

5.2.1 Functional Overview

5.2.1.1 EDMA3 Controller Block Diagram

Figure 5-1 shows a block diagram for the EDMA3 controller.

Figure 5-1. EDMA3 Controller Block Diagram



5.2.1.2 EDMA3 Channel Controller (EDMA3CC)

Figure 5-2 shows a functional block diagram of the EDMA3 channel controller (EDMA3CC).

The main blocks of the EDMA3CC are as follows:

- Parameter RAM (PaRAM): The PaRAM maintains parameter sets for channel and reload parameter sets. You must write the PaRAM with the transfer context for the desired channels and link parameter sets. EDMA3CC processes sets based on a trigger event and submits a transfer request (TR) to the transfer controller.
- EDMA3 event and interrupt processing registers: Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- Completion detection: The completion detect block detects completion of transfers by the EDMA3TC and/or slave peripherals. You can optionally use completion of transfers to chain trigger new transfers or to assert interrupts.
- Event queues: Event queues form the interface between the event detection logic and the transfer request submission logic.
- Memory protection registers: Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

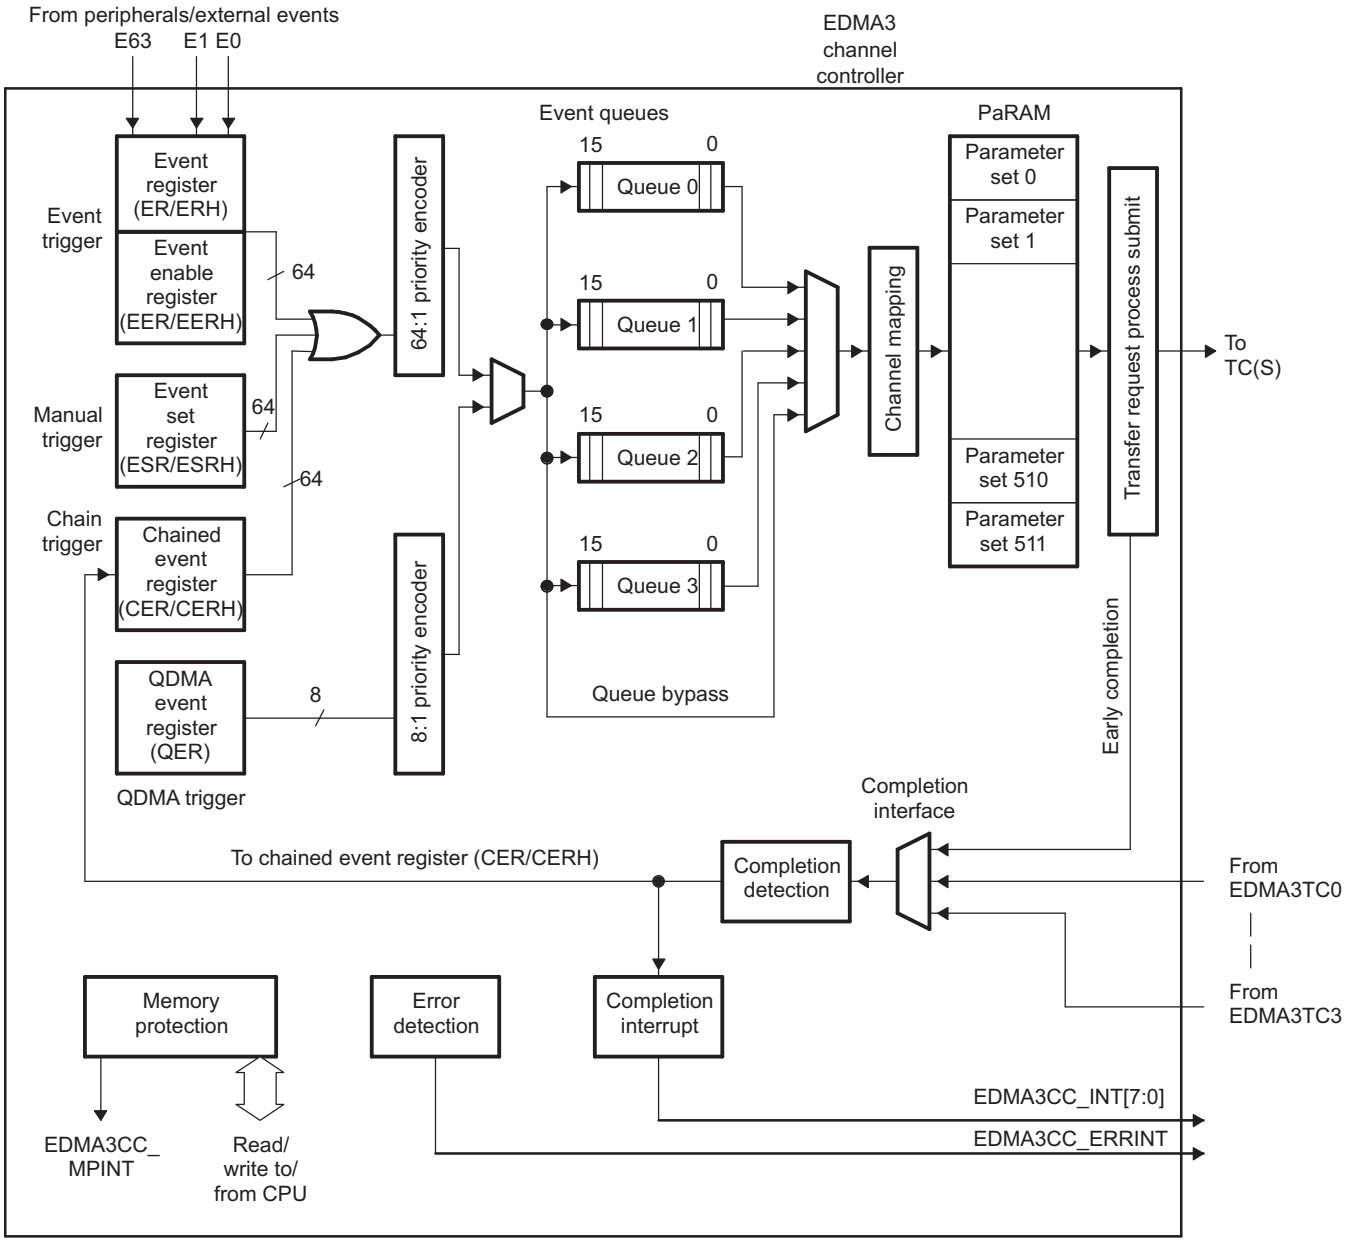
Other functions include the following:

- Region registers: Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA3 programmers own (for example, ARM or DSP).
- Debug registers: Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA3CC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main thing that differentiates a DMA channel from a QDMA channel is the method that the system uses to trigger transfers. See Section 5.2.4.

Figure 5-2. EDMA3 Channel Controller (EDMA3CC) Block Diagram



A trigger event is needed to initiate a transfer. A trigger event may be due to an external event, manual write to the event set register, or chained event for DMA channels. QDMA channels auto-trigger when a write to the trigger word that you program occurs on the associated PaRAM set. All such trigger events are logged into appropriate registers upon recognition.

Once a trigger event is recognized, the appropriate event gets queued in the EDMA3CC event queue. The assignment of each DMA/QDMA channel to an event queue is programmable. Each queue is 16 events deep; therefore, you can queue up to 16 events (on a single queue) in the EDMA3CC at a time. Additional pending events that are mapped to a full queue are queued when the event queue space becomes available. See Section 5.2.11.

If events on different channels are detected simultaneously, the events are queued based on a fixed priority arbitration scheme with the DMA channels being higher priority events than the QDMA channels. Among the two groups of channels, the lowest-numbered channel is the highest priority.

Each event in the event queue is processed in FIFO order. When the head of the queue is reached, the PaRAM associated with that channel is read to determine the transfer details. The TR submission logic evaluates the validity of the TR and is responsible for submitting a valid transfer request (TR) to the appropriate EDMA3TC (based on the event queue to the EDMA3TC association, Q0 goes to TC0 , Q1 goes to TC1, Q2 goes to TC2, and Q3 goes to TC3). For more information, refer to Section 5.2.3.

The EDMA3TC receives the request and is responsible for data movement, as specified in the transfer request packet (TRP), other necessary tasks like buffering, and ensuring transfers are carried out in an optimal fashion wherever possible. For more information on EDMA3TC, refer to Section 5.2.1.3.

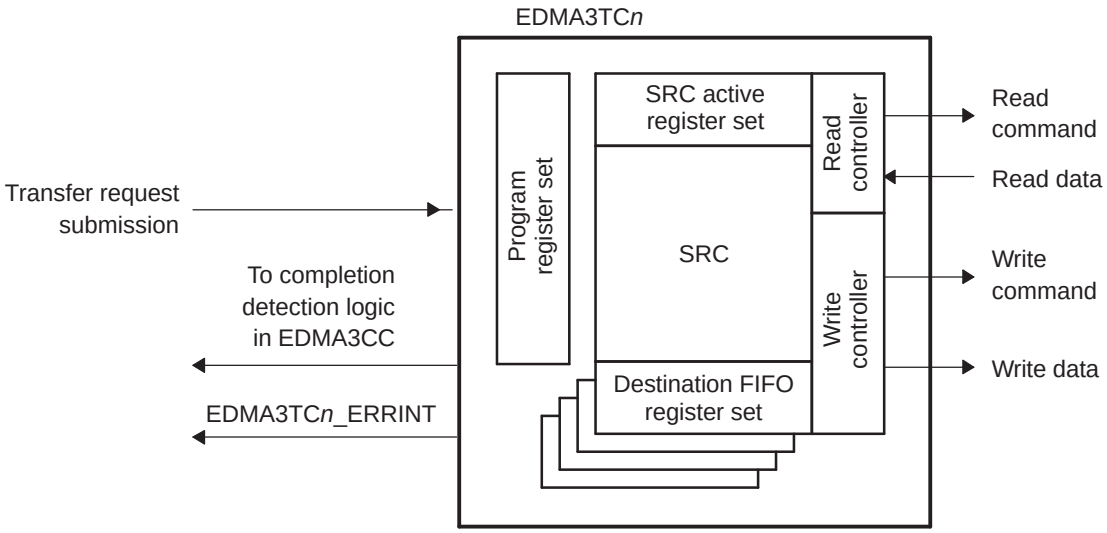
If you have decided to receive an interrupt or to chain to another channel on completion of the current transfer, the EDMA3TC signals completion to the EDMA3CC completion detection logic when the transfer is complete. You can alternately choose to trigger completion when a TR leaves the EDMA3CC boundary, rather than wait for all of the data transfers to complete. Based on the setting of the EDMA3CC interrupt registers, the completion interrupt generation logic is responsible for generating EDMA3CC completion interrupts to the CPU. For more information, refer to Section 5.2.5.

Additionally, the EDMA3CC also has an error detection logic that causes an error interrupt generation on various error conditions (like missed events, exceeding event queue thresholds, etc.). For more information on error interrupts, refer to Section 5.2.9.4.

5.2.1.3 EDMA3 Transfer Controller (EDMA3TC)

Section 5.2.9.4 shows a functional block diagram of the EDMA3 transfer controller (EDMA3TC).

Figure 5-3. EDMA3 Transfer Controller (EDMA3TC) Block Diagram



The main blocks of the EDMA3TC are:

- DMA program register set: The DMA program register set stores the transfer requests received from the EDMA3 channel controller (EDMA3CC).
- DMA source active register set: The DMA source active register set stores the context for the DMA transfer request currently in progress in the read controller.
- Read controller: The read controller issues read commands to the source address.
- Destination FIFO register set: The destination (DST) FIFO register set stores the context for the DMA transfer request(s) currently in progress in the write controller.
- Write controller: The write controller issues write commands/write data to the destination slave.

- Data FIFO: The data FIFO exists for holding temporary in-flight data.
- Completion interface: The completion interface sends completion codes to the EDMA3CC when a transfer completes, and generates interrupts and chained events (also, see Section 5.2.1.2 for more information on transfer completion reporting).

When the EDMA3TC is idle and receives its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA3CC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands governed by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization. For more information on command fragmentation and optimization, refer to Section 5.2.12.1.1.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

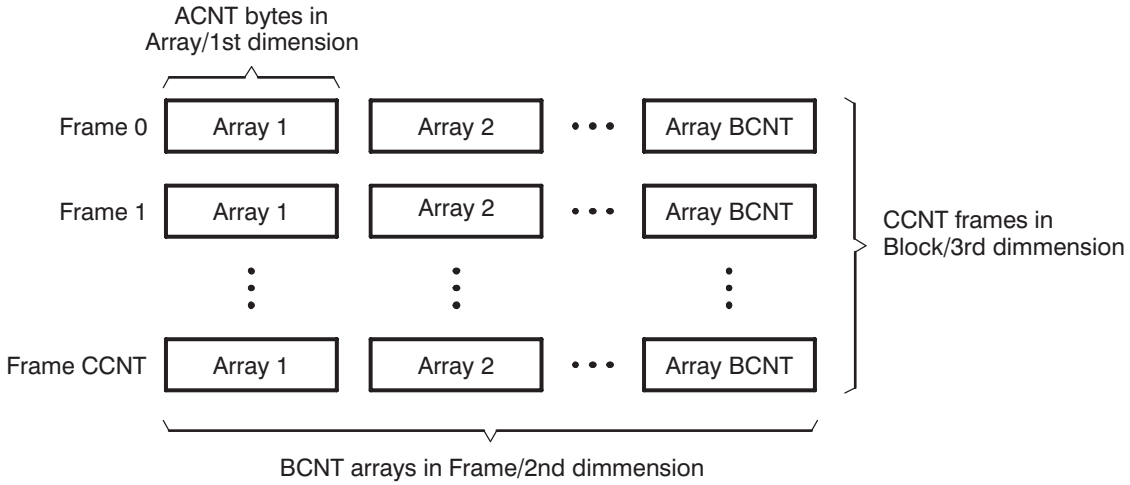
5.2.2 Types of EDMA3 Transfers

An EDMA3 transfer is always defined in terms of three dimensions. Figure 5-4 shows the three dimensions used by EDMA3 transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using SRCBIDX or DSTBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the 3rd dimension is separated from the previous by an index programmed using SRCCIDX or DSTCIDX.

Note that the reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (SYNCDIM bit in OPT). Of the three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

Figure 5-4. Definition of ACNT, BCNT, and CCNT



5.2.2.1 A-Synchronized Transfers

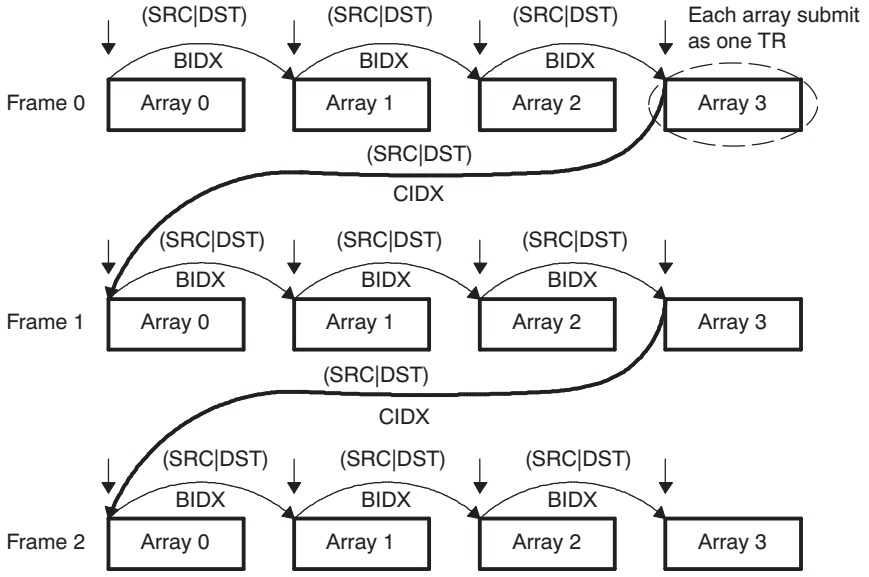
In an A-synchronized transfer, each EDMA3 sync event initiates the transfer of the 1st dimension of ACNT bytes, or one array of ACNT bytes. In other words, each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX, as shown in Figure 5-5, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) BIDX.

Frames are always separated by SRCCIDX and DSTCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in Figure 5-5, SRCCIDX/DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 5-5 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See Section 5.2.3.6 for details on parameter set updates.

Figure 5-5. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)



5.2.2.2 AB-Synchronized Transfers

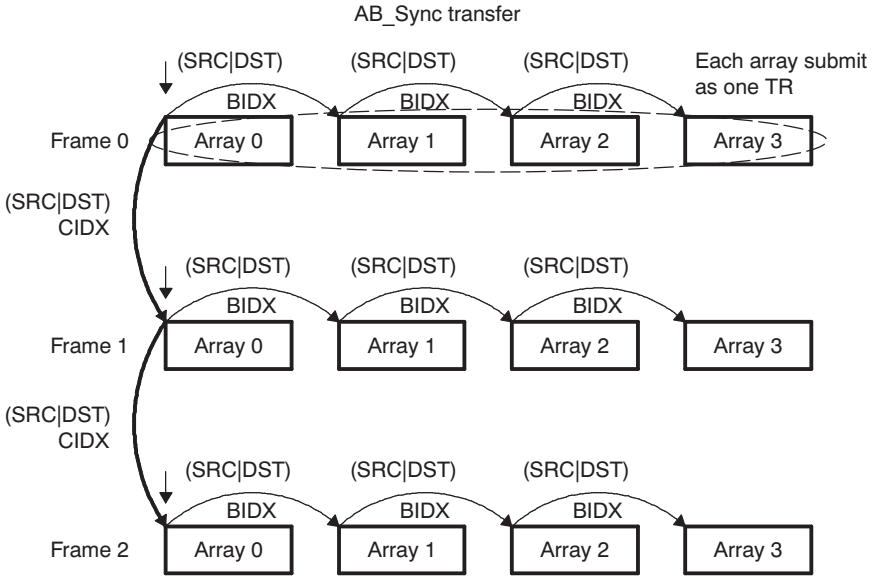
In a AB-synchronized transfer, each EDMA3 sync event initiates the transfer of 2 dimensions or one frame. In other words, each event/TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Thus, CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX as shown in Figure 5-6. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add SRCCIDX/DSTCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 5.2.3.6 for details on parameter set updates.

Figure 5-6 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of *n* (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

Figure 5-6. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)



NOTE: ABC-synchronized transfers are not directly supported. But can be logically achieved by chaining between multiple AB-synchronized transfers.

5.2.3 Parameter RAM (PaRAM)

The EDMA3 controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table within EDMA3CC, referred to as PaRAM. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 512 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels
- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0. These should be remapped before use. For more information, see Section 5.4.1.1.3 (DCHMAP registers) and Section 5.4.1.1.4 (QCHMAP registers).

Table 5-1. EDMA3 Parameter RAM Contents

PaRAM Set Number	Address[1]	Parameters[2]
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...	...	...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...	...	...
510	EDMA Base Address + 7FC0h to EDMA Base Address + 7FDFh	PaRAM set 510
511	EDMA Base Address + 7FE0h to EDMA Base Address + 7FFFh	PaRAM set 511

(1) The EDMA base addess can be obtained from the device-specific data manual.
(2) The device has 8 QDMA channels that can be mapped to any parameter set number from 0 to 511.

5.2.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in Figure 5-7 and described in Table 5-2. Each PaRAM set consists of 16-bit and 32-bit parameters.

Figure 5-7. PaRAM Set

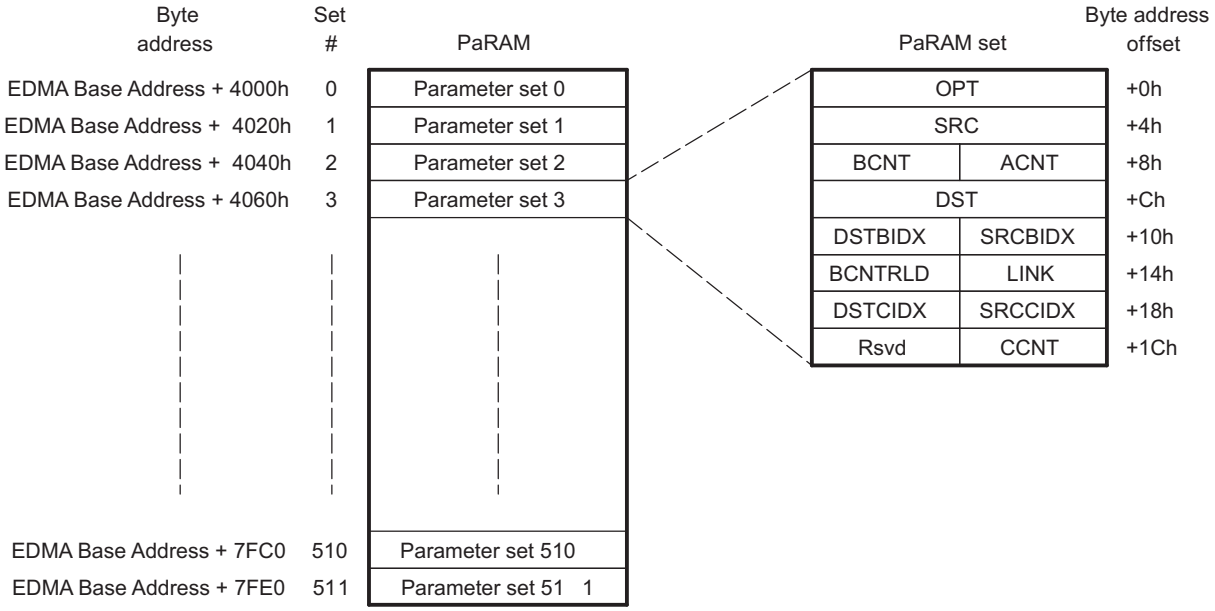


Table 5-2. EDMA3 Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options	Transfer configuration options
4h	SRC	Channel Source Address	The byte address from which data is transferred
8h[(1)]	ACNT	Count for 1st Dimension	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address	The byte address to which data is transferred
10h[(1)]	SRCBIDX	Source BCNT Index	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DSTBIDX	Destination BCNT Index	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h[(1)]	LINK	Link Address	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h[(1)]	SRCCIDX	Source CCNT Index	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DSTCIDX	Destination CCNT index	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	RSVD	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

(1) If OPT, SRC, or DST is the trigger word for a QDMA transfer then it is required to do a 32-bit access to that field. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor swaps addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

5.2.3.2 EDMA3 Channel PaRAM Set Entry Fields

5.2.3.2.1 Channel Options Parameter (OPT)

The channel options parameter (OPT) is shown in Figure 5-8 and described in Table 5-3.

Figure 5-8. Channel Options Parameter (OPT)

31	30 28	27 24	23	22	21	20	19 18	17 16
PRIV	Reserved	PRIVID	ITCCHEN	TCCHEN	ITCINTEN	TCINTEN	Reserved	TCC
R-0	R-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

15 12	11	10 8	7 4	3	2	1	0
TCC	TCCMODE	FWID	Reserved	STATIC	SYNCDIM	DAM	SAM
R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

Table 5-3. Channel Options Parameters (OPT) Field Descriptions

Bit	Field	Value	Description
31	PRIV		Privilege level (supervisor versus user) for the host/CPU/DMA that programmed this PaRAM set. This value is set with the EDMA3 master's privilege value when any part of the PaRAM set is written.
		0	User level privilege.
		1	Supervisor level privilege.
30-28	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
27-24	PRIVID	0-Fh	Privilege identification for the external host/CPU/DMA that programmed this PaRAM set. This value is set with the EDMA3 master's privilege identification value when any part of the PaRAM set is written.
23	ITCCHEN		Intermediate transfer completion chaining enable.
		0	Intermediate transfer complete chaining is disabled.
		1	Intermediate transfer complete chaining is enabled.
			When enabled, the chained event register (CER/CERH) bit is set on every intermediate chained transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in CER or CERH is the TCC value specified.
22	TCCHEN		Transfer complete chaining enable.
		0	Transfer complete chaining is disabled.
		1	Transfer complete chaining is enabled.
			When enabled, the chained event register (CER/CERH) bit is set on final chained transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in CER or CERH is the TCC value specified.
21	ITCINTEN		Intermediate transfer completion interrupt enable.
		0	Intermediate transfer complete interrupt is disabled.
		1	Intermediate transfer complete interrupt is enabled.
			When enabled, the interrupt pending register (IPR / IPRH) bit is set on every intermediate transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in IPR or IPRH is the TCC value specified. To generate a completion interrupt to the CPU, the corresponding IER [TCC] / IERH [TCC] bit must be set.
20	TCINTEN		Transfer complete interrupt enable.
		0	Transfer complete interrupt is disabled.
		1	Transfer complete interrupt is enabled.
			When enabled, the interrupt pending register (IPR / IPRH) bit is set on transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in IPR or IPRH is the TCC value specified. To generate a completion interrupt to the CPU, the corresponding IER[TCC] / IERH [TCC] bit must be set.
19-18	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
17-12	TCC	0-3Fh	Transfer complete code. This 6-bit code sets the relevant bit in the chaining enable register (CER [TCC] /CERH [TCC]) for chaining or in the interrupt pending register (IPR [TCC] / IPRH [TCC]) for interrupts.

Table 5-3. Channel Options Parameters (OPT) Field Descriptions (continued)

Bit	Field	Value	Description
11	TCCMODE		Transfer complete code mode. Indicates the point at which a transfer is considered completed for chaining and interrupt generation.
		0	Normal completion: A transfer is considered completed after the data has been transferred.
		1	Early completion: A transfer is considered completed after the EDMA3CC submits a TR to the EDMA3TC. TC may still be transferring data when the interrupt/chain is triggered.
10-8	FWID	0-7h	FIFO Width. Applies if either SAM or DAM is set to constant addressing mode.
		0	FIFO width is 8-bit.
		1h	FIFO width is 16-bit.
		2h	FIFO width is 32-bit.
		3h	FIFO width is 64-bit.
		4h	FIFO width is 128-bit.
		5h	FIFO width is 256-bit.
		6h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	STATIC		Static set.
		0	Set is not static. The PaRAM set is updated or linked after a TR is submitted. A value of 0 should be used for DMA channels and for non-final transfers in a linked list of QDMA transfers.
		1	Set is static. The PaRAM set is not updated or linked after a TR is submitted. A value of 1 should be used for isolated QDMA transfers or for the final transfer in a linked list of QDMA transfers.
2	SYNCDIM		Transfer synchronization dimension.
		0	A-synchronized. Each event triggers the transfer of a single array of ACNT bytes.
		1	AB-synchronized. Each event triggers the transfer of BCNT arrays of ACNT bytes.
1	DAM		Destination address mode.
		0	Increment (INCR) mode. Destination addressing within an array increments. Destination is not a FIFO.
		1	Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM		Source address mode.
		0	Increment (INCR) mode. Source addressing within an array increments. Source is not a FIFO.
		1	Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

5.2.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA3. For SAM in constant addressing mode, you must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See Section 5.2.12.3 for additional details.

5.2.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA3. For DAM in constant addressing mode, you must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See Section 5.2.12.3 for additional details.

5.2.3.2.4 Count for 1st Dimension (ACNT)

ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA3TC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

See Section 5.2.3.5 and Section 5.2.5.3 for details on dummy/null completion conditions.

5.2.3.2.5 Count for 2nd Dimension (BCNT)

BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

See Section 5.2.3.5 and Section 5.2.5.3 for details on dummy/null completion conditions.

5.2.3.2.6 Count for 3rd Dimension (CCNT)

CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

A CCNT value of 0 is considered either a null or dummy transfer. See Section 5.2.3.5 and Section 5.2.5.3 for details on dummy/null completion conditions.

5.2.3.2.7 BCNT Reload (BCNTRLD)

BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA3CC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA3CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA3CC submits the BCNT in the TR and the EDMA3TC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

5.2.3.2.8 Source B Index (SRCBIDX)

SRCBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for SRCBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- SRCBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- SRCBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- SRCBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

5.2.3.2.9 Destination B Index (DSTBIDX)

DSTBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for DSTBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. See SRCBIDX for examples.

5.2.3.2.10 Source C Index (SRCCIDX)

SRCCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for SRCCIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when SRCCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 5-5), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 5-6).

5.2.3.2.11 Destination C Index (DSTCIDX)

DSTCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when DSTCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 5-5), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 5-6).

5.2.3.2.12 Link Address (LINK)

The EDMA3CC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the EDMA3CC loads/reloads the next PaRAM set during linking.

You must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA3CC ignores the upper 2 bits of the LINK entry, allowing the programmer the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if you make use of the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

You should make sure to program the LINK field correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

A LINK value of FFFFh is referred to as a NULL link that should cause the EDMA3CC to perform an internal write of 0 to all entries of the current PaRAM set, except for the LINK field that is set to FFFFh. Also, see Section 5.2.5 for details on terminating a transfer.

5.2.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (ACNT, BCNT, and CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA3CC, the bit corresponding to the channel is set in the associated event missed register (EMR, EMRH, or QEMR). This bit remains set in the associated secondary event register (SER, SERH, or QSER). *This implies that any future events on the same channel are ignored by the EDMA3CC and you are required to clear the bit in SER, SERH, or QSER for the channel.* This is considered an error condition, since events are not expected on a channel that is configured as a null transfer. See Section 5.4.1.6.8 and Section 5.4.1.2.1 for more information on the SER and EMR registers, respectively.

5.2.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (ACNT, BCNT, or CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA3CC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EMR, EMRH, or QEMR) and the secondary event register (SER, SERH, or QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes. See Section 5.4.1.6.8 and Section 5.4.1.2.1 for more information on the SER and EMR registers, respectively.

5.2.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA3CC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E*n*) in EMR to get set and the E*n* bit in SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 5-4 summarizes the conditions and effects of null and dummy transfer requests.

Table 5-4. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EMR/EMRH/QEMR is set	Yes	No
SER/SERH/QSER remains set	Yes	No
Link update (STATIC = 0 in OPT)	Yes	Yes
QER is set	Yes	Yes
IPR/IPRH CER/CERH is set using early completion	Yes	Yes

5.2.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA3CC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of CCNT after submission of every transfer request.

See Table 5-5 for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in Section 5.2.3.7.

After the TR is read from the PaRAM (and is in process of being submitted to EDMA3TC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: ACNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK.
- AB-synchronized: ACNT, BCNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK.

Note that PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA3TC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in Section 5.2.12. For A-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes (BCNT = 1 and CCNT = 1). For AB-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes of BCNT arrays (CCNT = 1). The EDMA3TC is responsible for updating source and destination addresses within the array based on ACNT and FWID (in OPT). For AB-synchronized transfers, the EDMA3TC is also responsible to update source and destination addresses between arrays based on SRCBIDX and DSTBIDX.

Table 5-5 shows the details of parameter updates that occur within EDMA3CC for A-synchronized and AB-synchronized transfers.

Table 5-5. Parameter Updates in EDMA3CC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	CCNT > 1	CCNT == 1
SRC	+= SRCBIDX	+= SRCCIDX	= Link.SRC	in EDMA3TC	+= SRCCIDX	= Link.SRC
DST	+= DSTBIDX	+= DSTCIDX	= Link.DST	in EDMA3TC	+= DSTCIDX	= Link.DST
ACNT	None	None	= Link.ACNT	None	None	= Link.ACNT
BCNT	–= 1	= BCNTRLD	= Link.BCNT	in EDMA3TC	N/A	= Link.BCNT
CCNT	None	–= 1	= Link.CCNT	in EDMA3TC	–=1	= Link.CCNT
SRCBIDX	None	None	= Link.SRCBIDX	in EDMA3TC	None	= Link.SRCBIDX
DSTBIDX	None	None	= Link.DSTBIDX	None	None	= Link.DSTBIDX
SRCCIDX	None	None	= Link.SRCBIDX	in EDMA3TC	None	= Link.SRCBIDX
DSTCIDX	None	None	= Link.DSTBIDX	None	None	= Link.DSTBIDX
LINK	None	None	= Link.LINK	None	None	= Link.LINK
BCNTRLD	None	None	= Link.BCNTRLD	None	None	= Link.BCNTRLD
OPT[1]	None	None	= LINK.OPT	None	None	= LINK.OPT

(1) In all cases, no updates occur if OPT.STATIC == 1 for the current PaRAM set.

NOTE: The EDMA3CC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. You should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

5.2.3.7 Linking Transfers

The EDMA3CC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed that the 16-bit link address field of the current parameter set points to. Linking only occurs when the STATIC bit in OPT is cleared.

NOTE: You should always link a transfer (EDMA3 or QDMA) to another useful transfer. If you must terminate a transfer, then you should link the transfer to a NULL parameter set. See Section 5.2.3.3.

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA3 channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the STATIC bit in OPT and the LINK field. In both cases (null or dummy), if the value of LINK is FFFFh, then a null PaRAM set (with all 0s and LINK set to FFFFh) is written to the current PaRAM set. Similarly, if LINK is set to a value other than FFFFh, then the appropriate PaRAM location that LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA3CC reads the entire set (eight words) from the PaRAM set specified by LINK and writes all eight words to the PaRAM set that is associated with the current channel. Figure 5-9 shows an example of a linked transfer.

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (see Section 5.2.6) should only be used for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by QCHMAP*n*), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in QER because a write to the trigger word was performed. You can use this feature to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. See Section 5.2.4.2.

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA3 channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 5-9 shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

NOTE: If the STATIC bit in OPT is set for a PaRAM set, then link updates are not performed.

5.2.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either SAM or DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding BIDX should be an even multiple of 32 bytes (256 bits). The EDMA3CC does not recognize errors here, but the EDMA3TC asserts an error if this is not true. See Section 5.2.12.3.

NOTE: The constant addressing (CONST) mode has limited applicability. The EDMA3 should be configured for the constant addressing mode (SAM/DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. See the device-specific data manual and/or peripheral user`s guide to verify if the constant addressing mode is supported. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (SAM/DAM =0) by appropriately programming the count and indices values.

5.2.3.9 Element Size

The EDMA3 controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: ACNT, BCNT, and CCNT. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that need to be transferred. For example, if you have 16-bit audio data and 256 audio samples that must be transferred to a serial port, you can only do this by programming the ACNT = 2 (2 bytes) and BCNT = 256.

Figure 5-9. Linked Transfer

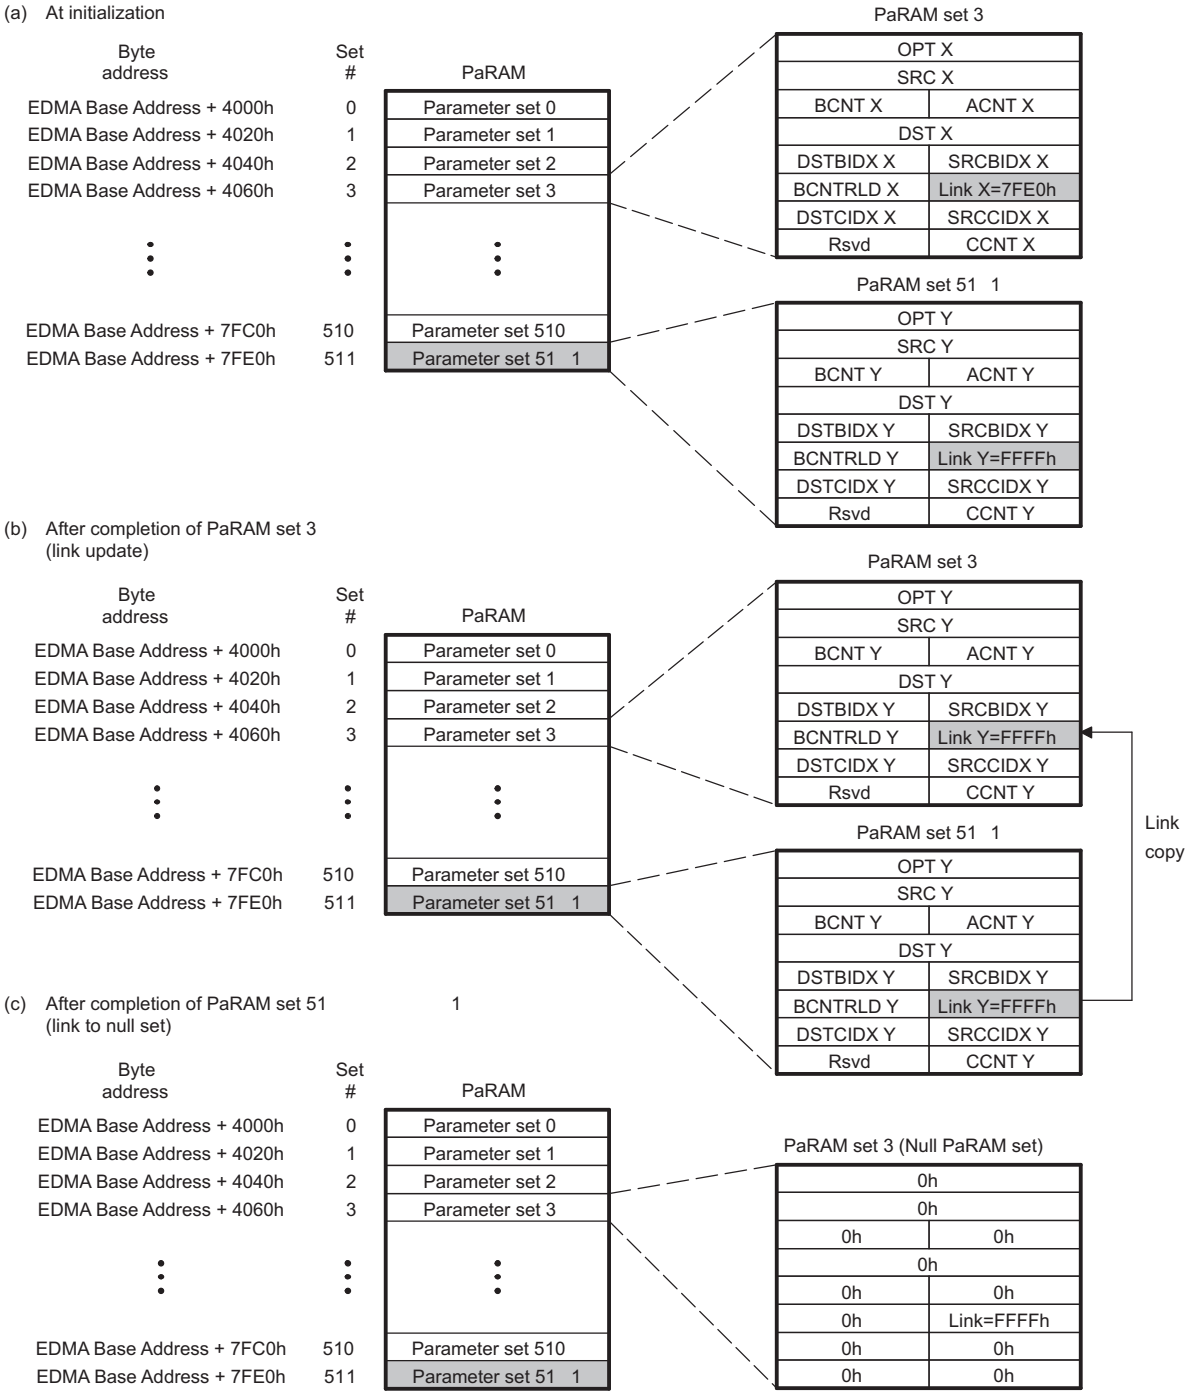

Figure 5-10. Link-to-Self Transfer

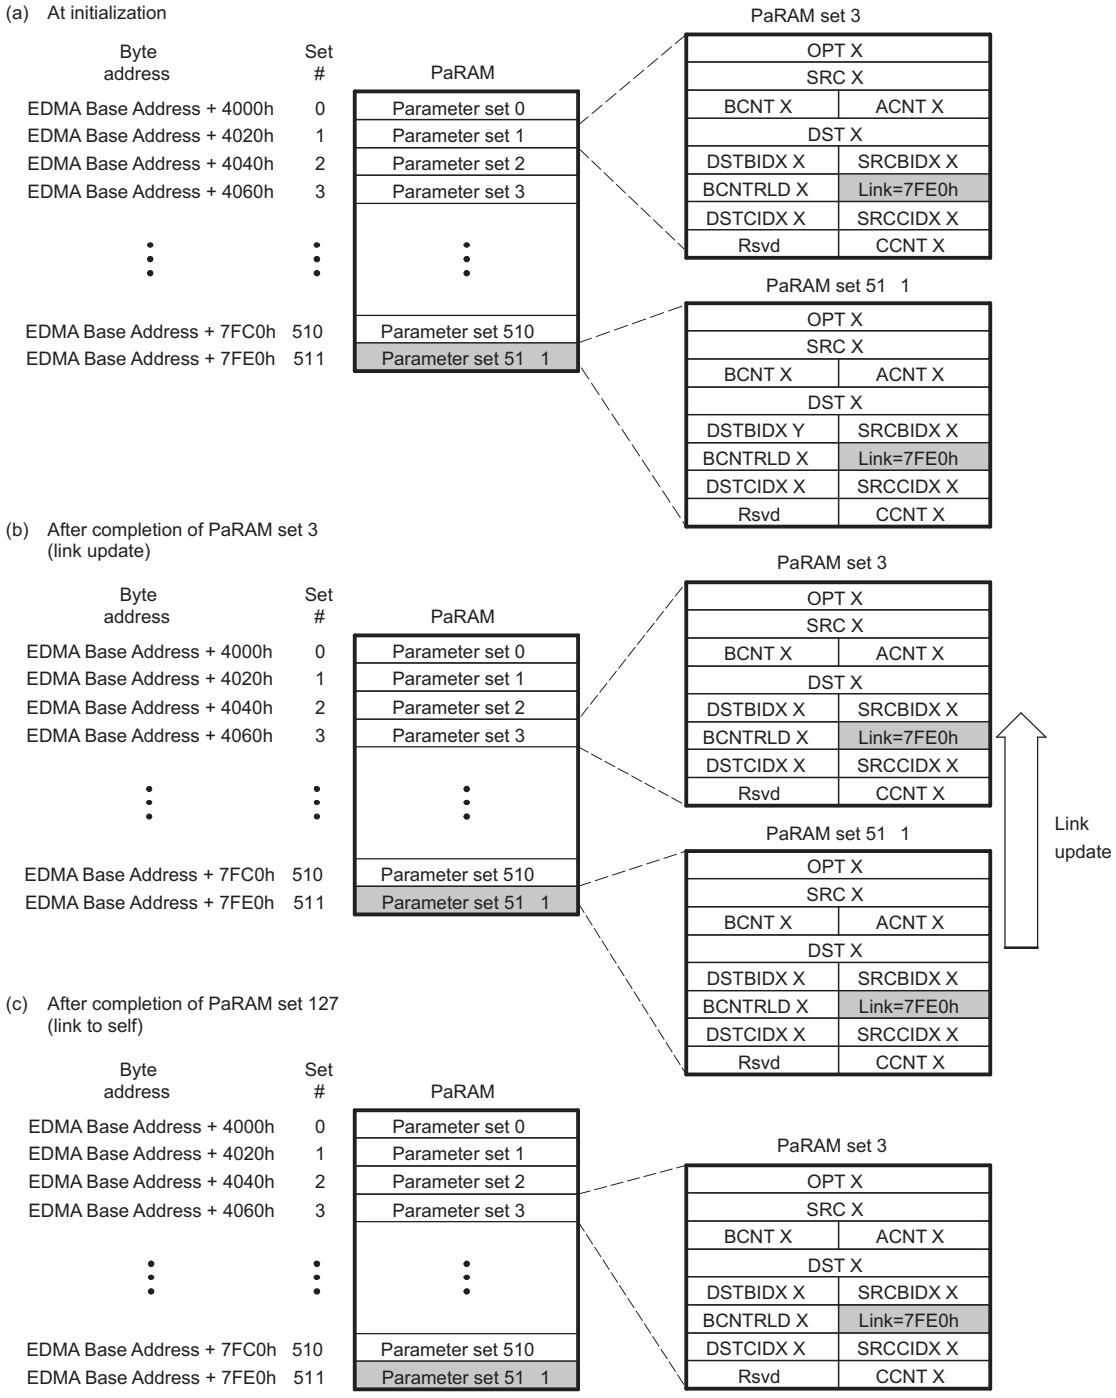


5.2.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA3 channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the more typical usage of EDMA3): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:**The CPU to manually triggers a transfer by writing a 1 to the corresponding bit in the event set register (ESR/ESRH).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

5.2.4.1 DMA Channel

5.2.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (ER.E*n* = 1). For peripheral event to DMA event mapping, see the device-specific data manual. If the corresponding event in the event enable register (EER) is enabled (EER.E*n* = 1), then the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA3TC and the E*n* bit in ER is cleared. At this point, a new event can be safely received by the EDMA3CC.

If the PaRAM set associated with the channel is a NULL set (see Section 5.2.3.3), then no transfer request (TR) is submitted and the corresponding E*n* bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (ER.E*n* = 1), regardless of the state of EER.E*n*. If the event is disabled when an external event is received (ER.E*n* = 1 and EER.E*n* = 0), the ER.E*n* bit remains set. If the event is subsequently enabled (EER.E*n* = 1), then the pending event is processed by the EDMA3CC and the TR is processed/submitted, after which the ER.E*n* bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (ER.E*n* != 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EMR.E*n* = 1).

The EDMA section in the device-specific data manual gives the table of the synchronization events associated with each of the programmable DMA channels in the device. It also provides the mapping of events to the EDMA event crossbar. See the device-specific data manual to determine the event to channel mapping.

5.2.4.1.2 Manually-Triggered Transfer Request

The CPU or any EDMA programmer initiates a DMA transfer by writing to the event set register (ESR). Writing a 1 to an event bit in the ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the EER.E*n* bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 5.2.3.3), then no transfer request (TR) is submitted and the corresponding E*n* bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register (ESR.E*n* = 1) prior to the original being cleared (ESR.E*n* = 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EMR.E*n* = 1).

5.2.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code (TCC[5:0] in OPT of the PaRAM set associated with the channel), it results in the corresponding bit in the chained event register (CER) to be set (CER.E[TCC] = 1).

Once a bit is set in CER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 5.2.3.3), then no transfer request (TR) is submitted and the corresponding E*n* bit in CER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared by you before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared (CER.E*n* != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register (EMR.E*n* = 1).

NOTE: Chained event registers, event registers, and event set registers operate independently. An event (E*n*) can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

5.2.4.2 QDMA Channels

5.2.4.2.1 Auto-triggered and Link-Triggered Transfer Request

NOTE: If OPT, SRC, or DST is the trigger word for a QDMA transfer then it is required to do a 32-bit access to that field.

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register (QER.E*n* = 1). A bit corresponding to a QDMA channel is set in the QDMA event register (QER) when the following occurs:

- A CPU (or any EDMA3 programmer) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register (QCHMAP*n*)) for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register (QEER.E*n* = 1).
- EDMA3CC performs a link update on a PaRAM set address that is configured as a QDMA channel (matches QCHMAP*n* settings) and the corresponding channel is enabled via the QDMA event enable register (QEER.E*n* = 1).

Once a bit is set in QER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If a bit is already set in QER (QER.E*n* = 1) and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register (QEMR.E*n* = 1).

5.2.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization. QDMA events are either auto-triggered or link triggered. auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other EDMA3 programmer) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA3CC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered). Note that for CPU triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register (ESR) to kick-off the transfer.

QDMA channels are typically for cases where a single event will accomplish a complete transfer since the CPU (or EDMA3 programmer) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. In other words, QDMA transfers are programmed with BCNT = CCNT = 1 for A-synchronized transfers, and CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if STATIC = 0 in OPT) for QDMA transfers, it allows you to initiate a linked list of QDMAs, so when EDMA3CC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel will automatically be recognized as a valid QDMA event and initiate another set of transfers as specified by the linked set.

5.2.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in Table 5-6 for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (BCNT and/or CCNT) are this value, the next TR results in a:

- Final chaining or interrupt codes to be sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 5-6. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	BCNT == 1 && CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	CCNT == 1

You must program the PaRAM OPT field with a specific transfer completion code (TCC) along with the other OPT fields (TCCHEN, TCINTEN, ITCCHEN, and ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register (CER[TCC]) and/or interrupt pending register (IPR[TCC]) is set.

You can also selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set (TCCHEN or TCINTEN), for all but the final transfer request (TR) of a parameter set (ITCCHEN or ITCINTEN), or for all TRs of a parameter set (both). See Section 5.2.8 for details on chaining (intermediate/final chaining) and Section 5.2.9 for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA3 channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value should point to another predefined PaRAM set. Alternatively, a non-repetitive transfer should set the link address value to the null link value. The null link value is defined as FFFFh. See Section 5.2.3.7 for more details.

NOTE: Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition should be cleared before the corresponding channel is used again. See Section 5.2.3.5.

There are three ways the EDMA3CC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

5.2.5.1 Normal Completion

In normal completion mode (TCCMODE = 0 in OPT), the transfer or sub-transfer is considered to be complete when the EDMA3 channel controller receives the completion codes from the EDMA3 transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

5.2.5.2 Early Completion

In early completion mode (TCCMODE = 1 in OPT), the transfer is considered to be complete when the EDMA3 channel controller submits the transfer request (TR) to the EDMA3 transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

5.2.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set (Section 5.2.3.4) or null set (Section 5.2.3.3). In both cases, the EDMA3 channel controller does not submit the associated transfer request to the EDMA3 transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it will set the appropriate bits in the interrupt pending registers (IPR/IPRH) or chained event register (CER/CERH). The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA3CC generates the completion code).

5.2.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (ACNT, BCNT, CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

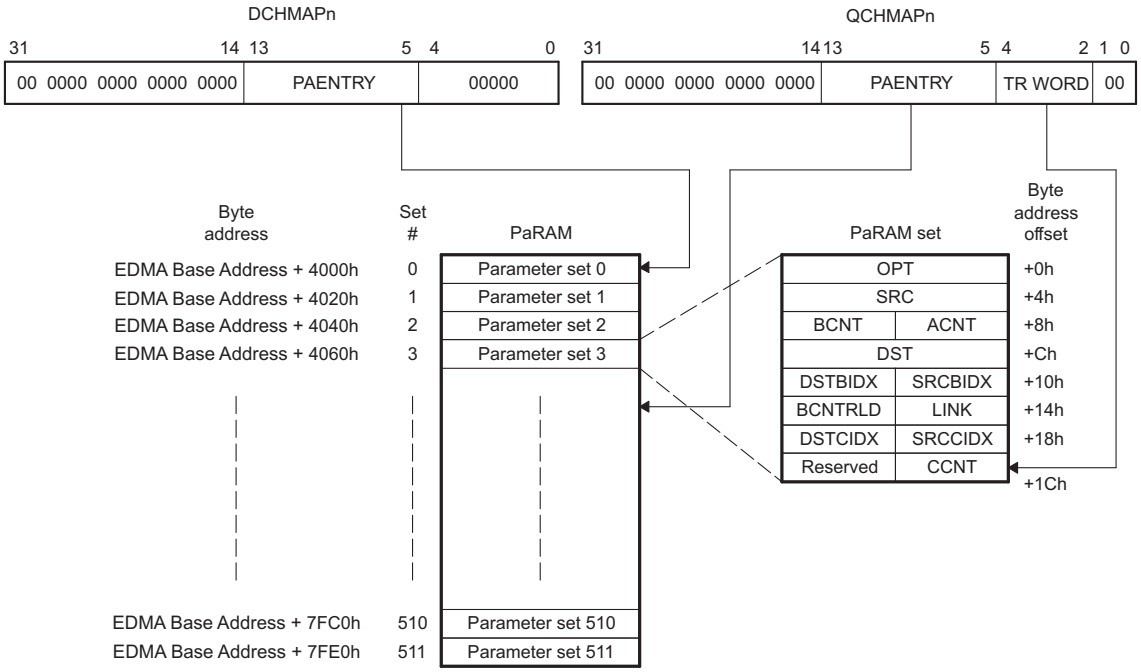
The association of an event to a channel is fixed, each DMA channel has one specific event associated with it. The device-specific data manual provides the synchronization events that are associated with each of the programmable DMA channels.

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

5.2.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see Table 5-1). The DMA channel mapping registers (DCHMAPn) in the EDMA3CC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 5-11 illustrates the use of DCHMAP. There is one DCHMAP register per channel.

Figure 5-11. DMA Channel and QDMA Channel to PaRAM Mapping

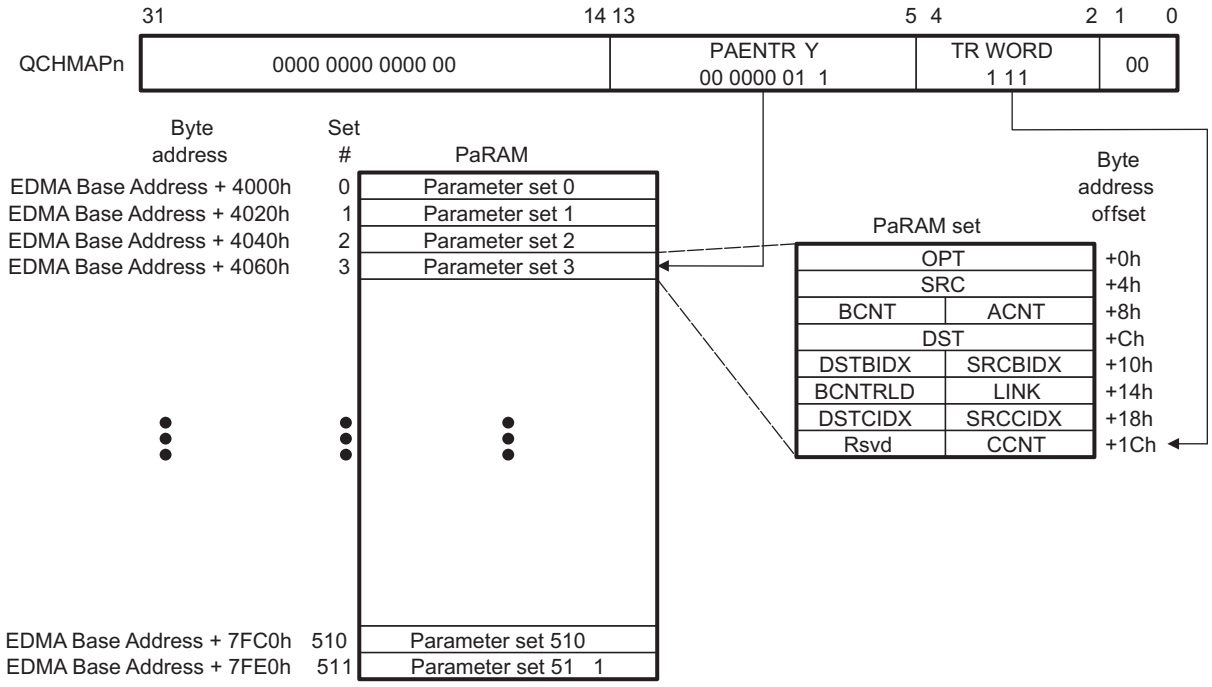


5.2.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register (QCHMAP) in the EDMA3CC allows you to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 5-12 illustrates the use of QCHMAP.

Additionally, QCHMAP allows you to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA3CC is a write to the trigger word in the PaRAM set pointed to by QCHMAP for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0. You must appropriately re-map PaRAM set 0 before you use it.

Figure 5-12. QDMA Channel to PaRAM Mapping



5.2.7 EDMA3 Channel Controller Regions

The EDMA3 channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific EDMA programmer.

You can design the application software to use regions or to ignore them altogether. You can use active memory protection in conjunction with regions so that only a specific EDMA programmer (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA programmer only modifies the state of the assigned resources. Memory protection is described in Section 5.2.10.

5.2.7.1 Region Overview

The EDMA3 channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA3CC memory map. These registers control EDMA3 resource mapping and provide debug visibility and error tracking information. See the device-specific data manual for the EDMA3CC memory map.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address range(s). For example, the event enable register (EER) is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, … EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers (DRAE*m*) and the QDMA region access enable registers (QRAE*n*) control the underlying control register bits that are accessible via the shadow region address space (except for IEVAL*n*). Table 5-7 lists the registers in the shadow region memory map. See the EDMA3CC memory map (Table 5-19) for the complete global and shadow region memory maps. Figure 5-13 illustrates the conceptual view of the regions.

Table 5-7. Shadow Region Registers

DRAE*m*	DRAEH*m*	QRAE*n*
ER	ERH	QER
ECR	ECRH	QEER
ESR	ESRH	QEECR
CER	CERH	QEESR
EER	EERH

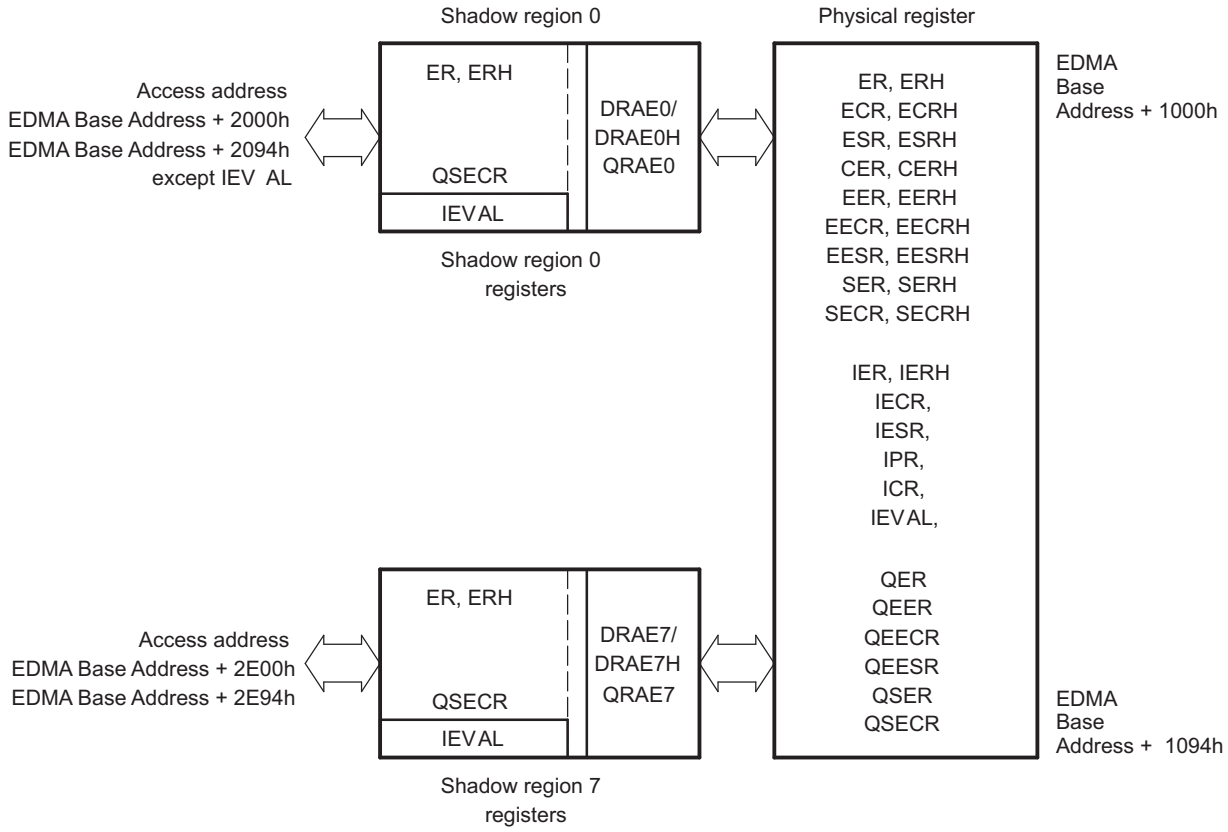
Register not affected by DRAE\DRAEH		
IEVAL		

Figure 5-13. Shadow Region Registers



5.2.7.2 Channel Controller Regions

There are eight EDMA3 shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- DRAE*m* and DRAEH*m*: One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAE/DRAEH pair. A value of 1 in the corresponding DRAE(H) bit implies that the corresponding DMA/interrupt channel is accessible; a value of 0 in the corresponding DRAE(H) bit forces writes to be discarded and returns a value of 0 for reads.
- QRAE*n*: One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 QEER, the respective bit in QRAE must be set or writing into QEESR will not have the desired effect.
- MPPA*n* and MPPAG: One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows for restricted access to EDMA3 resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the DRAE/ORAE registers. If exclusive access to any given channel / TCC code is required for a region, then only that region's DRAE/ORAE should have the associated bit set.

Example 5-1. Resource Pool Division Across Two Regions

This example illustrates a judicious resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63). Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47). DRAE should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEH, DRAE = 0xFFFF0000, 0x0000FFFF QRAE = 0x0000001
Region 1: DRAEH, DRAE = 0x0000FFFF, 0xFFFF0000 QRAE = 0x00000FE
```

5.2.7.3 Region Interrupts

In addition to the EDMA3CC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register (IER), DRAE acts as a secondary interrupt enable for the respective shadow region interrupts. See Section 5.2.9 for more information.

5.2.8 Chaining EDMA3 Channels

The channel chaining capability for the EDMA3 allows the completion of an EDMA3 channel transfer to trigger another EDMA3 channel transfer. The purpose is to allow you the ability to chain several events through one event occurrence.

Chaining is different from linking (Section 5.2.3.7). The EDMA3 link feature reloads the current channel parameter set with the linked parameter set. The EDMA3 chaining feature does not modify or update any channel parameter set; it provides a synchronization event to the chained channel (see Section 5.2.4.1.3 for chain-triggered transfer requests).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel *m* (DMA/QDMA) required to chain to channel *n*. Channel number *n* (0-63) needs to be programmed into the TCC bit of channel *m* channel options parameter (OPT) set.

- If final transfer completion chaining (TCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If intermediate transfer completion chaining (ITCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (TCCHEN = 1 and ITCCHEN = 1 in OPT) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 5-8 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

Table 5-8. Chain Event Triggers

	(Number of chained event triggers on channel 30)	
Options	**A-Synchronized**	**AB-Synchronized**
TCCHEN = 1, ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
TCCHEN = 0, ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
TCCHEN = 1, ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

5.2.9 EDMA3 Interrupts

The EDMA3 interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 5-9. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the DSP and ARM interrupt controllers.

Table 5-9. EDMA3 Transfer Completion Interrupts

Name	Description
EDMA3CC_INT0	EDMA3CC Transfer Completion Interrupt Shadow Region 0
EDMA3CC_INT1	EDMA3CC Transfer Completion Interrupt Shadow Region 1
EDMA3CC_INT2	EDMA3CC Transfer Completion Interrupt Shadow Region 2
EDMA3CC_INT3	EDMA3CC Transfer Completion Interrupt Shadow Region 3
EDMA3CC_INT4	EDMA3CC Transfer Completion Interrupt Shadow Region 4
EDMA3CC_INT5	EDMA3CC Transfer Completion Interrupt Shadow Region 5
EDMA3CC_INT6	EDMA3CC Transfer Completion Interrupt Shadow Region 6
EDMA3CC_INT7	EDMA3CC Transfer Completion Interrupt Shadow Region 7

Table 5-10. EDMA3 Error Interrupts

Name	Description
EDMA3CC_ERRINT	EDMA3CC Error Interrupt
EDMA3CC_MPINT	EDMA3CC Memory Protection Interrupt
EDMA3TC0_ERRINT	TC0 Error Interrupt
EDMA3TC1_ERRINT	TC1 Error Interrupt
EDMA3TC2_ERRINT	TC2 Error Interrupt
EDMA3TC3_ERRINT	TC3 Error Interrupt

5.2.9.1 Transfer Completion Interrupts

The EDMA3CC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA3 masters). The EDMA3 generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA3 interrupt generation.

The software architecture should either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code (TCC) value is directly mapped to the bits of the interrupt pending register (IPR/IPRH), as shown in Table 5-11. For example, if TCC = 10 0001b, IPRH[1] is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See Section 5.2.9.1.1 for details on enabling EDMA3 transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in IPR/IPRH is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

You can program the transfer completion code (TCC) to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and you intend for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in IER/IERH and in the corresponding shadow region's DMA region access registers (DRAE/DRAEH).

Table 5-11. Transfer Complete Code (TCC) to EDMA3CC Interrupt Mapping

TCC Bits in OPT (TCINTEN/ITCINTEN = 1)	IPR Bit Set	TCC Bits in OPT (TCINTEN/ITCINTEN = 1)	IPRH Bit Set[1]
0	IPR0	20h	IPR32/IPRH0
1	IPR1	21h	IPR33/IPRH1
2h	IPR2	22h	IPR34/IPRH2
3h	IPR3	23h	IPR35/IPRH3
4h	IPR4	24h	IPR36/IPRH4
...	...	...	...
1Eh	IPR30	3Eh	IPR62/IPRH30
1Fh	IPR31	3Fh	IPR63/IPRH31

(1) Bit fields IPR[32-63] correspond to bits 0 to 31 in IPRH, respectively.

You can enable Interrupt generation at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (TCCINT = 1 in OPT) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (ITCCINT = 1 in OPT) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (TCCINT = 1, and ITCCINT = 1 in OPT) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 5-12 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

Table 5-12. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
TCINTEN = 1, ITCINTEN = 0	1 (Last TR)	1 (Last TR)
TCINTEN = 0, ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
TCINTEN = 1, ITCINTEN = 1	20 (All TRs)	5 (All TRs)

5.2.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA3 channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA3CC. This is in addition to setting up the TCINTEN and ITCINTEN bits in OPT of the associated PaRAM set.

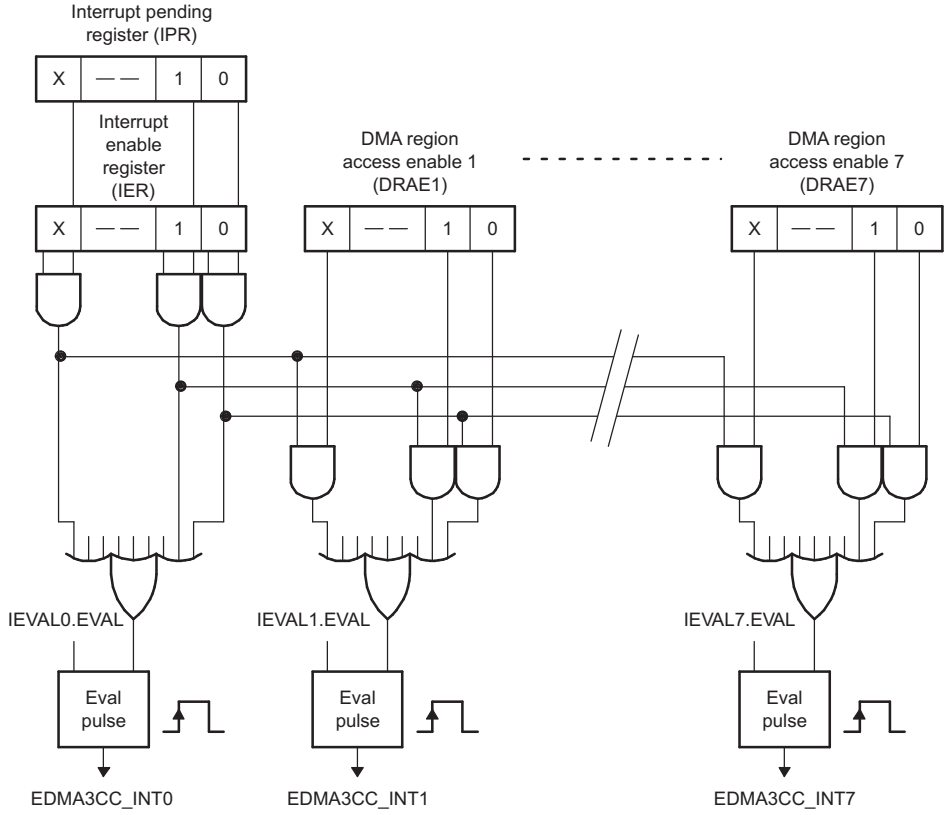
The EDMA3 channel controller has interrupt enable registers (IER/IERH) and each bit location in IER/IERH serves as a primary enable for the corresponding interrupt pending registers (IPR/IPRH).

All of the interrupt registers (IER, IESR, IECR, and IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA3 channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers (IPR/IPRH) and single set of interrupt enable registers (IER/IERH). The programmable DMA region access enable registers (DRAE/DRAEH) provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by IER/IERH. see Figure 5-14

The region interrupt outputs are gated by IER and the specific DRAE/DRAEH associated with the region. See Figure 5-14.

Figure 5-14. Interrupt Diagram



For the EDMA3CC to generate the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA3CC_INT0: (IPR.E0 & IER.E0 & DRAE0.E0) | (IPR.E1 & IER.E1 & DRAE0.E1) | …|(IPRH.E63 & IERH.E63 & DRAHE0.E63)
- EDMA3CC_INT1: (IPR.E0 & IER.E0 & DRAE1.E0) | (IPR.E1 & IER.E1 & DRAE1.E1) | …| (IPRH.E63 & IERH.E63 & DRAHE1.E63)
- EDMA3CC_INT2 : (IPR.E0 & IER.E0 & DRAE2.E0) | (IPR.E1 & IER.E1 & DRAE2.E1) | …|(IPRH.E63 & IERH.E63 & DRAHE2.E63)....
- Up to EDMA3CC_INT7 : (IPR.E0 & IER.E0 & DRAE7.E0) | (IPR.E1 & IER.E1 & DRAE7.E1) | …|(IPRH.E63 & IERH.E63 & DRAEH7.E63)

NOTE: The DRAE/DRAEH for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers should be used for dynamic enable/disable of individual interrupts.

Because there is no relation between the TCC value and the DMA/QDMA channel, it is possible, for example, for DMA channel 0 to have the OPT.TCC = 63 in its associated PaRAM set. This would mean that if a transfer completion interrupt is enabled (OPT.TCINTEN or OPT.ITCINTEN is set), then based on the TCC value, IPRH.E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map, you must program the DRAE/DRAEH that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to IPRH bit that is set upon completion).

5.2.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (ICR/ICRH). For example, a write of 1 to ICR.E0 clears a pending interrupt in IPR.E0.

If an incoming transfer completion code (TCC) gets latched to a bit in IPR/IPRH, then additional bits that get set due to a subsequent transfer completion will not result in asserting the EDMA3CC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

5.2.9.2 EDMA3 Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA3 channel controller sets the appropriate bit in the interrupt pending registers (IPR/IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in IPR/IPRH, thereby enabling recognition of future interrupts. The EDMA3CC will only assert additional completion interrupts when all IPR/IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in IPR/IPRH, thereby resulting in additional interrupts. Each of the bits in IPR/IPRH may need different types of service; therefore, the ISR may check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA3CC completion interrupt are shown in Example 5-2 and Example 5-3.

The ISR routine in Example 5-2 is more exhaustive and incurs a higher latency.

Example 5-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register (IPR/IPRH).
2. Performs the operations needed.
3. Writes to the interrupt pending clear register (ICR/ICRH) to clear the corresponding IPR/IPRH bit(s).
4. Reads IPR/IPRH again:
   (a) If IPR/IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).
   (b) If IPR/IPRH is equal to 0, this should assure you that all of the enabled interrupts are inactive.

NOTE: An event may occur during step 4 while the IPR/IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

Example 5-3 is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 5-3. Interrupt Servicing

If you want to leave any enabled and pending (possibly lower priority) interrupts; you must force the interrupt logic to reassert the interrupt pulse by setting the EVAL bit in the interrupt evaluation register (IEVAL).

The pseudo code is as follows:

1. Enters ISR.
2. Reads IPR/IPRH.
3. For the condition that is set in IPR/IPRH that you want to service, do the following:
   (a) Service interrupt as the application requires.
   (b) Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA3CC after step 2).
4. Reads IPR/IPRH prior to exiting the ISR:
   (a) If IPR/IPRH is equal to 0, then exit the ISR.
   (b) If IPR/IPRH is not equal to 0, then set IEVAL so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

5.2.9.3 Interrupt Evaluation Operations

The EDMA3CC has interrupt evaluate registers (IEVAL) that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers (DRAE/DRAEH). Writing a 1 to the EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via IER/IERH) is still pending (IPR/IPRH). This register assures that the CPU does not miss the interrupts (or the EDMA3 master associated with the shadow region) if the software architecture chooses not to use all interrupts. See Example 5-3 for the use of IEVAL in the EDMA3 interrupt service routine (ISR).

Similarly an error evaluation register (EEVAL) exists in the global region. Writing a 1 to the EVAL bit in EEVAL causes the pulsing of the error interrupt if any pending errors are in EMR/EMRH, QEMR, or CCERR. See Section 5.2.9.4 for additional information regarding error interrupts.

NOTE: While using IEVAL for shadow region completion interrupts, you should make sure that the IEVAL operated upon is from that particular shadow region memory map.

5.2.9.4 Error Interrupts

The EDMA3CC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA3CC error interrupt. If the EDMA3CC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA3CC has a single error interrupt (EDMA3CC_ERRINT) that is asserted for all EDMA3CC error conditions. There are four conditions that cause the error interrupt to pulse:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers (EMR/EMRH).
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register (QEMR).
- Threshold exceed: for all event queues. These are latched in EDMA3CC error register (CCERR).
- TCC error: for outstanding transfer requests that are expected to return completion code (TCCHEN or TCINTEN bit in OPT is set to 1) exceeding the maximum limit of 63. This is also latched in the EDMA3CC error register (CCERR).

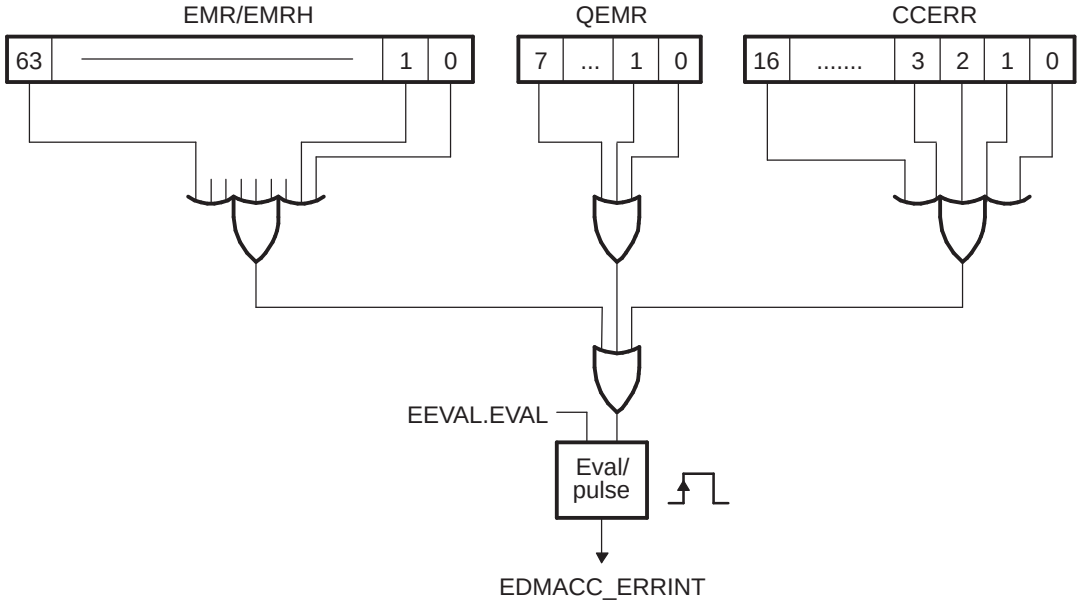
Figure 5-15 illustrates the EDMA3CC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA3CC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA3CC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA3CC does not generate additional interrupt pulses.

To reduce the burden on the software, there is an error evaluate register (EEVAL) that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register (IEVAL). You can use this so that the CPU(s) does not miss any error events.

NOTE: It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status); additionally, it provides a good debug mechanism for unexpected error conditions.

Figure 5-15. Error Interrupt Operation



5.2.10 Memory Protection

The EDMA3 channel controller supports two kinds of memory protection: active and proxy.

5.2.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses (by any EDMA3 programmer) to the EDMA3CC registers (based on permission characteristics that you program). Active memory protection is achieved by a set of memory protection permissions attribute (MPPA) registers.

The EDMA3CC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to section Table 5-7.

Each of the eight shadow regions has an associated MPPA register (MPPA*n*) that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register (MPPAG). The MPPAG applies to the global region and to the global channel region, except the other MPPA registers themselves. For more detailed information on the list of the registers in each region, refer to the register memory-map in section Table 5-14.

See Section 5.4.1.5.4 for the bit field descriptions of MPPA*n*. The MPPA*n* have a certain set of access rules.

Table 5-13 shows the accesses that are allowed or not allowed to the MPPAG and MPPA*n*. The active memory protection uses the PRIV and PRIVID attributes of the EDMA programmer. The PRIV is the privilege level (user versus supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA3 programmer. See the device-specific data manual for the PRIVIDs that are associated with potential EDMA3 programmers.

Table 5-13. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

Table 5-14 describes the MPPA register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based MPPA registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight MPPA region registers (MPPA[0-7]).

Table 5-14. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect[1]	Address Range
MPPAG	Global Range	0000h-1FFCh	N/A	N/A
MPPA0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPA1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPA2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPA3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPA4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPA5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPA6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
MPPA7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

(1) The PARAM region is divided into 8 regions referred to as an octant.

Example Access denied.

Write access to shadow region 7's event enable set register (EESR):

1. The original value of the event enable register (EER) at address offset 1020h is 0.
2. The MPPA[7] is set to prevent user level accesses (UW = 0, UR = 0), but it allows supervisor level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).
3. An EDMA3 programmer with a privilege ID of 0 attempts to perform a user-level write of a value of FF00 FF00h to shadow region 7's event enable set register (EESR) at address offset 2E30h. Note that the EER is a read-only register and the only way that you can write to it is by writing to the EESR. Also remember that there is only one physical register for EER, EESR, etc. and that the shadow regions only provide to the same physical set.
4. Since the MPPA[7] has UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EER is not written to.

Table 5-15. Example Access Denied

Register	Value	Description
EER (offset 1020h)	0000 0000h	Value in EER to begin with.
EESR (offset 2E30h)	FF00 FF00h ↓	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and Privilege ID of 0.
MPPA[7] (offset 082Ch)	0000 04B0h	Memory Protection Filter AID0 = 1, UW = 0, UR = 0, SW = 1, SR = 1.
	X	Access Denied
EER (offset 1020h)	0000 0000h	Final value of EER

Example Access Allowed

Write access to shadow region 7's event enable set register (EESR):

1. The original value of the event enable register (EER) at address offset 1020h is 0.
2. The MPPA[7] is set to allow user-level accesses (UW = 1, UR = 1) and supervisor-level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).
3. An EDMA3 programmer with a privilege ID of 0, attempts to perform a user-level write of a value of ABCD 0123h to shadow region 7's event enable set register (EESR) at address offset 2E30h. Note that the EER is a read-only register and the only way that you can write to it is by writing to the EESR. Also remember that there is only one physical register for EER, EESR, etc. and that the shadow regions only provide to the same physical set.
4. Since the MPPA[7] has UW = 1 and AID0 = 1, the user-level write access is allowed.
5. Remember that accesses to shadow region registers are masked by their respective DRAE register. In this example, the DRAE[7] is set of 9FF0 0FC2h.
6. The value finally written to EER is 8BC0 0102h.

Table 5-16. Example Access Allowed

Register	Value	Description
EER (offset 1020h)	0000 0000h	Value in EER to begin with.
EESR (offset 2E30h)	FF00 FF00h	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and Privilege ID of 0.
MPPA[7] (offset 082Ch)	0000 04B3h	Memory Protection Filter AID = 1, UW = 1, UR = 1, SW = 1, SR = 1.
	√ ↓	Access allowed.
DRAE[7] (offset 0378h)	9FF0 0FC2h ↓	DMA Region Access Enable Filter
EESR (offset 2E30h)	8BC0 0102h ↓	Value written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and a Privilege ID of 0.
EER (offset 1020h)	↓ BC0 0102h	Final value of EER.

5.2.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA3 transfer programmed by a given EDMA3 programmer to have its permissions travel with the transfer through the EDMA3TC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The PRIV bit and PRIVID bit in the channel options parameter (OPT) is set with the EDMA3 programmer's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The PRIV is the privilege level (user versus supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA3 programmer.

See the data manual for the PRIVIDs that are associated with potential EDMA3 programmers.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The PRIV is 0 for user-level and the CPU has a PRIVID of 0.

The PaRAM set is shown in Figure 5-16.

The PRIV and PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses (SR,SW), the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (SR, SW), the user-level write request above is refused. For the transfer to succeed, the source and destination pages should have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID 0. For more information regarding how to set memory protection attributes for pages of memory in L2/L1D, see the *TMS320C674x DSP CPU and Instruction Set Reference Guide* (SPRUFE8).

Because the programmers privilege level and privilege identification travel with the read and write requests, EDMA3 acts as a proxy.

Figure 5-17 illustrates the propagation of PRIV and PRIVID at the boundaries of all the interacting entities (CPU, EDMA3CC, EDMA3TC, and slave memories).

Figure 5-16. PaRAM Set Content for Proxy Memory Protection Example

5.2.11 Event Queue(s)

Event queues are a part of the EDMA3 channel controller. Event queues form the interface between the event detection logic in the EDMA3CC and the transfer request (TR) submission logic of the EDMA3CC. Each queue is 16 entries deep; thus, each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are four event queues for the device: Queue0, Queue1, Queue2, and Queue3. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. Similarly, transfer requests that are associated with events in Queue3 are submitted to TC3.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA3 transfer controller.

Queue0 has highest priority and Queue3 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

See Section 5.2.11.4 for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers (Q0E0, Q0E1,…Q1E15, etc.). Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. See Section 5.4.1.4.1 for a description of the bit fields in the queue event entry registers.

5.2.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register (DMAQNUM) and the QDMA queue number register (QDMANUM). The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. See Section 5.2.11.4.

NOTE: If an event is ready to be queued and both the event queue and the EDMA3 transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA3TC. In this case, the event is not logged in the event queue status registers.

5.2.11.2 Queue RAM Debug Visibility

There are four event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO manner. There is a queue status register (QSTAT) associated with each queue. These along with all of the 16 entries per queue can be read via registers QSTAT*n* and QxEy, respectively.

These registers provide user visibility and may be helpful while debugging real-time issues (typically post-mortem), involving multiple events and event sources. The event queue entry register (Q*x*E*y*) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA3CC memory-mapped register. By reading the event queue, you see the history of the last 16 TRs that have been processed by the EDMA3 on a given queue. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT*n*) includes fields for the start pointer (STRTPTR) which provides the offset to the head entry of an event. It also includes a field called NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The STRTPTR may be used to index appropriately into the 16 event entries. NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry may be read to determine what's already de-queued and submitted to the associated transfer controller.

5.2.11.3 Queue Resource Tracking

The EDMA3CC event queue includes watermarking/threshold logic that allows you to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA3 event queue.

You can program the maximum number of events that can queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register (QWMTHRA). The maximum queue usage is recorded actively in the watermark (WM) field of the queue status register (QSTAT*n*) that keeps getting updated based on a comparison of number of valid entries, which is also visible in the NUMVAL bit in QSTAT*n* and the maximum number of entries (WM bit in QSTAT*n*).

If the queue usage is exceeded, this status is visible in the EDMA3CC registers: the QTHRXCD*n* bit in the channel controller error register (CCERR) and the THRXCD bit in QSTAT*n*, where *n* stands for the event queue number. Any bits that are set in CCERR also generate an EDMA3CC error interrupt.

5.2.11.4 Performance Considerations

The main system bus infrastructure (L3) (see the device-specific data manual) arbitrates bus requests from all of the masters (TCs, CPU(S), PCIe and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA3 transfer controllers with respect to other masters within the system crossbar are programmed using the queue priority register (QUEPRI). QUEPRI programs the priority of the event queues (or indirectly, TC0-TC3, because Queue*N* transfer requests are submitted to TC*n*).

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA3TC (dictated by the priority set using QUEPRI).

5.2.12 EDMA3 Transfer Controller (EDMA3TC)

The EDMA3 channel controller is the user-interface of the EDMA3 and the EDMA3 transfer controller (EDMA3TC) is the data movement engine of the EDMA3. The EDMA3CC submits transfer requests (TR) to the EDMA3TC and the EDMA3TC performs the data transfers dictated by the TR; thus, the EDMA3TC is a slave to the EDMA3CC.

5.2.12.1 Architecture Details

5.2.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in Section 5.2.12.5.

The EDMA3TC attempts to issue the largest possible command size as limited by the DBS value or the ACNT/BCNT value of the TR. EDMA3TC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

Table 5-17 lists the TR segmentation rules that are followed by the EDMA3TC. In summary, if the ACNT value is larger than the DBS value, then the EDMA3TC breaks the ACNT array into DBS-sized commands to the source/destination addresses. Each BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA3TC recognizes that the 2D-transfer is organized as a single dimension (ACNT == BIDX) and the ACNT value is a power of 2.

Table 5-17 lists conditions in which the optimizations are performed.

Table 5-17. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

5.2.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 5-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. ACNT = 8, BCNT = 8, SRCBIDX = 8, DSTBIDX = 10, SRCADDR = 64, DSTADDR = 191

   Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to ACNT = 64, BCNT = 1.

   Cmd0 = 64 byte

   Write Controller: Because DSTBIDX != ACNT, it is not optimized.

   Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. ACNT=128, BCNT = 1,SRCADDR = 63, DSTADDR = 513

   Read Controller: Read address is not aligned.

   Cmd0 = 1 byte, (now the SRCADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 63 bytes

   Write Controller: The write address is also not aligned.

   Cmd0 = 63 bytes, (now the DSTADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 1 byte

5.2.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA3TC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA3TC is controlled by the RDRATE register. The RDRATE register defines the number of cycles that the EDMA3TC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA3TC consuming all available slave resources. The RDRATE value should be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

5.2.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA3TC and used by the EDMA3TC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA3 transfer in the channel controller.

5.2.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA3TC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.
- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is pulsed.

5.2.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA3TC status register (TCSTAT) has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The SRCACTV bit indicates whether the source active set is active.
- The DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

If the TRs are in progression, caution must be used and you must realize that there is a chance that the values read from the EDMA3TC status registers will be inconsistent since the EDMA3TC may change the values of these registers due to ongoing activities.

It is recommended that you ensure no additional submission of TRs to the EDMA3TC in order to facilitate ease of debug.

5.2.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA3TC maintains two important status details in TCSTAT that may be used during advanced debugging, if necessary. The DFSTRTPTR is a start pointer, that is, the index to the head of the destination FIFO register. The DSTACTV is a counter for the number of valid (occupied) entries. These registers may be used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- DFSTRTPTR = 0 and DSTACTV = 0 implies that no TRs are stored in the destination FIFO register.
- DFSTRTPTR = 1 and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- DFSTRTPTR = 3h and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

5.2.12.5 EDMA3TC Configuration

Table 5-18 provides the configuration of the individual EDMA3 transfer controllers present on the device. The DBS for each transfer controller is configurable using the TPTC_CFG register in the chip configuration module.

Table 5-18. EDMA3 Transfer Controller Configurations

Name	TC0	TC1	TC2	TC3
FIFOSIZE	1024 bytes	1024 bytes	1024 bytes	1024 bytes
BUSWIDTH	16 bytes	16 bytes	16 bytes	16 bytes
DSTREGDEPTH	4 entries	4 entries	4 entries	4 entries
DBS	Configurable	Configurable	Configurable	Configurable

5.2.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA3CC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the ER.E*n*/ERH.E*n* (or CER.E*n*/CERH.E*n*, ESR.E*n* /ESRH.E*n*, QER.E*n*) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the SER.E*n*\SERH.E*n* (or QSER.E*n*) bit is set to inform the event prioritization/processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA3CC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA3CC clears the ER.E*n*/ERH.E*n* (or CER.E*n*/CERH.E*n*, ESR.E*n*/ESRH.E*n*, QER.E*n*) bit and the SER.E*n*/SERH.E*n* bit as soon as it determines the TR is non-null. In the case of a null set, the SER.E*n*/SERH.E*n* bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA3CC immediately sets the interrupt pending register (IPR.I[TCC]/IPRH.I[TCC]-32).
5. If the TR was programmed for normal completion, the EDMA3CC sets the interrupt pending register (IPR.I[TCC]/IPRH.I[TCC]) when the EDMA3TC informs the EDMA3CC about completion of the transfer (returns transfer completion codes).
6. The EDMA3CC programs the associated EDMA3TC*n*'s Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA3TC*n*.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and on receiving the acknowledgement signal from the destination slave end point, the EDMA3TC*n* then signals completion status to the EDMA3CC.

5.2.14 EDMA3 Prioritization

The EDMA3 controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. Figure 5-18 shows the different places EDMA3 priorities come into play.

5.2.14.1 Channel Priority

The DMA event registers (ER and ERH) capture up to 64 events; likewise, the QDMA event register (QER) captures QDMA events for all QDMA channels; therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority; similarly, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

5.2.14.2 Trigger Source Priority

If a DMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel (ER.E*n* = 1, ESR.E*n* = 1 , CER.E*n* = 1) , then the EDMA3CC always services these events in the following priority order: event trigger (via ER) is higher priority than chain trigger (via CER) and chain trigger is higher priority than manual trigger (via ESR).

This implies that if for channel 0, both ER.E0 = 1 and CER.E0 = 1 at the same time, then the ER.E0 event is always queued before the CER.E0 event.

5.2.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by DMAQNUM and QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 3 the lowest.

5.2.14.4 System (Transfer Controller) Priority

INIT_PRIORITY_0 and INIT_PRIORITY_1 registers in the chip configuration module are used to configure the EDMA TC's priority through the system bus infrastructure. Additionally, the priority settings for DDR memory accesses are defined in the dynamic memory manager (DMM).

NOTE: The default priority for all TCs is the same, 0 or highest priority relative to other masters. It is recommended that this priority be changed based on system level considerations, such as real-time deadlines for all masters including the priority of the transfer controllers with respect to each other.

5.2.15 EDMA3 Operating Frequency (Clock Control)

The EDMA3 channel controller and transfer controller are clocked from PLL_L3 SYSCLK4. The EDMA3 system runs at the L3 clock frequency.

5.2.16 Reset Considerations

A hardware reset resets the EDMA3 (EDMA3CC and EDMA3TC) and the EDMA3 configuration registers. The PaRAM memory contents are undefined after device reset and you should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used.

5.2.17 Power Management

The EDMA3 (EDMA3CC and EDMA3TC) can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the power reset clock management (PRCM). The PRCM acts as a master controller for power management for all peripherals on the device.

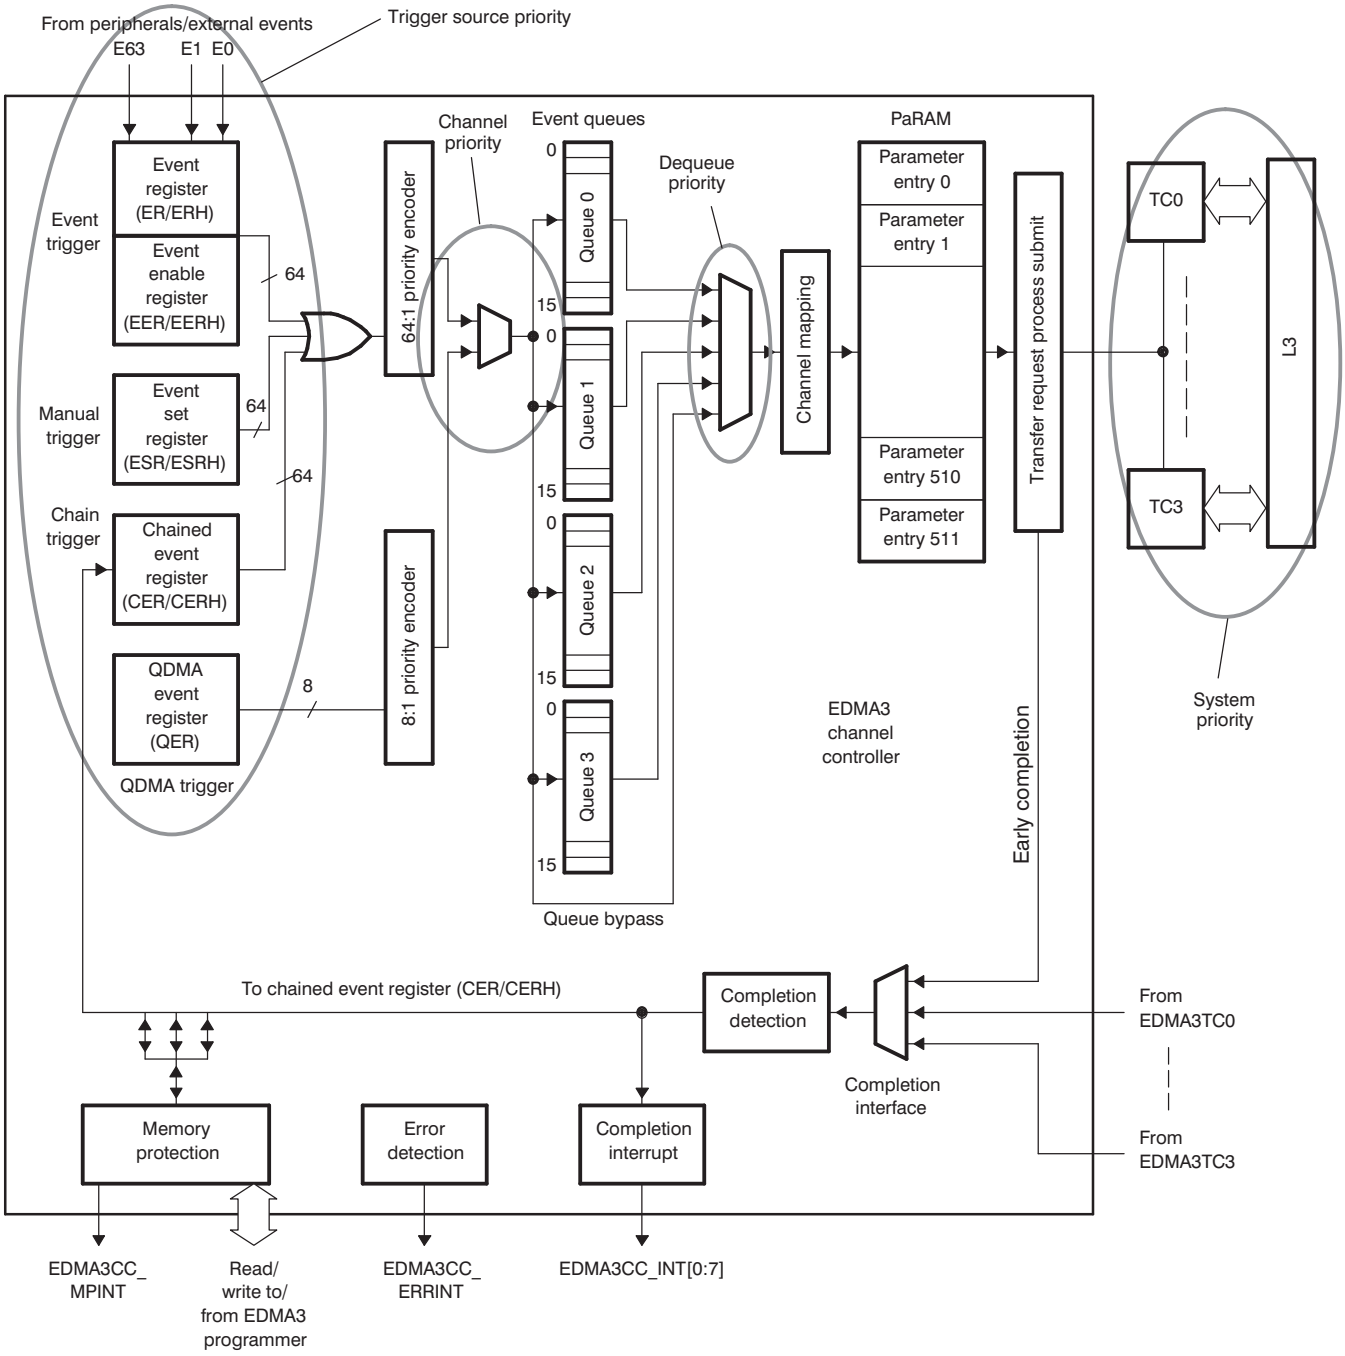
The EDMA3 controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA3CC and EDMA3TC are separate. In general, it should be verified that there are no pending activities in the EDMA3 controller

5.2.18 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA3 channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA3 is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA3 for emulation halts. EDMA3 functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts. For example, if a McASP is halted during an emulation access (FREE = 0 and SOFT = 0 or 1 in McASP registers), the McASP stops generating the McASP receive or transmit events (REVT or XEVT) to the EDMA. From the point of view of the McASP, the EDMA3 is suspended, but other peripherals (for example, a timer) still assert events and will be serviced by the EDMA.

Figure 5-18. EDMA3 Prioritization



5.3 EDMA Transfer Examples

The EDMA3 channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

5.3.1 Block Move Example

The most basic transfer performed by the EDMA3 is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 5-19. Figure 5-20 shows the parameters for this transfer.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 5-20 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The STATIC bit in OPT is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. You may program the QDMA trigger word to be the highest numbered offset in the PaRAM set that undergoes change.

5.3.2 Subframe Extraction Example

The EDMA3 can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA3 retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA3 places the subframe in internal L2 SRAM. Figure 5-21 shows the transfer of a subframe from external memory to L2. Figure 5-22 shows the parameters for this transfer.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The STATIC bit in OPT is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

5.3.3 Data Sorting Example

Many applications require the use of multiple data arrays; it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA3 can reorganize the data into the desired format. Figure 5-23 shows the data sorting.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SRCBIDX - Program this to be the size of the element or ACNT.
- DSTBIDX - CCNT × ACNT
- SRCCDX - ACNT × BCNT
- DSTCIDX - ACNT

The synchronization type needs to be AB-synchronized and the STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA3 channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 5-24 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

5.3.4 Peripheral Servicing Example

The EDMA3 channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA3 channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA3 has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register (EER). When programming an EDMA3 channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

5.3.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA3 channel configuration is the same.

The McASP transmit and receive data streams are treated independently by the EDMA3. The transmit and receive data streams can have completely different counts, data sizes, and formats. Figure 5-25 shows servicing incoming McASP data.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA3 channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA3 issue the transfer request for each element individually. Figure 5-26 shows the parameters for this transfer. The source address of the EDMA3 channel is set to the data port address(DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 01b (increment).

Based on the premise that serial data is typically a high priority, the EDMA3 channel should be programmed to be on queue 0.

5.3.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the processor one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory. Figure 5-27 shows this example.

To transfer data from an external peripheral to an external buffer one array at a time based on EVT*n* , channel *n* must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 5-28 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the SRCBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the DSTBIDX is set to pixel size, 2 bytes. ANCT is equal to the pixel size, 2 bytes. BCNT is set to the number of pixels in an array, 640. CCNT is equal to the total number of arrays in the block, 480. SRCCIDX is 0 because the source address undergoes no increment. The DSTCIDX is equal to the difference between the starting addresses of each array. Because a pixel is 16 bits (2 bytes), DSTCIDX is equal to 640 × 2.

5.3.4.3 Continuous Operation

Configuring an EDMA3 channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA3 channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown Figure 5-29.

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, them DMA channels associated with the McASP (channels 12 and 15) must be setup for 1D-to-1D transfers with A-synchronization.

Figure 5-30 shows the parameter entries for the channel for these transfers. To service the McASP continuously throughout, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA3 channels reload and continue. Figure 5-31 shows the reload parameters for the channel.

5.3.4.3.1 Receive Channel

EDMA3 channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

5.3.4.3.2 Transmit Channel

EDMA3 channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA3 channel, with duplicate PaRAM set entries at PaRAM set 65.

5.3.4.4 Ping-Pong Buffering

Although the previous configuration allows the EDMA3 to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA3 very closely to process the data. The EDMA3 receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA3 transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA3 activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA3 transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA3 activity completes, they switch. The EDMA3 then writes over the old input data and transfers the new output data. Figure 5-32 shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA3 channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaRAM set for the other and the data transfers continue. Figure 5-33 shows the EDMA3 channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA3 channel is initially loaded with the ping parameters (Figure 5-33). The link address for the ping set is set to the PaRAM offset of the pong parameter set (Figure 5-34). The link address for the pong set is set to the PaRAM offset of the ping parameter set (Figure 5-35). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

5.3.4.4.1 Synchronization with the CPU

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA3 to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register (IPR) is set; when channel 12 empties an output buffer, the E12 bit in IPR is set. The CPU must manually clear these bits. With the channel parameters set, the CPU polls IPR to determine when to switch. The EDMA3 and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA3 to complete.

5.3.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

5.3.4.5.1 Servicing Input/Output FIFOs with a Single Event

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA3 channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event. For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA3 needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). Figure 5-36 shows the EDMA3 setup and illustration for this example.

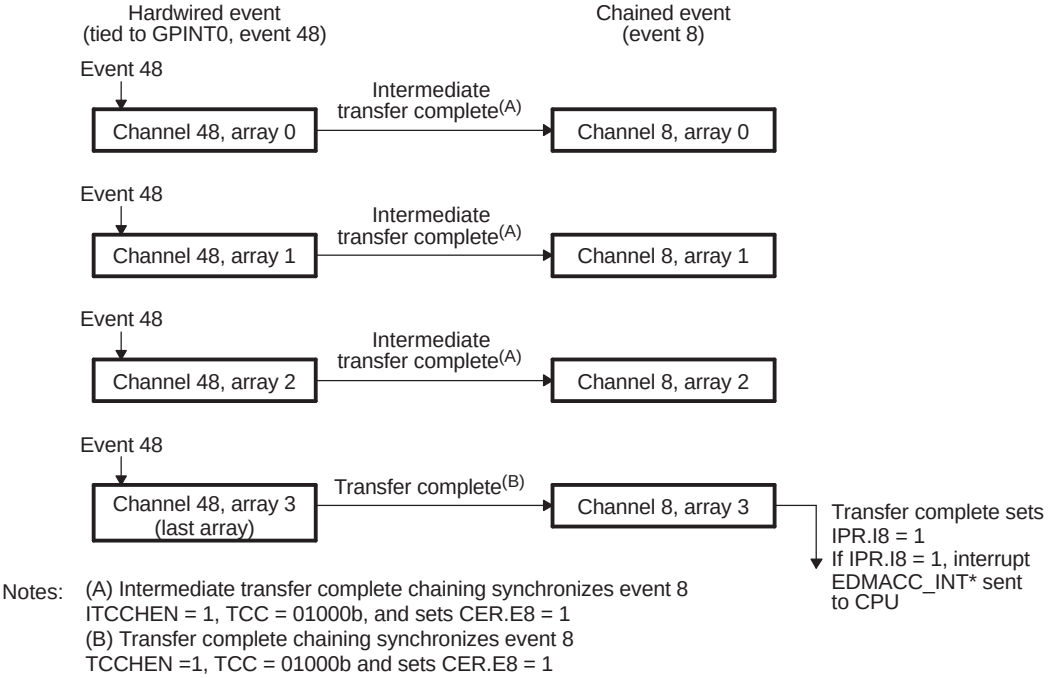
A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register (CER) and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in CER (specified by TCCMODE:TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by TCCMODE:TCC) in the interrupt pending register (IPR), which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register (IER) is set.

5.3.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

Another feature of intermediate transfer chaining (ITCCHEN) is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA3 transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. Figure 5-37 shows the EDMA3 setup and illustration of an example single large block transfer.

The intermediate transfer chaining enable (ITCCHEN) provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA3 performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA3 is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The TCC field in the channel options parameter (OPT) is set to the same value as the channel number and ITCCHEN are set. In this example, EDMA3 channel 25 is used and TCC is also set to 25. The TCINTEN may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA3 transfer by writing to the appropriate bit of the event set register (ESR.E25). The EDMA3 transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the TCC field. This intermediate transfer completion chaining event causes EDMA3 channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA3 has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. Figure 5-38 shows the EDMA3 setup and illustration of the broken up smaller packet transfers.

Figure 5-36. Intermediate Transfer Completion Chaining Example



Notes: (A) Intermediate transfer complete chaining synchronizes event 8 ITCCHEN = 1, TCC = 01000b, and sets CER.E8 = 1
(B) Transfer complete chaining synchronizes event 8 TCCHEN =1, TCC = 01000b and sets CER.E8 = 1

Setup

Channel 48 parameters for chaining

- ☐ Enable transfer complete chaining:
  OPT.TCCHEN = 1
  OPT.TCC = 01000b
- ☐ Enable intermediate transfer complete chaining:
  OPT.ITCCHEN = 1
  OPT.TCC = 01000b

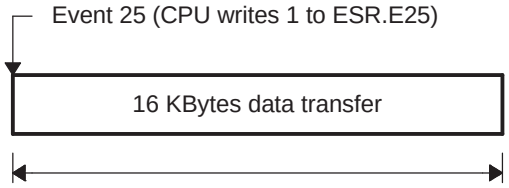
Channel 8 parameters for chaining

- ☐ Enable transfer complete chaining:
  OPT.TCINTEN = 1
  OPT.TCC = 01000b
- ☐ Disable intermediate transfer complete chaining:
  OPT.ITCCHEN = 0

Event enable register (EER)

- ☐ Enable channel 48
  EER.E48 = 1

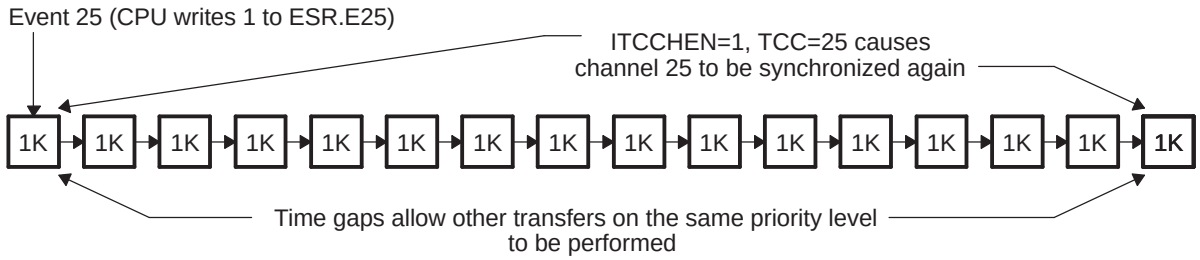
Figure 5-37. Single Large Block Transfer Example



EDMA3 channel 25 setup

ACNT = 16384
BCNT = 1
CCNT = 1
OPT.ITCINTEN = 0
OPT.TCC = Don't care
1D transfer of 16 KByte elements

Figure 5-38. Smaller Packet Data Transfers Example



EDMA3 channel 25 setup

ACNT = 1024
BCNT = 16
CCNT = 1
OPT.SYNCDIM = A SYNC
OPT.ITCCHEN = 1
OPT.TCINTEN = 1
OPT.TCC = 25

5.4 EDMA3 Registers

This section discusses the registers of the EDMA3 controller.

5.4.1 EDMA3 Channel Controller Control (EDMA3CC) Registers

Table 5-19 lists the memory-mapped registers for the EDMA3 channel controller (EDMACC). For the base address of these registers, see Table 1-11. All other register offset addresses not listed in Table 5-19 should be considered as reserved locations and the register contents should not be modified.

Table 5-19. EDMA3 Channel Controller Control (EDMA3CC) Registers

Offset	Acronym	Register Description	Section
00h	PID	Peripheral Identification Register	Section 5.4.1.1.1

5.4.1.1 Global Registers

5.4.1.1.1 Peripheral Identification Register (PID)

The peripheral identification register (PID) uniquely identifies the EDMA3CC and the specific revision of the EDMA3CC.

The PID is shown in Figure 5-39 and described in Table 5-20.

Figure 5-39. Peripheral ID Register (PID)

31	16	15	0
PID		PID	
R-4001h		R-1B00h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 5-20. Peripheral ID Register (PID) Field Descriptions

Bit	Field	Value	Description
31-0	PID	0-FFFF FFFFh	Peripheral identifier uniquely identifies the EDMA3CC and the specific revision of the EDMA3CC.

5.4.1.1.2 EDMA3CC Configuration Register (CCCFG)

The EDMA3CC configuration register (CCCFG) provides the features/resources for the EDMA3CC in a particular device.

The CCCFG is shown in Figure 5-40 and described in Table 5-21.

Figure 5-40. EDMA3CC Configuration Register (CCCFG)

31	26	25	24

Table 5-21. EDMA3CC Configuration Register (CCCFG) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
25	MP_EXIST		Memory protection existence.
		0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		1	Memory protection logic included.
24	CHMAP_EXIST		Channel mapping existence.
		0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		1	Channel mapping logic included.
23-22	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
21-20	NUM_REGN	0-3h	Number of MP and shadow regions.
		0-2h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		3h	8 regions.
19	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
18-16	NUM_EVQUE	0-7h	Number of queues/number of TCs.
		0-2h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		3h	4 EDMA3TCs/Event Queues.
		4h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

Table 5-21. EDMA3CC Configuration Register (CCCFG) Field Descriptions (continued)

Bit	Field	Value	Description
14-12	NUM_PAENTRY	0-7h	Number of PaRAM sets.
		0-3h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		5h	512 PaRAM sets.
		5h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
11	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
10-8	NUM_INTCH	0-7h	Number of interrupt channels.
		0-3h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		4h	64 interrupt channels.
		5h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
6-4	NUM_QDMACH	0-7h	Number of QDMA channels.
		0-1h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		4h	8 QDMA channels.
		3h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2-0	NUM_DMACH	0-7h	Number of DMA channels.
		0-4h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		5h	64 DMA channels.
		6h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

5.4.1.1.3 DMA Channel Map *n* Registers (DCHMAP*n*)

The DMA channel map *n* register (DCHMAP*n*) is shown in Figure 5-41 and described in Table 5-22.

Figure 5-41. DMA Channel Map *n* Registers (DCHMAP*n*)

31	16

Table 5-22. DMA Channel Map *n* Registers (DCHMAP*n*) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved
13-5	PAENTRY	0-1FFh	Points to the PaRAM set number for DMA channel *n*.
4-0	Reserved	0	Reserved

5.4.1.1.4 QDMA Channel Map *n* Registers (QCHMAP*n*)

Each QDMA channel in EDMA3CC can be associated with any PaRAM set available on the device. Furthermore, the specific trigger word (0-7) of the PaRAM set can be programmed. The PaRAM set association and trigger word for every QDMA channel register is configurable using the QDMA channel map *n* register (QCHMAP*n*).

The QCHMAP*n* is shown in Figure 5-42 and described in Table 5-23.

NOTE: At reset the QDMA channel map registers for all QDMA channels point to PaRAM set 0. If an application makes use of both a DMA channel that points to PaRAM set 0 and any QDMA channels, ensure that QCHMAP*n* is programmed appropriately to point to a different PaRAM entry.

Figure 5-42. QDMA Channel Map *n* Registers (QCHMAP*n*)

Table 5-23. QDMA Channel Map *n* Registers (QCHMAP*n*) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13-5	PAENTRY	0-1FFh	PAENTRY points to the PaRAM set number for QDMA channel *n*.
		0-FFh	Parameter entry 0 through 511.
		100h-1FFh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
4-2	TRWORD	0-7h	Points to the specific trigger word of the PaRAM set defined by PAENTRY. A write to the trigger word results in a QDMA event being recognized.
1-0	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

5.4.1.1.5 DMA Channel Queue *n* Number Registers (DMAQNUM*n*)

The DMA channel queue number register (DMAQNUM*n*) allows programmability of each of the 64 DMA channels in the EDMA3CC to submit its associated synchronization event to any event queue in the EDMA3CC. At reset, all channels point to event queue 0.

The DMAQNUM*n* is shown in Figure 5-43 and described in Table 5-24. Table 5-25 shows the channels and their corresponding bits in DMAQNUM*n*.

NOTE: Because the event queues in EDMA3CC have a fixed association to the transfer controllers, that is, Q0 TRs are submitted to TC0, Q1 TRs are submitted to TC1, etc., by programming DMAQNUM*n* for a particular DMA channel *n* also dictates which transfer controller is utilized for the data movement (or which EDMA3TC receives the TR request).

Figure 5-43. DMA Channel Queue *n* Number Registers (DMAQNUM*n*)

28-30	E7	E15	E23	E31	E39	E47	E55	E63

5.4.1.1.6 QDMA Channel Queue Number Register (QDMAQNUM)

The QDMA channel queue number register (QDMAQNUM) is used to program all the QDMA channels in the EDMA3CC to submit the associated QDMA event to any of the event queues in the EDMA3CC.

The QDMAQNUM is shown in Figure 5-44 and described in Table 5-26.

Table 5-26. QDMA Channel Queue Number Register (QDMAQNUM) Field Descriptions

Bit	Field	Value	Description
31-0	E*n*	0-7h	QDMA queue number. Contains the event queue number to be used for the corresponding QDMA channel.
		0	Event *n* is queued on Q0.
		1h	Event *n* is queued on Q1.
		2h	Event *n* is queued on Q2.
		3h	Event *n* is queued on Q3.
		4h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

5.4.1.1.7 Queue Priority Register (QUEPRI)

The queue priority register (QUEPRI) allows you to change the priority of the individual queues and the priority of the transfer request (TR) associated with the events queued in the queue. Because the queue to EDMA3TC mapping is fixed, programming QUEPRI essentially governs the priority of the associated transfer controller(s) read/write commands with respect to the other bus masters in the device. You can modify the EDMA3TC priority to obtain the desired system performance.

The QUEPRI is shown in Figure 5-45 and described in Table 5-27.

Table 5-27. Queue Priority Register (QUEPRI) Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
14-12	PRIQ3	0-7h	Priority level for queue 3. Dictates the priority level used by TC3 relative to other masters in the device. A value of 0 means highest priority and a value of 7 means lowest priority.
11	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
10-8	PRIQ2	0-7h	Priority level for queue 2. Dictates the priority level used by TC2 relative to other masters in the device. A value of 0 means highest priority and a value of 7 means lowest priority.
7	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
6-4	PRIQ1	0-7h	Priority level for queue 1. Dictates the priority level used by TC1 relative to other masters in the device. A value of 0 means highest priority and a value of 7 means lowest priority.
3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2-0	PRIQ0	0-7h	Priority level for queue 0. Dictates the priority level used by TC0 relative to other masters in the device. A value of 0 means highest priority and a value of 7 means lowest priority.

5.4.1.2 Error Registers

The EDMA3CC contains a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

5.4.1.2.1 Event Missed Registers (EMR/EMRH)

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed registers (EMR/EMRH). All trigger types are treated individually, that is, manual triggered (ESR/ESRH), chain triggered (CER/CERH), and event triggered (ER/ERH) are all treated separately. The EMR/EMRH bits for a channel are also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EMR/EMRH bit is set (and all errors, including bits in other error registers (QEMR, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. See Section 5.2.9.4 for details on EDMA3CC error interrupt generation.

The EMR is shown in Figure 5-46 and described in Table 5-28. The EMRH is shown in Figure 5-47 and described in Table 5-29.

Table 5-29. Event Missed Register High (EMRH) Field Descriptions

Bit	Field	Value	Description
31-0	E*n*		Channel 32–63 event missed. E*n* is cleared by writing a 1 to the corresponding bit in the event missed clear register high (EMCRH).
		0	No missed event.
		1	Missed event occurred.

5.4.1.2.2 Event Missed Clear Registers (EMCR/EMCRH)

Once a missed event is posted in the event missed registers (EMR/EMRH), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the event missed clear registers (EMCR/EMCRH). Writing a 1 to any of the bits clears the corresponding missed event (bit) in EMR/EMRH; writing a 0 has no effect.

The EMCR is shown in Figure 5-48 and described in Table 5-30. The EMCRH is shown in Figure 5-49 and described in Table 5-31.

Figure 5-48. Event Missed Clear Register (EMCR)

		0	No effect.
		1	Corresponding missed event bit in the event missed register high (EMRH) is cleared (E*n* = 0).

5.4.1.2.3 QDMA Event Missed Register (QEMR)

For a particular QDMA channel, if two QDMA events are detected without the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the QDMA event missed register (QEMR). The QEMR bits for a channel are also set if a QDMA event on the channel encounters a NULL entry (or a NULL TR is serviced). If any QEMR bit is set (and all errors, including bits in other error registers (EMR/EMRH, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. See Section 5.2.9.4 for details on EDMA3CC error interrupt generation.

The QEMR is shown in Figure 5-50 and described in Table 5-32.

7-0	E*n*		Channel 0-7 QDMA event missed. E*n* is cleared by writing a 1 to the corresponding bit in the QDMA event missed clear register (QEMCR).
		0	No missed event.
		1	Missed event occurred.

5.4.1.2.4 QDMA Event Missed Clear Register (QEMCR)

Once a missed event is posted in the QDMA event missed registers (QEMR), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the QDMA event missed clear registers (QEMCR). Writing a 1 to any of the bits clears the corresponding missed event (bit) in QEMR; writing a 0 has no effect.

The QEMCR is shown in Figure 5-51 and described in Table 5-33.

7-0	E*n*		QDMA event missed clear. All error bits must be cleared before additional error interrupts will be asserted by the EDMA3CC.
		0	No effect.
		1	Corresponding missed event bit in the QDMA event missed register (QEMR) is cleared (E*n* = 0).

5.4.1.2.5 EDMA3CC Error Register (CCERR)

The EDMA3CC error register (CCERR) indicates whether or not at any instant of time the number of events queued up in any of the event queues exceeds or equals the threshold/watermark value that is set in the queue watermark threshold register (QWMTHRA). Additionally, CCERR also indicates if when the number of outstanding TRs that have been programmed to return transfer completion code (TRs which have the TCINTEN or TCCHEN bit in OPT set) to the EDMA3CC has exceeded the maximum allowed value of 63. If any bit in CCERR is set (and all errors, including bits in other error registers (EMR/EMRH, QEMR) were previously cleared), the EDMA3CC generates an error interrupt. See Section 5.2.9.4 for details on EDMA3CC error interrupt generation. Once the error bits are set in CCERR, they can only be cleared by writing to the corresponding bits in the EDMA3CC error clear register (CCERRCLR).

The CCERR is shown in Figure 5-52 and described in Table 5-34.

Bit	Field	Value	Description
31-17	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
16	TCCERR		Transfer completion code error. TCCERR is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Total number of allowed TCCs outstanding has not been reached.
		1	Total number of allowed TCCs has been reached.
15-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	QTHRXCD3		Queue threshold error for queue 3. QTHRXCD3 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.
2	QTHRXCD2		Queue threshold error for queue 2. QTHRXCD2 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.
1	QTHRXCD1		Queue threshold error for queue 1 . QTHRXCD1 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.
0	QTHRXCD0		Queue threshold error for queue 0. QTHRXCD0 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.

5.4.1.2.6 EDMA3CC Error Clear Register (CCERRCLR)

The EDMA3CC error clear register (CCERRCLR) is used to clear any error bits that are set in the EDMA3CC error register (CCERR). In addition, CCERRCLR also clears the values of some bit fields in the queue status registers (QSTAT*n*) associated with a particular event queue. Writing a 1 to any of the bits clears the corresponding bit in CCERR; writing a 0 has no effect.

The CCERRCLR is shown in Figure 5-53 and described in Table 5-35.

Table 5-35. EDMA3CC Error Clear Register (CCERRCLR) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
16	TCCERR		Transfer completion code error clear.
		0	No effect.
		1	Clears the TCCERR bit in the EDMA3CC error register (CCERR).
15-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	QTHRXCD3		Queue threshold error clear for queue 3.
		0	No effect.
		1	Clears the QTHRXCD3 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 3 (QSTAT3).
2	QTHRXCD2		Queue threshold error clear for queue 2.
		0	No effect.
		1	Clears the QTHRXCD2 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 2 (QSTAT2).
1	QTHRXCD1		Queue threshold error clear for queue 1.
		0	No effect.
		1	Clears the QTHRXCD1 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 1 (QSTAT1).
0	QTHRXCD0		Queue threshold error clear for queue 0.
		0	No effect.
		1	Clears the QTHRXCD0 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 0 (QSTAT0).

5.4.1.2.7 Error Evaluation Register (EEVAL)

The EDMA3CC error interrupt is asserted whenever an error bit is set in any of the error registers (EMR/EMRH, QEMR, and CCERR). For subsequent error bits that get set, the EDMA3CC error interrupt is reasserted only when transitioning from an “all the error bits cleared” to “at least one error bit is set”. Alternatively, a CPU write of 1 to the EVAL bit in the error evaluation register (EEVAL) results in reasserting the EDMA3CC error interrupt, if there are any outstanding error bits set due to subsequent error conditions. Writes of 0 have no effect.

The EEVAL is shown in Figure 5-54 and described in Table 5-36.

1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	EVAL		Error interrupt evaluate.
		0	No effect.
		1	EDMA3CC error interrupt will be pulsed if any errors have not been cleared in any of the error registers (EMR/EMRH, QEMR, or CCERR).

5.4.1.3 Region Access Enable Registers

The region access enable register group consists of the DMA access enable registers (DRAE*m* and DRAEH*m*) and the QDMA access enable registers (QRAE*m*). Where *m* is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

5.4.1.3.1 DMA Region Access Enable for Region m (DRAEm)

The DMA region access enable register for shadow region *m* (DRAE*m*/DRAEH*m*) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region *m* view of the DMA channel registers. See the EDMA3CC register memory map (Table 5-19) for a list of all the DMA channel and interrupt registers mapped in the shadow region view. Additionally, the DRAE*m*/DRAEH*m* configuration determines completion of which DMA channels will result in assertion of the shadow region *m* DMA completion interrupt (see Section 5.2.9).

The DRAE*m* is shown in Figure 5-55 and described in Table 5-37. The DRAEH*m* is shown in Figure 5-56 and described in Table 5-37.

Figure 5-55. DMA Region Access Enable Register for Region *m* (DRAE*m*)

Table 5-37. DMA Region Access Enable Registers for Region M (DRAE*m*/DRAEH*m*) Field Descriptions

Bit	Field	Value	Description
31-0	E*n*		DMA region access enable for bit *n*/channel *n* in region *m*.
		0	Accesses via region *m* address space to bit *n* in any DMA channel register are not allowed. Reads return 0 on bit *n* and writes do not modify the state of bit *n*. Enabled interrupt bits for bit *n* do not contribute to the generation of a transfer completion interrupt for shadow region *m*.
		1	Accesses via region *m* address space to bit *n* in any DMA channel register are allowed. Reads return the value from bit *n* and writes modify the state of bit *n*. Enabled interrupt bits for bit *n* contribute to the generation of a transfer completion interrupt for shadow region *m*.

5.4.1.3.2 QDMA Region Access Enable Registers (QRAE*m*)

The QDMA region access enable register for shadow region *m* (QRAE*m*) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all QDMA registers in the shadow region *m* view of the QDMA registers. This includes all 4-bit QDMA registers.

The QRAE*m* is shown in Figure 5-57 and described in Table 5-38.

Table 5-38. QDMA Region Access Enable for Region M (QRAE*m*) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	E*n*		QDMA region access enable for bit *n*/QDMA channel *n* in region *m*.
		0	Accesses via region *m* address space to bit *n* in any QDMA channel register are not allowed. Reads return 0 on bit *n* and writes do not modify the state of bit *n*.
		1	Accesses via region *m* address space to bit *n* in any QDMA channel register are allowed. Reads return the value from bit *n* and writes modify the state of bit *n*.

5.4.1.4 Status/Debug Visibility Registers

The following set of registers provide visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

5.4.1.4.1 Event Queue Entry Registers (QxEy)

The event queue entry registers (Q*x*E*y*) exist for all 16 queue entries (the maximum allowed queue entries) for all event queues in the EDMA3CC.

There are Q0E0 to Q0E15, Q1E0 to Q1E15, Q2E0 to Q2E15, and Q3E0 to Q3E15. Each register details the event number (ENUM) and the event type (ETYPE). For example, if the value in Q1E4 is read as 000 004Fh, this means the 4th entry in queue 1 is a manually-triggered event on DMA channel 15.

The Q*x*E*y* is shown in Figure 5-58 and described in Table 5-39.

Table 5-39. Event Queue Entry Registers (Q*x*E*y*) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-6	ETYPE	0-3h	Event entry *y* in queue *x*. Specifies the specific event type for the given entry in the event queue.
		0	Event triggered via ER.
		1h	Manual triggered via ESR.
		2h	Chain triggered via CER.
		3h	Auto-triggered via QER.
5-0	ENUM	0-3Fh	Event entry *y* in queue *x*. Event number:
		0-3h	QDMA channel number (0 to 3).
		0-3Fh	DMA channel/event number (0 to 63).

5.4.1.4.2 Queue Status Registers (QSTAT*n*)

The queue status registers (QSTAT*n*) is shown in Figure 5-59 and described in Table 5-40.

Figure 5-59. Queue Status Register *n* (QSTAT*n*)

Table 5-40. Queue Status Register *n* (QSTAT*n*) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
24	THRXCD		Threshold exceeded. THRXCD is cleared by writing a 1 to the corresponding QTHRXCD*n* bit in the EDMA3CC error clear register (CCERRCLR).
		0	Threshold specified by the Q*n* bit in the queue watermark threshold A register (QWMTHRA) has not been exceeded.
		1	Threshold specified by the Q*n* bit in the queue watermark threshold A register (QWMTHRA) has been exceeded.
23-21	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
20-16	WM	0-10h	Watermark for maximum queue usage. Watermark tracks the most entries that have been in queue *n* since reset or since the last time that the watermark (WM) bit was cleared. WM is cleared by writing a 1 to the corresponding QTHRXCD*n* bit in the EDMA3CC error clear register (CCERRCLR).
		0-10h	Legal values are 0 (empty) to 10h (full).
		11h-1Fh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15-13	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
12-8	NUMVAL	0-10h	Number of valid entries in queue *n*. The total number of entries residing in the queue manager FIFO at a given instant. Always enabled.
		0-10h	Legal values are 0 (empty) to 10h (full).
		11h-1Fh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3-0	STRTPTR	0-Fh	Start pointer. The offset to the head entry of queue *n*, in units of entries. Always enabled. Legal values are 0 (0th entry) to Fh (15th entry).

5.4.1.4.3 Queue Watermark Threshold A Register (QWMTHRA)

The queue watermark threshold A register (QWMTHRA) is shown in Figure 5-60 and described in Table 5-41.

Figure 5-60. Queue Watermark Threshold A Register (QWMTHRA)

Bit	Field	Value	Description
31-29	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
28-24	Q3	0-1Fh	Queue threshold for queue 3 value. The QTHRXCD3 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 3 (QSTAT3) are set when the number of events in queue 3 at an instant in time (visible via the NUMVAL bit in QSTAT3) equals or exceeds the value specified by Q3.
		0-10h	The default is 16 (maximum allowed).
		11h	Disables the threshold errors.
		12h-1Fh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
23-21	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
20-16	Q2	0-1Fh	Queue threshold for queue 2 value. The QTHRXCD2 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 2 (QSTAT2) are set when the number of events in queue 2 at an instant in time (visible via the NUMVAL bit in QSTAT2) equals or exceeds the value specified by Q2.
		0-10h	The default is 16 (maximum allowed).
		11h	Disables the threshold errors.
		12h-1Fh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15-13	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
12-8	Q1		Queue threshold for queue 1 value. The QTHRXCD1 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 1 (QSTAT1) are set when the number of events in queue 1 at an instant in time (visible via the NUMVAL bit in QSTAT1) equals or exceeds the value specified by Q1.
		0-10h	The default is 16 (maximum allowed).
		11h	Disables the threshold errors.
		12h-1Fh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-5	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
4-0	Q0		Queue threshold for queue 0 value. The QTHRXCD0 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 0 (QSTAT0) are set when the number of events in queue 0 at an instant in time (visible via the NUMVAL bit in QSTAT0) equals or exceeds the value specified by Q0.
		0-10h	The default is 16 (maximum allowed).
		11h	Disables the threshold errors.
		12h-1Fh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

5.4.1.4.4 EDMA3CC Status Register (CCSTAT)

The EDMA3CC status register (CCSTAT) has a number of status bits that reflect which parts of the EDMA3CC logic is active at any given instant of time. The CCSTAT is shown in Figure 5-61 and described in Table 5-42.

Figure 5-61. EDMA3CC Status Register (CCSTAT)

R-0			R-0	R-0	R-0	R-0	R-0

LEGEND: R = Read only; -*n* = value after reset

Table 5-42. EDMA3CC Status Register (CCSTAT) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
19	QUEACTV3		Queue 3 active.
		0	No events are queued in queue 3.
		1	At least one TR is queued in queue 3.
18	QUEACTV2		Queue 2 active.
		0	No events are queued in queue 2.
		1	At least one TR is queued in queue 2.
17	QUEACTV1		Queue 1 active.
		0	No events are queued in queue 1.
		1	At least one TR is queued in queue 1.
16	QUEACTV0		Queue 0 active.
		0	No events are queued in queue 0.
		1	At least one TR is queued in queue 0.
15-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13-8	COMPACTV	0-3Fh	Completion request active. The COMPACTV field reflects the count for the number of completion requests submitted to the transfer controllers. This count increments every time a TR is submitted and is programmed to report completion (the TCINTEN or TCCCHEN bits in OPT in the parameter entry associated with the TR are set). The counter decrements for every valid TCC received back from the transfer controllers. If at any time the count reaches a value of 63, the EDMA3CC will not service any new TRs until the count is less then 63 (or return a transfer completion code from a transfer controller, which would decrement the count).
		0	No completion requests outstanding.
		1h-3Fh	Total of 1 completion request to 63 completion requests are outstanding.
7-5	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

Table 5-42. EDMA3CC Status Register (CCSTAT) Field Descriptions (continued)

Bit	Field	Value	Description
4	ACTV		Channel controller active. Channel controller active is a logical-OR of each of the *ACTV bits. The ACTV bit remains high through the life of a TR.
		0	Channel is idle..
		1	Channel is busy.
3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2	TRACTV		Transfer request active.
		0	Transfer request processing/submission logic is inactive.
		1	Transfer request processing/submission logic is active.
1	QEVTACTV		QDMA event active.
		0	No enabled QDMA events are active within the EDMA3CC.
		1	At least one enabled QDMA event (QER) is active within the EDMA3CC.
0	EVTACTV		DMA event active.
		0	No enabled DMA events are active within the EDMA3CC.
		1	At least one enabled DMA event (ER and EER, ESR, CER) is active within the EDMA3CC.

5.4.1.5 Memory Protection Address Space

5.4.1.5.1 Memory Protection Fault Address Register (MPFAR)

The memory protection fault address register (MPFAR) is shown in Figure 5-62 and described in Table 5-43. A CPU write of 1 to the MPFCLR bit in the memory protection fault command register (MPFCR) causes any error conditions stored in MPFAR to be cleared.

Figure 5-62. Memory Protection Fault Address Register (MPFAR)

		0	User read accesses are not allowed from region M.
		1	User read accesses are allowed from region N addresses.
1	UW		User write permission.
		0	User write accesses are not allowed to region M.
		1	User write accesses are allowed to region M addresses.
0	UX		User execute permission.
		0	User execute accesses are not allowed from region M.
		1	User execute accesses are allowed from region M addresses.

5.4.1.6 DMA Channel Registers

The following sets of registers pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUM*n*) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format *reg_name* that corresponds to DMA channels 0 through 31 and *reg_name_High* that corresponds to DMA channels 32 through 64.

For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register.

The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAE*m*/DRAEH*m*). The registers are described in Section 5.4.1.3.1 and the details for shadow region/global region usage is explained in Section 5.2.7.

5.4.1.6.1 Event Registers (ER, ERH)

All external events are captured in the event register (ER/ERH). The events are latched even when the events are not enabled. If the event bit corresponding to the latched event is enabled (EER.E*n*/EERH.E*n* = 1), then the event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. The event register bits are automatically cleared (ER.E*n*/ERH.E*n* = 0) once the corresponding events are prioritized and serviced. If ER.E*n*/ERH.E*n* are already set and another event is received on the same channel/event, then the corresponding event is latched in the event miss register (EMR.E*n*/EMRH.E*n*), provided that the event was enabled (EER.E*n*/EERH.E*n* = 1).

Event *n* can be cleared by the CPU writing a 1 to corresponding event bit in the event clear register (ECR/ECRH). The setting of an event is a higher priority relative to clear operations (via hardware or software). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

Table 5-110 provides the type of synchronization events and the EDMA3CC channels associated to each of these external events.

The ER is shown in Figure 5-66 and described in Table 5-47. The ERH is shown in Figure 5-67 and described in Table 5-48.

Table 5-48. Event Register High (ERH) Field Descriptions

Bit	Field	Value	Description
31-0	E*n*		Event 32-63. Events 32-63 are captured by the EDMA3CC and are latched into ERH. The events are set (E*n* = 1) even when events are disabled (E*n* = 0 in the event enable register high, EERH).
		0	EDMA3CC event is not asserted.
		1	EDMA3CC event is asserted. Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

5.4.1.6.2 Event Clear Registers (ECR, ECRH)

Once an event has been posted in the event registers (ER/ERH), the event is cleared in two ways. If the event is enabled in the event enable register (EER/EERH) and the EDMA3CC submits a transfer request for the event to the EDMA3TC, it clears the corresponding event bit in the event register. If the event is disabled in the event enable register (EER/EERH), the CPU can clear the event by way of the event clear registers (ECR/ECRH).

Writing a 1 to any of the bits clears the corresponding event; writing a 0 has no effect. Once an event bit is set in the event register, it remains set until EDMA3CC submits a transfer request for that event or the CPU clears the event by setting the corresponding bit in ECR/ECRH.

The ECR is shown in Figure 5-68 and described in Table 5-49. The ECRH is shown in Figure 5-69 and described in Table 5-50.

Figure 5-68. Event Clear Register (ECR)

Bit	Field	Value	Description
31-0	E*n*		Event clear for event 32-63. Any of the event bits in ECRH are set to clear the event (E*n*) in the event register high (ERH). A write of 0 has no effect.
		0	No effect.
		1	EDMA3CC event is cleared in the event register high (ERH).

5.4.1.6.3 Event Set Registers (ESR, ESRH)

The event set registers (ESR/ESRH) allow the CPU (EDMA3 programmers) to manually set events to initiate DMA transfer requests. CPU writes of 1 to any event set register (E*n*) bits set the corresponding bits in the registers. The set event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. Writing a 0 has no effect.

The event set registers operate independent of the event registers (ER/ERH), and a write of 1 is always considered a valid event regardless of whether the event is enabled (the corresponding event bits are set or cleared in EER.E*n*/EERH.E*n*).

Once the event is set in the event set registers, it cannot be cleared by CPU writes, in other words, the event clear registers (ECR/ECRH) have no effect on the state of ESR/ESRH. The bits will only be cleared once the transfer request corresponding to the event has been submitted to the transfer controller. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

Manually-triggered transfers via writes to ESR/ESRH allow the CPU to submit DMA requests in the system, these are relevant for memory-to-memory transfer scenarios. If the ESR.E*n*/ESRH.E*n* bit is already set and another CPU write of 1 is attempted to the same bit, then the corresponding event is latched in the event missed registers (EMR.E*n*/EMRH.E*n* = 1).

The ESR is shown in Figure 5-70 and described in Table 5-51. The ESRH is shown in Figure 5-71 and described in Table 5-52.

		0	No effect.
		1	Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

5.4.1.6.4 Chained Event Registers (CER, CERH)

When the OPTIONS parameter for a PaRAM entry is programmed to returned a chained completion code (ITCCHEN = 1 and/or TCCHEN = 1), then the value dictated by the TCC[5:0] (also programmed in OPT) forces the corresponding event bit to be set in the chained event registers (CER/CERH). The set chained event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. This results in a chained-triggered transfer.

The chained event registers do not have any enables. The generation of a chained event is essentially enabled by the PaRAM entry that has been configured for intermediate and/or final chaining on transfer completion. The E*n* bit is set (regardless of the state of EER.E*n*/EERH.E*n*) when a chained completion code is returned from one of the transfer controllers or is generated by the EDMA3CC via the early completion path. The bits in the chained event register are cleared when the corresponding events are prioritized and serviced.

If the E*n* bit is already set and another chaining completion code is return for the same event, then the corresponding event is latched in the event missed registers (EMR.E*n*/EMRH.E*n* = 1). The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The CER is shown in Figure 5-72 and described in Table 5-53. The CERH is shown in Figure 5-73 and described in Table 5-54.

5.4.1.6.5 Event Enable Registers (EER, EERH)

The EDMA3CC provides the option of selectively enabling/disabling each event in the event registers (ER/ERH) by using the event enable registers (EER/EERH). If an event bit in EER/EERH is set (using the event enable set registers, EESR/EESRH), it will enable that corresponding event. Alternatively, if an event bit in EER/EERH is cleared (using the event enable clear registers, EECR/EECRH), it will disable the corresponding event.

The event registers latch all events that are captured by EDMA3CC, even if the events are disabled (although EDMA3CC does not process it). Enabling an event with a pending event already set in the event registers enables the EDMA3CC to process the already set event like any other new event. The EER/EERH settings do not have any effect on chained events (CER.E*n*/CERH.E*n* = 1) and manually set events (ESR.E*n*/ESRH.E*n* = 1).

The EER is shown in Figure 5-74 and described in Table 5-55. Th EERH is shown in Figure 5-75 and described in Table 5-56.

		0	Event is not enabled. An external event latched in the event register high (ERH) is not evaluated by the EDMA3CC.
		1	Event is enabled. An external event latched in the event register high (ERH) is evaluated by the EDMA3CC.

5.4.1.6.6 Event Enable Clear Register (EECR, EECRH)

The event enable registers (EER/EERH) cannot be modified by directly writing to them. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable clear registers (EECR/EECRH) are used to disable events. Writes of 1 to the bits in EECR/EECRH clear the corresponding event bits in EER/EERH; writes of 0 have no effect.

The EECR is shown in Figure 5-76 and described in Table 5-57. The EECRH is shown in Figure 5-77 and described in Table 5-58.

Figure 5-76. Event Enable Clear Register (EECR)

		0	No effect.
		1	Event is enabled. Corresponding bit in the event enable register high (EERH) is set (E*n* = 1).

5.4.1.6.8 Secondary Event Registers (SER, SERH)

The secondary event registers (SER/SERH) provide information on the state of a DMA channel or event (0 through 63). If the EDMA3CC receives a TR synchronization due to a manual-trigger, event-trigger, or chained-trigger source (ESR.E*n*/ESRH.E*n* = 1, ER.E*n*/ERH.E*n* = 1, or CER.E*n*/CERH.E*n* = 1), which results in the setting of a corresponding event bit in SER/SERH (SER.E*n*/SERH.E*n* = 1), it implies that the corresponding DMA event is in the queue.

Once a bit corresponding to an event is set in SER/SERH, the EDMA3CC does not prioritize additional events on the same DMA channel. Depending on the condition that lead to the setting of the SER bits, either the EDMA3CC hardware or the software (using SECR/SECRH) needs to clear the SER/SERH bits for the EDMA3CC to evaluate subsequent events (subsequent transfers) on the same channel. See Section 5.1.1 for additional conditions that can cause the secondary event registers to be set.

The SER is shown in Figure 5-80 and described in Table 5-61. The SERH is shown in Figure 5-81 and described in Table 5-62.

		0	Event is not currently stored in the event queue.
		1	Event is currently stored in the event queue. Event submission/prioritization logic will not prioritize additional events.

5.4.1.6.9 Secondary Event Clear Registers (SECR, SECRH)

The secondary event clear registers (SECR/SECRH) clear the status of the secondary event registers (SER/SERH). CPU writes of 1 clear the corresponding set bits in SER/SERH. Writes of 0 have no effect.

The SECR is shown in Figure 5-82 and described in Table 5-63. The SECRH is shown in Figure 5-83 and described in Table 5-64.

5.4.1.7 Interrupt Registers

All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. The following set of registers is used for the transfer completion interrupt reporting/generating by the EDMA3CC. See Section 5.2.9 for more details on EDMA3CC completion interrupt generation.

5.4.1.7.1 Interrupt Enable Registers (IER, IERH)

Interrupt enable registers (IER/IERH) are used to enable/disable the transfer completion interrupt generation by the EDMA3CC for all DMA/QDMA channels. The IER/IERH cannot be written to directly. To set any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable set registers (IESR/IESRH). Similarly, to clear any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable clear registers (IECR/IECRH).

The IER is shown in Figure 5-84 and described in Table 5-65. The IERH is shown in Figure 5-85 and described in Table 5-66.

5.4.1.7.2 Interrupt Enable Clear Register (IECR, IECRH)

The interrupt enable clear registers (IECR/IECRH) are used to clear interrupts. Writes of 1 to the bits in IECR/IECRH clear the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect.

The IECR is shown in Figure 5-86 and described in Table 5-67. The IECRH is shown in Figure 5-87 and described in Table 5-68.

5.4.1.7.3 Interrupt Enable Set Registers (IESR, IESRH)

The interrupt enable set registers (IESR/IESRH) are used to enable interrupts. Writes of 1 to the bits in IESR/IESRH set the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect.

The IESR is shown in Figure 5-88 and described in Table 5-69. The IESRH is shown in Figure 5-89 and described in Table 5-70.

31-0	E*n*		Interrupt enable clear for channels 32-63.
		0	No effect.
		1	Corresponding bit in the interrupt enable register high (IERH) is set (I*n* = 1).

5.4.1.7.4 Interrupt Pending Register (IPR, IPRH)

If the TCINTEN and/or ITCINTEN bit in the channel option parameter (OPT) is set in the PaRAM entry associated with the channel (DMA or QDMA), then the EDMA3TC (for normal completion) or the EDMA3CC (for early completion) returns a completion code on transfer or intermediate transfer completion. The value of the returned completion code is equal to the TCC bit in OPT for the PaRAM entry associated with the channel.

When an interrupt transfer completion code with TCC = *n* is detected by the EDMA3CC, then the corresponding bit is set in the interrupt pending register (IPR.I*n*, if *n* = 0 to 31; IPRH.I*n,* if *n* = 32 to 63). Note that once a bit is set in the interrupt pending registers, it remains set; it is your responsibility to clear these bits. The bits set in IPR/IPRH are cleared by writing a 1 to the corresponding bits in the interrupt clear registers (ICR/ICRH).

The IPR is shown in Figure 5-90 and described in Table 5-71. The IPRH is shown in Figure 5-91 and described in Table 5-72.

5.4.1.7.5 Interrupt Clear Registers (ICR, ICRH)

The bits in the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bits in the interrupt clear registers(ICR/ICRH). Writes of 0 have no effect. All set bits in IPR/IPRH must be cleared to allow EDMA3CC to assert additional transfer completion interrupts.

The ICR is shown in Figure 5-92 and described in Table 5-73. The ICRH is shown in Figure 5-93 and described in Table 5-74.

		0	No effect.
		1	Corresponding bit in the interrupt pending register high (IPRH) is cleared (I*n* = 0).

5.4.1.7.6 Interrupt Evaluate Register (IEVAL)

The interrupt evaluate register (IEVAL) is the only register that physically exists in both the global region and the shadow regions. In other words, the read/write accessibility for the shadow region IEVAL is not affected by the DMA/QDMA region access registers (DRAE*m*/DRAEH*m*, QRAE*n*/QRAEH*n*). IEVAL is needed for robust ISR operations to ensure that interrupts are not missed by the CPU.

The IEVAL is shown in Figure 5-94 and described in Table 5-75.

Figure 5-94. Interrupt Evaluate Register (IEVAL)

Table 5-75. Interrupt Evaluate Register (IEVAL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	EVAL		Interrupt evaluate.
		0	No effect.
		1	Causes EDMA3CC completion interrupt to be pulsed, if any enabled (IER*n*/IERH*n* = 1) interrupts are still pending (IPR*n*/IPRH*n* = 1). The EDMA3CC completion interrupt that is pulsed depends on which IEVAL is being exercised. For example, writing to the EVAL bit in IEVAL pulses the global completion interrupt, but writing to the EVAL bit in IEVAL0 pulses the region 0 completion interrupt.

5.4.1.8 QDMA Registers

The following sets of registers control the QDMA channels in the EDMA3CC. The QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAE*n*/QRAEH*n*). Section 5.2.7 details shadow region/global region usage.

5.4.1.8.1 QDMA Event Register (QER)

The QDMA event register (QER) channel *n* bit is set (E*n* = 1) when the CPU or any EDMA3 programmer (including EDMA3) performs a write to the trigger word (using the QDMA channel mapping register (QCHMAP*n*)) in the PaRAM entry associated with QDMA channel *n* (which is also programmed using QCHMAP*n*). The E*n* bit is also set when the EDMA3CC performs a link update on a PaRAM address that matches the QCHMAP*n* settings. The QDMA event is latched only if the QDMA event enable register (QEER) channel *n* bit is also enabled (QEER.E*n* = 1). Once a bit is set in QER, then the corresponding QDMA event (auto-trigger) is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. See Section 5.1.1 for additional conditions that can lead to the setting of QER bits.

The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then the QDMA event missed register (QEMR) would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The set bits in QER are only cleared when the transfer request associated with the corresponding channels has been processed by the EDMA3CC and submitted to the transfer controller. If the E*n* bit is already set and a QDMA event for the same QDMA channel occurs prior to the original being cleared, then the second missed event is latched in QEMR (E*n* = 1).

The QER is shown in Figure 5-95 and described in Table 5-76.

Table 5-76. QDMA Event Register (QER) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	E*n*		QDMA event for channels 0-7.
		0	No effect.
		1	Corresponding QDMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

5.4.1.8.2 QDMA Event Enable Register (QEER)

The EDMA3CC provides the option of selectively enabling/disabling each channel in the QDMA event register (QER) by using the QDMA event enable register (QEER). If any of the event bits in QEER is set (using the QDMA event enable set register, QEESR), it will enable that corresponding event. Alternatively, if any event bit in QEER is cleared (using the QDMA event enable clear register, QEECR), it will disable the corresponding QDMA channel. The QDMA event register will not latch any event for a QDMA channel, if it is not enabled via QEER.

The QEER is shown in Figure 5-96 and described in Table 5-77.

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	E*n*		QDMA event enable for channels 0-7.
		0	QDMA channel *n* is not enabled. QDMA event will not be recognized and will not latch in the QDMA event register (QER).
		1	QDMA channel *n* is enabled. QDMA events will be recognized and will get latched in the QDMA event register (QER).

5.4.1.8.3 QDMA Event Enable Clear Register (QEECR)

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable clear register (QEECR) is used to disable events. Writes of 1 to the bits in QEECR clear the corresponding QDMA channel bits in QEER; writes of 0 have no effect.

The QEECR is shown in Figure 5-97 and described in Table 5-78.

7-0	E*n*		QDMA event enable clear for channels 0-7.
		0	No effect.
		1	QDMA event is disabled. Corresponding bit in the QDMA event enable register (QEER) is cleared (E*n* = 0).

5.4.1.8.4 QDMA Event Enable Set Register (QEESR)

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable set register (QEESR) is used to enable events. Writes of 1 to the bits in QEESR set the corresponding QDMA channel bits in QEER; writes of 0 have no effect.

The QEESR is shown in Figure 5-98 and described in Table 5-79.

7-0	E*n*		QDMA event enable set for channels 0-7.
		0	No effect.
		1	QDMA event is enabled. Corresponding bit in the QDMA event enable register (QEER) is set (E*n* = 1).

5.4.1.8.5 QDMA Secondary Event Register (QSER)

The QDMA secondary event register (QSER) provides information on the state of a QDMA event. If at any time a bit corresponding to a QDMA channel is set in QSER, that implies that the corresponding QDMA event is in the queue. Once a bit corresponding to a QDMA channel is set in QSER, the EDMA3CC does not prioritize additional events on the same QDMA channel. Depending on the condition that lead to the setting of the QSER bits, either the EDMA3CC hardware or the software (using QSECR) needs to clear the QSER bits for the EDMA3CC to evaluate subsequent QDMA events on the channel. Based on whether the associated TR request is valid, or it is a null or dummy TR, the implications on the state of QSER and the required user actions to submit another QDMA transfer might be different. See Section 5.1.1 for additional conditions that can cause the secondary event registers (QSER\SER) to be set.

The QSER is shown in Figure 5-99 and described in Table 5-80.

7-0	E*n*		QDMA secondary event register for channels 0-7.
		0	QDMA event is not currently stored in the event queue.
		1	QDMA event is currently stored in the event queue. EDMA3CC will not prioritize additional events.

5.4.1.8.6 QDMA Secondary Event Clear Register (QSECR)

The QDMA secondary event clear register (QSECR) clears the status of the QDMA secondary event register (QSER) and the QDMA event register (QER). CPU writes of 1 clear the corresponding set bits in QSER and QER. Writes of 0 have no effect. Note that this differs from the secondary event clear register (SECR) operation, which only clears the secondary event register (SER) bits and does not affect the event registers.

The QSECR is shown in Figure 5-100 and described in Table 5-81.

7	6	4	3	2	1	0
Reserved	DSTACTV		Reserved	WSACTV	SRCACTV	PROGBUSY
R-0	R-0		R-0	R-0	R-0	R-0

LEGEND: R = Read only; -*n* = value after reset

Table 5-85. EDMA3TC Channel Status Register (TCSTAT) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13-12	DFSTRTPTR	0-3h	Destination FIFO start pointer. Represents the offset to the head entry of the destination register FIFO, in units of entries.
11-9	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
8	Reserved	1	Reserved. Always read as 1.
7	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
6-4	DSTACTV	0-7h	Destination active state. Specifies the number of transfer requests (TRs) that are resident in the destination register FIFO at a given instant. This bit field can be primarily used for advanced debugging. Legal values are constrained by the destination register FIFO depth parameterization (DSTREGDEPTH) parameter.
		0	Destination FIFO is empty.
		1h	Destination FIFO contains 1 TR.
		2h	Destination FIFO contains 2 TRs.
		3h	Destination FIFO contains 3 TRs.
		4h	Destination FIFO contains 4 TRs. (Full if DSTREGDEPTH==4).
			If the destination register FIFO is empty, then any TR written to Prog Set immediately transitions to the destination register FIFO. If the destination register FIFO is not empty and not full, then any TR written to Prog Set immediately transitions to the destination register FIFO set if the source active state (SRCACTV) bit is set to idle.
			If the destination register FIFO is full, then TRs cannot transition to the destination register FIFO. The destination register FIFO becomes not full when the TR at the head of the destination register FIFO is completed.
		5h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2	WSACTV		Write status active
		0	Write status is not pending. Write status has been received for all previously issued write commands.
		1	Write status is pending. Write status has not been received for all previously issued write commands.
1	SRCACTV		Source active state
		0	Source controller is idle. Source active register set contains a previously processed transfer request.
		1	Source controller is busy servicing a transfer request.

Table 5-85. EDMA3TC Channel Status Register (TCSTAT) Field Descriptions (continued)

Bit	Field	Value	Description
0	PROGBUSY		Program register set busy
		0	Program set idle and is available for programming by the EDMA3CC.
		1	Program set busy

5.4.2.4 Error Registers

5.4.2.4.1 Error Register (ERRSTAT)

The error status register (ERRSTAT) is shown in Figure 5-104 and described in Table 5-86.

Figure 5-104. Error Register (ERRSTAT)

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	MMRAERR		MMR address error.
		0	Condition is not detected.
		1	User attempted to read or write to an invalid address in configuration memory map.
2	TRERR		Transfer request (TR) error event.
		0	Condition is not detected.
		1	TR detected that violates constant addressing mode transfer (SAM or DAM is set) alignment rules or has ACNT or BCNT == 0.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	BUSERR		Bus error event.
		0	Condition is not detected.
		1	EDMA3TC has detected an error at source or destination address. Error information can be read from the error details register (ERRDET).

5.4.2.4.2 Error Enable Register (ERREN)

The error enable register (ERREN) is shown in Figure 5-105 and described in Table 5-87.

When any of the enable bits are set, a bit set in the corresponding ERRSTAT causes an assertion of the EDMA3TC interrupt.

Figure 5-105. Error Enable Register (ERREN)

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 5-89. Error Details Register (ERRDET) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
17	TCCHEN	0-1	Transfer completion chaining enable. Contains the TCCHEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
16	TCINTEN	0-1	Transfer completion interrupt enable. Contains the TCINTEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
15-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13 - 8	TCC	0-3Fh	Transfer complete code. Contains the TCC value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3-0	STAT	0-Fh	Transaction status. Stores the nonzero status/error code that was detected on the read status or write status bus. If read status and write status are returned on the same cycle, then the EDMA3TC chooses nonzero version. If both are nonzero, then the write status is treated as higher priority.
		0	No error.
		1h-7h	Read error.
		8h-Fh	Write error.

5.4.2.4.5 Error Interrupt Command Register (ERRCMD)

The error command register (ERRCMD) is shown in Figure 5-108 and described in Table 5-90.

Figure 5-108. Error Interrupt Command Register (ERRCMD)

31	16

R-0	

15	2	1	0
Reserved		Rsvd	EVAL
R-0		W-0	W-0

LEGEND: R = Read only; W = Write only; -*n* = value after reset

Table 5-90. Error Interrupt Command Register (ERRCMD) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	EVAL		Error evaluate
		0	No effect
		1	EDMA3TC error line is pulsed if any of the error status register (ERRSTAT) bits are set.

5.4.2.5 Read Rate Register (RDRATE)

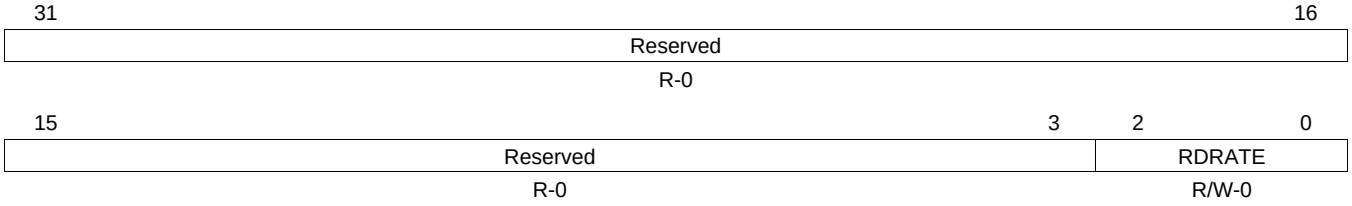
The EDMA3 transfer controller issues read commands at a rate controlled by the read rate register (RDRATE). The RDRATE defines the number of idle cycles that the read controller must wait before issuing subsequent commands. This applies both to commands within a transfer request packet (TRP) and for commands that are issued for different transfer requests (TRs). For instance, if RDRATE is set to 4 cycles between reads, there are 3 inactive cycles between reads.

RDRATE allows flexibility in transfer controller access requests to an endpoint. For an application, RDRATE can be manipulated to slow down the access rate, so that the endpoint may service requests from other masters during the inactive EDMA3TC cycles.

The RDRATE is shown in Figure 5-109 and described in Table 5-91.

NOTE: It is expected that the RDRATE value for a transfer controller is static, as it is decided based on the application requirement. It is not recommended to change this setting on the fly.

Figure 5-109. Read Rate Register (RDRATE)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 5-91. Read Rate Register (RDRATE) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2-0	RDRATE	0-7h	Read rate. Controls the number of cycles between read commands. This is a global setting that applies to all TRs for this EDMA3TC.
		0	Reads issued as fast as possible.
		1h	4 cycles between reads.
		2h	8 cycles between reads.
		3h	16 cycles between reads.
		4h	32 cycles between reads.
		5h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

5.4.2.6 EDMA3TC Channel Registers

The EDMA3TC channel registers are split into three parts: the programming registers, the source active registers, and the destination FIFO register. This section describes the registers and their functions. The program register set is programmed by the channel controller, and is for internal use. The other two sets are read-only and provided to facilitate advanced debug capabilities. The number of destination FIFO register sets depends on the destination FIFO depth.

TC0 has a FIFO depth of 2, so there are two sets of destination FIFO registers associated with TC0. TC1, TC2, and TC3 have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

5.4.2.6.1 Source Active Options Register (SAOPT)

The source active options register (SAOPT) is shown in Figure 5-110 and described in Table 5-92.

Figure 5-110. Source Active Options Register (SAOPT)

31	23	22	21	20	19	18	17	16

Table 5-92. Source Active Options Register (SAOPT) Field Descriptions

Bit	Field	Value	Description
31-23	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
22	TCCHEN		Transfer complete chaining enable
		0	Transfer complete chaining is disabled.
		1	Transfer complete chaining is enabled.
21	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
20	TCINTEN		Transfer complete interrupt enable.
		0	Transfer complete interrupt is disabled.
		1	Transfer complete interrupt is enabled.
19-18	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
17-12	TCC	0-3Fh	Transfer complete code. This 6-bit code is used to set the relevant bit in CER or IPR of the EDMA3PCC module.
11	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
10-8	FWID	0-7h	FIFO width. Applies if either SAM or DAM is set to constant addressing mode.
		0	FIFO width is 8-bit.
		1h	FIFO width is 16-bit.
		2h	FIFO width is 32-bit.
		3h	FIFO width is 64-bit.
		4h	FIFO width is 128-bit.
		5h	FIFO width is 256-bit.
		6h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

Table 5-92. Source Active Options Register (SAOPT) Field Descriptions (continued)

Bit	Field	Value	Description
6-4	PRI	0-7h	Transfer priority. Reflects the values programmed in the QUEPRI register in the EDMACC.
		0	Priority 0 - Highest priority
		1h-6h	Priority 1 to priority 6
		7h	Priority 7 - Lowest priority
3-2	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
1	DAM		Destination address mode within an array
		0	Increment (INCR) mode. Destination addressing within an array increments.
		1	Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM		Source address mode within an array
		0	Increment (INCR) mode. Source addressing within an array increments.
		1	Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

5.4.2.6.2 Source Active Source Address Register (SASRC)

The source active source address register (SASRC) is shown in Figure 5-111 and described in Table 5-93.

Figure 5-111. Source Active Source Address Register (SASRC)

5.5 Debug Checklist

This section lists some tips to keep in mind while debugging applications using the EDMA3.

The following table provides some common issues and their probable causes and resolutions.

Table 5-110. Debug List

Issue	Description/Solution
The transfer associated with the channel does not happen. The channel does not get serviced.	The EDMA3CC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following: 1) Verify that events are enabled, if an external/peripheral event is latched in Event Registers (ER/ERH), make sure that the event is enabled in the Event Enable Registers (EER/EERH). Similarly, for QDMA channels, make sure that QDMA events are appropriately enabled in the QDMA Event Enable Register (QEER). 2) Verify that the DMA or QDMA Secondary Event Register (SER/SERH/QSERH) bits corresponding to the particular event or channel are not set.
The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.	It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases: 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (OPT.STATIC = 0, LINK = FFFFh), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the QEMR and QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the SER.Ex and EMR.Ex set, preventing further event prioritization. You must ensure that the number of events received is limited to the expected number of events for which the parameter set is programmed, or you must ensure that bits corresponding to particular channel or event are not set in the Secondary event registers (SER/SERH/QSER) and Event Missed Registers (EMR/EMRH/QEMR) before trying to perform subsequent transfers for the event/channel.
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	You must ensure the following: 1) The interrupt generation is enabled in the OPT of the associated PaRAM set (TCINTEN = 1 and/or ITCINTEN = 1). 2) The interrupts are enabled in the EDMA3 Channel Controller, via the Interrupt Enable Registers (IER/IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (IPR/IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 5.2.9.1.2 for details on writing EDMA3 ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (DRAE/DRAEH) are set up properly, because the DRAE/DRAEH registers act as secondary enables for shadow region completion interrupts, along with the IER/IERH registers. If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code (TCC) value are also enabled in the DRAE/DRAEH registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 (OPT.TCC=63), ensure that DRAEH.E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be IPRH.I63 (not IPR.I0).

5.6 Miscellaneous Programming/Debug Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the Event Register (ER/ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (ECR/ECRH). Similarly, the Event Enable Register (EER/EERH) bits can only be set with writes of 1 to the Event Enable Set Registers (EESR/EESRH) and cleared with writes of 1 to the corresponding bits in the Event Enable Clear Register (EECR/EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (DRAE/DRAEH/QRAE). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (DRAE/DRAEH) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts. For example, if DRAE0.E0 and DRAE1.E0 are both set, then on completion of a transfer that returns a TCC=0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the CCNT is not left to zero.
5. Enable the EDMA3CC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, you may want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, you might choose to use the early chaining option to reduce the time between the sets of transfers and increase the throughput. However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA3CC internally signals completion when the TR is submitted to the EDMA3TC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

5.7 Setting Up a Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

1. Initiating a DMA/QDMA channel
   (a) Determine the type of channel (QDMA or DMA) to be used.
   (b) Channel mapping
      (i) If using a QDMA channel, program the QCHMAP with the parameter set number to which the channel maps and the trigger word.
      (ii) If using a DMA channel, program the DCHMAP with the parameter set number to which the channel maps.
   (c) If the channel is being used in the context of a shadow region, ensure the DRAE/DRAEH for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in Section 5.2.7.1.)
   (d) Determine the type of triggering used.
      (i) If external events are used for triggering (DMA channels), enable the respective event in EER/EERH by writing into EESR/EESRH.
      (ii) If QDMA Channel is used, enable the channel in QEER by writing into QEESR.
   (e) Queue setup
      (i) If a QDMA channel is used, set up the QDMAQNUM to map the channel to the respective event queue.
      (ii) If a DMA channel is used, set up the DMAQNUM to map the event to the respective event queue.
2. Parameter set setup
   (a) Program the PaRAM set number associated with the channel. Note that if it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.
   See Section 5.3 for parameter set field setups for different types of transfers. See the sections on chaining (Section 5.2.8) and interrupt completion (Section 5.2.9) on how to set up final/intermediate completion chaining and/or interrupts.
3. Interrupt setup
   (a) Enable the interrupt in the IER/IERH by writing into IESR/IESRH.
   (b) Ensure that the EDMA3CC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
   (c) Ensure the EDMA3CC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
   (d) Set up the interrupt controller properly to receive the expected EDMA3 interrupt.
4. Initiate transfer
   (a) This step is highly dependent on the event trigger source:
      (i) If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA3 events that can be latched to the ER transfer.
      (ii) For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
      (iii) Manually triggered transfers will be initiated by writes to the Event Set Registers (ESR/ESRH).
      (iv) Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

5. Wait for completion
   (a) If the interrupts are enabled as mentioned in step 3 above, then the EDMA3CC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register (IPR/IPRH). The set bits must be cleared in the IPR\IPRH by writing to corresponding bit in ICR\ICRH.
   (b) If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the IPR\IPRH. Again, the set bits in the IPR\IPRH must be manually cleared via ICR\ICRH before the next set of transfers is performed for the same transfer completion code values.

EMAC/MDIO Module

This chapter provides a functional description of the Ethernet Media Access Controller (EMAC) and physical layer (PHY) device Management Data Input/Output (MDIO) module integrated in the device. Included are the features of the EMAC and MDIO modules, a discussion of their architecture and operation, how these modules connect to the outside world, and a description of the registers for each module.

Topic **Page**

6.1 Introduction

6.1.1 Overview

The EMAC controls the flow of packet data from the system to the PHY. The MDIO module controls PHY configuration and status monitoring.

Both the EMAC and the MDIO modules interface to the system core through a custom interface that allows efficient data transmission and reception. This custom interface is referred to as the EMAC control module and is considered integral to the EMAC/MDIO peripheral.

The EMAC module is used to move data between this device and another host connected to the same network, in compliance with the Ethernet protocol.

6.1.2 Features

The EMAC/MDIO has the following features:

- Synchronous 10/100/1000 Mbps operation
- G/MII interface to the physical layer device (PHY)
- Full-duplex gigabit operation (half-duplex not supported)
- EMAC acts as DMA master to either internal or external device memory space
- Hardware error handling including CRC
- Eight receive channels with VLAN tag discrimination for receive quality-of-service (QOS) support
- Eight transmit channels with round-robin or fixed priority for transmit quality-of-service (QOS) support
- Ether-Stats and 802.3-Stats RMON statistics gathering
- Transmit CRC generation selectable on a per channel basis
- Broadcast frames selection for reception on a single channel
- Multicast frames selection for reception on a single channel
- Promiscuous receive mode frames selection for reception on a single channel (all frames, all good frames, short frames, error frames)
- Hardware flow control
- 8K-byte local EMAC descriptor memory that allows the peripheral to operate on descriptors without affecting the CPU. The descriptor memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention.
- Programmable interrupt logic permits the software driver to restrict the generation of back-to-back interrupts, which allows more work to be performed in a single call to the interrupt service routine.
- TI Adaptive Performance Optimization for improved half duplex performance
- Configurable receive address matching/filtering, receive FIFO depth, and transmit FIFO depth
- No-chain mode truncates frame to first buffer for network analysis applications
- Emulation support
- Loopback mode

6.1.3 Functional Block Diagram

Figure 6-1 shows the three main functional modules of the EMAC/MDIO peripheral:

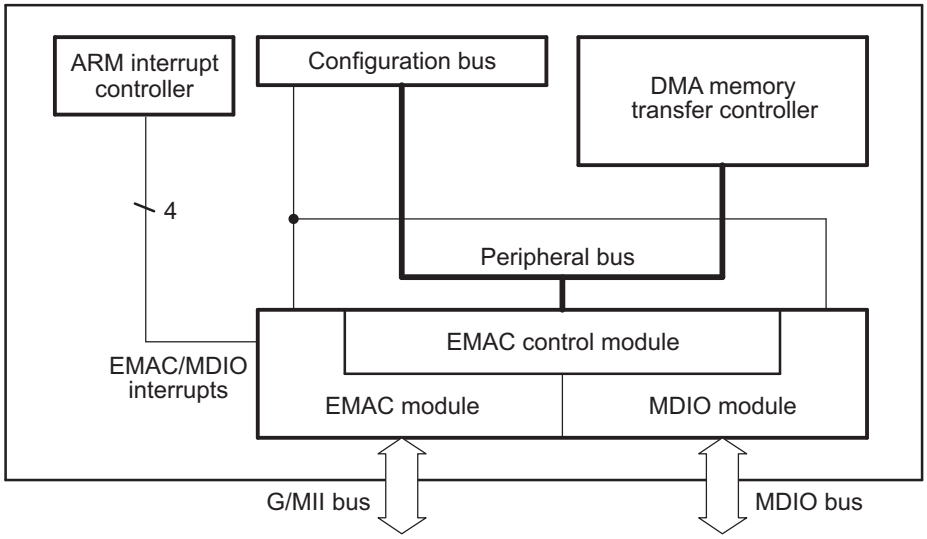
- EMAC control module
- EMAC module
- MDIO module

The EMAC control module is the main interface between the device core processor and the EMAC module and MDIO module. The EMAC control module contains the necessary components to allow the EMAC to make efficient use of device memory, plus it controls device interrupts. The EMAC control module incorporates 8K-byte internal RAM to hold EMAC buffer descriptors.

The MDIO module implements the 802.3 serial management interface to interrogate and control up to 32 Ethernet PHYs connected to the device, using a shared two-wire bus. Host software uses the MDIO module to configure the autonegotiation parameters of each PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC module for correct operation. The module is designed to allow almost transparent operation of the MDIO interface, with very little maintenance from the core processor.

The EMAC module provides an efficient interface between the processor and the networked community. The EMAC on this device supports 10Base-T (10 Mbits/second) and 100BaseTX (100 Mbits/second) in either half-duplex or full-duplex mode and 1000BaseT (1000 Mbits/second) in full-duplex mode, with hardware flow control and quality-of-service (QOS) support.

Figure 6-1. EMAC and MDIO Block Diagram



6.1.4 EMAC and MDIO Block Diagram

Figure 6-1 also shows the main interface between the EMAC control module and the CPU. The following connections are made to the device core:

- The peripheral bus connection from the EMAC control module allows the EMAC module to read and write both internal and external memory through the DMA memory transfer controller.
- The EMAC control module, EMAC, and MDIO all have control registers. These registers are memory-mapped into device memory space via the device configuration bus. Along with these registers, the control module's internal RAM is mapped into this same range.
- The EMAC and MDIO interrupts are combined into a single interrupt within the control module. The interrupt from the control module then goes to the ARM interrupt controller.

The EMAC and MDIO interrupts are combined within the control module, so only the control module interrupt needs to be monitored by the application software or device driver. The EMAC control module combines the EMAC and MDIO interrupts and generates 4 separate interrupts to the ARM through the ARM interrupt controller. See Section 6.2.16.4 for details of interrupt multiplex logic of the EMAC control module.

6.1.5 Industry Standard(s) Compliance Statement

The EMAC peripheral conforms to the IEEE 802.3 standard, describing the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer specifications. The IEEE 802.3 standard has also been adopted by ISO/IEC and re-designated as ISO/IEC 8802-3:2000(E).

In difference from this standard, the EMAC peripheral does not use the Transmit Coding Error signal MTXER. Instead of driving the error pin when an underflow condition occurs on a transmitted frame, the EMAC intentionally generates an incorrect checksum by inverting the frame CRC, so that the transmitted frame is detected as an error by the network.

6.1.6 List of Terms

Broadcast MAC Address— A special Ethernet MAC address used to send data to all Ethernet devices on the local network. The broadcast address is FFh-FFh-FFh-FFh-FFh-FFh. The LSB of the first byte is odd, qualifying it as a group address; however, its value is reserved for broadcast. It is classified separately by the EMAC.

Descriptor (Packet Buffer Descriptor)— A small memory structure that describes a larger block of memory in terms of size, location, and state. Descriptors are used by the EMAC and application to describe the memory buffers that hold Ethernet data.

Device — In this document, device refers to the processor.

Ethernet MAC Address (MAC Address)— A unique 6-byte address that identifies an Ethernet device on the network. In an Ethernet packet, a MAC address is used twice, first to identify the packet's destination, and second to identify the packet's sender or source. An Ethernet MAC address is normally specified in hexadecimal, using dashes to separate bytes. For example, 08h-00h-28h-32h-17h-42h.

The first three bytes normally designate the manufacturer of the device. However, when the first byte of the address is odd (LSB is 1), the address is a group address (broadcast or multicast). The second bit specifies whether the address is globally or locally administrated (not considered in this document).

Ethernet Packet (Packet)— An Ethernet packet is the collection of bytes that represents the data portion of a single Ethernet frame on the wire.

Full Duplex— Full-duplex operation allows simultaneous communication between a pair of stations using point-to-point media (dedicated channel). Full-duplex operation does not require that transmitters defer, nor do they monitor or react to receive activity, as there is no contention for a shared medium in this mode. Full-duplex mode can only be used when all of the following are true:

- The physical medium is capable of supporting simultaneous transmission and reception without interference.
- There are exactly two stations connected with a full duplex point-to-point link. As there is no contention for use of a shared medium, the multiple access (that is, CSMA/CD) algorithms are unnecessary.
- Both stations on the LAN are capable of, and have been configured to use, full-duplex operation.

The most common configuration envisioned for full-duplex operation consists of a central bridge (also known as a switch) with a dedicated LAN connecting each bridge port to a single device.

Full-duplex operation constitutes a proper subset of the MAC functionality required for half-duplex operation.

Half Duplex— In half-duplex mode, the CSMA/CD media access method is the means by which two or more stations share a common transmission medium. To transmit, a station waits (defers) for a quiet period on the medium, that is, no other station is transmitting. It then sends the intended message in bit-serial form. If, after initiating a transmission, the message collides with that of another station, then each transmitting station intentionally transmits for an additional predefined period to ensure propagation of the collision throughout the system. The station remains silent for a random amount of time (backoff) before attempting to transmit again.

Host— The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port (EMAC) interrupts. In this document, host refers to the device.

Jabber— A condition wherein a station transmits for a period of time longer than the maximum permissible packet length, usually due to a fault condition.

Link— The transmission path between any two instances of generic cabling.

Multicast MAC Address— A class of MAC address that sends a packet to potentially more than one recipient. A group address is specified by setting the LSB of the first MAC address byte to 1. Thus, 01h-02h-03h-04h-05h-06h is a valid multicast address. Typically, an Ethernet MAC looks for only certain multicast addresses on a network to reduce traffic load. The multicast address list of acceptable packets is specified by the application.

Physical Layer and Media Notation— To identify different Ethernet technologies, a simple, three-field, type notation is used. The Physical Layer type used by the Ethernet is specified by these fields:

<data rate in Mb/s><medium type><maximum segment length (×100m)>

The definitions for the technologies mentioned in this document are in Table 6-1.

Table 6-1. Physical Layer Definitions

Term	Definition
10Base-T	IEEE 802.3 Physical Layer specification for a 10 Mb/s CSMA/CD local area network over two pairs of twisted-pair telephone wire.
100Base-T	IEEE 802.3 Physical Layer specification for a 100 Mb/s CSMA/CD local area network over two pairs of Category 5 unshielded twisted-pair (UTP) or shielded twisted-pair (STP) wire.
Twisted pair	A cable element that consists of two insulated conductors twisted together in a regular fashion to form a balanced transmission line.

Port— Ethernet device.

Promiscuous Mode— EMAC receives frames that do not match its address.

6.2 Architecture

This section discusses the architecture and basic function of the EMAC/MDIO module.

6.2.1 Clock Control

The frequencies for the transmit and receive clocks are fixed by the IEEE 802.3 specification as:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

All EMAC logic is clocked synchronously with the peripheral clock (SYSCLK5). The MDIO clock can be controlled through the application software, by programming the divide-down factor in the MDIO control register (CONTROL).

6.2.1.1 MII Clocking

In the 10/100 Mbps mode, the transmit and receive clock sources are provided from an external PHY via the MTCLK and MRCLK pins. These clocks are inputs to the EMAC module and operate at 2.5 MHz in 10 Mbps mode and at 25 MHz in 100 Mbps mode. The MII clocking interface is not used in 1000 Mbps mode. For timing purposes, data is transmitted and received with reference to MTCLK and MRCLK, respectively.

6.2.1.2 GMII Clocking

In the 1000 Mbps mode, the transmit and receive clock sources for 10/100 Mbps operation are provided from an external PHY via the MTCLK and MRCLK pins, as in the MII clocking. For 1000 Mbps operation, the receive clock is provided by an external PHY via the MRCLK pin. For transmit in 1000 Mbps mode, the clock is sourced synchronous with the data and is provided by the EMAC to be output on the GMTCLK pin.

The EMAC module is internally clocked at 148.5 MHz. For timing purposes, data in 10/100 Mbps mode is transmitted and received with reference to MTCLK and MRCLK, respectively. For 1000 Mbps mode, receive timing is the same, but transmit is relative to GMTCLK.

6.2.2 Memory Map

The EMAC peripheral includes internal memory that is used to hold information about the Ethernet packets received and transmitted. This internal RAM is 2K × 32 bits in size. Data can be written to and read from the EMAC internal memory by either the EMAC or the CPU. It is used to store buffer descriptors that are 4-words (16-bytes) deep. This 8K local memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention.

The packet buffer descriptors can also be placed in the internal processor memory, or in EMIF memory (DDR). There are some tradeoffs in terms of cache performance and throughput when descriptors are placed in the system memory, versus when they are placed in the EMAC's internal memory. Cache performance is improved when the buffer descriptors are placed in internal memory. However, the EMAC throughput is better when the descriptors are placed in the local EMAC RAM.

6.2.3 Signal Descriptions

The device supports both MII interface (for 10/100 Mbps operation) and GMII interface (for 10/100/1000 Mbps) operation.

Figure 6-2 shows a device with integrated EMAC and MDIO interfaced via a GMII connection. This interface is available in 10 Mbps, 100 Mbps, and 1000 Mbps modes.

The GMII interface supports 10/100/1000 Mbps modes. Only full-duplex mode is available in 1000 Mbps mode. In 10/100 Mbps modes, the GMII interface acts like an MII interface and only the lower 4 bits of data are transferred for each of the data buses. The individual EMAC and MDIO signals for the GMII interface are summarized in Figure 6-2.

Figure 6-2. Ethernet Configuration—GMII Connections

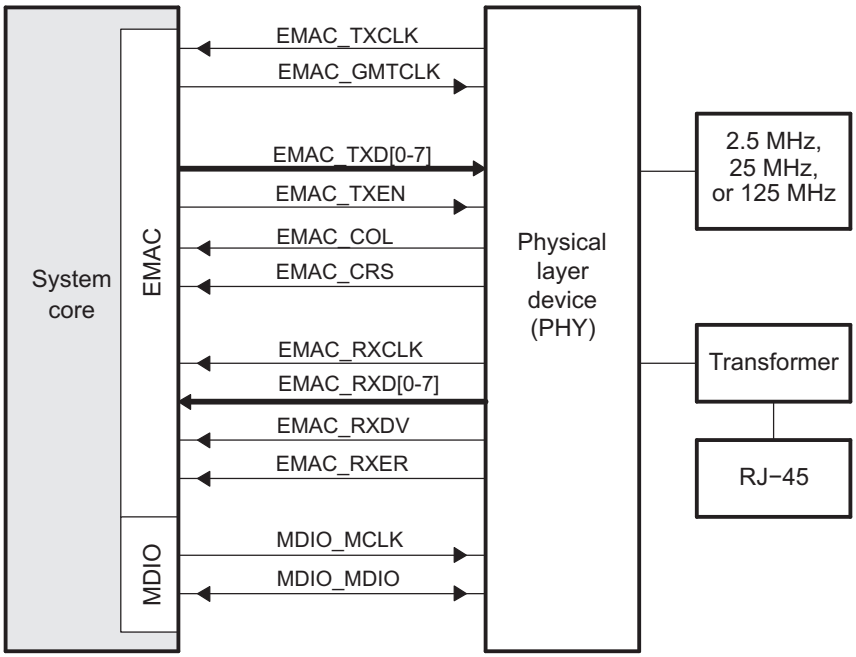


Table 6-2. EMAC and MDIO Signals for GMII Interface

Signal	Type	Description
EMAC_TXCLK	I	Transmit clock (EMAC_TXCLK). The transmit clock is a continuous clock that provides the timing reference for transmit operations in 10/100 Mbps mode. The EMAC_TXD and EMAC_TXEN signals are tied to this clock when in 10/100 Mbps mode. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, and 25 MHz at 100 Mbps operation.
EMAC_GMTCLK	O	GMII source asynchronous transmit clock (EMAC_GMTCLK). This clock is used in 1000 Mbps mode only, providing a continuous 125 MHz frequency for transmit operations. The EMAC_TXD and EMAC_TXEN signals are tied to this clock when in Gigabit mode. The clock is generated by the EMAC and is 125 MHz.
EMAC_TXD[0-7]	O	Transmit data (EMAC_TXD). The transmit data pins are a collection of 8 data signals comprising 8 bits of data. EMAC_TXD[0] is the least-significant bit (LSB). The signals are synchronized by EMAC_TXCLK in 10/100 Mbps mode, and by EMAC_GMTCLK in Gigabit mode, and valid only when EMAC_TXEN is asserted.
EMAC_TXEN	O	Transmit data enable (EMAC_TXEN). The transmit data enable signal indicates that the EMAC_TXD pins are generating nibble data for use by the PHY. It is driven synchronously to EMAC_TXCLK in 10/100 Mbps mode, and to EMAC_GMTCLK in Gigabit mode.
EMAC_COL	I	Collision detected (EMAC_COL). The EMAC_COL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to EMAC_TXCLK nor EMAC_RXCLK. This pin is used in half-duplex operation only.
EMAC_CRS	I	Carrier sense (EMAC_CRS). The EMAC_CRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is deasserted when both transmit and receive are idle. This signal is not necessarily synchronous to EMAC_TXCLK nor EMAC_RXCLK. This pin is used in half-duplex operation only.
EMAC_RXCLK	I	Receive clock (EMAC_RXCLK). The receive clock is a continuous clock that provides the timing reference for receive operations. The EMAC_RXD, EMAC_RXDV, and EMAC_RXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation and 125 MHz at 1000 Mbps operation.
EMAC_RXD[0-7]	I	Receive data (EMAC_RXD). The receive data pins are a collection of 8 data signals comprising 8 bits of data. EMAC_RXD[0] is the least-significant bit (LSB). The signals are synchronized by EMAC_RXCLK and valid only when EMAC_RXDV is asserted.
EMAC_RXDV	I	Receive data valid (EMAC_RXDV). The receive data valid signal indicates that the EMAC_RXD pins are generating nibble data for use by the EMAC. It is driven synchronously to EMAC_RXCLK.
EMAC_RXER	I	Receive data error (EMAC_RXER). The receive data error signal is asserted for one or more EMAC_RXCLK periods to indicate that an error was detected in the received frame. This is meaningful only during data reception when EMAC_RXDV is active.
MDIO_MCLK	O	Management data serial clock (MDIO_MCLK). The MDIO data serial clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL).
MDIO_MDIO	I/O	Management data input/output (MDIO_MDIO). The MDIO_MDIO pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_MDIO pin acts as an output for everything except the data bit cycles, when the pin acts as an input for read operations.

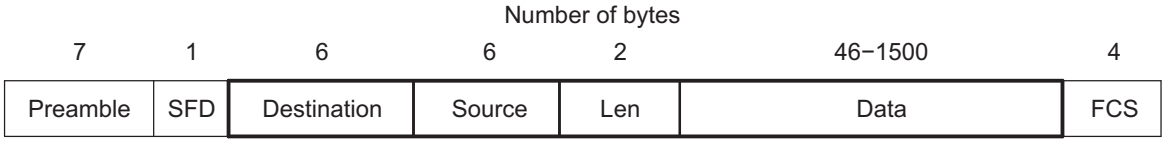
6.2.4 Ethernet Protocol Overview

Ethernet provides an unreliable, connection-less service to a networking application. A brief overview of the Ethernet protocol is given in the following subsections. For in-depth information on the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method, which is the Ethernet's multiple access protocol, see the IEEE 802.3 standard document.

6.2.4.1 Ethernet Frame Format

The format of an Ethernet frame is shown in Figure 6-3 and described in Table 6-3.

Figure 6-3. Ethernet Frame Format



Legend: SFD = Start Frame Delimeter; FCS = Frame Check Sequence (CRC)

Table 6-3. Ethernet Frame Description

Field	Bytes	Description
Preamble	7	Preamble. These 7 bytes have a fixed value of 55h and serve to wake up the receiving EMAC ports and to synchronize their clocks to that of the sender's clock.
SFD	1	Start of Frame Delimiter. This field with a value of 5Dh immediately follows the preamble pattern and indicates the start of important data.
Destination	6	Destination address. This field contains the Ethernet MAC address of the EMAC port for which the frame is intended. It may be an individual or multicast (including broadcast) address. When the destination EMAC port receives an Ethernet frame with a destination address that does not match any of its MAC physical addresses, and no promiscuous, multicast or broadcast channel is enabled, it discards the frame.
Source	6	Source address. This field contains the MAC address of the Ethernet port that transmits the frame to the Local Area Network.
Len	2	Length/Type field. The length field indicates the number of EMAC client data bytes contained in the subsequent data field of the frame. This field can also be used to identify the type of data the frame is carrying.
Data	46 to (RXMAXLEN - 18)	Data field. This field carries the datagram containing the upper layer protocol frame, that is, IP layer datagram. The maximum transfer unit (MTU) of Ethernet is (RXMAXLEN - 18) bytes. This means that if the upper layer protocol datagram exceeds (RXMAXLEN - 18) bytes, then the host has to fragment the datagram and send it in multiple Ethernet packets. The minimum size of the data field is 46 bytes. This means that if the upper layer datagram is less then 46 bytes, the data field has to be extended to 46 bytes by appending extra bits after the data field, but prior to calculating and appending the FCS.
FCS	4	Frame Check Sequence. A cyclic redundancy check (CRC) is used by the transmit and receive algorithms to generate a CRC value for the FCS field. The frame check sequence covers the 60 to (RXMAXLEN - 4) bytes of the packet data. Note that this 4-byte field may or may not be included as part of the packet data, depending on how the EMAC is configured.

6.2.4.2 Ethernet's Multiple Access Protocol

Nodes in an Ethernet Local Area Network are interconnected by a broadcast channel, as a result, when an EMAC port transmits a frame, all the adapters on the local network receive the frame. Carrier Sense Multiple Access with Collision Detection (CSMA/CD) algorithms are used when the EMAC operates in half-duplex mode. When operating in full-duplex mode, there is no contention for use of a shared medium, since there are exactly two ports on the local network.

Each port runs the CSMA/CD protocol without explicit coordination with the other ports on the Ethernet network. Within a specific port, the CSMA/CD protocol works as follows:

1. The port obtains data from upper layers protocols at its node, prepares an Ethernet frame, and puts the frame in a buffer.
2. If the port senses that the medium is idle it starts to transmit the frame. If the port senses that the transmission medium is busy, it waits until it senses no signal energy (plus an Inter-Packet Gap time) and then starts to transmit the frame.
3. While transmitting, the port monitors for the presence of signal energy coming from other ports. If the port transmits the entire frame without detecting signal energy from other Ethernet devices, the port is done with the frame.
4. If the port detects signal energy from other ports while transmitting, it stops transmitting its frame and instead transmits a 48-bit jam signal.
5. After transmitting the jam signal the port enters an exponential backoff phase. Specifically, when transmitting a given frame, after experiencing a number of collisions in a row for the frame, the port chooses a random value that is dependent on the number of collisions. The port then waits an amount of time that is multiple of this random value, and returns to step 2.

6.2.5 Programming Interface

6.2.5.1 Packet Buffer Descriptors

The buffer descriptor is a central part of the EMAC module and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data. The basic descriptor format is shown in Figure 6-4 and described in Table 6-4.

For example, consider three packets to be transmitted, Packet A is a single fragment (60 bytes), Packet B is fragmented over three buffers (1514 bytes total), and Packet C is a single fragment (1514 bytes). The linked list of descriptors to describe these three packets is shown in Figure 6-5.

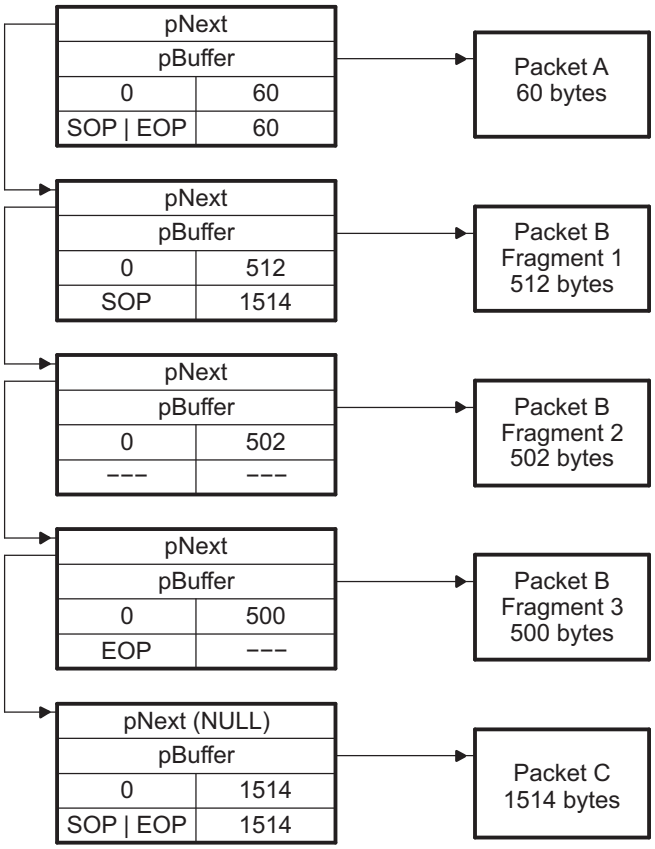
Figure 6-4. Basic Descriptor Format

	Bit Fields	
Word Offset	31 16	15 0
0	Next Descriptor Pointer	
1	Buffer Pointer	
2	Buffer Offset	Buffer Length
3	Flags	Packet Length

Table 6-4. Basic Descriptor Description

Word Offset	Field	Field Description
0	Next Descriptor Pointer	The next descriptor pointer is used to create a single linked list of descriptors. Each descriptor describes a packet or a packet fragment. When a descriptor points to a single buffer packet or the first fragment of a packet, the start of packet (SOP) flag is set in the flags field. When a descriptor points to a single buffer packet or the last fragment of a packet, the end of packet (EOP) flag is set. When a packet is fragmented, each fragment must have its own descriptor and appear sequentially in the descriptor linked list.
1	Buffer Pointer	The buffer pointer refers to the actual memory buffer that contains packet data during transmit operations, or is an empty buffer ready to receive packet data during receive operations.
2	Buffer Offset	The buffer offset is the offset from the start of the packet buffer to the first byte of valid data. This field only has meaning when the buffer descriptor points to a buffer that actually contains data.
	Buffer Length	The buffer length is the actual number of valid packet data bytes stored in the buffer. If the buffer is empty and waiting to receive data, this field represents the size of the empty buffer.
3	Flags	The flags field contains more information about the buffer, such as, is it the first fragment in a packet (SOP), the last fragment in a packet (EOP), or contains an entire contiguous Ethernet packet (both SOP and EOP). The flags are described in Section 6.2.5.4 and Section 6.2.5.5.
	Packet Length	The packet length only has meaning for buffers that both contain data and are the start of a new packet (SOP). In the case of SOP descriptors, the packet length field contains the length of the entire Ethernet packet, regardless if it is contained in a single buffer or fragmented over several buffers.

Figure 6-5. Typical Descriptor Linked List



6.2.5.2 Transmit and Receive Descriptor Queues

The EMAC module processes descriptors in linked list chains as discussed in Section 6.2.5.1. The lists controlled by the EMAC are maintained by the application software through the use of the head descriptor pointer registers (HDP). Since the EMAC supports eight channels for both transmit and receive, there are eight head descriptor pointer registers for both. They are:

- TX*n*HDP - Transmit Channel *n* DMA Head Descriptor Pointer Register
- RX*n*HDP - Receive Channel *n* DMA Head Descriptor Pointer Register

After an EMAC reset and before enabling the EMAC for send or receive, all 16 head descriptor pointer registers must be initialized to 0.

The EMAC uses a simple system to determine if a descriptor is currently owned by the EMAC or by the application software. There is a flag in the buffer descriptor flags called OWNER. When this flag is set, the packet that is referenced by the descriptor is considered to be owned by the EMAC. Note that ownership is done on a packet based granularity, not on descriptor granularity, so only SOP descriptors make use of the OWNER flag. As packets are processed, the EMAC patches the SOP descriptor of the corresponding packet and clears the OWNER flag. This is an indication that the EMAC has finished processing all descriptors up to and including the first with the EOP flag set, indicating the end of the packet (note this may only be one descriptor with both the SOP and EOP flags set).

To add a descriptor or a linked list of descriptors to an EMAC descriptor queue for the first time, the software application simply writes the pointer to the descriptor or first descriptor of a list to the corresponding HDP register. Note that the last descriptor in the list must have its “next” pointer cleared to 0. This is the only way the EMAC has of detecting the end of the list. So in the case where only a single descriptor is added, its “next descriptor” pointer must be initialized to 0.

The HDP must never be written to a second time while a previous list is active. To add additional descriptors to a descriptor list already owned by the EMAC, the NULL “next” pointer of the last descriptor of the previous list is patched with a pointer to the first descriptor in the new list. The list of new descriptors to be appended to the existing list must itself be NULL terminated before the pointer patch is performed.

There is a potential race condition where the EMAC may read the “next” pointer of a descriptor as NULL in the instant before an application appends additional descriptors to the list by patching the pointer. This case is handled by the software application always examining the buffer descriptor flags of all EOP packets, looking for a special flag called end of queue (EOQ). The EOQ flag is set by the EMAC on the last descriptor of a packet when the descriptor’s “next” pointer is NULL. This is the way the EMAC indicates to the software application that it believes it has reached the end of the list. When the software application sees the EOQ flag set, and there are more descriptors to process, the application may at that time submit the new list, or the portion of the appended list that was missed, by writing the new list pointer to the same HDP that started the process.

This process applies when adding packets to a transmit list, and empty buffers to a receive list.

6.2.5.3 Transmit and Receive EMAC Interrupts

The EMAC processes descriptors in linked list chains as discussed in Section 6.2.5.1, using the linked list queue mechanism discussed in Section 6.2.5.2.

The EMAC synchronizes descriptor list processing through the use of interrupts to the software application. The interrupts are controlled by the application using the interrupt masks, global interrupt enable, and the completion pointer register (CP). The CP is also called the interrupt acknowledge register.

As the EMAC supports eight channels for both transmit and receive, there are eight completion pointer registers for both. They are:

- TX*n*CP - Transmit Channel *n* Completion Pointer (Interrupt Acknowledge) Register
- RX*n*CP - Receive Channel *n* Completion Pointer (Interrupt Acknowledge) Register

These registers serve two purposes. When read, they return the pointer to the last descriptor that the EMAC has processed. When written by the software application, the value represents the last descriptor processed by the software application. When these two values do not match, the interrupt remains asserted, after the respective End of interrupt bit is signaled in the EMAC control module.

The system configuration determines whether or not an active interrupt actually interrupts the CPU. In general, the individual interrupts for different events from the EMAC and MDIO must be enabled in the EMAC control module, and it also must be mapped in the ARM interrupt controller and enabled as a CPU interrupt. If the system is configured properly, the interrupt for a specific receive or transmit channel executes under the previously described conditions when the corresponding interrupt is enabled in the EMAC using the receive interrupt mask set register (RXINTMASKSET) or the transmit interrupt mask set register (TXINTMASKSET).

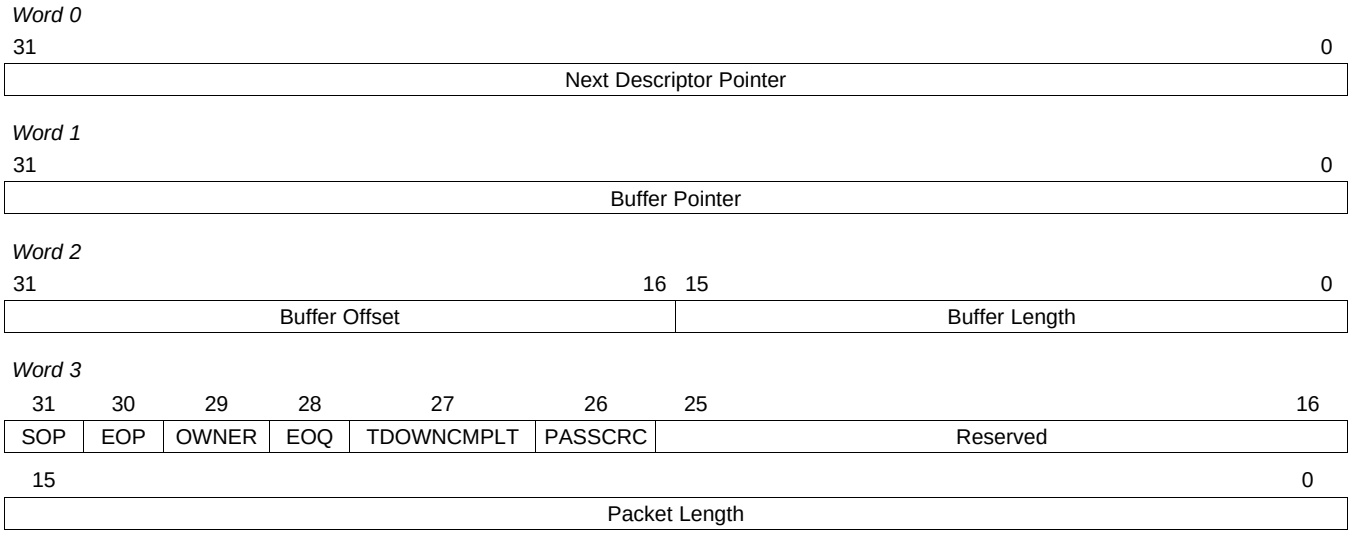
Whether or not the interrupt is enabled, the current state of the receive or transmit channel interrupt can be examined directly by the software application reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and transmit interrupt status (unmasked) register (TXINTSTATRAW).

Interrupts are acknowledged when the application software updates the value of TX*n*CP or RX*n*CP with a value that matches the internal value kept by the EMAC. This mechanism ensures that the application software never misses an EMAC interrupt, since the interrupt and its acknowledgment are tied directly to the actual buffer descriptors processing.

6.2.5.4 Transmit Buffer Descriptor Format

A transmit (TX) buffer descriptor (Figure 6-6) is a contiguous block of four 32-bit data words aligned on a 32-bit boundary that describes a packet or a packet fragment. Example 6-1 shows the transmit buffer descriptor described by a C structure.

Figure 6-6. Transmit Buffer Descriptor Format



Example 6-1. Transmit Buffer Descriptor in C Structure Format

```
/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
 struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
 Uint8 *pBuffer; /* Pointer to data buffer */
 Uint32 BufOffLen; /* Buffer Offset(MSW) and Length(LSW) */
 Uint32 PktFlgLen; /* Packet Flags(MSW) and Length(LSW) */
} EMAC_Desc;

/* Packet Flags */
#define EMAC_DSC_FLAG_SOP 0x80000000u
#define EMAC_DSC_FLAG_EOP 0x40000000u
#define EMAC_DSC_FLAG_OWNER 0x20000000u
#define EMAC_DSC_FLAG_EOQ 0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMPLT 0x08000000u
#define EMAC_DSC_FLAG_PASSCRC 0x04000000u
```

6.2.5.4.1 Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

6.2.5.4.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

6.2.5.4.3 Buffer Offset

This 16-bit field indicates how many unused bytes are at the start of the buffer. For example, a value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer, while a value of 000Fh indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

Note that this value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set). It can not be used to specify the offset of subsequent packet fragments. Also, since the buffer pointer may point to any byte–aligned address, this field may be entirely superfluous, depending on the device driver architecture.

The range of legal values for this field is 0 to (Buffer Length – 1).

6.2.5.4.4 Buffer Length

This 16-bit field indicates how many valid data bytes are in the buffer. On single fragment packets, this value is also the total length of the packet data to be transmitted. If the buffer offset field is used, the offset bytes are not counted as part of this length. This length counts only valid data bytes. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

6.2.5.4.5 Packet Length

This 16-bit field specifies the number of data bytes in the entire packet. Any leading buffer offset bytes are not included. The sum of the buffer length fields of each of the packet's fragments (if more than one) must be equal to the packet length. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC. This value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set).

6.2.5.4.6 Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

6.2.5.4.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

6.2.5.4.8 Ownership (OWNER) Flag

When set, this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

6.2.5.4.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

6.2.5.4.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission.

Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not even processed by the EMAC.

6.2.5.4.11 Pass CRC (PASSCRC) Flag

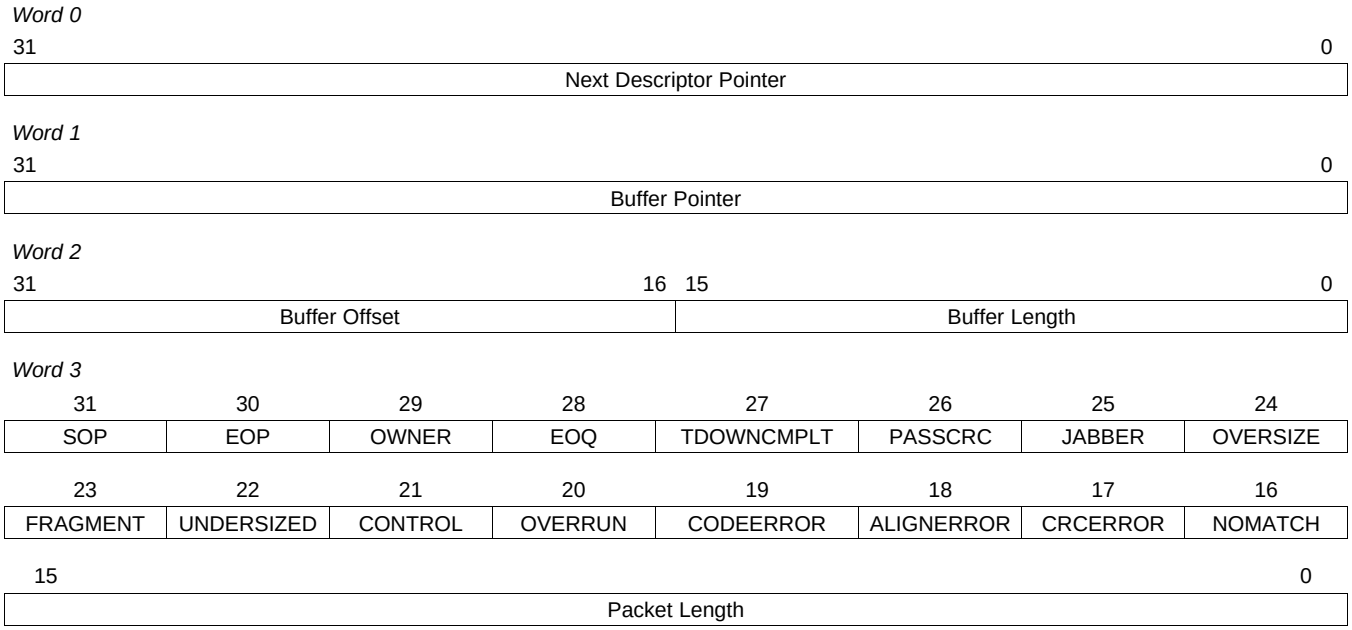
This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC.

When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

6.2.5.5 Receive Buffer Descriptor Format

A receive (RX) buffer descriptor (Figure 6-7) is a contiguous block of four 32-bit data words aligned on a 32-bit boundary that describes a packet or a packet fragment. Example 6-2 shows the receive buffer descriptor described by a C structure.

Figure 6-7. Receive Buffer Descriptor Format



6.2.5.5.1 Next Descriptor Pointer

This pointer points to the 32–bit word aligned memory address of the next buffer descriptor in the receive queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active receive queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more empty buffers can be added to the pool, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the receiver will halt the receive channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

6.2.5.5.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

Example 6-2. Receive Buffer Descriptor in C Structure Format

```
/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
 struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
 Uint8 *pBuffer; /* Pointer to data buffer */
 Uint32 BufOffLen; /* Buffer Offset(MSW) and Length(LSW) */
 Uint32 PktFlgLen; /* Packet Flags(MSW) and Length(LSW) */
} EMAC_Desc;

/* Packet Flags */
#define EMAC_DSC_FLAG_SOP 0x80000000u
#define EMAC_DSC_FLAG_EOP 0x40000000u
#define EMAC_DSC_FLAG_OWNER 0x20000000u
#define EMAC_DSC_FLAG_EOQ 0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMPLT 0x08000000u
#define EMAC_DSC_FLAG_PASSCRC 0x04000000u
#define EMAC_DSC_FLAG_JABBER 0x02000000u
#define EMAC_DSC_FLAG_OVERSIZE 0x01000000u
#define EMAC_DSC_FLAG_FRAGMENT 0x00800000u
#define EMAC_DSC_FLAG_UNDERSIZED 0x00400000u
#define EMAC_DSC_FLAG_CONTROL 0x00200000u
#define EMAC_DSC_FLAG_OVERRUN 0x00100000u
#define EMAC_DSC_FLAG_CODEERROR 0x00080000u
#define EMAC_DSC_FLAG_ALIGNERROR 0x00040000u
#define EMAC_DSC_FLAG_CRCERROR 0x00020000u
#define EMAC_DSC_FLAG_NOMATCH 0x00010000u
```

6.2.5.5.3 Buffer Offset

This 16-bit field must be initialized to zero by the software application before adding the descriptor to a receive queue.

Whether or not this field is updated depends on the setting of the RXBUFFEROFFSET register. When the offset register is set to a non-zero value, the received packet is written to the packet buffer at an offset given by the value of the register, and this value is also written to the buffer offset field of the descriptor.

When a packet is fragmented over multiple buffers because it does not fit in the first buffer supplied, the buffer offset only applies to the first buffer in the list, which is where the start of packet (SOP) flag is set in the corresponding buffer descriptor. In other words, the buffer offset field is only updated by the EMAC on SOP descriptors.

The range of legal values for the BUFFEROFFSET register is 0 to (Buffer Length – 1) for the smallest value of buffer length for all descriptors in the list.

6.2.5.5.4 Buffer Length

This 16-bit field is used for two purposes:

- Before the descriptor is first placed on the receive queue by the application software, the buffer length field is first initialized by the software to have the physical size of the empty data buffer pointed to by the buffer pointer field.
- After the empty buffer has been processed by the EMAC and filled with received data bytes, the buffer length field is updated by the EMAC to reflect the actual number of valid data bytes written to the buffer.

6.2.5.5.5 Packet Length

This 16-bit field specifies the number of data bytes in the entire packet. This value is initialized to zero by the software application for empty packet buffers. The value is filled in by the EMAC on the first buffer used for a given packet. This is signified by the EMAC setting a start of packet (SOP) flag. The packet length is set by the EMAC on all SOP buffer descriptors.

6.2.5.5.6 Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

6.2.5.5.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

6.2.5.5.8 Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

6.2.5.5.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

6.2.5.5.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

6.2.5.5.11 Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

6.2.5.5.12 Jabber Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

6.2.5.5.13 Oversize Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an oversized frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

6.2.5.5.14 Fragment Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

6.2.5.5.15 Undersized Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is undersized and was not discarded because the RXCSFEN bit was set in the RXMBPENABLE.

6.2.5.5.16 Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RXCMFEN bit was set in the RXMBPENABLE.

6.2.5.5.17 Overrun Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

6.2.5.5.18 Code Error (CODEERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a code error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

6.2.5.5.19 Alignment Error (ALIGNERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained an alignment error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

6.2.5.5.20 CRC Error (CRCERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a CRC error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

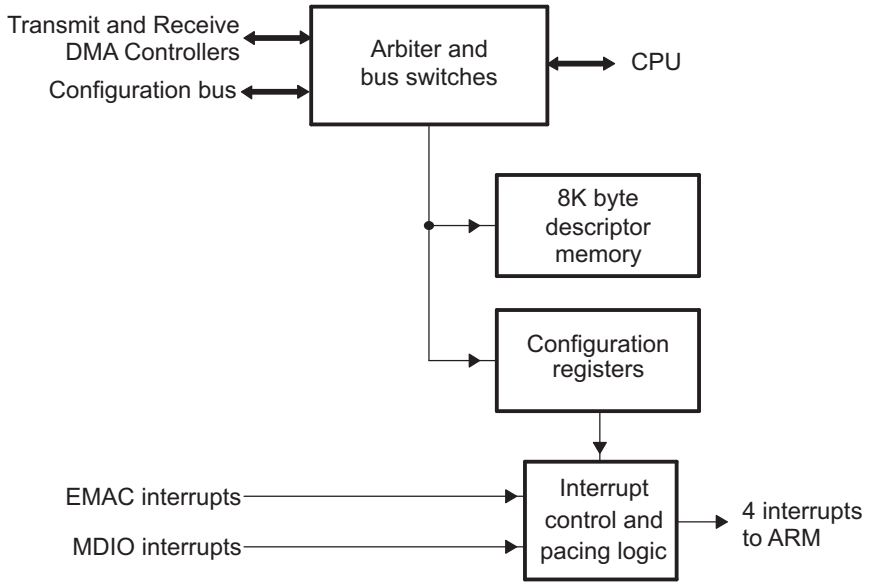
6.2.5.5.21 No Match (NOMATCH) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet did not pass any of the EMAC's address match criteria and was not discarded because the RXCAFEN bit was set in the RXMBPENABLE. Although the packet is a valid Ethernet data packet, it was only received because the EMAC is in promiscuous mode.

6.2.6 EMAC Control Module

The basic functions of the EMAC control module (Figure 6-8) are to interface the EMAC and MDIO modules to the rest of the system, and to provide for a local memory space to hold EMAC packet buffer descriptors. Local memory is used to help avoid contention to device memory spaces. Other functions include the bus arbiter, and interrupt control and pacing logic control.

Figure 6-8. EMAC Control Module Block Diagram



6.2.6.1 Internal Memory

The EMAC control module includes 8K bytes of internal memory. The internal memory block is essential for allowing the EMAC to operate more independently of the CPU. It also prevents memory underflow conditions when the EMAC issues read or write requests to descriptor memory. (Memory accesses to read or write the actual Ethernet packet data are protected by the EMAC's internal FIFOs).

A descriptor is a 16-byte memory structure that holds information about a single Ethernet packet buffer, which may contain a full or partial Ethernet packet. Thus with the 8K memory block provided for descriptor storage, the EMAC module can send and received up to a combined 512 packets before it needs to be serviced by application or driver software.

6.2.6.2 Bus Arbiter

The EMAC control module bus arbiter operates transparently to the rest of the system. It is used:

- To arbitrate between the CPU and EMAC buses for access to internal descriptor memory.
- To arbitrate between internal EMAC buses for access to system memory.

6.2.6.3 Interrupt Control

The EMAC control module combines multiple interrupt conditions generated by the EMAC and MDIO modules into four separate interrupt signals (Table 6-5) that are mapped to a CPU interrupt via the CPU interrupt controller. The four separate sources of interrupt can be individually enabled for each channel by the CMRXTHRESHINTEN, CMRXINTEN, CMTXINTEN, and CMMISCINTEN registers.

Table 6-5. EMAC Control Module Interrupts

ARM Event	Acronym	Source
24	MAC_RXTH	EMAC Receive Threshold
25	MAC_RX	EMAC Receive
26	MAC_TX	EMAC Transmit
27	MAC_MISC	EMAC Miscellaneous

6.2.6.3.1 Transmit Pulse Interrupt

The EMAC control module receives the eight individual transmit interrupts originating from the EMAC module, one for each of the eight channels, and combines them into a single transmit pulse interrupt to the CPU. This transmit pulse interrupt is paced, as described in Section 6.2.6.4. The eight individual transmit pending interrupt(s) are selected at the EMAC control module level, by setting one or more bits in the EMAC control module transmit interrupt enable register (CMTXINTEN). The masked interrupt status can be read in the EMAC control module transmit interrupt status register (CMTXINTSTAT).

Upon reception of a transmit pulse interrupt, the ISR performs the following:

1. Read CMTXINTSTAT to determine which channel(s) caused the interrupt.
2. Process received packets for the interrupting channel(s).
3. Write the appropriate CPGMAC transmit channel *n* completion pointer register(s) (TX*n*CP) with the address of the last buffer descriptor of the last packet processed by the application software.
4. Write the MAC end of interrupt vector register (MACEOIVECTOR) in the EMAC module with a value of 2h to signal the end of the transmit interrupt processing.

6.2.6.3.2 Receive Pulse Interrupt

The EMAC control module receives the eight individual receive interrupts originating from the EMAC module, one for each of the eight channels, and combines them into a single receive pulse interrupt to the CPU. This receive pulse interrupt is paced, as described in Section 6.2.6.4. The eight individual receive pending interrupt(s) are selected at the EMAC control module level, by setting one or more bits in the EMAC control module receive interrupt enable register (CMRXINTEN). The masked interrupt status can be read in the EMAC control module receive interrupt status register (CMRXINTSTAT).

Upon reception of a receive pulse interrupt, the ISR performs the following:

1. Read CMRXINTSTAT to determine which channel(s) caused the interrupt.
2. Process received packets for the interrupting channel(s).
3. Write the appropriate CPGMAC receive channel *n* completion pointer register(s) (RX*n*CP) with the address of the last buffer descriptor of the last packet processed by the application software.
4. Write the MAC end of interrupt vector register (MACEOIVECTOR) in the EMAC module with a value of 1h to signal the end of the receive interrupt processing.

6.2.6.3.3 Receive Threshold Pulse Interrupt

The EMAC control module receives the eight individual receive threshold interrupts originating from the EMAC module, one for each of the eight channels, and combines them into a single receive threshold pulse interrupt to the CPU. This receive threshold pulse interrupt is not paced. The eight individual receive threshold pending interrupt(s) are selected at the EMAC control module level, by setting one or more bits in the EMAC control module receive threshold interrupt enable register (CMRXTHRESHINTEN). The masked interrupt status can be read in the EMAC control module receive threshold interrupt status register (CMRXTHRESHINTSTAT).

Upon reception of a receive threshold pulse interrupt, the ISR performs the following:

1. Read CMRXTHRESHINTSTAT to determine which channel(s) caused the interrupt.
2. Process received packets in order to add more buffers to any channel that is below the threshold value.
3. Write the appropriate CPGMAC receive channel *n* completion pointer register(s) (RX*n*CP) with the address of the last buffer descriptor of the last packet processed by the application software.
4. Write the MAC end of interrupt vector register (MACEOIVECTOR) in the EMAC module with a value of 0 to signal the end of the receive threshold interrupt processing.

6.2.6.3.4 Miscellaneous Pulse Interrupt

The EMAC control module receives the STATPEND and HOSTPEND interrupts from the EMAC module and the MDIO_LINKINT and MDIO_USERINT interrupts from the MDIO module. The EMAC control module combines these four interrupts into a single miscellaneous pulse interrupt to the CPU. This miscellaneous interrupt is not paced. The four individual interrupts are selected at the EMAC control module level, by setting one or more bits in the EMAC control module miscellaneous interrupt enable register (CMMISCINTEN). The masked interrupt status can be read in the EMAC control module miscellaneous interrupt status register (CMMISCINTSTAT).

Upon reception of a miscellaneous pulse interrupt, the ISR performs the following:

1. Read CMMISCINTSTAT to determine which of the four condition(s) caused the interrupt.
2. Process those interrupts accordingly.
3. Write the MAC end of interrupt vector register (MACEOIVECTOR) in the EMAC module with a value of 3h to signal the end of the miscellaneous interrupt processing.

6.2.6.4 Interrupt Pacing

The receive and transmit pulse interrupts can be paced. The receive threshold and miscellaneous interrupts can not be paced. The interrupt pacing feature limits the number of interrupts to the CPU during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate, the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. The receive and transmit pulse interrupts contain a separate interrupt pacing sub-blocks. Each sub-block is disabled by default allowing the selected interrupt inputs to pass-through unaffected.

The interrupt pacing module counts the number of interrupts that occur over a 1 ms interval of time. At the end of each 1 ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated EMAC control module interrupts per millisecond registers, CMTXINTMAX and CMRXINTMAX). Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1 ms interval is derived from a 4 µs pulse that is created from a prescale counter whose value is set in the INTPRESCALE field of the EMAC control module interrupt control register (CMINTCTRL). This INTPRESCALE value should be written with the number of peripheral clock periods in 4 µs. The pacing timer determines the interval during which interrupts are blocked and decrements every 4 µs. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1 ms, according to the dynamic algorithm in the hardware.

If the rate of transmit pulse interrupt inputs is much less than the target transmit pulse interrupt rate specified in CMTXINTMAX, then the interrupts are not blocked to the CPU. If the transmit pulse interrupt rate is greater than the specified target rate in CMTXINTMAX, the interrupt is paced at the rate specified in this register, which should be written with a value between 2 and 63 inclusive, indicating the target number of interrupts per 1 ms going to the CPU. Similarly, the number of receive interrupt pulses to the CPU is also separately controlled.

6.2.7 MDIO Module

The MDIO module is used to manage up to 32 physical layer (PHY) devices connected to the Ethernet Media Access Controller (EMAC). The device supports a single PHY being connected to the EMAC at any given time. The MDIO module is designed to allow almost transparent operation of the MDIO interface with little maintenance from the CPU.

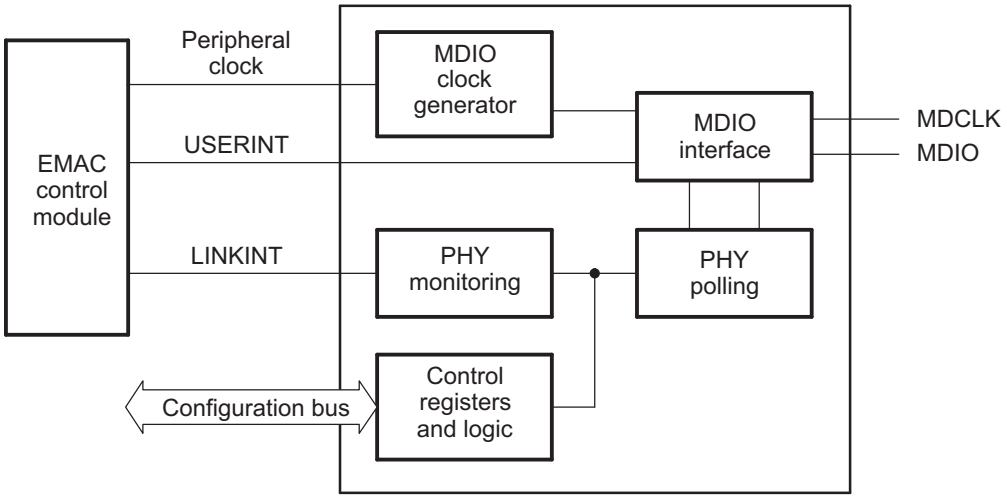
The MDIO module continuously polls 32 MDIO addresses in order to enumerate all PHY devices in the system. Once a PHY device has been detected, the MDIO module reads the MDIO PHY link status register (LINK) to monitor the PHY link state. Link change events are stored in the MDIO module, which can interrupt the CPU. This storing of the events allows the CPU to poll the link status of the PHY device without continuously performing MDIO module accesses. However, when the CPU must access the MDIO module for configuration and negotiation, the MDIO module performs the MDIO read or write operation independent of the CPU. This independent operation allows the processor to poll for completion or interrupt the CPU once the operation has completed.

6.2.7.1 MDIO Module Components

The MDIO module (Figure 6-9) interfaces to the PHY components through two MDIO pins (MDCLK and MDIO), and to the CPU through the EMAC control module and the configuration bus. The MDIO module consists of the following logical components:

- MDIO clock generator
- Global PHY detection and link state monitoring
- Active PHY monitoring
- PHY register user access

Figure 6-9. MDIO Module Block Diagram



6.2.7.1.1 MDIO Clock Generator

The MDIO clock generator controls the MDIO clock based on a divide-down of the peripheral clock (SYSCLK5) in the EMAC control module. The MDIO clock is specified to run up to 2.5 MHz, although typical operation would be 1.0 MHz. Since the peripheral clock frequency is variable (SYSCLK5), the application software or driver controls the divide-down amount.

6.2.7.1.2 Global PHY Detection and Link State Monitoring

The MDIO module continuously polls all 32 MDIO addresses in order to enumerate the PHY devices in the system. The module tracks whether or not a PHY on a particular address has responded, and whether or not the PHY currently has a link. Using this information allows the software application to quickly determine which MDIO address the PHY is using.

6.2.7.1.3 Active PHY Monitoring

Once a PHY candidate has been selected for use, the MDIO module transparently monitors its link state by reading the MDIO PHY link status register (LINK). Link change events are stored on the MDIO device and can optionally interrupt the CPU. This allows the system to poll the link status of the PHY device without continuously performing costly MDIO accesses.

6.2.7.1.4 PHY Register User Access

When the CPU must access MDIO for configuration and negotiation, the PHY access module performs the actual MDIO read or write operation independent of the CPU. This allows the CPU to poll for completion or receive an interrupt when the read or write operation has been performed. The user access registers USERACCESS*n* allows the software to submit the access requests for the PHY connected to the device.

6.2.7.2 MDIO Module Operational Overview

The MDIO module implements the 802.3 serial management interface to interrogate and control an Ethernet PHY, using a shared two-wired bus. It separately performs autodetection and records the current link status of up to 32 PHYs, polling all 32 MDIO addresses.

Application software uses the MDIO module to configure the autonegotiation parameters of the PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC.

In this device, the Ethernet PHY attached to the system can be directly controlled and queried. The Media Independent Interface (MII) address of this PHY device is specified in one of the PHYADRMON bits in the MDIO user PHY select register (USERPHYSEL*n*). The MDIO module can be programmed to trigger a CPU interrupt on a PHY link change event, by setting the LINKINTENB bit in USERPHYSEL*n*. Reads and writes to registers in this PHY device are performed using the MDIO user access register (USERACCESS*n*).

The MDIO module powers-up in an idle state until specifically enabled by setting the ENABLE bit in the MDIO control register (CONTROL). At this time, the MDIO clock divider and preamble mode selection are also configured. The MDIO preamble is enabled by default, but can be disabled when the connected PHY does not require it. Once the MDIO module is enabled, the MDIO interface state machine continuously polls the PHY link status (by reading the generic status register) of all possible 32 PHY addresses and records the results in the MDIO PHY alive status register (ALIVE) and MDIO PHY link status register (LINK). The corresponding bit for the connected PHY (0-31) is set in ALIVE, if the PHY responded to the read request. The corresponding bit is set in LINK, if the PHY responded and also is currently linked. In addition, any PHY register read transactions initiated by the application software using USERACCESS*n* causes ALIVE to be updated.

The USERPHYSEL*n* is used to track the link status of the connected PHY address. A change in the link status of the PHY being monitored sets the appropriate bit in the MDIO link status change interrupt registers (LINKINTRAW and LINKINTMASKED), if enabled by the LINKINTENB bit in USERPHYSEL*n*.

While the MDIO module is enabled, the host issues a read or write transaction over the MII management interface using the DATA, PHYADR, REGADR, and WRITE bits in USERACCESS*n*. When the application sets the GO bit in USERACCESS*n*, the MDIO module begins the transaction without any further intervention from the CPU. Upon completion, the MDIO module clears the GO bit and sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS*n* used. The corresponding USERINTMASKED bit (0 or 1) in the MDIO user command complete interrupt register (USERINTMASKED) may also be set, depending on the mask setting configured in the MDIO user command complete interrupt mask set register (USERINTMASKSET) and the MDIO user interrupt mask clear register (USERINTMASKCLEAR).

A round-robin arbitration scheme is used to schedule transactions that may be queued using both USERACCESS0 and USERACCESS1. The application software must check the status of the GO bit in USERACCESS*n* before initiating a new transaction, to ensure that the previous transaction has completed. The application software can use the ACK bit in USERACCESS*n* to determine the status of a read transaction.

6.2.7.2.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO control register (CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in CONTROL.
3. The MDIO PHY alive status register (ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (USERPHYSEL*n*), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) to use the MDIO user access register (USERACCESS*n*). Since only one PHY is used in this device, the application software can use one USERACCESS*n* to trigger a completion interrupt; the other USERACCESS*n* is not setup.

6.2.7.2.2 Writing Data To a PHY Register

The MDIO module includes a user access register (USERACCESS*n*) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS*n*) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in USERACCESS*n* corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in USERACCESS*n* for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS*n* used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

6.2.7.2.3 Reading Data From a PHY Register

The MDIO module includes a user access register (USERACCESS*n*) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS*n*) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in USERACCESS*n* corresponding to the PHY and PHY register you want to read.

3. The read data value is available in the DATA bits in USERACCESS*n* after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in USERACCESS n . Once the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS*n* used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

6.2.7.2.4 Example of MDIO Register Access Code

The MDIO module uses the MDIO user access register (USERACCESS*n*) to access the PHY control registers. Software functions that implement the access process may simply be the following four macros:

- PHYREG_read(regadr, phyadr) — Start the process of reading a PHY register
- PHYREG_write(regadr, phyadr, data) — Start the process of writing a PHY register
- PHYREG_wait( ) — Synchronize operation (make sure read/write is idle)
- PHYREG_waitResults(results) — Wait for read to complete and return data read

Note that it is not necessary to wait after a write operation, as long as the status is checked before every operation to make sure the MDIO hardware is idle. An alternative approach is to call PHYREG_wait() after every write, and PHYREG_waitResults( ) after every read, then the hardware can be assumed to be idle when starting a new operation.

The implementation of these macros using the chip support library (CSL) is shown in Example 6-3 (USERACCESS0 is assumed).

Note that this implementation does not check the ACK bit in USERACCESS*n* on PHY register reads (does not follow the procedure outlined in Section 6.2.7.2.3). Since the MDIO PHY alive status register (ALIVE) is used to initially select a PHY, it is assumed that the PHY is acknowledging read operations. It is possible that a PHY could become inactive at a future point in time. An example of this would be a PHY that can have its MDIO addresses changed while the system is running. It is not very likely, but this condition can be tested by periodically checking the PHY state in ALIVE.

Example 6-3. MDIO Register Access Macros

```
#define PHYREG_read(regadr, phyadr)
    MDIO_REGS->USERACCESS0 =
        CSL_FMK(MDIO_USERACCESS0_GO,1u)                        | /
        CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)                | /
        CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)
#define PHYREG_write(regadr, phyadr, data)
    MDIO_REGS->USERACCESS0 =
        CSL_FMK(MDIO_USERACCESS0_GO,1u)                        | /
        CSL_FMK(MDIO_USERACCESS0_WRITE,1)                      | /
        CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)                | /
        CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)                | /
        CSL_FMK(MDIO_USERACCESS0_DATA, data)
#define PHYREG_wait()
    while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_GO) )
#define PHYREG_waitResults( results ) {
    while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_GO) );
results = CSL_FEXT(MDIO_REGS->USERACCESS0, MDIO_USERACCESS0_DATA); }
```

6.2.8 EMAC Module

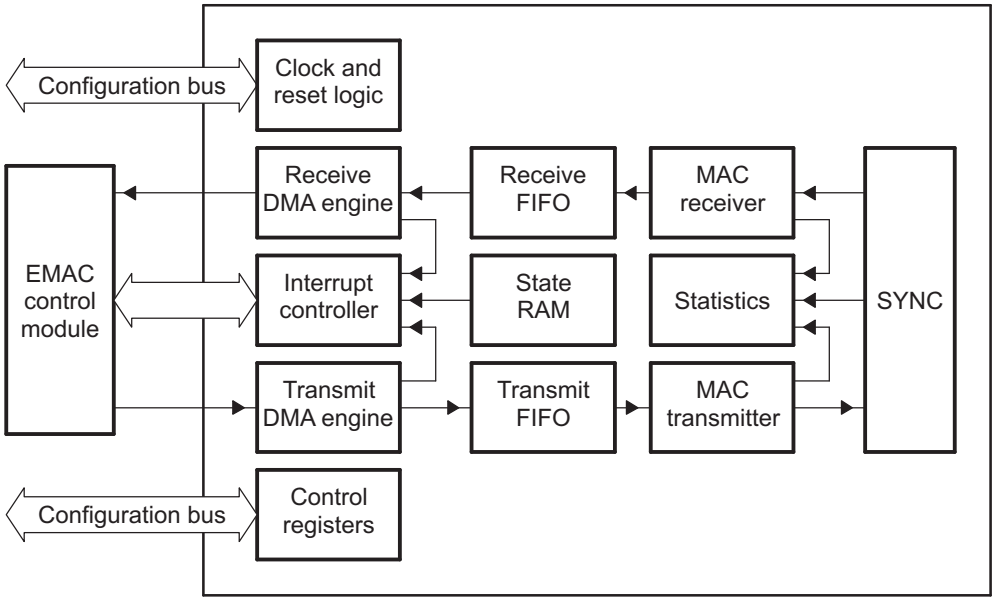
This section discusses the architecture and basic function of the EMAC module.

6.2.8.1 EMAC Module Components

The EMAC module (Figure 6-10) interfaces to the outside world through the Media Independent Interface (MII) and interfaces to the system core through the EMAC control module. The EMAC consists of the following logical components:

- The receive path includes: receive DMA engine, receive FIFO, and MAC receiver
- The transmit path includes: transmit DMA engine, transmit FIFO, and MAC transmitter
- Statistics logic
- State RAM
- Interrupt controller
- Control registers and logic
- Clock and reset logic

Figure 6-10. EMAC Module Block Diagram



6.2.8.1.1 Receive DMA Engine

The receive DMA engine is the interface between the receive FIFO and the system core. It interfaces to the CPU through the bus arbiter in the EMAC control module. This DMA engine is totally independent of the device DMA.

6.2.8.1.2 Receive FIFO

The receive FIFO consists of 68 cells of 64 bytes each and associated control logic. The FIFO buffers receive data in preparation for writing into packet buffers in device memory, and also enable receive FIFO flow control.

6.2.8.1.3 MAC Receiver

The MAC receiver detects and processes incoming network frames, de-frames them, and puts them into the receive FIFO. The MAC receiver also detects errors and passes statistics to the statistics RAM.

6.2.8.1.4 Receive Address

This sub-module performs address matching and address filtering based on the incoming packet's destination address. It contains a 32-by-53 bit two-port RAM, in which up to 32 addresses can be stored to be either matched or filtered by the EMAC. The RAM may contain multicast packet addresses, but the associated channel must have the unicast enable bit set, even though it is a multicast address. The unicast enable bits are used with multicast addresses in the receive address RAM (not the multicast hash enable bits). Therefore, hash matches can be disabled, but specific multicast addresses can be matched (or filtered) in the RAM. If a multicast packet hash matches, the packet may still be filtered in the RAM. Each packet can be sent to only a single channel.

6.2.8.1.5 Transmit DMA Engine

The transmit DMA engine is the interface between the transmit FIFO and the CPU. It interfaces to the CPU through the bus arbiter in the EMAC control module.

6.2.8.1.6 Transmit FIFO

The transmit FIFO consists of 24 cells of 64 bytes each and associated control logic. This enables a packet of 1518 bytes (standard Ethernet packet size) to be sent without the possibility of underrun. The FIFO buffers data in preparation for transmission.

6.2.8.1.7 MAC Transmitter

The MAC transmitter formats frame data from the transmit FIFO and transmits the data using the CSMA/CD access protocol. The frame CRC can be automatically appended, if required. The MAC transmitter also detects transmission errors and passes statistics to the statistics registers.

6.2.8.1.8 Statistics Logic

The Ethernet statistics are counted and stored in the statistics logic RAM. This statistics RAM keeps track of 36 different Ethernet packet statistics.

6.2.8.1.9 State RAM

State RAM contains the head descriptor pointers and completion pointers registers for both transmit and receive channels.

6.2.8.1.10 EMAC Interrupt Controller

The interrupt controller contains the interrupt related registers and logic. The 18 raw EMAC interrupts are input to this submodule and masked module interrupts are output.

6.2.8.1.11 Control Registers and Logic

The EMAC is controlled by a set of memory-mapped registers. The control logic also signals transmit, receive, and status related interrupts to the CPU through the EMAC control module.

6.2.8.1.12 Clock and Reset Logic

The clock and reset submodule generates all the EMAC clocks and resets. For more details on reset capabilities, see Section 14.2.9.1.

6.2.8.2 EMAC Module Operational Overview

After reset, initialization, and configuration, the application software running on the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the state RAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory. The DMA controller writes the packet into the transmit FIFO in bursts of 64-byte cells. When the threshold number of cells, configurable using the TXCELLTHRESH bit in the FIFO control register (FIFOCONTROL), have been written to the transmit FIFO, or a complete packet, whichever is smaller, the MAC transmitter then initiates the packet transmission. The SYNC block transmits the packet over the MII interfaces in accordance with the 802.3 protocol. Transmit statistics are counted by the statistics block.

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The SYNC submodule receives packets and strips off the Ethernet related protocol. The packet data is input to the MAC receiver, which checks for address match and processes errors. Accepted packets are then written to the receive FIFO in bursts of 64-byte cells. The receive DMA controller then writes the packet data to memory. Receive statistics are counted by the statistics block.

The EMAC module operates independently of the CPU. It is configured and controlled by its register set mapped into device memory. Information about data packets is communicated by use of 16-byte descriptors that are placed in an 8K-byte block of RAM in the EMAC control module.

For transmit operations, each 16-byte descriptor describes a packet or packet fragment in the system's internal or external memory. For receive operations, each 16-byte descriptor represents a free packet buffer or buffer fragment. On both transmit and receive, an Ethernet packet is allowed to span one or more memory fragments, represented by one 16-byte descriptor per fragment. In typical operation, there is only one descriptor per receive buffer, but transmit packets may be fragmented, depending on the software architecture.

An interrupt is issued to the CPU whenever a transmit or receive operation has completed. However, it is not necessary for the CPU to service the interrupt while there are additional resources available. In other words, the EMAC continues to receive Ethernet packets until its receive descriptor list has been exhausted. On transmit operations, the transmit descriptors need only be serviced to recover their associated memory buffer. Thus, it is possible to delay servicing of the EMAC interrupt if there are real-time tasks to perform.

Eight channels are supplied for both transmit and receive operations. On transmit, the eight channels represent eight independent transmit queues. The EMAC can be configured to treat these channels as an equal priority "round-robin" queue or as a set of eight fixed-priority queues. On receive, the eight channels represent eight independent receive queues with packet classification. Packets are classified based on the destination MAC address. Each of the eight channels is assigned its own MAC address, enabling the EMAC module to act like eight virtual MAC adapters. Also, specific types of frames can be sent to specific channels. For example, multicast, broadcast, or other (promiscuous, error, etc.), can each be received on a specific receive channel queue.

The EMAC keeps track of 36 different statistics, plus keeps the status of each individual packet in its corresponding packet descriptor.

6.2.9 Media Independent Interface (MII)

The following sections discuss the operation of the Media Independent Interface (MII) in 10 Mbps and 100 Mbps mode. An IEEE 802.3 compliant Ethernet MAC controls the interface.

6.2.9.1 Data Reception

6.2.9.1.1 Receive Control

Data received from the PHY is interpreted and output to the EMAC receive FIFO. Interpretation involves detection and removal of the preamble and start-of-frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation. Address detection and frame filtering is performed outside the MII interface.

6.2.9.1.2 Receive Inter-Frame Interval

The 802.3 standard requires an interpacket gap (IPG), which is 24 MII clocks (96 bit times). However, the EMAC can tolerate a reduced IPG (2 MII clocks or 8 bit times) with a correct preamble and start frame delimiter. This interval between frames must comprise (in the following order):

1. An Interpacket Gap (IPG).
2. A 7-byte preamble (all bytes 55h).
3. A 1-byte start of frame delimiter (5DH).

6.2.9.1.3 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the EMAC from further frame reception. Two forms of receive flow control are implemented on the device:

- Receive buffer flow control
- Receive FIFO flow control

When enabled and triggered, receive buffer flow control prevents further frame reception based on the number of free buffers available. Receive buffer flow control issues flow control collisions in half-duplex mode and IEEE 802.3X pause frames for full-duplex mode. Receive buffer flow control is triggered when the number of free buffers in any enabled receive channel free buffer count register (RX*n* FREEBUFFER) is less than or equal to the receive channel flow control threshold register (RX*n* FLOWTHRESH) value. Receive flow control is independent of receive QOS, except that both use the free buffer values.

When enabled and triggered, receive FIFO flow control prevents further frame reception based on the number of cells currently in the receive FIFO. Receive FIFO flow control may be enabled only in full-duplex mode (FULLDUPLEX bit is set in the in the MAC control register, MACCONTROL). Receive flow control prevents reception of frames on the port until all of the triggering conditions clear, at which time frames may again be received by the port.

Receive FIFO flow control is triggered when the occupancy of the FIFO is greater than or equal to the RXFIFOFLOWTHRESH value in the FIFO control register (FIFOCONTROL). The RXFIFOFLOWTHRESH value must be greater than or equal to 1h and less than or equal to 42h (decimal 66). The RXFIFOFLOWTHRESH reset value is 2h.

Receive flow control is enabled by the RXBUFFERFLOWEN bit and the RXFIFOFLOWEN bit in MACCONTROL. The FULLDUPLEX bit in MACCONTROL configures the EMAC for collision or IEEE 802.3X flow control.

6.2.9.1.3.1 Collision-Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in half-duplex mode (the FULLDUPLEX bit is cleared in MACCONTROL). When receive flow control is enabled and triggered, the EMAC generates collisions for received frames. The jam sequence transmitted is the 12-byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3h. The jam sequence begins no later than approximately as the source address starts to be received. Note that these forced collisions are not limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm.

Receive flow control does not depend on the value of the incoming frame destination address. A collision is generated for any incoming packet, regardless of the destination address, if any EMAC enabled channel's free buffer register value is less than or equal to the channel's flow threshold value.

6.2.9.1.3.2 IEEE 802.3x-Based Receive Buffer Flow Control

IEEE 802.3x-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in full-duplex mode (the FULLDUPLEX bit is set in MACCONTROL). When receive flow control is enabled and triggered, the EMAC transmits a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The EMAC transmits a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle or following the completion of the frame currently being transmitted). The pause frame contains the maximum possible value for the pause time (FFFFh). The EMAC counts the receive pause frame time (decrements FF00h to 0) and retransmits an outgoing pause frame, if the count reaches 0. When the flow control request is removed, the EMAC transmits a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval are received normally (provided the receive FIFO is not full).

Pause frames are transmitted if enabled and triggered, regardless of whether or not the EMAC is observing the pause time period from an incoming pause frame.

The EMAC transmits pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01h.
- The 48-bit source address (set using the MACSRCADDRLO and MACSRCADDRHI registers).
- The 16-bit length/type field containing the value 88.08h.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time value of FF.FFh. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request have a pause time value of 00.00h.
- Zero padding to 64-byte data length (EMAC transmits only 64-byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

If the RXBUFFERFLOWEN bit in MACCONTROL is cleared to 0 while the pause time is nonzero, then the pause time is cleared to 0 and a zero count pause frame is sent.

6.2.9.2 Data Transmission

The EMAC passes data to the PHY from the transmit FIFO (when enabled). Data is synchronized to the transmit clock rate. Transmission begins when there are TXCELLTHRESH cells of 64 bytes each, or a complete packet, in the FIFO.

6.2.9.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted), the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full-duplex mode, the carrier sense (MCRS) and collision-sensing (MCOL) modes are disabled.

6.2.9.2.2 CRC Insertion

If the SOP buffer descriptor PASSCRC flag is cleared, the EMAC generates and appends a 32-bit Ethernet CRC onto the transmitted data. For the EMAC-generated CRC case, a CRC (or placeholder) at the end of the data is allowed but not required. The buffer byte count value should not include the CRC bytes, if they are present.

If the SOP buffer descriptor PASSCRC flag is set, then the last four bytes of the transmit data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the buffer byte count value. The MAC performs no error checking on the outgoing CRC.

6.2.9.2.3 Adaptive Performance Optimization (APO)

The EMAC incorporates adaptive performance optimization (APO) logic that may be enabled by setting the TXPACE bit in the MAC control register (MACCONTROL). Transmission pacing to enhance performance is enabled when the TXPACE bit is set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions), thereby, increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions, or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision, or excessive collision), the pacing counter is decremented by 1, down to 0.

With pacing enabled, a new frame is permitted to immediately (after one interpacket gap) attempt transmission only if the pacing counter is 0. If the pacing counter is nonzero, the frame is delayed by the pacing delay of approximately four interpacket gap (IPG) delays. APO only affects the IPG preceding the first attempt at transmitting a frame; APO does not affect the back-off algorithm for retransmitted frames.

6.2.9.2.4 Interpacket-Gap (IPG) Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision and MCRS is deasserted within approximately 48 bit times of MTXEN being deasserted, then 96 bit times is measured from MTXEN. If the frame suffered a collision or MCRS is not deasserted until more than approximately 48 bit times after MTXEN is deasserted, then 96 bit times (approximately, but not less) is measured from MCRS.

6.2.9.2.5 Back Off

The EMAC implements the 802.3 binary exponential back-off algorithm.

6.2.9.2.6 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the EMAC from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TXFLOWEN bits in the MAC control register (MACCONTROL) are set. Pause frames are not acted upon in half-duplex mode. Pause frame action is taken if enabled, but normally the frame is filtered and not transferred to memory. MAC control frames are transferred to memory, if the RXCMFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) is set. The TXFLOWEN and FULLDUPLEX bits affect whether or not MAC control frames are acted upon, but they have no affect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC control frames with an opcode field of 0001h. Incoming pause frames are only acted upon by the EMAC if:

- TXFLOWEN bit is set in MACCONTROL
- The frame's length is 64 to RXMAXLEN bytes inclusive
- The frame contains no CRC error or align/code errors

The pause time value from valid frames is extracted from the two bytes following the opcode. The pause time is loaded into the EMAC transmit pause timer and the transmit pause time period begins. If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- If the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer immediately expires, or
- If the new pause time value is 0, then the transmit pause timer immediately expires, else
- The EMAC transmit pause timer immediately is set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame is discarded).

If the TXFLOWEN bit in MACCONTROL is cleared, then the pause timer immediately expires.

The EMAC does not start the transmission of a new data frame any sooner than 512 bit-times after a pause frame with a nonzero pause time has finished being received (MRXDV going inactive). No transmission begins until the pause timer has expired (the EMAC may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received is completed and unaffected.

Incoming pause frames consist of:

- A 48-bit destination address equal to one of the following:
  - The reserved multicast destination address 01.80.C2.00.00.01h
  - Any EMAC 48-bit unicast address. Pause frames are accepted, regardless of whether the channel is enabled or not.
- The 16-bit length/type field containing the value 88.08h.
- The 48-bit source address of the transmitting device.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The EMAC recognizes any pause frame between 64 bytes and RXMAXLEN bytes in length.

6.2.9.2.7 Speed, Duplex, and Pause Frame Support

The MAC operates at 10 Mbps or 100 Mbps, in half-duplex or full-duplex mode, and with or without pause frame support as configured by the host.

6.2.10 Packet Receive Operation

6.2.10.1 Receive DMA Host Configuration

To configure the receive DMA for operation the host must:

- Initialize the receive addresses.
- Initialize the receive channel *n* DMA head descriptor pointer registers (RX*n*HDP) to 0.
- Write the MAC address hash *n* registers (MACHASH1 and MACHASH2), if hash matching multicast addressing is desired.
- If flow control is to be enabled, initialize:
  - the receive channel *n* free buffer count registers (RX*n*FREEBUFFER)
  - the receive channel *n* flow control threshold register (RX*n*FLOWTHRESH)
  - the receive filter low priority frame threshold register (RXFILTERLOWTHRESH)
- Enable the desired receive interrupts using the receive interrupt mask set register (RXINTMASKSET) and the receive interrupt mask clear register (RXINTMASKCLEAR).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
- Setup the receive channel(s) buffer descriptors and initialize RX*n*HDP.
- Enable the receive DMA controller by setting the RXEN bit in the receive control register (RXCONTROL).
- Configure and enable the receive operation, as desired, in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) and by using the receive unicast set register (RXUNICASTSET) and the receive unicast clear register (RXUNICASTCLEAR).

6.2.10.2 Receive Channel Enabling

Each of the eight receive channels has an enable bit (RXCH*n*EN) in the receive unicast enable set register (RXUNICASTSET) that is controlled using RXUNICASTSET and the receive unicast clear register (RXUNICASTCLEAR). The RXCH*n*EN bits determine whether the given channel is enabled (set to 1) to receive frames with a matching unicast or multicast destination address.

The RXBROADEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) determines if broadcast frames are enabled or filtered. If broadcast frames are enabled, then they are copied to only a single channel selected by the RXBROADCH field in RXMBPENABLE.

The RXMULTEN bit in RXMBPENABLE determines if hash matching multicast frames are enabled or filtered. Incoming multicast addresses (group addresses) are hashed into an index in the hash table. If the indexed bit is set, the frame hash will match and it will be transferred to the channel selected by the RXMULTCH field in RXMBPENABLE when multicast frames are enabled. The multicast hash bits are set in the MAC address hash n registers (MACHASH1 and MACHASH2).

The RXPROMCH bits in RXMBPENABLE select the promiscuous channel to receive frames selected by the RXCMFEN, RXCSFEN, RXCEFEN, and RXCAFEN bits. These four bits allow reception of MAC control frames, short frames, error frames, and all frames (promiscuous), respectively.

The address RAM can be configured to set multiple unicast and/or multicast addresses to a given channel (if the match bit is set in the RAM). Multicast addresses in the RAM are enabled by RXUNICASTSET and not by the RXMULTEN bit in RXMBPENABLE, the RXMULTEN bit enables the hash multicast match only. The address RAM takes precedence over the hash match.

If a multicast packet is received that hash matches (multicast packets enabled), but is filtered in the RAM, then the packet is filtered. If a multicast packet does not hash match, regardless of whether or not hash matching is enabled, but matches an enabled multicast address in the RAM, then the packet will be transferred to the associated channel.

6.2.10.3 Receive Address Matching

The receive address block can store up to 32 addresses to be filtered or matched. Before enabling packet reception, all the address RAM locations should be initialized, including locations to be unused. The system software is responsible for adding and removing addresses from the RAM.

A MAC address location in RAM is 53 bits wide and consists of:

- 48 bits of the MAC address.
- 3 bits for the channel to which a valid address match will be transferred. The channel is a don't care if MATCHFILT bit is cleared
- A valid bit
- A match or filter bit

First, write the index into the address RAM in the MACINDEX register to start writing a MAC address. Then write the upper 32 bits of the MAC address (MACADDRHI register), and then the lower 16 bits of MAC address with the VALID and MATCHFILT control bits (MACADDRLO). The valid bit should be cleared for the unused locations in the receive address RAM.

The most common uses for the receive address sub-module are:

- Set EMAC in promiscuous mode, using RXCAFEN and RXPROMCH bits in the RXMBPENABLE register. Then filter up to 32 individual addresses, which can be both unicast and/or multicast.
- Disable the promiscuous mode (RXCAFEN = 0) and match up to 32 individual addresses, multicast and/or unicast.

6.2.10.4 Hardware Receive QOS Support

Hardware receive quality of service (QOS) is supported, when enabled, by the Tag Protocol Identifier format and the associated Tag Control Information (TCI) format priority field. When the incoming frame length/type value is equal to 81.00h, the EMAC recognizes the frame as an Ethernet Encoded Tag Protocol Type. The two octets immediately following the protocol type contain the 16-bit TCI field. Bits 15-13 of the TCI field contain the received frames priority (0 to 7). The received frame is a low-priority frame, if the priority value is 0 to 3; the received frame is a high-priority frame, if the priority value is 4 to 7. All frames that have a length/type field value not equal to 81.00h are low-priority frames. Received frames that contain priority information are determined by the EMAC as:

- A 48-bit (6 bytes) destination address equal to:
  - The destination station's individual unicast address.
  - The destination station's multicast address (MACHASH1 and MACHASH2).
  - The broadcast address of all ones.
- A 48-byte (6 bytes) source address.
- The 16-bit (2 bytes) length/type field containing the value 81.00h.
- The 16-bit (2 bytes) TCI field with the priority field in the upper 3 bits.
- Data bytes
- The 4 bytes CRC.

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) and the receive channel *n* free buffer count registers (RX *n* FREEBUFFER) are used in conjunction with the priority information to implement receive hardware QOS. Low-priority frames are filtered if the number of free buffers (RX *n* FREEBUFFER) for the frame channel is less than or equal to the filter low threshold (RXFILTERLOWTHRESH) value. Hardware QOS is enabled by the RXQOSEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

6.2.10.5 Host Free Buffer Tracking

The host must track free buffers for each enabled channel (including unicast, multicast, broadcast, and promiscuous), if receive QOS or receive flow control is used. Disabled channel free buffer values are do not cares. During initialization, the host should write the number of free buffers for each enabled channel to the appropriate receive channel *n* free buffer count registers (RX*n*FREEBUFFER). The EMAC decrements the appropriate channel's free buffer value for each buffer used. When the host reclaims the frame buffers, the host should write the channel free buffer register with the number of reclaimed buffers (write to increment). There are a maximum of 65,535 free buffers available. RX*n*FREEBUFFER only needs to be updated by the host if receive QOS or flow control is used.

6.2.10.6 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the receive teardown register (RXTEARDOWN). When a teardown command is issued to an enabled receive channel, the following occurs:

- Any current frame in reception completes normally.
- The TDOWNCMPLT flag is set in the next buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A receive interrupt for the channel is issued to the host.
- The corresponding receive channel *n* completion pointer register (RX*n*CP) contains the value FFFF FFFCh.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to RX*n*CP (note that there is no buffer descriptor in this case). Software may read RX*n*CP to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

6.2.10.7 Receive Frame Classification

Received frames are proper (good) frames, if they are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length (inclusive) and contain no code, align, or CRC errors.

Received frames are long frames, if their frame count exceeds the value in RXMAXLEN. The RXMAXLEN reset (default) value is 5EEh (1518 in decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames; long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames, if their frame count is less than 64 bytes. Short frames that address match and contain no errors are undersized frames; short frames with CRC, code, or alignment errors are fragment frames. If the frame length is less than or equal to 20, then the frame CRC is passed, regardless of whether the RXPASSCRC bit is set or cleared in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

A received long packet always contains RXMAXLEN number of bytes transferred to memory (if the RXCEFEN bit is set in RXMBPENABLE), regardless of the value of the RXPASSCRC bit. The following is an example with RXMAXLEN set to 1518:

- If the frame length is 1518, then the packet is not a long packet and there are 1514 or 1518 bytes transferred to memory depending on the value of the RXPASSCRC bit.
- If the frame length is 1519, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last three bytes are the first three CRC bytes.
- If the frame length is 1520, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last two bytes are the first two CRC bytes.
- If the frame length is 1521, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last byte is the first CRC byte.

- If the frame length is 1522, there are 1518 bytes transferred to memory. The last byte is the last data byte.

6.2.10.8 Promiscuous Receive Mode

When the promiscuous receive mode is enabled by setting the RXCAFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE), nonaddress matching frames that would normally be filtered are transferred to the promiscuous channel. Address matching frames that would normally be filtered due to errors are transferred to the address match channel when the RXCAFEN and RXCEFEN bits in RXMBPENABLE are set. A frame is considered to be an address matching frame only if it is enabled to be received on a unicast, multicast, or broadcast channel. Frames received to disabled unicast, multicast, or broadcast channels are considered nonaddress matching.

MAC control frames address match only if the RXCMFEN bit in RXMBPENABLE is set. The RXCEFEN and RXCSFEN bits in RXMBPENABLE determine whether error frames are transferred to memory or not, but they do not determine whether error frames are address matching or not. Short frames are a special type of error frames.

A single channel is selected as the promiscuous channel by the RXPROMCH bit in RXMBPENABLE. The promiscuous receive mode is enabled by the RXCMFEN, RXCEFEN, RXCSFEN, and RXCAFEN bits in RXMBPENABLE. Table 6-6 shows the effects of the promiscuous enable bits. Proper frames are frames that are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length inclusive and contain no code, align, or CRC errors.

Table 6-6. Receive Frame Treatment Summary

Address Match	RXCAFEN	RXCEFEN	RXCMFEN	RXCSFEN	Receive Frame Treatment
0	0	X	X	X	No frames transferred.
0	1	0	0	0	Proper frames transferred to promiscuous channel.
0	1	0	0	1	Proper/undersized data frames transferred to promiscuous channel.
0	1	0	1	0	Proper data and control frames transferred to promiscuous channel.
0	1	0	1	1	Proper/undersized data and control frames transferred to promiscuous channel.
0	1	1	0	0	Proper/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control or undersized/fragment frames are transferred.
0	1	1	0	1	Proper/undersized/fragment/oversize/jabber/code/ align/CRC data frames transferred to promiscuous channel. No control frames are transferred.
0	1	1	1	0	Proper/oversize/jabber/code/align/CRC data and control frames transferred to promiscuous channel. No undersized frames are transferred.
0	1	1	1	1	All nonaddress matching frames with and without errors transferred to promiscuous channel.
1	X	0	0	0	Proper data frames transferred to address match channel.
1	X	0	0	1	Proper/undersized data frames transferred to address match channel.
1	X	0	1	0	Proper data and control frames transferred to address match channel.
1	X	0	1	1	Proper/undersized data and control frames transferred to address match channel.
1	X	1	0	0	Proper/oversize/jabber/code/align/CRC data frames transferred to address match channel. No control or undersized frames are transferred.
1	X	1	0	1	Proper/oversize/jabber/fragment/undersized/code/ align/CRC data frames transferred to address match channel. No control frames are transferred.

Table 6-6. Receive Frame Treatment Summary (continued)

Address Match	RXCAFEN	RXCEFEN	RXCMFEN	RXCSFEN	Receive Frame Treatment
1	X	1	1	0	Proper/oversize/jabber/code/align/CRC data and control frames transferred to address match channel. No undersized/fragment frames are transferred.
1	X	1	1	1	All address matching frames with and without errors transferred to the address match channel

6.2.10.9 Receive Overrun

The types of receive overrun are:

- FIFO start of frame overrun (FIFO_SOF)
- FIFO middle of frame overrun (FIFO_MOF)
- DMA start of frame overrun (DMA_SOF)
- DMA middle of frame overrun (DMA_MOF)

The statistics counters used to track these types of receive overrun are:

- Receive start of frame overruns register (RXSOFOVERRUNS)
- Receive middle of frame overruns register (RXMOFOVERRUNS)
- Receive DMA overruns register (RXDMAOVERRUNS)

Start of frame overruns happen when there are no resources available when frame reception begins. Start of frame overruns increment the appropriate overrun statistic(s) and the frame is filtered.

Middle of frame overruns happen when there are some resources to start the frame reception, but the resources run out during frame reception. In normal operation, a frame that overruns after starting the frame reception is filtered and the appropriate statistic(s) are incremented; however, the RXCEFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) affects overrun frame treatment. Table 6-7 shows how the overrun condition is handled for the middle of frame overrun.

Table 6-7. Middle of Frame Overrun Treatment

Address Match	RXCAFEN	RXCEFEN	Middle of Frame Overrun Treatment
0	0	X	Overrun frame filtered.
0	1	0	Overrun frame filtered.
0	1	1	As much frame data as possible is transferred to the promiscuous channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN and NOMATCH flags are set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated and be a jabber or oversize).
1	X	0	Overrun frame filtered with the appropriate overrun statistic(s) incremented.
1	X	1	As much frame data as possible is transferred to the address match channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN flag is set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated).

6.2.11 Packet Transmit Operation

The transmit DMA is an eight channel interface. Priority between the eight queues may be either fixed or round-robin as selected by the TXPTYPE bit in the MAC control register (MACCONTROL). If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round-robin priority proceeds from channel 0 to channel 7.

6.2.11.1 Transmit DMA Host Configuration

To configure the transmit DMA for operation the host must perform:

- Write the MAC source address low bytes register (MACSRCADDRLO) and the MAC source address high bytes register (MACSRCADDRHI) (used for pause frames on transmit).
- Initialize the transmit channel *n* DMA head descriptor pointer registers (TX*n*HDP) to 0.
- Enable the desired transmit interrupts using the transmit interrupt mask set register (TXINTMASKSET) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Setup the transmit channel(s) buffer descriptors in host memory.
- Enable the transmit DMA controller by setting the TXEN bit in the transmit control register (TXCONTROL).
- Write the appropriate TX*n*HDP with the pointer to the first descriptor to start transmit operations.

6.2.11.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the transmit teardown register (TXTEARDOWN). When a teardown command is issued to an enabled transmit channel, the following occurs:

- Any frame currently in transmission completes normally.
- The TDOWNCMPLT flag is set in the next SOP buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A transmit interrupt is issued to inform the host of the channel teardown.
- The corresponding transmit channel *n* completion pointer register (TX*n*CP) contains the value FFFF FFFCh.
- The host should acknowledge a teardown interrupt with an FFFF FFFCh acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to TX*n*CP (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location (TX*n*CP) to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

6.2.12 Receive and Transmit Latency

The transmit FIFO contains twenty-four 64-byte cells and the receive FIFO contains sixty-eight 64-byte cells. The EMAC begins transmission of a packet on the wire after TXCELLTHRESH cells (configurable through the FIFO control register, FIFOCONTROL) or a complete packet are available in the FIFO.

Transmit underrun cannot occur for packet sizes of TXCELLTHRESH × 64 bytes (or less). For larger packet sizes, transmit underrun can occur if the memory latency is greater than the time required to transmit a 64-byte cell on the wire; this is 0.512 ms in 1 Gbit mode, 5.12 ms in 100 Mbps mode, and 51.2 ms in 10 Mbps mode. The memory latency time includes all buffer descriptor reads for the entire cell data. The EMAC transmit FIFO uses 24 cells; thus, underrun cannot happen for a normal size packet (less than 1536 packet bytes). Cell transmission can be configured to start only after an entire packet is contained in the FIFO; for a maximum-size packet, set the TXCELLTHRESH field to the maximum possible value of 24.

Receive overrun is prevented if the receive memory cell latency is less than the time required to transmit a 64-byte cell on the wire (0.512 ms in 1 Gbps mode, 5.12 ms in 100 Mbps mode, or 51.2ms in 10 Mbps mode). The latency time includes any required buffer descriptor reads for the cell data.

Latency to descriptor RAM is low because RAM is local to the EMAC, as it is part of the EMAC control module.

6.2.13 Transfer Node Priority

The device contains a chip-level register, master priority register (MSTPRI), that is used to set the priority of the transfer node used in issuing memory transfer requests to system memory.

Although the EMAC has internal FIFOs to help alleviate memory transfer arbitration problems, the average transfer rate of data read and written by the EMAC to internal or external processor memory must be at least that of the Ethernet wire rate. In addition, the internal FIFO system can not withstand a single memory latency event greater than the time it takes to fill or empty a TXCELLTHRESH number of internal 64-byte FIFO cells.

For 100 Mbps operation, these restrictions translate into the following rules:

- The short-term average, each 64-byte memory read/write request from the EMAC must be serviced in no more than 5.12 µs.
- Any single latency event in request servicing can be no longer than (5.12 × TXCELLTHRESH) µs.

Bits 0-2 of the second chip-level master priority register (MSTPRI1) are used to set the transfer node priority within the Switched Central Resource (SCR5) for the EMAC master peripheral.

A value of 000b has the highest priority, while 111b has the lowest priority. The default priority assigned to the EMAC is 100b. It is important to have a balance between all peripherals. In most cases, the default priorities will not need adjustment. For more information on the master peripherals priorities, see the device-specific data manual.

6.2.14 Reset Considerations

6.2.14.1 Software Reset Considerations

Peripheral clock and reset control is done through the PRCM module included with the device. For more on how the EMAC, MDIO, and EMAC control module are disabled or placed in reset at runtime from the registers located in the PRCM module, see Section 14.2.13.

NOTE: For proper operation, both the EMAC and EMAC control module must be reset in the following sequence. First, the soft reset of the EMAC module should be commanded. After the reset takes effect (verified by reading back SOFTRESET), the soft reset of the EMAC control module should be commanded.

Within the peripheral there are two controls to separately reset the EMAC and the EMAC control module.

- The EMAC component of the Ethernet MAC peripheral can be placed in a reset state by writing to the soft reset register (SOFTRESET). Writing a 1 to the SOFTRESET bit, causes the EMAC logic to be reset and the register values to be set to their default values. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the configuration bus; it is the responsibility of the software to verify that there are no pending frames to be transferred. After writing a 1 to the SOFTRESET bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred; if a 0 is read, then a reset has occurred.
- The Software Reset Register (SOFT_RESET) is used to place the EMAC control module logic in soft reset. This resets the control logic, the EMAC registers, as well as, the EMAC control module 8KB internal memory that may be used for storing the transfer descriptors.

After a software reset operation, all the EMAC registers need to be reinitialized for proper data transmission.

Unlike the EMAC module, the MDIO and EMAC control modules cannot be placed in reset from a register inside their memory map.

6.2.14.2 Hardware Reset Considerations

When a hardware reset occurs, the EMAC peripheral has its register values reset and all the components return to their default state. After the hardware reset, the EMAC needs to be initialized before being able to resume its data transmission, as described in Section 6.2.15.

A hardware reset is the only means of recovering from the error interrupts (HOSTPEND), which are triggered by errors in packet buffer descriptors. Before doing a hardware reset, you should inspect the error codes in the MAC status register (MACSTATUS) that gives information about the type of software error that needs to be corrected. For detailed information on error interrupts, see Section 6.2.16.1.5.

6.2.15 Initialization

6.2.15.1 Enabling the EMAC/MDIO Peripheral

When the device is powered on, the EMAC peripheral is in a disabled state. Before any EMAC specific initialization can take place, the EMAC needs to be enabled; otherwise, its registers cannot be written and the reads will all return a value of zero.

The EMAC/MDIO is enabled through the PRCM registers. For information on how to enable the EMAC peripheral from the PRCM, see the PRCM Reference Guide.

When first enabled, the EMAC peripheral registers are set to their default values. After enabling the peripheral, you may proceed with the module specific initialization.

6.2.15.2 EMAC Control Module Initialization

The EMAC control module is used for global interrupt enable, and to pace back-to-back interrupts using an interrupt retrigger count based on the peripheral clock (SYSCLK5). There is also an 8K block of RAM local to the EMAC that is used to hold packet buffer descriptors.

Note that although the EMAC control module and the EMAC module have slightly different functions, in practice, the type of maintenance performed on the EMAC control module is more commonly conducted from the EMAC module software (as opposed to the MDIO module).

The initialization of the EMAC control module consists of two parts:

1. Configuration of the interrupt to the CPU.
2. Initialization of the EMAC control module:
   - Setting the registers related to interrupt pacing. This applies only to RXPulse and TXPulse interrupts. By default, interrupts pacing is disabled. If pacing is enabled by programming the EMAC control module interrupt control register (CMINTCTRL), then the CMTXINTMAX and CMRXINTMAX registers have to be programmed, to indicate the maximum number of TX_PULSE and RX_PULSE interrupts per millisecond.
   - Initializing the EMAC and MDIO modules.
   - Enabling interrupts in the EMAC control module using the EMAC control module interrupt control registers (CMRXTHRESHINTEN, CMRXINTEN, CMTXINTEN, and CMMISCINTEN).

When using the register-level CSL, the code to perform the actions associated with the second part may appear as in Example 6-4.

The process of mapping the EMAC interrupts to one of the CPU's interrupts is done using the ARM interrupt controller. Once the interrupt is mapped to a CPU interrupt, general masking and unmasking of the interrupt (to control reentrancy) should be done at the chip level by manipulating the interrupt enable mask.

Example 6-4. EMAC Control Module Initialization Code

```
Uint32 tmpval ;

/* Disable all the EMAC/MDIO interrupts in the control module */
EmacControlRegs->CONTROL.CMRXINTEN        = 0;
EmacControlRegs->CONTROL.C_TX_EN        = 0;
EmacControlRegs->CONTROL.CMRXTHRESHINTEN = 0;
EmacControlRegs->CONTROL.C_MISC_EN      = 0;

/* Wait about 100 cycles */
for( I=0; i<5; I++ )
  tmpval = ECTL_REGS->EWCTL ;

#ifdef INTT_PACING
/* Set the control related to pacing of TX and RX interrupts */
    EmacControlRegs->INTR_COUNT->C_RX_IMAX = 0x4; // 4 RX intt/ms
    EmacControlRegs->INTR_COUNT->C_TX_IMAX = 0x4; // 4 TX intt/ms
    EmacControlRegs->CMINTCTRL = 0x30000; //bit16,bit17 for enabling TX and Rx intt pacing.
    EmacControlRegs->CMINTCTRL |= 0x258; // 600 clocks of 150MHz in 4us time
#endif

/* Initialize MDIO and EMAC Module */
[Discussed later in this document]

/* Enable all the EMAC/MDIO interrupts in the control module */
EmacControlRegs->CONTROL.CMRXINTEN        = 0xff;
EmacControlRegs->CONTROL.C_TX_EN        = 0xff;
EmacControlRegs->CONTROL.CMRXTHRESHINTEN = 0xff;
EmacControlRegs->CONTROL.C_MISC_EN      = 0xf;
```

6.2.15.3 MDIO Module Initialization

The MDIO module is used to initially configure and monitor one or more external PHY devices. Other than initializing the software state machine (details on this state machine can be found in the IEEE 802.3 standard), all that needs to be done for the MDIO module is to enable the MDIO engine and to configure the clock divider. To set the clock divider, supply an MDIO clock of 1 MHz. For example, since the base clock used is the peripheral clock (SYSCLK5), for a SYSCLK5 at a frequency of 250 MHz the divider can be set to 99, with slower MDIO clocks for slower peripheral clock frequencies being perfectly acceptable.

Both the state machine enable and the MDIO clock divider are controlled through the MDIO control register (CONTROL). If none of the potentially connected PHYs require the access preamble, the PREAMBLE bit in CONTROL can also be set to speed up PHY register access. The code for this may appear as in Example 6-5.

Example 6-5. MDIO Module Initialization Code

```
#define PCLK 99
 ...
 /* Enable MDIO and setup divider */
 MDIO_REGS->CONTROL = CSL_FMKT( MDIO_CONTROL_ENABLE, YES) |
 CSL_FMK( MDIO_CONTROL_CLKDIV, PCLK ) ;
```

If the MDIO module is to operate on an interrupt basis, the interrupts can be enabled at this time using the MDIO user command complete interrupt mask set register (USERINTMASKSET) for register access and the MDIO user PHY select register (USERPHYSEL*n*) if a target PHY is already known.

Once the MDIO state machine has been initialized and enabled, it starts polling all 32 PHY addresses on the MDIO bus, looking for an active PHY. Since it can take up to 50 µs to read one register, it can be some time before the MDIO module provides an accurate representation of whether a PHY is available. Also, a PHY can take up to 3 seconds to negotiate a link. Thus, it is advisable to run the MDIO software off a time-based event rather than polling.

For more information on PHY control registers, see your PHY device documentation.

6.2.15.4 EMAC Module Initialization

The EMAC module is used to send and receive data packets over the network. This is done by maintaining up to eight transmit and receive descriptor queues. The EMAC module configuration must also be kept up-to-date based on PHY negotiation results returned from the MDIO module. Most of the work in developing an application or device driver for Ethernet is programming this module.

The following is the initialization procedure a device driver would follow to get the EMAC to the state where it is ready to receive and send Ethernet packets. Some of these steps are not necessary when performed immediately after device reset.

1. Program the VDD3P3V_PWDN register in the System module to power up the CPGMAC I/O cells (see the device-specific data manual). There are separate controls for MII I/O pins and GMII I/O pins, which are powered down by default at system reset, to save power.
2. If enabled, clear the device interrupt enable in the EMAC control module interrupt control registers (CMRXTHRESHINTEN, CMRXINTEN, CMTXINTEN, and CMMISCINTEN).
3. Clear the MAC control register (MACCONTROL), receive control register (RXCONTROL), and transmit control register (TXCONTROL) (not necessary immediately after reset).
4. Initialize all 16 header descriptor pointer registers (RX*n*HDP and TX*n*HDP) to 0.
5. Clear all 36 statistics registers by writing 0 (not necessary immediately after reset).
6. Setup the local Ethernet MAC address by programming the MAC index register (MACINDEX), MAC address high bytes register (MACADDRHI), and MAC address low bytes register (MACADDRLO). Be sure to program all eight MAC addresses - whether the receive channel is to be enabled or not. Duplicate the same MAC address across all unused channels. When using more than one receive channel, start with channel 0 and progress upwards.
7. Initialize the receive channel *n* free buffer count registers (RX*n*FREEBUFFER), receive channel *n* flow control threshold register (RX*n*FLOWTHRESH), and receive filter low priority frame threshold register (RXFILTERLOWTHRESH), if buffer flow control is to be enabled.
8. Most device drivers open with no multicast addresses, so clear the MAC address hash registers (MACHASH1 and MACHASH2) to 0.
9. Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
10. Initially clear all unicast channels by writing FFh to the receive unicast clear register (RXUNICASTCLEAR). If unicast is desired, it can be enabled now by writing the receive unicast set register (RXUNICASTSET). Some drivers will default to unicast on device open while others will not.
11. Setup the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) with an initial configuration. The configuration is based on the current receive filter settings of the device driver. Some drivers may enable things like broadcast and multicast packets immediately, while others may not.
12. Set the appropriate configuration bits in MACCONTROL (do not set the GMIIEN bit yet).
13. Clear all unused channel interrupt bits by writing the receive interrupt mask clear register (RXINTMASKCLEAR) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
14. Enable the receive and transmit channel interrupt bits in the receive interrupt mask set register (RXINTMASKSET) and the transmit interrupt mask set register (TXINTMASKSET) for the channels to be used, and enable the HOSTMASK and STATMASK bits using the MAC interrupt mask set register (MACINTMASKSET).
15. Initialize the receive and transmit descriptor list queues.
16. Prepare receive by writing a pointer to the head of the receive buffer descriptor list to RX*n*HDP.
17. Enable the receive and transmit DMA controllers by setting the RXEN bit in RXCONTROL and the TXEN bit in TXCONTROL. Then set the GMIIEN bit in MACCONTROL.
18. Enable the device interrupt in the EMAC control module interrupt control registers (CMRXTHRESHINTEN, CMRXINTEN, CMTXINTEN, and CMMISCINTEN).

6.2.16 Interrupt Support

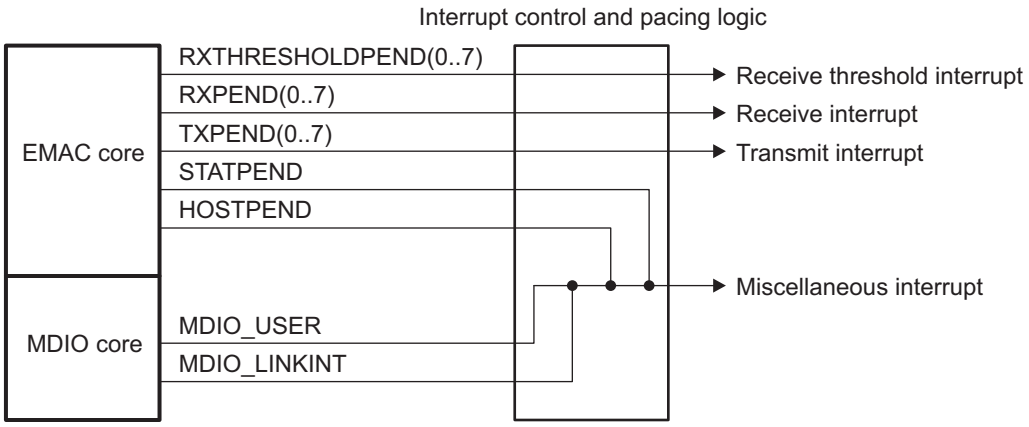
6.2.16.1 EMAC Module Interrupt Events and Requests

The EMAC module generates the following interrupt events:

- RXTHRESHOLDPEND*n*: Receive threshold interrupt for receive channels 0 through 7
- RXPEND*n*: Receive packet completion interrupt for receive channels 0 through 7
- TXPEND*n*: Transmit packet completion interrupt for transmit channels 0 through 7
- STATPEND: Statistics interrupt
- HOSTPEND: Host error interrupt
- USERINT: MDIO user Interrupt
- LINKINT: MDIO link Interrupt

As shown in Figure 6-11, the EMAC and MDIO interrupts are multiplexed on four interrupts lines going to the CPU.

Figure 6-11. EMAC Control Module Interrupt Logic Diagram



6.2.16.1.1 Receive Threshold Interrupts

Each of the eight receive channels have a corresponding receive threshold interrupt (RX_THRESH_PEND[0:7]). The receive threshold interrupts are level interrupts that remain asserted until the triggering condition is cleared by the host. Each of the eight threshold interrupts may be individually enabled by setting the corresponding bit in the receive interrupt mask set register (RXINTMASKSET) to 1. Each of the eight channel interrupts may be individually disabled by clearing the corresponding bit in the receive interrupt mask clear register (RXINTMASKCLEAR) to 0. The raw and masked receive interrupt status may be read from the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively. An RX_THRES_PEND[7:0] interrupt bit is asserted when enabled and when the channel's associated receive channel *n* free buffer count register (RX*n*FREEBUFFER) is less than or equal to the channel's associated receive channel *n* flow control threshold register (RX*n*FLOWTHRESH). The receive threshold interrupts use the same free buffer count and threshold logic as does flow control, but the interrupts are independently enabled from flow control. The threshold interrupts are intended to give the host an indication that resources are running low for a particular channel(s).

6.2.16.1.2 Transmit Packet Completion Interrupts

The transmit DMA engine has eight channels, with each channel having a corresponding interrupt (TXPEND*n*). The transmit interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight transmit channel interrupts may be individually enabled by setting the corresponding bit in the transmit interrupt mask set register (TXINTMASKSET) to 1. Each of the eight transmit channel interrupts may be individually disabled by clearing the corresponding bit in the transmit interrupt mask clear register (TXINTMASKCLEAR) to 0. The raw and masked transmit interrupt status may be read from the transmit interrupt status (unmasked) register (TXINTSTATRAW) and the transmit interrupt status (masked) register (TXINTSTATMASKED), respectively.

When the EMAC completes the transmission of a packet, the EMAC issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges an interrupt by writing the address of the last buffer descriptor processed to the queue's associated transmit completion pointer in the transmit DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC port (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has transmitted more packets than the CPU has processed interrupts for), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has transferred), the pending interrupt is cleared. The value that the EMAC is expecting is found by reading the transmit channel *n* completion pointer register (TX*n*CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

6.2.16.1.3 Receive Packet Completion Interrupts

The receive DMA engine has eight channels, which each channel having a corresponding interrupt (RXPEND*n*). The receive interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight receive channel interrupts may be individually enabled by setting the corresponding bit in the receive interrupt mask set register (RXINTMASKSET) to 1. Each of the eight receive channel interrupts may be individually disabled by clearing the corresponding bit in the receive interrupt mask clear register (RXINTMASKCLEAR) to 0. The raw and masked receive interrupt status may be read from the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively.

When the EMAC completes a packet reception, the EMAC issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer in the receive DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has received more packets than the CPU has processed interrupts for), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has received), the pending interrupt is de-asserted. The value that the EMAC is expecting is found by reading the receive channel *n* completion pointer register (RX*n*CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

6.2.16.1.4 Statistics Interrupt

The statistics level interrupt (STATPEND) is issued when any statistics value is greater than or equal to 8000 0000h, if enabled by setting the STATMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. As long as the most-significant bit of any statistics value is set, the interrupt remains asserted.

6.2.16.1.5 Host Error Interrupt

The host error interrupt (HOSTPEND) is issued, if enabled, under error conditions dealing with the handling of buffer descriptors, detected during transmit or receive DMA transactions. The failure of the software application to supply properly formatted buffer descriptors results in this error. The error bit can only be cleared by resetting the EMAC module in hardware.

The host error interrupt is enabled by setting the HOSTMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The host error interrupt is disabled by clearing the appropriate bit in the MAC interrupt mask clear register (MACINTMASKCLEAR) to 0. The raw and masked host error interrupt status may be read by reading the MAC interrupt status (unmasked) register (MACINTSTATRAW) and the MAC interrupt status (masked) register (MACINTSTATMASKED), respectively.

The transmit host error conditions are:

- SOP error
- Ownership bit not set in SOP buffer
- Zero next buffer descriptor pointer with EOP
- Zero buffer pointer
- Zero buffer length
- Packet length error

The receive host error conditions are:

- Ownership bit not set in input buffer
- Zero buffer pointer

6.2.16.2 MDIO Module Interrupt Events and Requests

The MDIO module generates two interrupt events:

- LINKINT: Serial interface link change interrupt. Indicates a change in the state of the PHY link
- USERINT: Serial interface user command event complete interrupt

6.2.16.2.1 Link Change Interrupt

The MDIO module asserts a link change interrupt (LINKINT) if there is a change in the link state of the PHY corresponding to the address in the PHYADRMON bit in the MDIO user PHY select register *n* (USERPHYSEL*n*), and if the LINKINTENB bit is also set in USERPHYSEL*n*. This interrupt event is also captured in the LINKINTRAW bit in the MDIO link status change interrupt register (LINKINTRAW). LINKINTRAW bits 0 and 1 correspond to USERPHYSEL0 and USERPHYSEL1, respectively.

When the interrupt is enabled and generated, the corresponding LINKINTMASKED bit is also set in the MDIO link status change interrupt register (LINKINTMASKED). The interrupt is cleared by writing back the same bit to LINKINTMASKED (write to clear).

6.2.16.2.2 User Access Completion Interrupt

When the GO bit in one of the MDIO user access registers (USERACCESS*n*) transitions from 1 to 0 (indicating completion of a user access) and the corresponding USERINTMASKSET bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) corresponding to USERACCESS0 or USERACCESS1 is set, a user access completion interrupt (USERINT) is asserted. This interrupt event is also captured in the USERINTRAW bit in the MDIO user command complete interrupt register (USERINTRAW). USERINTRAW bits 0 and bit 1 correspond to USERACCESS0 and USERACCESS1, respectively.

When the interrupt is enabled and generated, the corresponding USERINTMASKED bit is also set in the MDIO user command complete interrupt register (USERINTMASKED). The interrupt is cleared by writing back the same bit to USERINTMASKED (write to clear).

6.2.16.3 Proper Interrupt Processing

All the interrupts signaled from the EMAC and MDIO modules are level driven, so if they remain active, their level remains constant; the CPU core requires edge-triggered interrupts. In order to properly convert the level-driven interrupt signal to an edge-triggered signal, the application software must make use of the interrupt control logic contained in the EMAC control module.

Section 6.2.6.3 discusses the interrupt control contained in the EMAC control module. For safe interrupt processing, upon entry to the ISR, the software application should disable interrupts using the EMAC control module interrupt control registers (CMRXTHRESHINTEN, CMRXINTEN, CMTXINTEN, and CMMISCINTEN), and then reenable them upon leaving the ISR. If any interrupt signals are active at that time, this creates another rising edge on the interrupt signal going to the CPU interrupt controller, thus triggering another interrupt. The EMAC control module also implements the optional interrupt pacing.

6.2.16.4 Interrupt Multiplexing

TThe EMAC control module combines all the different interrupt signals from both the EMAC and MDIO modules and generates four separate interrupt signals (Table 6-5) that are routed to the host processor(s).

Once this interrupt is generated, the reason for the interrupt can be read from the MAC input vector register (MACINVECTOR) located in the EMAC memory map. MACINVECTOR combines the status of the following 28 interrupt signals: TXPEND*n*, RXPEND*n*, RXTHRESHPEND*n*, STATPEND, HOSTPEND, LINKINT, and USERINT.

For more details on the ARM interrupt controller (AINTC), see the SoC Subsystem Reference Guide.

6.2.17 Power Management

Each of the three main components of the EMAC peripheral can independently be placed in reduced-power modes to conserve power during periods of low activity. The power management of the EMAC peripheral is controlled by the PRCM. The PRCM acts as a master controller for power management on behalf of all of the peripherals on the device.

The power conservation modes available for each of the three components of the EMAC/MDIO peripheral are:

- *Idle/Disabled state*. This mode stops the clocks going to the peripheral, and prevents all the register accesses. After reenabling the peripheral from this idle state, all the registers values prior to setting into the disabled state are restored, and data transmission can proceed. No reinitialization is required.
- *Synchronized reset.* This state is similar to the Power-on Reset (POR) state, when the processor is turned-on; reset to the peripheral is asserted, and clocks to the peripheral are gated after that. The registers are reset to their default value. When powering-up after a synchronized reset, all the EMAC submodules need to be reinitialized before any data transmission can happen.

For more information on the use of the PRCM, see the PRCM Reference Guide.

6.2.18 Emulation Considerations

NOTE: For correct operation, the EMAC and EMAC control module must both be suspended. Thus, the EMCONTROL and CMEMCONTROL registers must be configured alike.

EMAC emulation control is implemented for compatibility with other peripherals. The SOFT and FREE bits in the emulation control register (EMCONTROL) allow EMAC operation to be suspended. Additionally, emulation control is also implemented in the EMAC control module with the EMAC control module emulation control register (CMEMCONTROL) to allow the EMAC control module activity to be suspended.

When the emulation suspend state is entered, the EMAC stops processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission is completed normally without suspension. For transmission, any complete or partial frame in the transmit cell FIFO is transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics are kept for ignored frames.

Table 6-8 shows how the SOFT and FREE bits affect the operation of the emulation suspend.

Table 6-8. Emulation Control

SOFT	FREE	Description
0	0	Normal operation
1	0	Emulation suspend
X	1	Normal operation

6.3 EMAC/MDIO Registers

Table 6-9 shows the base address offset for the EMAC/MDIO module.

Table 6-9. EMAC/MDIO Registers

Description	Base Address Offset	Section
EMAC control module	0000 0900h	Section 6.3.1

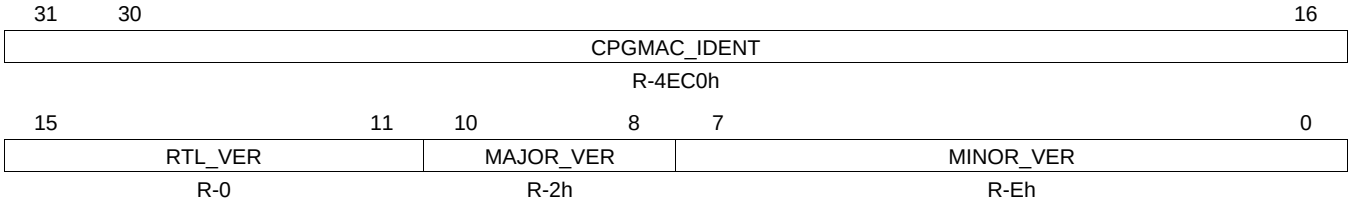
6.3.2.1 Identification and Version Register (CPGMACIDVER)

The identification and version register (CPGMACIDVER) is shown in Figure 6-26 and described in Table 6-26.

Figure 6-26. Identification and Version Register (CPGMACIDVER)



LEGEND: R = Read only; -*n* = value after reset

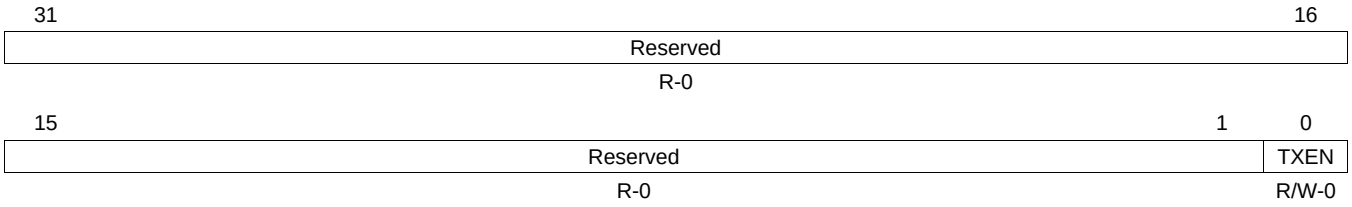
Table 6-26. Identification and Version Register (CPGMACIDVER) Field Descriptions

Bit	Field	Value	Description
31-16	CPGMAC_IDENT		Identification value.
		4EC0h	Current identification value.
15-11	RTL_VER		RTL version value.
		0	Current RTL version value.
10-8	MAJOR_VER		Major version value. Revisions are indicated by a revision code taking the format MAJOR_VER.MINOR_VER.
		2h	Current major version value.
7-0	MINOR_VER		Minor version value. Revisions are indicated by a revision code taking the format MAJOR_VER.MINOR_VER.
		Eh	Current minor version value.

6.3.2.2 Transmit Control Register (TXCONTROL)

The transmit control register (TXCONTROL) is shown in Figure 6-27 and described in Table 6-27.

Figure 6-27. Transmit Control Register (TXCONTROL)



LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 6-27. Transmit Control Register (TXCONTROL) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	TXEN		Transmit enable
		0	Transmit is disabled.
		1	Transmit is enabled.

6.3.2.3 Transmit Teardown Register (TXTEARDOWN)

The transmit teardown register (TXTEARDOWN) is shown in Figure 6-28 and described in Table 6-28.

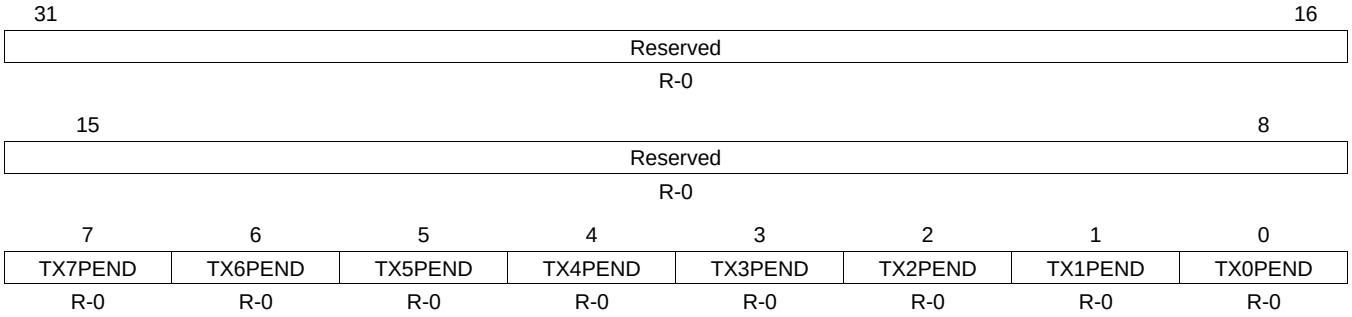
3	TX3PEND	0-1	TX3PEND raw interrupt read (before mask)
2	TX2PEND	0-1	TX2PEND raw interrupt read (before mask)
1	TX1PEND	0-1	TX1PEND raw interrupt read (before mask)
0	TX0PEND	0-1	TX0PEND raw interrupt read (before mask)

6.3.2.7 Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED)

The transmit interrupt status (masked) register (TXINTSTATMASKED) is shown in Figure 6-32 and described in Table 6-32.

Figure 6-32. Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED)



LEGEND: R = Read only; -*n* = value after reset

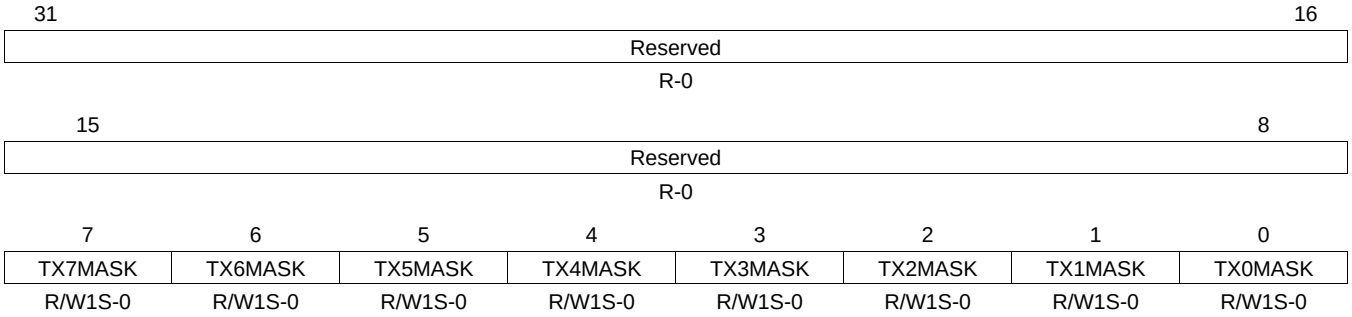
Table 6-32. Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	TX7PEND	0-1	TX7PEND masked interrupt read
6	TX6PEND	0-1	TX6PEND masked interrupt read
5	TX5PEND	0-1	TX5PEND masked interrupt read
4	TX4PEND	0-1	TX4PEND masked interrupt read
3	TX3PEND	0-1	TX3PEND masked interrupt read
2	TX2PEND	0-1	TX2PEND masked interrupt read
1	TX1PEND	0-1	TX1PEND masked interrupt read
0	TX0PEND	0-1	TX0PEND masked interrupt read

6.3.2.8 Transmit Interrupt Mask Set Register (TXINTMASKSET)

The transmit interrupt mask set register (TXINTMASKSET) is shown in Figure 6-33 and described in Table 6-33.

Figure 6-33. Transmit Interrupt Mask Set Register (TXINTMASKSET)



LEGEND: R = Read only; R/W = Read/Write; W1S = Write 1 to set, write of 0 has no effect; -*n* = value after reset

Table 6-33. Transmit Interrupt Mask Set Register (TXINTMASKSET) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	TX7MASK	0-1	Transmit channel 7 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect.
6	TX6MASK	0-1	Transmit channel 6 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect.
5	TX5MASK	0-1	Transmit channel 5 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect.
4	TX4MASK	0-1	Transmit channel 4 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect.
3	TX3MASK	0-1	Transmit channel 3 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect.
2	TX2MASK	0-1	Transmit channel 2 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect.
1	TX1MASK	0-1	Transmit channel 1 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect.
0	TX0MASK	0-1	Transmit channel 0 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect.

6.3.2.9 Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR)

The transmit interrupt mask clear register (TXINTMASKCLEAR) is shown in Figure 6-34 and described in Table 6-34.

Figure 6-34. Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR)

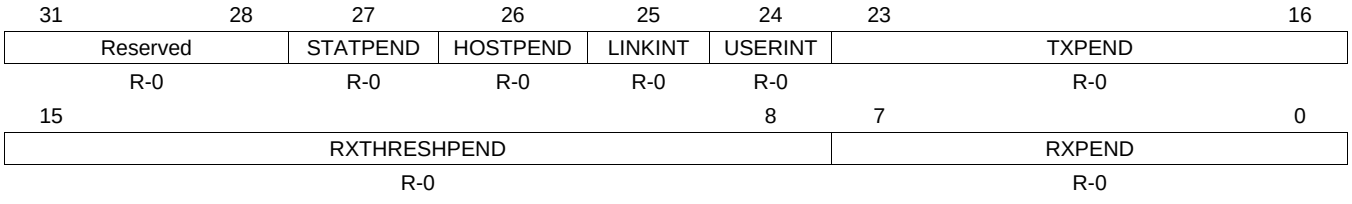
5	TX5MASK	0-1	Transmit channel 5 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect.
4	TX4MASK	0-1	Transmit channel 4 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect.
3	TX3MASK	0-1	Transmit channel 3 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect.
2	TX2MASK	0-1	Transmit channel 2 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect.
1	TX1MASK	0-1	Transmit channel 1 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect.
0	TX0MASK	0-1	Transmit channel 0 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect.

6.3.2.10 MAC Input Vector Register (MACINVECTOR)

The MAC input vector register (MACINVECTOR) is shown in Figure 6-35 and described in Table 6-35.

Figure 6-35. MAC Input Vector Register (MACINVECTOR)



LEGEND: R = Read only; -*n* = value after reset

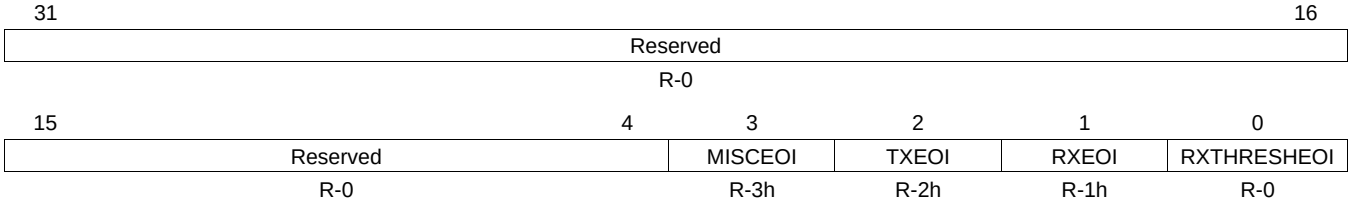
Table 6-35. MAC Input Vector Register (MACINVECTOR) Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Reserved
27	STATPEND	0-1	EMAC module statistics interrupt (STATPEND) pending status bit.
26	HOSTPEND	0-1	EMAC module host error interrupt (HOSTPEND) pending status bit.
25	LINKINT	0-1	MDIO module link change interrupt (LINKINT) pending status bit.
24	USERINT	0-1	MDIO module user interrupt (USERINT) pending status bit.
23-16	TXPEND	0-FFh	Transmit channels 0-7 interrupt pending (TXPEND*n*) status bit. Bit 16 is transmit channel 0.
15-8	RXTHRESHPEND	0-FFh	Receive threshold channels 0-7 interrupt pending (RXTHRESHPEND*n*) status bit. Bit 8 is receive channel 0.
7-0	RXPEND	0-FFh	Receive channels 0-7 interrupt pending (RXPEND*n*) status bit. Bit 0 is receive channel 0.

6.3.2.11 MAC End Of Interrupt Vector Register (MACEOIVECTOR)

The MAC end of interrupt vector register (MACEOIVECTOR) is shown in Figure 6-36 and described in Table 6-36.

Figure 6-36. MAC End Of Interrupt Vector Register (MACEOIVECTOR)



LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

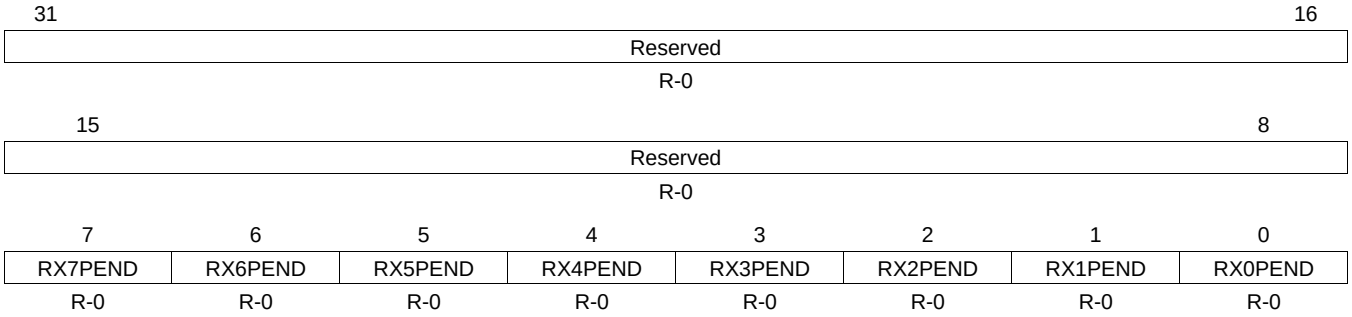
Table 6-36. MAC End Of Interrupt Vector Register (MACEOIVECTOR) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	MISCEOI	3h	End of interrupt processing for Miscellaneous interrupt.
2	TXEOI	2h	End of interrupt processing for TXPULSE interrupt.
1	RXEOI	1h	End of interrupt processing for RXPULSE interrupt.
0	RXTHRESHEOI	0	End of interrupt processing for RXTHRESH interrupt.

6.3.2.12 Receive Interrupt Status (Unmasked) Register (RXINTSTATRAW)

The receive interrupt status (unmasked) register (RXINTSTATRAW) is shown in Figure 6-37 and described in Table 6-37.

Figure 6-37. Receive Interrupt Status (Unmasked) Register (RXINTSTATRAW)



LEGEND: R = Read only; -*n* = value after reset

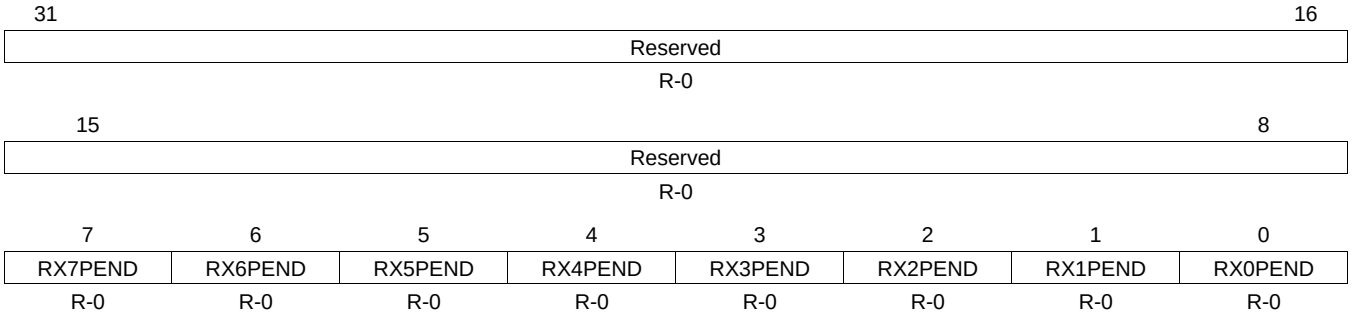
Table 6-37. Receive Interrupt Status (Unmasked) Register (RXINTSTATRAW) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	RX7PEND	0-1	RX7PEND raw interrupt read (before mask)
6	RX6PEND	0-1	RX6PEND raw interrupt read (before mask)
5	RX5PEND	0-1	RX5PEND raw interrupt read (before mask)
4	RX4PEND	0-1	RX4PEND raw interrupt read (before mask)
3	RX3PEND	0-1	RX3PEND raw interrupt read (before mask)
2	RX2PEND	0-1	RX2PEND raw interrupt read (before mask)
1	RX1PEND	0-1	RX1PEND raw interrupt read (before mask)
0	RX0PEND	0-1	RX0PEND raw interrupt read (before mask)

6.3.2.13 Receive Interrupt Status (Masked) Register (RXINTSTATMASKED)

The receive interrupt status (masked) register (RXINTSTATMASKED) is shown in Figure 6-38 and described in Table 6-38.

Figure 6-38. Receive Interrupt Status (Masked) Register (RXINTSTATMASKED)



LEGEND: R = Read only; -*n* = value after reset

Table 6-38. Receive Interrupt Status (Masked) Register (RXINTSTATMASKED) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	RX7PEND	0-1	RX7PEND masked interrupt read
6	RX6PEND	0-1	RX6PEND masked interrupt read
5	RX5PEND	0-1	RX5PEND masked interrupt read
4	RX4PEND	0-1	RX4PEND masked interrupt read
3	RX3PEND	0-1	RX3PEND masked interrupt read
2	RX2PEND	0-1	RX2PEND masked interrupt read
1	RX1PEND	0-1	RX1PEND masked interrupt read
0	RX0PEND	0-1	RX0PEND masked interrupt read

6.3.2.14 Receive Interrupt Mask Set Register (RXINTMASKSET)

The receive interrupt mask set register (RXINTMASKSET) is shown in Figure 6-39 and described in Table 6-39.

Figure 6-39. Receive Interrupt Mask Set Register (RXINTMASKSET)

LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 6-45. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved
30	RXPASSCRC		Pass receive CRC enable bit
		0	Received CRC is discarded for all channels and is not included in the buffer descriptor packet length field.
		1	Received CRC is transferred to memory for all channels and is included in the buffer descriptor packet length.
29	RXQOSEN		Receive quality of service enable bit
		0	Receive QOS is disabled.
		1	Receive QOS is enabled.
28	RXNOCHAIN		Receive no buffer chaining bit
		0	Received frames can span multiple buffers.
		1	The Receive DMA controller transfers each frame into a single buffer, regardless of the frame or buffer size. All remaining frame data after the first buffer is discarded. The buffer descriptor buffer length field will contain the entire frame byte count (up to 65535 bytes).
27-25	Reserved	0	Reserved
24	RXCMFEN		Receive copy MAC control frames enable bit. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in MACCONTROL, regardless of the value of RXCMFEN. Frames transferred to memory due to RXCMFEN will have the CONTROL bit set in their EOP buffer descriptor.
		0	MAC control frames are filtered (but acted upon if enabled).
		1	MAC control frames are transferred to memory.
23	RXCSFEN		Receive copy short frames enable bit. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RXCSFEN will have the FRAGMENT or UNDERSIZE bit set in their EOP buffer descriptor. Fragments are short frames that contain CRC / align / code errors and undersized are short frames without errors.
		0	Short frames are filtered.
		1	Short frames are transferred to memory.

Table 6-45. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) Field Descriptions (continued)

Bit	Field	Value	Description
22	RXCEFEN		Receive copy error frames enable bit. Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame EOP buffer descriptor.
		0	Frames containing errors are filtered.
		1	Frames containing errors are transferred to memory.
21	RXCAFEN		Receive copy all frames enable bit. Enables frames that do not address match (includes multicast frames that do not hash match) to be transferred to the promiscuous channel selected by RXPROMCH bits. Such frames will be marked with the NOMATCH bit in their EOP buffer descriptor.
		0	Frames that do not address match are filtered.
		1	Frames that do not address match are transferred to the promiscuous channel selected by RXPROMCH bits.
20-19	Reserved	0	Reserved
18-16	RXPROMCH	0-7h	Receive promiscuous channel select
		0	Select channel 0 to receive promiscuous frames
		1h	Select channel 1 to receive promiscuous frames
		2h	Select channel 2 to receive promiscuous frames
		3h	Select channel 3 to receive promiscuous frames
		4h	Select channel 4 to receive promiscuous frames
		5h	Select channel 5 to receive promiscuous frames
		6h	Select channel 6 to receive promiscuous frames
		7h	Select channel 7 to receive promiscuous frames
15-14	Reserved	0	Reserved
13	RXBROADEN		Receive broadcast enable. Enable received broadcast frames to be copied to the channel selected by RXBROADCH bits.
		0	Broadcast frames are filtered.
		1	Broadcast frames are copied to the channel selected by RXBROADCH bits.
12-11	Reserved	0	Reserved
10-8	RXBROADCH	0-7h	Receive broadcast channel select
		0	Select channel 0 to receive broadcast frames
		1h	Select channel 1 to receive broadcast frames
		2h	Select channel 2 to receive broadcast frames
		3h	Select channel 3 to receive broadcast frames
		4h	Select channel 4 to receive broadcast frames
		5h	Select channel 5 to receive broadcast frames
		6h	Select channel 6 to receive broadcast frames
		7h	Select channel 7 to receive broadcast frames
7-6	Reserved	0	Reserved
5	RXMULTEN		RX multicast enable. Enable received hash matching multicast frames to be copied to the channel selected by RXMULTCH bits.
		0	Multicast frames are filtered.
		1	Multicast frames are copied to the channel selected by RXMULTCH bits.
4-3	Reserved	0	Reserved

Table 6-45. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) Field Descriptions (continued)

Bit	Field	Value	Description
2-0	RXMULTCH	0-7h	Receive multicast channel select
		0	Select channel 0 to receive multicast frames
		1h	Select channel 1 to receive multicast frames
		2h	Select channel 2 to receive multicast frames
		3h	Select channel 3 to receive multicast frames
		4h	Select channel 4 to receive multicast frames
		5h	Select channel 5 to receive multicast frames
		6h	Select channel 6 to receive multicast frames
		7h	Select channel 7 to receive multicast frames

6.3.2.21 Receive Unicast Enable Set Register (RXUNICASTSET)

The receive unicast enable set register (RXUNICASTSET) is shown in Figure 6-46 and described in Table 6-46.

Figure 6-46. Receive Unicast Enable Set Register (RXUNICASTSET)

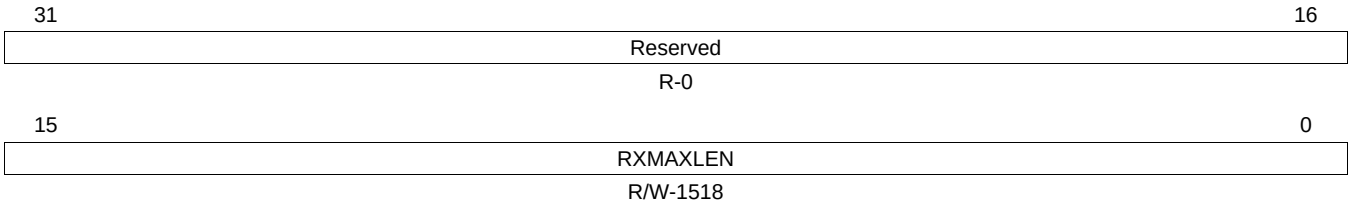
0	RXCH0EN	0-1	Receive channel 0 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect.

6.3.2.23 Receive Maximum Length Register (RXMAXLEN)

The receive maximum length register (RXMAXLEN) is shown in Figure 6-48 and described in Table 6-48.

Figure 6-48. Receive Maximum Length Register (RXMAXLEN)



LEGEND: R = Read only; R/W = Read/Write; *-n* = value after reset

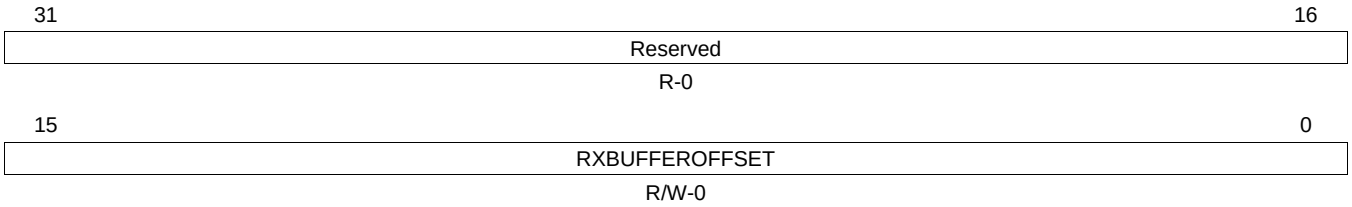
Table 6-48. Receive Maximum Length Register (RXMAXLEN) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	RXMAXLEN	0-FFFFh	Receive maximum frame length. These bits determine the maximum length of a received frame. The reset value is 5EEh (1518). Frames with byte counts greater than RXMAXLEN are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames.

6.3.2.24 Receive Buffer Offset Register (RXBUFFEROFFSET)

The receive buffer offset register (RXBUFFEROFFSET) is shown in Figure 6-49 and described in Table 6-49.

Figure 6-49. Receive Buffer Offset Register (RXBUFFEROFFSET)



LEGEND: R = Read only; R/W = Read/Write; *-n* = value after reset

Table 6-49. Receive Buffer Offset Register (RXBUFFEROFFSET) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	RXBUFFEROFFSET	0-FFFFh	Receive buffer offset value. These bits are written by the EMAC into each frame SOP buffer descriptor Buffer Offset field. The frame data begins after the RXBUFFEROFFSET value of bytes. A value of 0 indicates that there are no unused bytes at the beginning of the data, and that valid data begins on the first byte of the buffer. A value of Fh (15) indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.

6.3.2.25 Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) is shown in Figure 6-50 and described in Table 6-50.

Figure 6-50. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RX*n*FLOWTHRESH	0-FFh	Receive flow threshold. These bits contain the threshold value for issuing flow control on incoming frames for channel *n* (when enabled).

6.3.2.27 Receive Channel 0-7 Free Buffer Count Register (RX*n*FREEBUFFER)

The receive channel 0-7 free buffer count register (RX*n*FREEBUFFER) is shown in Figure 6-52 and described in Table 6-52.

Figure 6-52. Receive Channel *n* Free Buffer Count Register (RX*n*FREEBUFFER)

31	16
Reserved	
R-0	

15	0
RX*n*FREEBUF	
WI-0	

LEGEND: R = Read only; WI = Write to increment; -*n* = value after reset

Table 6-52. Receive Channel *n* Free Buffer Count Register (RX*n*FREEBUFFER) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	RX*n*FREEBUF	0-FFh	Receive free buffer count. These bits contain the count of free buffers available. The RXFILTERTHRESH value is compared with this field to determine if low priority frames should be filtered. The RX*n*FLOWTHRESH value is compared with this field to determine if receive flow control should be issued against incoming packets (if enabled). This is a write-to-increment field. This field rolls over to 0 on overflow. If hardware flow control or QOS is used, the host must initialize this field to the number of available buffers (one register per channel). The EMAC decrements the associated channel register for each received frame by the number of buffers in the received frame. The host must write this field with the number of buffers that have been freed due to host processing.

6.3.2.28 MAC Control Register (MACCONTROL)

The MAC control register (MACCONTROL) is shown in Figure 6-53 and described in Table 6-53.

LEGEND: R = Read only; R/W = Read/Write; *-n* = value after reset

Table 6-53. MAC Control Register (MACCONTROL) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reserved. Any writes to these bit(s) must always have a value of 0.
17	GIGFORCE	0-1	Gigabit force mode. This bit is used to force the EMAC into gigabit mode if the input MTCLK signal has been stopped by the PHY.
16-15	Reserved	0	Reserved. Any writes to these bit(s) must always have a value of 0.
14	RXOFFLENBLOCK		Receive offset/length word write block.
		0	Do not block the DMA writes to the receive buffer descriptor offset/buffer length word.
		1	Block all EMAC DMA controller writes to the receive buffer descriptor offset/buffer length words during packet processing. When this bit is set, the EMAC will never write the third word to any receive buffer descriptor.
13	RXOWNERSHIP		Receive ownership write bit value.
		0	EMAC writes the Receive ownership bit to 0 at the end of packet processing.
		1	EMAC writes the Receive ownership bit to 1 at the end of packet processing. If you do not use the ownership mechanism, you can set this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.
12	RXFIFOFLOWEN		Receive FIFO flow control enable bit.
		0	Receive flow control is disabled. Full-duplex mode: no outgoing pause frames are sent.
		1	Receive flow control is enabled. Full-duplex mode: outgoing pause frames are sent when receive FIFO flow control is triggered.
11	CMDIDLE		Command Idle bit.
		0	Idle is not commanded.
		1	Idle is commanded (read the IDLE bit in the MACSTATUS register).
10	Reserved	0	Any writes to these bit(s) must always have a value of 0.
9	TXPTYPE		Transmit queue priority type.
		0	The queue uses a round-robin scheme to select the next channel for transmission.
		1	The queue uses a fixed-priority (channel 7 is highest priority) scheme to select the next channel for transmission.
8	Reserved	0	Any writes to these bit(s) must always have a value of 0.
7	GIG		Gigabit mode.
		0	Gigabit mode is disabled; 10/100 mode is in operation.
		1	Gigabit mode is enabled (full-duplex only).
6	TXPACE		Transmit pacing enable bit.
		0	Transmit pacing is disabled.
		1	Transmit pacing is enabled.

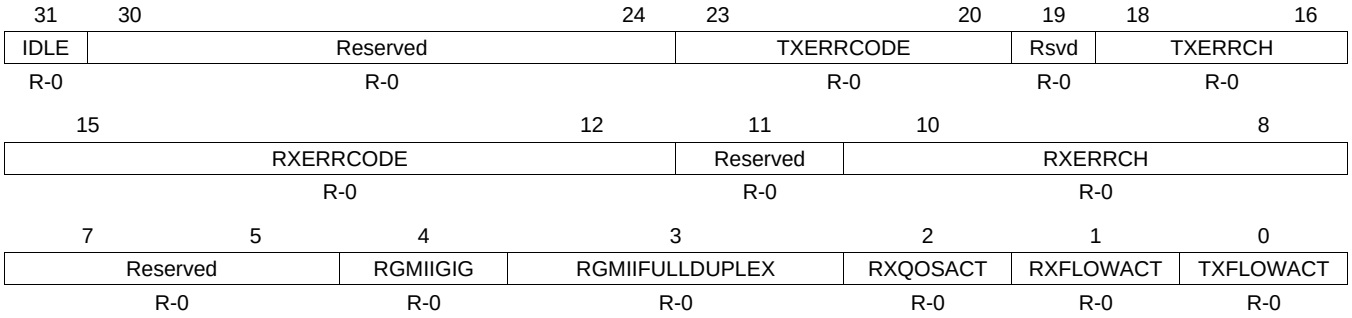
Table 6-53. MAC Control Register (MACCONTROL) Field Descriptions (continued)

Bit	Field	Value	Description
5	GMIIEN		GMII enable bit.
		0	GMII RX and TX are held in reset.
		1	GMII RX and TX are enabled for receive and transmit.
4	TXFLOWEN		Transmit flow control enable bit. This bit determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode, regardless of the TXFLOWEN bit setting. The RXMBPENABLE bits determine whether or not received pause frames are transferred to memory.
		0	Transmit flow control is disabled. Full-duplex mode: incoming pause frames are not acted upon.
		1	Transmit flow control is enabled. Full-duplex mode: incoming pause frames are acted upon.
3	RXBUFFERFLOWEN		Receive buffer flow control enable bit.
		0	Receive flow control is disabled. Half-duplex mode: no flow control generated collisions are sent. Full-duplex mode: no outgoing pause frames are sent.
		1	Receive flow control is enabled. Half-duplex mode: collisions are initiated when receive buffer flow control is triggered. Full-duplex mode: outgoing pause frames are sent when receive flow control is triggered.
2	Reserved	0	Reserved.
1	LOOPBACK		Loopback mode. The loopback mode forces internal full-duplex mode regardless of the FULLDUPLEX bit setting. The loopback bit should be changed only when GMII bit is deasserted.
		0	Loopback mode is disabled.
		1	Loopback mode is enabled.
0	FULLDUPLEX		Full-duplex mode. The gigabit mode (GIG = 1) forces full-duplex mode regardless of the FULLDUPLEX bit setting.
		0	Half-duplex mode is enabled.
		1	Full-duplex mode is enabled.

6.3.2.29 MAC Status Register (MACSTATUS)

The MAC status register (MACSTATUS) is shown in Figure 6-54 and described in Table 6-54.

Figure 6-54. MAC Status Register (MACSTATUS)



LEGEND: R = Read only; R/W = Read/Write; *-n* = value after reset

Table 6-54. MAC Status Register (MACSTATUS) Field Descriptions

Bit	Field	Value	Description
31	IDLE		EMAC idle bit. This bit is set to 0 at reset; one clock after reset it goes to 1.
		0	The EMAC is not idle.
		1	The EMAC is in the idle state.
30-24	Reserved	0	Reserved
23-20	TXERRCODE	0-Fh	Transmit host error code. These bits indicate that EMAC detected transmit DMA related host errors. The host should read this field after a host error interrupt (HOSTPEND) to determine the error. Host error interrupts require hardware reset in order to recover. A 0 packet length is an error, but it is not detected.
		0	No error
		1h	SOP error; the buffer is the first buffer in a packet, but the SOP bit is not set in software.
		2h	Ownership bit not set in SOP buffer
		3h	Zero next buffer descriptor pointer without EOP
		4h	Zero buffer pointer
		5h	Zero buffer length
		6h	Packet length error (sum of buffers is less than packet length)
19	Reserved	0	Reserved
18-16	TXERRCH	0-7h	Transmit host error channel. These bits indicate which transmit channel the host error occurred on. This field is cleared to 0 on a host read.
		0	The host error occurred on transmit channel 0
		1h	The host error occurred on transmit channel 1
		2h	The host error occurred on transmit channel 2
		3h	The host error occurred on transmit channel 3
		4h	The host error occurred on transmit channel 4
		5h	The host error occurred on transmit channel 5
		6h	The host error occurred on transmit channel 6
		7h	The host error occurred on transmit channel 7
15-12	RXERRCODE	0-Fh	Receive host error code. These bits indicate that EMAC detected receive DMA related host errors. The host should read this field after a host error interrupt (HOSTPEND) to determine the error. Host error interrupts require hardware reset in order to recover.
		0	No error
		2h	Ownership bit not set in SOP buffer
		4h	Zero buffer pointer
11	Reserved	0	Reserved

Table 6-54. MAC Status Register (MACSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
10-8	RXERRCH	0-3h	Receive host error channel. These bits indicate which receive channel the host error occurred on. This field is cleared to 0 on a host read.
		0	The host error occurred on receive channel 0
		1h	The host error occurred on receive channel 1
		2h	The host error occurred on receive channel 2
		3h	The host error occurred on receive channel 3
		4h	The host error occurred on receive channel 4
		5h	The host error occurred on receive channel 5
		6h	The host error occurred on receive channel 6
		7h	The host error occurred on receive channel 7
7-5	Reserved	0	Reserved.
4	RGMIIGIG	0-1	RGMII gigabit. This is the value of RGMIIGIG input.
3	RGMIIFULLDUPLEX	0-1	RGMII full-duplex. This is the value of RGMIIFULLDUPLEX input.
2	RXQOSACT		Receive Quality of Service (QOS) active bit. When asserted, indicates that receive quality of service is enabled and that at least one channel freebuffer count (RX*n*FREEBUFFER) is less than or equal to the RXFILTERLOWTHRESH value.
		0	Receive quality of service is disabled.
		1	Receive quality of service is enabled.
1	RXFLOWACT		Receive flow control active bit. When asserted, at least one channel freebuffer count (RX*n*FREEBUFFER) is less than or equal to the channel's corresponding RX*n*FILTERTHRESH value.
		0	Receive flow control is inactive.
		1	Receive flow control is active.
0	TXFLOWACT		Transmit flow control active bit. When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted, except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete.
		0	Transmit flow control is inactive.
		1	Transmit flow control is active.

6.3.2.30 Emulation Control Register (EMCONTROL)

The emulation control register (EMCONTROL) is shown in Figure 6-55 and described in Table 6-55.

Figure 6-55. Emulation Control Register (EMCONTROL)

31	16
Reserved	
R-0

Table 6-55. Emulation Control Register (EMCONTROL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	SOFT	0-1	Emulation soft bit
0	FREE	0-1	Emulation free bit

6.3.2.31 FIFO Control Register (FIFOCONTROL)

The FIFO control register (FIFOCONTROL) is shown in Figure 6-56 and described in Table 6-56.

Figure 6-56. FIFO Control Register (FIFOCONTROL)

31	23	22	16
Reserved		RXFIFOFLOWTHRESH	
R-0		R/W-2h	

15	5	4	0
Reserved		TXCELLTHRESH	
R-0		R/W-24h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 6-56. FIFO Control Register (FIFOCONTROL) Field Descriptions

Bit	Field	Value	Description
31-23	Reserved	0	Reserved
22-16	RXFIFOFLOWTHRESH	0-7Fh	Receive FIFO flow control threshold. Occupancy of the receive FIFO when receive FIFO flow control is triggered (if enabled). The default value is 2h, which means that receive FIFO flow control is triggered when the occupancy of the FIFO reaches 2 cells.
15-5	Reserved	0	Reserved
4-0	TXCELLTHRESH	0-1Fh	Transmit FIFO cell threshold. Indicates the number of 64-byte packet cells required to be in the transmit FIFO before the packet transfer is initiated. Packets with fewer cells are initiated when the complete packet is contained in the FIFO. This value must be greater than or equal to 2 and less than or equal to 24 (2 ≥ TXCELLTHRESH ≤ 24).

6.3.2.32 MAC Configuration Register (MACCONFIG)

The MAC configuration register (MACCONFIG) is shown in Figure 6-57 and described in Table 6-57.

Figure 6-57. MAC Configuration Register (MACCONFIG)

31	24	23	16
TXCELLDEPTH		RXCELLDEPTH	
R-18h		R-44h	

15	8	7	0
ADDRESSTYPE		MACCFIG	
R-2h		R-3h	

LEGEND: R = Read only; -*n* = value after reset

Table 6-57. MAC Configuration Register (MACCONFIG) Field Descriptions

Bit	Field	Value	Description
31-24	TXCELLDEPTH	0-FFh	Transmit cell depth. Indicate the number of cells in the transmit FIFO.
23-16	RXCELLDEPTH	0-FFh	Receive cell depth. Indicate the number of cells in the receive FIFO.
15-8	ADDRESSTYPE	0-FFh	Address type.
7-0	MACCFIG	0-FFh	MAC configuration value.

6.3.2.33 Soft Reset Register (SOFTRESET)

The soft reset register (SOFTRESET) is shown in Figure 6-58 and described in Table 6-58.

Figure 6-58. Soft Reset Register (SOFTRESET)

31	16
Reserved	
R-0	

15	1	0
Reserved		SOFTRESET
R-0		R/W-0

LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 6-58. Soft Reset Register (SOFTRESET) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	SOFTRESET		Software reset. Writing a 1 to this bit causes the EMAC logic to be reset. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the Configuration bus. After writing a 1 to this bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred. If a 0 is read, then a reset has occurred.
		0	A software reset has not occurred.
		1	A software reset has occurred.

6.3.2.34 MAC Source Address Low Bytes Register (MACSRCADDRLO)

The MAC source address low bytes register (MACSRCADDRLO) is shown in Figure 6-59 and described in Table 6-59.

Figure 6-59. MAC Source Address Low Bytes Register (MACSRCADDRLO)

31	16
Reserved

15-8	MACSRCADDR0	0-FFh	MAC source address lower 8 bits (byte 0)
7-0	MACSRCADDR1	0-FFh	MAC source address bits 15-8 (byte 1)

6.3.2.35 MAC Source Address High Bytes Register (MACSRCADDRHI)

The MAC source address high bytes register (MACSRCADDRHI) is shown in Figure 6-60 and described in Table 6-60.

Figure 6-60. MAC Source Address High Bytes Register (MACSRCADDRHI)

31	24	23	16
MACSRCADDR2		MACSRCADDR3	
R/W-0		R/W-0	

15	8	7	0
MACSRCADDR4		MACSRCADDR5	
R/W-0		R/W-0	

LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 6-60. MAC Source Address High Bytes Register (MACSRCADDRHI) Field Descriptions

Bit	Field	Value	Description
31-24	MACSRCADDR2	0-FFh	MAC source address bits 23-16 (byte 2)
23-16	MACSRCADDR3	0-FFh	MAC source address bits 31-24 (byte 3)
15-8	MACSRCADDR4	0-FFh	MAC source address bits 39-32 (byte 4)
7-0	MACSRCADDR5	0-FFh	MAC source address bits 47-40 (byte 5)

6.3.2.36 MAC Hash Address Register 1 (MACHASH1)

The MAC hash registers allow group addressed frames to be accepted on the basis of a hash function of the address. The hash function creates a 6-bit data value (Hash_fun) from the 48-bit destination address (DA) as follows:

```
Hash_fun(0)=DA(0) XOR DA(6) XOR DA(12) XOR DA(18) XOR DA(24) XOR DA(30) XOR DA(36) XOR DA(42);

Hash_fun(1)=DA(1) XOR DA(7) XOR DA(13) XOR DA(19) XOR DA(25) XOR DA(31) XOR DA(37) XOR DA(43);

Hash_fun(2)=DA(2) XOR DA(8) XOR DA(14) XOR DA(20) XOR DA(26) XOR DA(32) XOR DA(38) XOR DA(44);

Hash_fun(3)=DA(3) XOR DA(9) XOR DA(15) XOR DA(21) XOR DA(27) XOR DA(33) XOR DA(39) XOR DA(45);

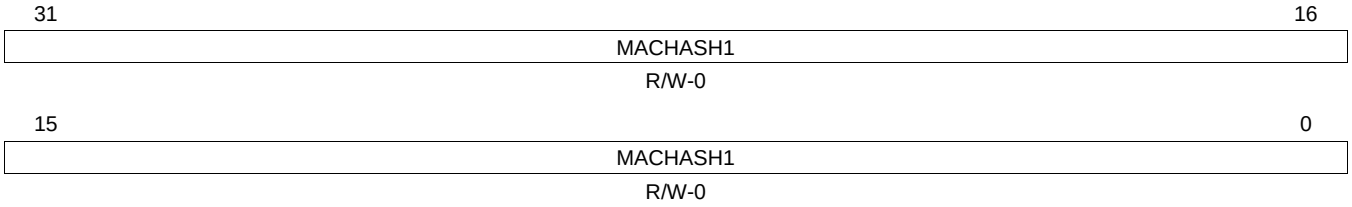
Hash_fun(4)=DA(4) XOR DA(10) XOR DA(16) XOR DA(22) XOR DA(28) XOR DA(34) XOR DA(40) XOR DA(46);

Hash_fun(5)=DA(5) XOR DA(11) XOR DA(17) XOR DA(23) XOR DA(29) XOR DA(35) XOR DA(41) XOR DA(47);
```

This function is used as an offset into a 64-bit hash table stored in MACHASH1 and MACHASH2 that indicates whether a particular address should be accepted or not.

The MAC hash address register 1 (MACHASH1) is shown in Figure 6-61 and described in Table 6-61.

Figure 6-61. MAC Hash Address Register 1 (MACHASH1)



LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

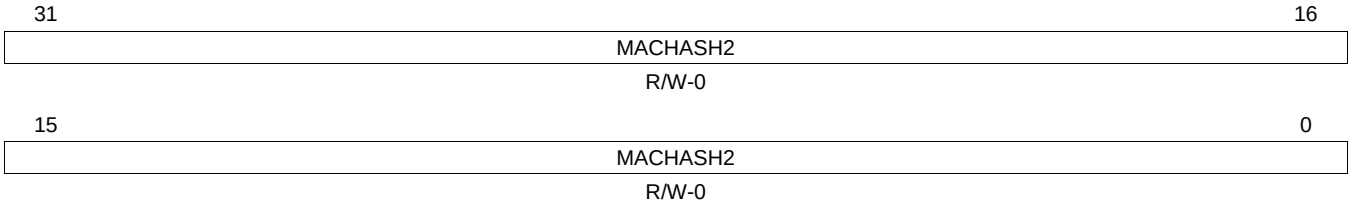
Table 6-61. MAC Hash Address Register 1 (MACHASH1) Field Descriptions

Bit	Field	Value	Description
31-0	MACHASH1	0-FFFF FFFFh	Least-significant 32 bits of the hash table corresponding to hash values 0 to 31. If a hash table bit is set, then a group address that hashes to that bit index is accepted.

6.3.2.37 MAC Hash Address Register 2 (MACHASH2)

The MAC hash address register 2 (MACHASH2) is shown in Figure 6-62 and described in Table 6-62.

Figure 6-62. MAC Hash Address Register 2 (MACHASH2)



LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 6-62. MAC Hash Address Register 2 (MACHASH2) Field Descriptions

Bit	Field	Value	Description
31-0	MACHASH2	0-FFFF FFFFh	Most-significant 32 bits of the hash table corresponding to hash values 32 to 63. If a hash table bit is set, then a group address that hashes to that bit index is accepted.

6.3.2.38 Back Off Test Register (BOFFTEST)

The back off test register (BOFFTEST) is shown in Figure 6-63 and described in Table 6-63.

Figure 6-63. Back Off Random Number Generator Test Register (BOFFTEST)

31	26	25	16
Reserved		RNDNUM	
R-0		R-0	

15	12	11	10	9	0
COLLCOUNT		Reserved		TXBACKOFF	
R-0		R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 6-63. Back Off Test Register (BOFFTEST) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reserved
25-16	RNDNUM	0-3FFh	Backoff random number generator. This field allows the Backoff Random Number Generator to be read. Reading this field returns the generator's current value. The value is reset to 0 and begins counting on the clock after the deassertion of reset.
15-12	COLLCOUNT	0-Fh	Collision count. These bits indicate the number of collisions the current frame has experienced.
11-10	Reserved	0	Reserved
9-0	TXBACKOFF	0-3FFh	Backoff count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.

6.3.2.39 Transmit Pacing Algorithm Test Register (TPACETEST)

The transmit pacing algorithm test register (TPACETEST) is shown in Figure 6-64 and described in Table 6-64.

Figure 6-64. Transmit Pacing Algorithm Test Register (TPACETEST)

31	16
Reserved	
R-0	

15	5	4	0
Reserved		PACEVAL	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

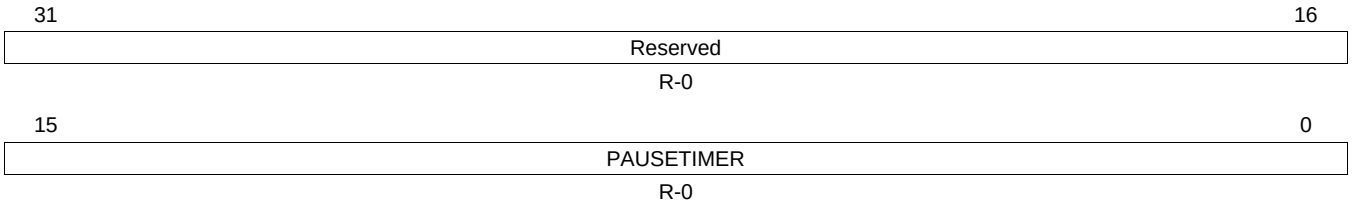
Table 6-64. Transmit Pacing Algorithm Test Register (TPACETEST) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4-0	PACEVAL	0-1Fh	Pacing register current value. A nonzero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with 1Fh (31); good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to 0. When PACEVAL is nonzero, the transmitter delays four Inter Packet Gaps between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. If a transmit frame is deferred or suffers a collision, the IPG time is not stretched to four times the normal value. Transmit pacing helps reduce capture effects, which improves overall network bandwidth.

6.3.2.40 Receive Pause Timer Register (RXPAUSE)

The receive pause timer register (RXPAUSE) is shown in Figure 6-65 and described in Table 6-65.

Figure 6-65. Receive Pause Timer Register (RXPAUSE)



LEGEND: R = Read only; -*n* = value after reset

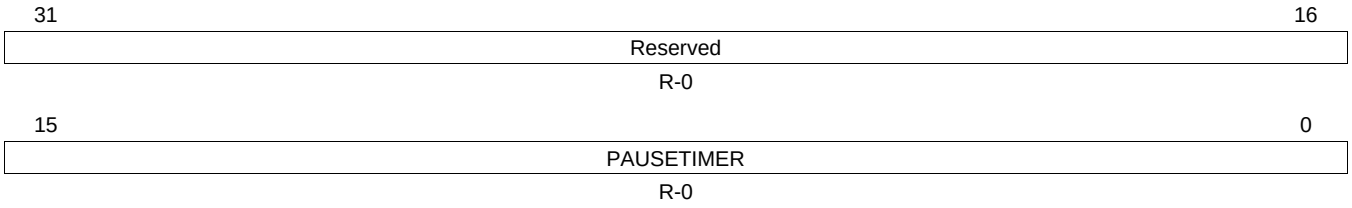
Table 6-65. Receive Pause Timer Register (RXPAUSE) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	PAUSETIMER	0-FFh	Receive pause timer value. These bits allow the contents of the receive pause timer to be observed. The receive pause timer is loaded with FF00h when the EMAC sends an outgoing pause frame (with pause time of FFFFh). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to 0, then another outgoing pause frame is sent and the load/decrement process is repeated.

6.3.2.41 Transmit Pause Timer Register (TXPAUSE)

The transmit pause timer register (TXPAUSE) is shown in Figure 6-66 and described in Table 6-66.

Figure 6-66. Transmit Pause Timer Register (TXPAUSE)



LEGEND: R = Read only; -*n* = value after reset

Table 6-66. Transmit Pause Timer Register (TXPAUSE) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	PAUSETIMER	0-FFh	Transmit pause timer value. These bits allow the contents of the transmit pause timer to be observed. The transmit pause timer is loaded by a received (incoming) pause frame, and then decremented at slot time intervals down to 0, at which time EMAC transmit frames are again enabled.

6.3.2.42 MAC Address Low Bytes Register (MACADDRLO)

The MAC address low bytes register used in address matching (MACADDRLO), is shown in Figure 6-67 and described in Table 6-67.

Figure 6-67. MAC Address Low Bytes Register (MACADDRLO)

31	21	20	19	18	16
Reserved		VALID	MATCHFILT	CHANNEL	
R-0		R/W-x	R/W-x	R/W-x	

15	8	7	0
MACADDR0		MACADDR1	
R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; -x = value is indeterminate after reset

Table 6-67. MAC Address Low Bytes Register (MACADDRLO) Field Descriptions

Bit	Field	Value	Description
31-21	Reserved	0	Reserved
20	VALID		Address valid bit. This bit should be cleared to zero for unused address RAM locations.
		0	Address location is not valid and will not be used in determining whether or not an incoming packet matches or is filtered.
		1	Address location is valid and will be used in determining whether or not an incoming packet matches or is filtered.
19	MATCHFILT		Match or filter bit
		0	The address will be used (if the VALID bit is set) to determine if the incoming packet address should be filtered.
		1	The address will be used (if the VALID bit is set) to determine if the incoming packet address is a match.
18-16	CHANNEL	0-7h	Channel bit. Determines which receive channel a valid address match will be transferred to. The channel is a don't care if the MATCHFILT bit is cleared to 0.
15-8	MACADDR0	0-FFh	MAC address lower 8 bits (byte 0)
7-0	MACADDR1	0-FFh	MAC address bits 15-8 (byte 1)

6.3.2.43 MAC Address High Bytes Register (MACADDRHI)

The MAC address high bytes register (MACADDRHI) is shown in Figure 6-68 and described in Table 6-68.

Figure 6-68. MAC Address High Bytes Register (MACADDRHI)

31	24	23	16
MACADDR2		MACADDR3	
R/W-0		R/W-0	

15	8	7	0
MACADDR4		MACADDR5	
R/W-0		R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 6-68. MAC Address High Bytes Register (MACADDRHI) Field Descriptions

Bit	Field	Value	Description
31-24	MACADDR2	0-FFh	MAC source address bits 23-16 (byte 2)
23-16	MACADDR3	0-FFh	MAC source address bits 31-24 (byte 3)
15-8	MACADDR4	0-FFh	MAC source address bits 39-32 (byte 4)
7-0	MACADDR5	0-FFh	MAC source address bits 47-40 (byte 5). Bit 40 is the group bit. It is forced to 0 and read as 0. Therefore, only unicast addresses are represented in the address table.

6.3.2.44 MAC Index Register (MACINDEX)

The MAC index register (MACINDEX) is shown in Figure 6-69 and described in Table 6-69.

Figure 6-69. MAC Index Register (MACINDEX)

31	16
Reserved	
R-0	

15	5	4	0
Reserved		MACINDEX	
R-0		R/W-0	

LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

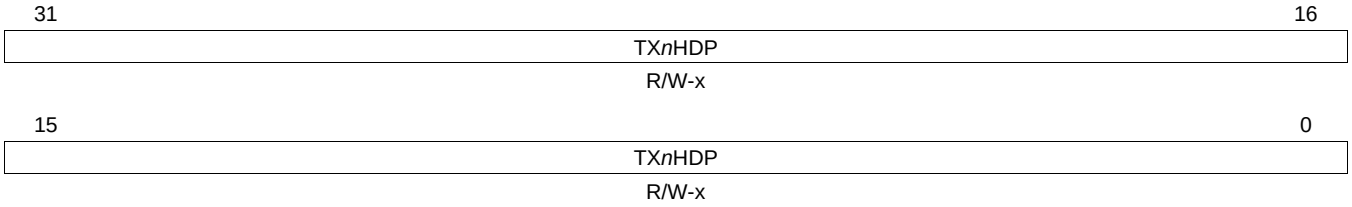
Table 6-69. MAC Index Register (MACINDEX) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4-0	MACINDEX	0-1Fh	MAC address index. The host must write the index into the RX ADDR RAM in the MACINDEX field, followed by the upper 32-bits of address, followed by the lower 16-bits of address (with control bits). The 53-bit indexed RAM location is written when the low location is written. All 32 address RAM locations must be initialized prior to enabling packet reception.

6.3.2.45 Transmit Channel 0-7 DMA Head Descriptor Pointer Register (TX*n*HDP)

The transmit channel 0-7 DMA head descriptor pointer register (TX*n*HDP) is shown in Figure 6-70 and described in Table 6-70.

Figure 6-70. Transmit Channel *n* DMA Head Descriptor Pointer Register (TX*n*HDP)



LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

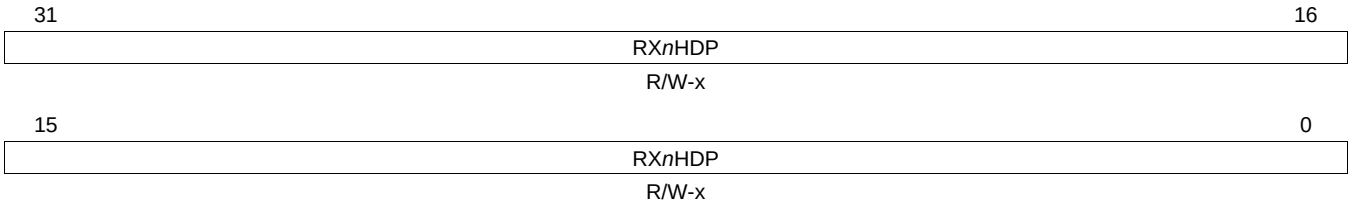
Table 6-70. Transmit Channel *n* DMA Head Descriptor Pointer Register (TX*n*HDP) Field Descriptions

Bit	Field	Value	Description
31-0	TX*n*HDP	0-FFFF FFFFh	Transmit channel *n* DMA Head Descriptor pointer. Writing a transmit DMA buffer descriptor address to a head pointer location initiates transmit DMA operations in the queue for the selected channel. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset.

6.3.2.46 Receive Channel 0-7 DMA Head Descriptor Pointer Register (RX*n*HDP)

The receive channel 0-7 DMA head descriptor pointer register (RX*n*HDP) is shown in Figure 6-71 and described in Table 6-71.

Figure 6-71. Receive Channel *n* DMA Head Descriptor Pointer Register (RX*n*HDP)



LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

Table 6-71. Receive Channel *n* DMA Head Descriptor Pointer Register (RX*n*HDP) Field Descriptions

Bit	Field	Value	Description
31-0	RX*n*HDP	0-FFFF FFFFh	Receive channel *n* DMA Head Descriptor pointer. Writing a receive DMA buffer descriptor address to this location allows receive DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset.

6.3.2.47 Transmit Channel 0-7 Completion Pointer Register (TX*n*CP)

The transmit channel 0-7 completion pointer register (TX*n*CP) is shown in Figure 6-72 and described in Table 6-72.

Figure 6-72. Transmit Channel *n* Completion Pointer Register (TX*n*CP)

31	16
TX*n*CP	
R/W-x	

15	0
TX*n*CP	
R/W-x	

LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

Table 6-72. Transmit Channel *n* Completion Pointer Register (TX*n*CP) Field Descriptions

Bit	Field	Value	Description
31-0	TX*n*CP	0-FFFF FFFFh	Transmit channel *n* completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted.

6.3.2.48 Receive Channel 0-7 Completion Pointer Register (RX*n*CP)

The receive channel 0-7 completion pointer register (RX*n*CP) is shown in Figure 6-73 and described in Table 6-73.

Figure 6-73. Receive Channel *n* Completion Pointer Register (RX*n*CP)

Table 6-73. Receive Channel *n* Completion Pointer Register (RX*n*CP) Field Descriptions

Bit	Field	Value	Description
31-0	RX*n*CP	0-FFFF FFFFh	Receive channel *n* completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted.

6.3.2.49 Network Statistics Registers

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero 38 clocks after the rising edge of reset. When the GMII bit in the MACCONTROL register is set, all statistics registers (see Figure 6-74) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMII bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STATPEND) is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

LEGEND: R/W = Read/Write; WD = Write to decrement; -*n* = value after reset

6.3.2.49.1 Good Receive Frames Register (RXGOODFRAMES)

The total number of good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See **Section 6.2.5.5** for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.2 Broadcast Receive Frames Register (RXBCASTFRAMES)

The total number of good broadcast frames received on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for address FF-FF-FF-FF-FF-FFh only
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See Section 6.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.3 Multicast Receive Frames Register (RXMCASTFRAMES)

The total number of good multicast frames received on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See Section 6.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.4 Pause Receive Frames Register (RXPAUSEFRAMES)

The total number of IEEE 802.3X pause frames received by the EMAC (whether acted upon or not). A pause frame is defined as having all of the following:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08h and the opcode 0001h
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error
- Pause-frames had been enabled on the EMAC (TXFLOWEN bit is set in MACCONTROL).

The EMAC could have been in either half-duplex or full-duplex mode. See Section 6.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.5 Receive CRC Errors Register (RXCRCERRORS)

The total number of frames received on the EMAC that experienced a CRC error. A frame with CRC errors is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no alignment or code error
- Had a CRC error. A CRC error is defined as having all of the following:
  - A frame containing an even number of nibbles
  - Fails the frame check sequence test

See Section 6.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.6 Receive Alignment/Code Errors Register (RXALIGNCODEERRORS)

The total number of frames received on the EMAC that experienced an alignment error or code error. Such a frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had either an alignment error or a code error
  - An alignment error is defined as having all of the following:
    - A frame containing an odd number of nibbles
    - Fails the frame check sequence test, if the final nibble is ignored
  - A code error is defined as a frame that has been discarded because the EMAC_RXER pin is driven with a one for at least one bit-time's duration at any point during the frame's reception.

Overruns have no effect on this statistic.

CRC alignment or code errors can be calculated by summing receive alignment errors, receive code errors, and receive CRC errors.

6.3.2.49.7 Receive Oversized Frames Register (RXOVERSIZED)

The total number of oversized frames received on the EMAC. An oversized frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN in bytes
- Had no CRC error, alignment error, or code error

See Section 6.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.8 Receive Jabber Frames Register (RXJABBER)

The total number of jabber frames received on the EMAC. A jabber frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN bytes long
- Had a CRC error, alignment error, or code error

See Section 6.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.9 Receive Undersized Frames Register (RXUNDERSIZED)

The total number of undersized frames received on the EMAC. An undersized frame is defined as having all of the following:

- Was any data frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes long
- Had no CRC error, alignment error, or code error

See Section 6.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.10 Receive Frame Fragments Register (RXFRAGMENTS)

The total number of frame fragments received on the EMAC. A frame fragment is defined as having all of the following:

- Any data frame (address matching does not matter)
- Was less than 64 bytes long
- Had a CRC error, alignment error, or code error
- Was not the result of a collision caused by half duplex, collision based flow control

See Section 6.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.11 Filtered Receive Frames Register (RXFILTERED)

The total number of frames received on the EMAC that the EMAC address matching process indicated should be discarded. Such a frame is defined as having all of the following:

- Was any data frame (not MAC control frame) destined for any unicast, broadcast, or multicast address
- Did not experience any CRC error, alignment error, code error
- The address matching process decided that the frame should be discarded (filtered) because it did not match the unicast, broadcast, or multicast address, and it did not match due to promiscuous mode.

To determine the number of receive frames discarded by the EMAC for any reason, sum the following statistics (promiscuous mode disabled):

- Receive fragments
- Receive undersized frames
- Receive CRC errors
- Receive alignment/code errors
- Receive jabbers
- Receive overruns
- Receive filtered frames

This may not be an exact count because the receive overruns statistic is independent of the other statistics, so if an overrun occurs at the same time as one of the other discard reasons, then the above sum double-counts that frame.

6.3.2.49.12 Receive QOS Filtered Frames Register (RXQOSFILTERED)

The total number of frames received on the EMAC that were filtered due to receive quality of service (QOS) filtering. Such a frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- The frame destination channel flow control threshold register (RX*n*FLOWTHRESH) value was greater than or equal to the channel's corresponding free buffer register (RX*n*FREEBUFFER) value
- Was of length 64 to RXMAXLEN
- RXQOSEN bit is set in RXMBPENABLE
- Had no CRC error, alignment error, or code error

See Section 6.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.13 Receive Octet Frames Register (RXOCTETS)

The total number of bytes in all good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See Section 6.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

6.3.2.49.14 Good Transmit Frames Register (TXGOODFRAMES)

The total number of good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

6.3.2.49.15 Broadcast Transmit Frames Register (TXBCASTFRAMES)

The total number of good broadcast frames transmitted on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame destined for address FF-FF-FF-FF-FF-FFh only
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

6.3.2.49.16 Multicast Transmit Frames Register (TXMCASTFRAMES)

The total number of good multicast frames transmitted on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

6.3.2.49.17 Pause Transmit Frames Register (TXPAUSEFRAMES)

The total number of IEEE 802.3X pause frames transmitted by the EMAC. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect on this statistic. Pause frames sent by software are not included in this count. Since pause frames are only transmitted in full-duplex mode, carrier loss and collisions have no effect on this statistic.

Transmitted pause frames are always 64-byte multicast frames so appear in the multicast transmit frames register and 64 octet frames register statistics.

6.3.2.49.18 Deferred Transmit Frames Register (TXDEFERRED)

The total number of frames transmitted on the EMAC that first experienced deferment. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect on this statistic.

6.3.2.49.19 Transmit Collision Frames Register (TXCOLLISION)

The total number of times that the EMAC experienced a collision. Collisions occur under two circumstances:

- When a transmit data or MAC control frame has all of the following:
  - Was destined for any unicast, broadcast, or multicast address
  - Was any size
  - Had no carrier loss and no underrun
  - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic increments on each occasion if a frame experiences multiple collisions (and increments on late collisions).
- When the EMAC is in half-duplex mode, flow control is active, and a frame reception begins.

CRC errors have no effect on this statistic.

6.3.2.49.20 Transmit Single Collision Frames Register (TXSINGLECOLL)

The total number of frames transmitted on the EMAC that experienced exactly one collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect on this statistic.

6.3.2.49.21 Transmit Multiple Collision Frames Register (TXMULTICOLL)

The total number of frames transmitted on the EMAC that experienced multiple collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect on this statistic.

6.3.2.49.22 Transmit Excessive Collision Frames Register (TXEXCESSIVECOLL)

The total number of frames when transmission was abandoned due to excessive collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect on this statistic.

6.3.2.49.23 Transmit Late Collision Frames Register (TXLATECOLL)

The total number of frames when transmission was abandoned due to a late collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions that had previously required the transmission to be reattempted. The late collisions statistic dominates over the single, multiple, and excessive collisions statistics. If a late collision occurs, the frame is not counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect on this statistic.

6.3.2.49.24 Transmit Underrun Error Register (TXUNDERRUN)

The number of frames sent by the EMAC that experienced FIFO underrun. Late collisions, CRC errors, carrier loss, and underrun have no effect on this statistic.

6.3.2.49.25 Transmit Carrier Sense Errors Register (TXCARRIERSENSE)

The total number of frames on the EMAC that experienced carrier loss. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted)

CRC errors and underrun have no effect on this statistic.

6.3.2.49.26 Transmit Octet Frames Register (TXOCTETS)

The total number of bytes in all good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

6.3.2.49.27 Transmit and Receive 64 Octet Frames Register (FRAME64)

The total number of 64-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was exactly 64-bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame is recorded in this statistic).

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

6.3.2.49.28 Transmit and Receive 65 to 127 Octet Frames Register (FRAME65T127)

The total number of 65-byte to 127-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 65-bytes to 127-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

6.3.2.49.29 Transmit and Receive 128 to 255 Octet Frames Register (FRAME128T255)

The total number of 128-byte to 255-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 128-bytes to 255-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

6.3.2.49.30 Transmit and Receive 256 to 511 Octet Frames Register (FRAME256T511)

The total number of 256-byte to 511-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 256-bytes to 511-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

6.3.2.49.31 Transmit and Receive 512 to 1023 Octet Frames Register (FRAME512T1023)

The total number of 512-byte to 1023-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 512-bytes to 1023-bytes long

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

6.3.2.49.32 Transmit and Receive 1024 to RXMAXLEN Octet Frames Register (FRAME1024TUP)

The total number of 1024-byte to RXMAXLEN-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 1024-bytes to RXMAXLEN-bytes long

CRC/alignment/code errors, underruns, and overruns do not affect frame recording in this statistic.

6.3.2.49.33 Network Octet Frames Register (NETOCTETS)

The total number of bytes of frame data received and transmitted on the EMAC. Each frame counted has all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address (address match does not matter)
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced (multiple retries are counted each time)
- Every byte received if the EMAC is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence is not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns, and underruns do not affect the recording of bytes in this statistic. The objective of this statistic is to give a reasonable indication of Ethernet utilization.

6.3.2.49.34 Receive FIFO or DMA Start of Frame Overruns Register (RXSOFOVERRUNS)

The total number of frames received on the EMAC that had either a FIFO or DMA start of frame (SOF) overrun. An SOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available at the start of the frame).

CRC errors, alignment errors, and code errors have no effect on this statistic.

6.3.2.49.35 Receive FIFO or DMA Middle of Frame Overruns Register (RXMOFOVERRUNS)

The total number of frames received on the EMAC that had either a FIFO or DMA middle of frame (MOF) overrun. An MOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available after the frame was successfully started - no SOF overrun).

CRC errors, alignment errors, and code errors have no effect on this statistic.

6.3.2.49.36 Receive DMA Overruns Register (RXDMAOVERRUNS)

The total number of frames received on the EMAC that had either a DMA start of frame (SOF) overrun or a DMA middle of frame (MOF) overrun. A receive DMA overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception).

CRC errors, alignment errors, and code errors have no effect on this statistic.

6.3.3 MDIO Registers

Table 6-74 lists the memory-mapped registers for the MDIO module. For the base address of these registers, see Table 1-13.

Table 6-74. Management Data Input/Output (MDIO) Registers

Address Offset	Acronym	Register Description	Section
0h	VERSION	MDIO Version Register	Section 6.3.3.1
4h	CONTROL	MDIO Control Register	Section 6.3.3.2
8h	ALIVE	PHY Alive Status register	Section 6.3.3.3
Ch	LINK	PHY Link Status Register	Section 6.3.3.4
10h	LINKINTRAW	MDIO Link Status Change Interrupt (Unmasked) Register	Section 6.3.3.5
14h	LINKINTMASKED	MDIO Link Status Change Interrupt (Masked) Register	Section 6.3.3.6
20h	USERINTRAW	MDIO User Command Complete Interrupt (Unmasked) Register	Section 6.3.3.7
24h	USERINTMASKED	MDIO User Command Complete Interrupt (Masked) Register	Section 6.3.3.8
28h	USERINTMASKSET	MDIO User Command Complete Interrupt Mask Set Register	Section 6.3.3.9
2Ch	USERINTMASKCLEAR	MDIO User Command Complete Interrupt Mask Clear Register	Section 6.3.3.10
80h	USERACCESS0	MDIO User Access Register 0	Section 6.3.3.11
84h	USERPHYSEL0	MDIO User PHY Select Register 0	Section 6.3.3.12
88h	USERACCESS1	MDIO User Access Register 1	Section 6.3.3.13
8Ch	USERPHYSEL1	MDIO User PHY Select Register 1	Section 6.3.3.14

6.3.3.1 MDIO Version Register (VERSION)

The MDIO version register (VERSION) is shown in Figure 6-75 and described in Table 6-75.

Figure 6-75. MDIO Version Register (VERSION)

31	16
MODID	
R-7h	

15	8	7	0
REVMAJ		REVMIN	
R-1h		R-4h	

LEGEND: R = Read only; -*n* = value after reset

Table 6-75. MDIO Version Register (VERSION) Field Descriptions

Bit	Field	Value	Description
31-16	MODID	0-FFFFh	Identifies type of peripheral.
15-8	REVMAJ	0-FFh	Management Interface Module major revision value.
7-0	REVMIN	0-FFh	Management Interface Module minor revision value.

6.3.3.2 MDIO Control Register (CONTROL)

The MDIO control register (CONTROL) is shown in Figure 6-76 and described in Table 6-76.

Figure 6-76. MDIO Control Register (CONTROL)

31	30	29	28 24	23 21	20	19	18	17 16

15 0
CLKDIV
R/W-FFh

LEGEND: R/W = R = Read only; R/W = Read/Write; W1C = Write 1 to clear, write of 0 has no effect; -*n* = value after reset

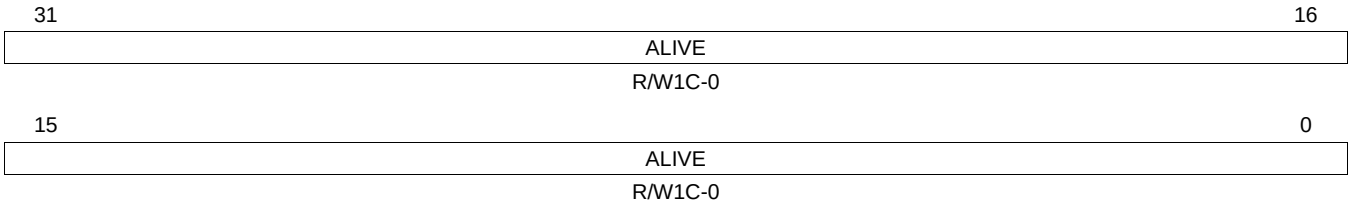
Table 6-76. MDIO Control Register (CONTROL) Field Descriptions

Bit	Field	Value	Description
31	IDLE		State machine IDLE status bit.
		0	State machine is not in idle state.
		1	State machine is in idle state.
30	ENABLE		State machine enable control bit. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit.
		0	Disables the MDIO state machine.
		1	Enable the MDIO state machine.
29	Reserved	0	Reserved.
28-24	HIGHEST_USER_CHANNEL	0-1Fh	Highest user channel that is available in the module. It is currently set to 1. This implies that MDIOUserAccess1 is the highest available user access channel.
23-21	Reserved	0	Reserved.
20	PREAMBLE		Preamble disable.
		0	Standard MDIO preamble is used.
		1	Disables this device from sending MDIO frame preambles.
19	FAULT		Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit, writing a 0 has no effect.
		0	No failure.
		1	Physical layer fault; the MDIO state machine is reset.
18	FAULTENB		Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection.
		0	Disables the physical layer fault detection.
		1	Enables the physical layer fault detection.
17-16	Reserved	0	Reserved.
15-0	CLKDIV	0-FFFFh	Clock Divider bits. This field specifies the division ratio between the peripheral clock and the frequency of MCLK. MCLK is disabled when CLKDIV is set to 0. MCLK frequency = peripheral clock frequency/(CLKDIV + 1).

6.3.3.3 PHY Acknowledge Status Register (ALIVE)

The PHY acknowledge status register (ALIVE) is shown in Figure 6-77 and described in Table 6-77.

Figure 6-77. PHY Acknowledge Status Register (ALIVE)



LEGEND: R/W = Read/Write; W1C = Write 1 to clear, write of 0 has no effect; -*n* = value after reset

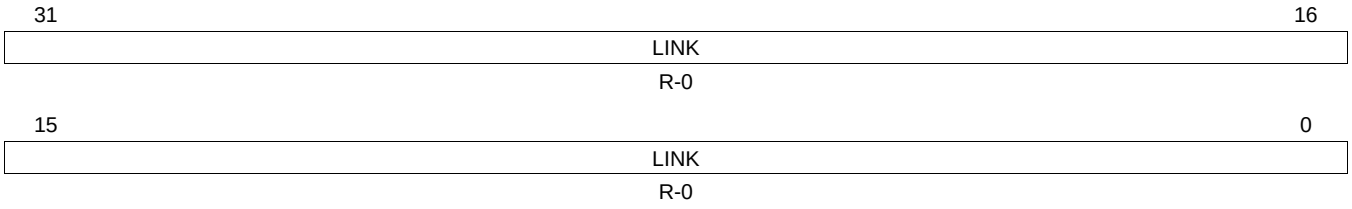
Table 6-77. PHY Acknowledge Status Register (ALIVE) Field Descriptions

Bit	Field	Value	Description
31-0	ALIVE	0-FFFF FFFFh	MDIO Alive bits. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY; the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect.
		0	The PHY fails to acknowledge the access.
		1	The most recent access to the PHY with an address corresponding to the register bit number was acknowledged by the PHY.

6.3.3.4 PHY Link Status Register (LINK)

The PHY link status register (LINK) is shown in Figure 6-78 and described in Table 6-78.

Figure 6-78. PHY Link Status Register (LINK)



LEGEND: R = Read only; -*n* = value after reset

Table 6-78. PHY Link Status Register (LINK) Field Descriptions

Bit	Field	Value	Description
31-0	LINK	0-FFFF FFFFh	MDIO Link state bits. This register is updated after a read of the generic status register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect.
		0	The PHY indicates it does not have a link or fails to acknowledge the read transaction.
		1	The PHY with the corresponding address has a link and the PHY acknowledges the read transaction.

6.3.3.5 MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)

The MDIO link status change interrupt (unmasked) register (LINKINTRAW) is shown in Figure 6-79 and described in Table 6-79.

DDR2/DDR3 Memory Controller

This chapter describes the DDR2/DDR3 memory controller.

Topic **Page**

7.1 Introduction

7.1.1 Overview

The DDR2/3 memory controller is used to interface with JESD79-2E/JESD79-3C standard compliant DDR2/3 SDRAM devices. Memory types such as DDR1 SDRAM, SDR SDRAM, SBSRAM, and asynchronous memories are not supported. The DDR2/3 memory controller is the major memory location for program and data storage.

7.1.2 Features

The DDR2/3 memory controller supports the following features:

- JESD79-2E standard compliant DDR2 SDRAM
- JESD79-3C standard compliant DDR3 SDRAM
- 1024 Mbyte memory space
- Data bus width of 32 or 16 bits
- CAS latencies (DDR2): 3, 4, 5, 6, and 7
- CAS latencies (DDR3): 5, 6, 7, 8, 9, 10, and 11
- Internal banks:1,2,4,8
- Two Chip Select Signals (CS) (see your data manual for number of chip selects supported on your device)
- Burst length: 8
- Burst type: Sequential
- Page sizes: 256, 512, 1024, and 2048
- SDRAM initialization from configuration change
- Self Refresh and Power-Down modes for low power
- Periodic ZQ calibration (DDR3 only)
- Self-refresh mode
- Prioritized refresh
- Programmable refresh rate and backlog counter
- Programmable timing parameters
- Little endian
- Support for Fly-By-Topology board routing for DDR3 interfaces via leveling
- Software read/write leveling (calibration)

7.1.3 Features Not Supported

The following features are not supported on the DDR2/3 memory controller:

- Burst lengths other than 8
- Interleave Burst type
- OCD calibration for DDR2
- Burst chop for DDR3

7.1.4 Industry Standard(s) Compliance Statement

The DDR2/3 memory controller subsystem supports JEDEC standard compliant DDR2 (JESD79-2E) and DDR3 (JESD79-3C) devices. It does not support CAS latency of 2 for DDR2 due to data and command macro limitations. It supports a 128-bit wide OCP interface on the core side for programmability. The subsystem can be used to connect to 16-bit or 32-bit memory devices.

7.2 Architecture

7.2.1 Signal Descriptions

The DDR2/3 memory controller signals are shown in Figure 7-1 and described in Table 7-1. The following features are included:

- The maximum data bus width is 32-bits (DDR[x]_D[31:0]).
- The address bus (DDR[x]_A[14:0]) is 15-bits wide with an additional 3 bank address pins (DDR[x]_BA[2:0]).
- Two differential output clocks (DDR[x]_CLK[y] and $\overline{\text{DDR[x]\_CLK[y]}}$) driven by internal clock sources.
- Command signals: Row and column address strobes ($\overline{\text{DDR[x]\_RAS}}$ and $\overline{\text{DDR[x]\_CAS}}$), write enable strobe ($\overline{\text{DDR[x]\_WE}}$), data strobes (DDR[x]_DQS[3:0] and $\overline{\text{DDR[x]\_DQS[3:0]}}$), and data mask (DDR[x]_DQM[3:0]).
- Two chip select signals ($\overline{\text{DDR[x]\_CS[1:0]}}$) and one clock enable signal (DDR[x]_CKE).
- Two on-die termination output signals (DDR[x]_ODT[1:0]).

Where

x = 0 indicates support of one DDR2/3 memory controller

x = 1:0 indicates support of two DDR2/3 memory controllers

y = 0 indicates support of one chip select or one rank per DDR2/3 memory controller

y = 1:0 indicates support of two chip selects or two ranks per DDR2/3 memory controller

See your device-specific data manual for the number of DDR2/3 controllers and number of chip selects supported per DDR2/3 memory controller.

Figure 7-1. DDR2/3 Memory Controller Signals

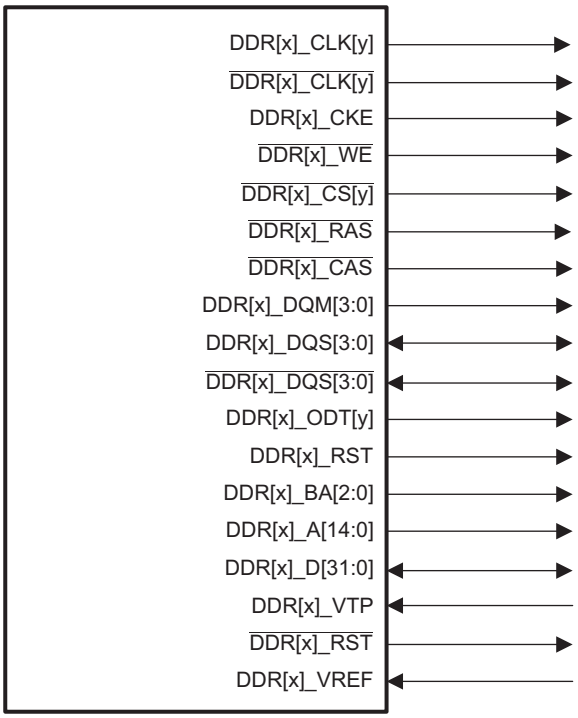

Table 7-1. DDR2/3 Memory Controller Signal Descriptions

Pin	Description
DDR[x]_D[31:0]	Bidirectional data bus. Input for data reads and output for data writes.
DDR[x]_A[14:0]	External address output
$\overline{\text{DDR[x]\_CS[y]}}$	Chip select output. Allows 2 ranks per DDR2/3 controller in $\overline{\text{DDR[x]\_CS[1:0]}}$
DDR[x]_DQM[3:0]	Active-low output data mask.
DDR[x]_CLK[y]/$\overline{\text{DDR[x]\_CLK[y]}}$	Differential clock outputs. All DDR2/3 interface signals are synchronous to these clocks
DDR[x]_CKE	Clock enable. Used to select Power-Down and Self-Refresh operations.
$\overline{\text{DDR[x]\_CAS}}$	Active-low column address strobe.
$\overline{\text{DDR[x]\_RAS}}$	Active-low row address strobe.
$\overline{\text{DDR[x]\_WE}}$	Active-low write enable.
DDR[x]_DQS[3:0]/$\overline{\text{DDR[x]\_DQS[3:0]}}$	Differential data strobe bidirectional signals. Edge-aligned inputs on reads and center-aligned outputs on writes
DDR[x]_ODT[1:0]	On-die termination signals to external DDR2/3 SDRAM
DDR[x]_BA[2:0]	Bank-address control outputs.
DDR[x]_VREF	Memory controller reference voltage. This voltage must be supplied externally. See the device-specific data manual for more details.
DDR[x]_VTP	DDR2/3 VTP Compensation Resistor Connection
$\overline{\text{DDR[x]\_RST}}$	Reset output. Asynchronous reset for DDR3 devices.

7.2.2 Memory Map

See your device-specific data manual for information describing the device memory map.

7.2.3 Clock Control

The DDR2/3 clock is derived directly from the DDR PLL's VCO output. The frequency of DDR[x]_CLK[y] can be determined by using the following formula:

DDR[x]_CLK[y] frequency = (DDRPLL input clock frequency × multiplier) / (pre-divider × post-divider)

The second output clock of the DDR2/3 memory controller $\overline{\text{DDR[x]\_CLK[y]}}$, is the inverse of DDR[x]_CLK[y]. You can change the multiplier, pre-divider and post-divider to get the desired DDR[x]_CLK[y] frequency.

For detailed information on the DDRPLL, see the *Chip Level Resources* chapter.

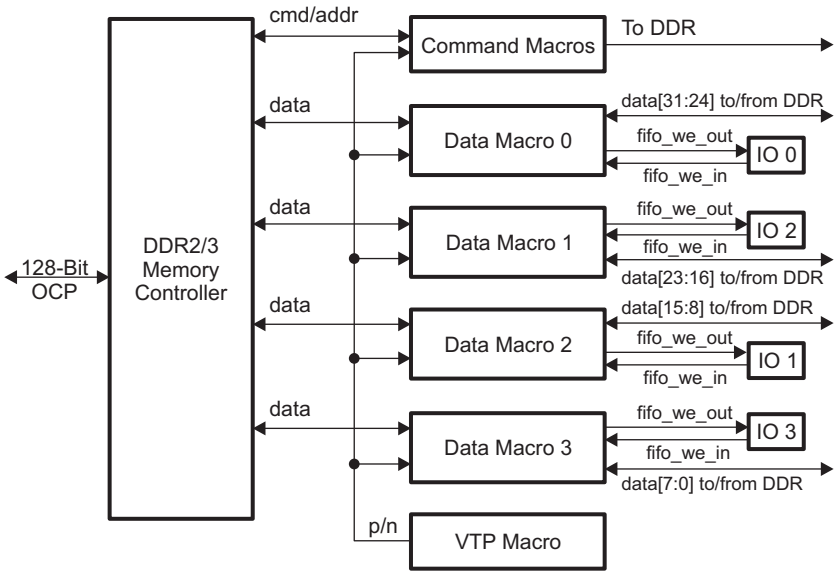
7.2.4 DDR2/3 Memory Controller Subsystem Overview

The DDR2/3 memory controller can gluelessly interface to most standard DDR2/3 SDRAM devices and supports such features as self-refresh mode and prioritized refresh. In addition, it provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The DDR2/3 subsystem consists of:

- DDR2/3 memory controller
- Command macro
- Data macro
- VTP controller macro
- IOs for DQS gate

Figure 7-2 shows the DDR2/3 subsystem block diagram.

Figure 7-2. DDR2/3 Subsytem Block Diagram



Where:

fifo_we_out: DQS enable output for timing match between DQS and system (Memory) clock.

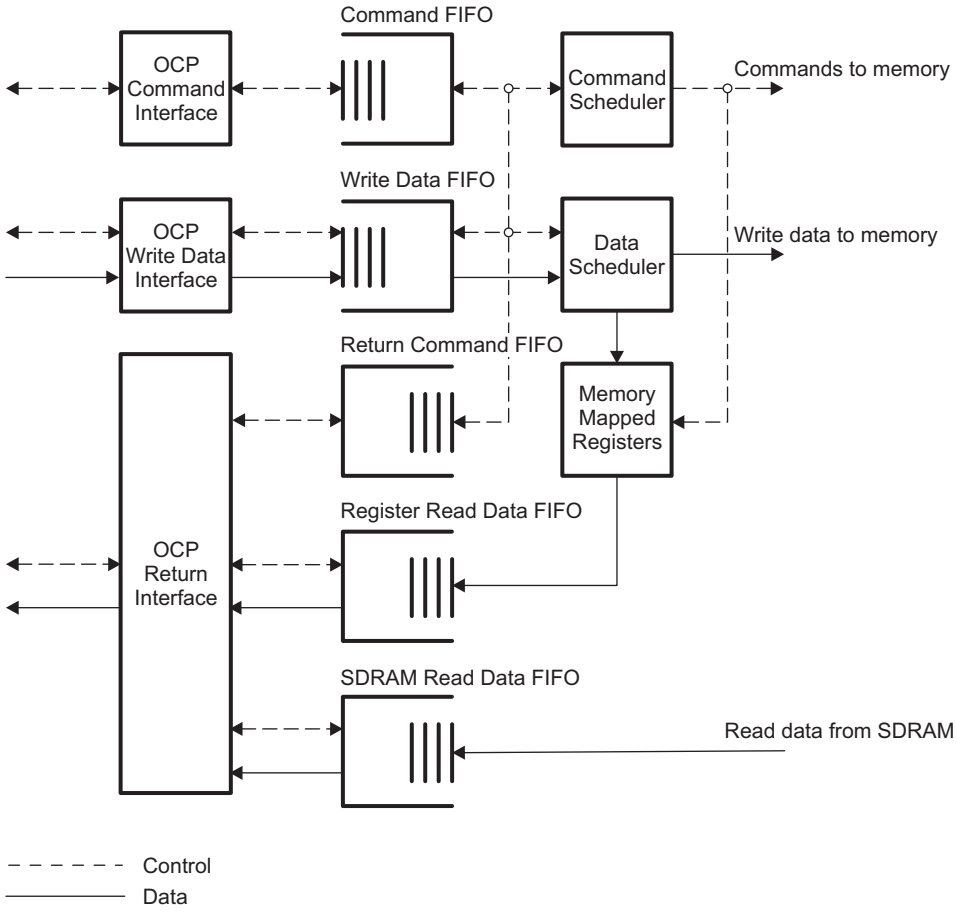
fifo_we_in: DQS enable input for timing match between DQS and system (Memory) clock.

7.2.4.1 DDR2/3 Memory Controller

To move data efficiently from on-chip resources to an external DDR2/3 SDRAM device, the DDR2/3 memory controller makes use of a command FIFO, a write data FIFO, a return command FIFO, and two read data FIFOs. Figure 7-3 shows the block diagram of the DDR2/3 memory controller FIFOs. Commands, write data, and read data arrive at the DDR2/3 memory controller parallel to each other. The same peripheral bus is used to write and read data from external memory as well as internal memory-mapped registers.

- The command FIFO stores all the commands coming in on the OCP command interface.
- The write data FIFO stores the write data for all the write transactions coming in on the OCP write data interface.
- The return command FIFO stores all the return transactions that are to be issued to the OCP return interface. These include the write status return and the read data return commands.
- There are two read data FIFOs that store the read data to be sent to the OCP return interface. One Read Data FIFO stores read data from the memory mapped registers and other Read Data FIFO stores read data from external memory.

Figure 7-3. DDR2/3 Memory Controller FIFO Block Diagram



7.2.4.2 Data Macro

The data macro consists of 8 data channels, one pair of complementary strobes (one pair for 8 bits of data), and one data mask channel (one for 8 bits of data).

The data macros consists of PHY Data Macro, DLLs, and IOs integrated into a macro. The data macro is a bidirectional interface. It is used to transmit data from the memory controller to the external memory chip during a write operation and receive data from memory and transmit it to the memory controller during a read operation.

During a write operation, the data macro translates 32/16-bit words from memory controller to 8-bit words and transmits them at double the bit rate to the memory along with the strobe. The strobe is center-aligned to the data. Data can be prevented from writing to the memory using data mask signal.

During a read operation, the data macro receives 8-bit DDR data along with the strobe and converts it to 32/16- bit words and transmits them to the memory controller along with the read-valid signals.

7.2.4.3 Command Macro

It consists of PHY Command Macro, DLLs, and the IOs integrated together. The command macro acts as a unidirectional macro that transmits address and control bits from memory controller to the memory chip. The clocks DDR[x]_CLK[y] and $\overline{\text{DDR[x]\_CLK[y]}}$ are used by the memory to register the command and address transmitted on the transmit channels. All address and control signals are transmitted clock-centered with respect to DDR[x]_CLK[y] and $\overline{\text{DDR[x]\_CLK[y]}}$. The memory, on the positive edge of DDR[x]_CLK[y] and the negative edge of $\overline{\text{DDR[x]\_CLK[y]}}$, samples all address and control signals.

7.2.4.4 VTP Controller Macro

The VTP controller macro evaluates silicon performance at current voltage, temperature, and process (VTP) in the chip to enable drivers to set constant predetermined output driver impedance. The controller operates by comparing driver impedances to the external reference resistor and adjusting driver impedance to obtain an impedance match. VTP Controller supports the following features

- The VTP controller generates information regarding the Voltage, temperature, and process (VTP) on a chip to be shared with the drivers on the periphery of an ASIC
- Requires a Clock input from the core running at 20 MHz or less.
- 110 clock cycles are needed to assure the VTP outputs are initially set after reset is removed.
- Can be used in static or dynamic update mode of operation.
- The VTP controller has internal noise filtering which allows it to provide continuous VTP bit updates (dynamic update) to the IO macros.

Impedance of the drivers and terminations must be updated often even while in operation, a system referred to as dynamic update. In contrast, static update requires the bus to stop sending data for the impedances to be updated.

Table 7-2. VTP Controller Macro

F2	F1	F0	Description
0	0	0	Off
0	0	1	Update on 5 consecutive update requests
0	1	0	Update on 3 consecutive update requests
0	1	1	Update on 7 consecutive update requests
1	0	0	Update on 2 consecutive update requests
1	0	1	Update on 6 consecutive update requests
1	1	0	Update on 4 consecutive update requests
1	1	1	Update on 8 consecutive update requests

7.2.4.5 DQS-Gate IOs

To effectively model the I/O delay on the DQS gating signal during a read request (the DQS receiver and the CLK driver I/Os), the signal is expected to be looped on a single I/O connecting fifo_we_in to fifo_we_out. The board and memory delay, being fairly constant across PTV variations, are calibrated within the data and command macros using a compensated delay line. The delay need not be modeled, and the loop-back can be done at the die level without bringing the signals out to the package level. A single I/O for fifo_we_in and fifo_we_out is required for every 8-bit data data and command macros.

The data and command macros are responsible for system-level flight time compensation. The following controls are supported by the DDR2/3 controller subsystem:

- Aligning DDR[x]_DQS with respect to DDR[x]_CLK[y] during Write Cycle: For DDR3 operation, initiate the write leveling state machine on each rank in turn to capture the proper delay settings to align DDR[x]_DQS with DDR[x]_CLK[y] clock for each memory chip. If you want to do this manually, write to the control register that controls the delay of DDR[x]_DQS versus DDR[x]_CLK[y] clock position.
- Aligning DDR[x]_DQ[31:0] with respect to DDR[x]_DQS during Write Operation

For each SDRAM part you need to align the DDR[x]_DQS to the center of the DDR[x]_D bits. Set the appropriate bits of the controller to change the delay of the DDR[x]_D signals such that DDR[x]_DQS is aligned in the center of the DQ eye to have proper setup and hold margin.

If you want to do this manually, write to the control register that control the delay of DDR[x]_D versus DDR[x]_DQS. To produce a given amount of skew to center the DDR[x]_D versus DDR[x]_DQS at the SDRAM, the following register is programmed:

- Align FIFO WE Window (Read DQS Gate)

The FIFO WE (Write Enable) signal is used as an input to gate the time where DDR[x]_DQS is valid into the controller on Read cycles to find a delay setting that allows the read data to be captured without errors. The alignment of FIFO WE to the valid Read cycle DDR[x]_DQS window is done internally in the controller PHY.

To adjust the delay of FIFO_WE to center the FIFO WE vs. DDR[x]_DQS valid window at the SDRAM, the data macro 0/1/2/3 DQS gate slave ratio register is programmed.

7.2.5 Address Mapping

The DDR2/3 memory controller views external DDR2/3 SDRAM as one continuous block of memory. This statement is true regardless of the number of memory devices located on the chip select space. The DDR2/3 memory controller receives DDR2/3 memory access requests along with a 32-bit logical address from the rest of the system. In turn, DDR2/3 memory controller uses the logical address to generate a row/page, column, and bank address for the DDR2/3 SDRAM. The number of column, row and bank address bits used is determined by the IBANK, RSIZE, and PAGESIZE fields (see Table 7-3). The DDR2/3 memory controller uses up to 15 bits for the row/page address.

Table 7-3. Address Mapping

Bit Field	Bit Value	Bit Description
RSIZE		Defines the number of address lines to be connected to DDR2/3 memory device
	0	9 row bits
	1h	10 row bits
	2h	11 row bits
	3h	12 row bits
	4h	13 row bits
	5h	14 row bits
	6h	15 row bits
PAGESIZE		Defines the page size of each page of the external DDR2/3 memory device
	0	256 words (requires 8 column address bits)
	1h	512 words (requires 9 column address bits)
	2h	1024 words (requires 10 column address bits)
	3h	2048 words (requires 11 column address bits)
IBANK		Defines the number of internal banks on the external DDR2/3 memory device
	0	1 bank
	1h	2 banks
	2h	4 banks
	3h	8 banks
EBANK		Defines whether DDR2/3 memory controller accesses use 1 or 2 chip selects
	0	CS0 only
	1h	CS0 and CS1

When addressing SDRAM, if the IBANK_POS field in the SDRCR is cleared to 0, the DDR2/3 memory controller uses 3 fields—IBANK, EBANK, and PAGESIZE in the SDRCR to determine the mapping from source address to DDR2/3 memory device row, column, bank and chip select. If IBANK_POS is set to 1, 2, or 3, the DDR2/3 controller uses 4 fields—IBANK, EBANK, PAGESIZE, and RSIZE in the SDRCR to determine the mapping from source address to DDR2/3 memory device row, column, bank, and chip select. In all cases, the DDR2/3 controller considers its DDR2/3 memory device address space to be a single logical block, regardless of the number of physical devices or whether the devices are mapped to 1 chip select or 2 DDR2/3 controller chip selects.

Since the DDR2/3 memory controller interleaves among less number of banks when IBANK_POS ≠ 0 or EBANK_POS = 1, these cases are lower in performance than the IBANK_POS = 0 case. Thus, these cases are only recommended to be used along with partial array self-refresh where performance can be traded off for power savings.

7.2.5.1 Address Mapping When IBANK_POS = 0 and EBANK_POS = 0

For IBANK_POS = 0 and EBANK_POS = 0 (see Table 7-4), the effect of the address mapping scheme is that as the source address increments across DDR2/3 memory device page boundaries, the DDR2/3 controller moves onto the same page in the next bank in the current device $\overline{\text{DDR[x]\_CS[0]}}$. This movement along the banks of the current proceeds to the same page in the next device (if EBANK = 1, $\overline{\text{DDR[x]\_CS[1]}}$) and proceeds through the same page in all its banks before moving over to the next page in the first device ($\overline{\text{DDR[x]\_CS[0]}}$). The DDR2/3 controller exploits this traversal across internal banks and chip selects while remaining on the same page to maximize the number of open DDR2/3 memory device banks within the overall DDR2/3 memory device space.

Thus, the DDR2/3 controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, and can interleave among all of them.

Table 7-4. OCP Address to DDR2/3 Address Mapping for IBANK_POS = 0 and EBANK_POS = 0

Logical Address			
Row Address	**Chip Select**	**Bank Address**	**Column Address**
15 bits	Number of bits defined by EBANK of SDRCR:	Number of bits defined by IBANK of SDRCR:	Number of bits defined by PAGESIZE of SDRCR:
	EBANK = 0 => 0 bits	IBANK = 0 => 0 bits	PAGESIZE = 0 => 8 bits
	EBANK = 1 => 1 bit	IBANK = 1 => 1 bit	PAGESIZE = 1 => 9 bits
		IBANK = 2 => 2 bits	PAGESIZE = 2 => 10 bits
		IBANK = 3 => 3 bits	PAGESIZE = 3 => 11 bits

7.2.5.2 Address Mapping when IBANK_POS = 1 and EBANK_POS = 0

For IBANK_POS = 1 and EBANK_POS = 0 (see Table 7-5), the interleaving of banks within a device (per chip select) is limited to 4 banks. However, it can still interleave banks between the two chip selects. Thus, the DDR2/3 controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 8 of them.

Table 7-5. OCP Address to DDR2/3 Address Mapping for IBANK_POS = 1 and EBANK_POS = 0

Logical Address				
Bank Address[2]	**Row Address**	**Chip Select**	**Bank Address[1:0]**	**Column Address**
Number of bits defined by IBANK of SDRCR:	Number of bits defined by RSIZE of SDRCR:	Number of bits defined by EBANK of SDRCR:	Number of bits defined by IBANK of SDRCR:	Number of bits defined by PAGESIZE of SDRCR:
IBANK = 0 => 0 bits	RSIZE = 0 => 9 bits	EBANK = 0 => 0 bits	IBANK = 0 => 0 bits	PAGESIZE = 0 => 8 bits
IBANK = 1 => 0 bits	RSIZE = 1 => 10 bits	EBANK = 1 => 1 bit	IBANK = 1 => 1 bit	PAGESIZE = 1 => 9 bits
IBANK = 2 => 0 bits	RSIZE = 2 => 11 bits		IBANK = 2 => 2 bits	PAGESIZE = 2 => 10 bits
IBANK = 3 => 1 bit	RSIZE = 3 => 12 bits		IBANK = 3 => 2 bits	PAGESIZE = 3 => 11 bits
	RSIZE = 4 => 13 bits			
	RSIZE = 5 => 14 bits			
	RSIZE = 6 => 15 bits			

7.2.5.3 Address Mapping when IBANK_POS = 2 and EBANK_POS = 0

For IBANK_POS = 2 and EBANK_POS = 0 (see Table 7-6), the interleaving of banks within a device (per chip select) is limited to 2 banks. However, it can still interleave banks between the two chip selects. Thus, the DDR2/3 controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 4 of them.

Table 7-6. OCP Address to DDR2/3 Address Mapping for IBANK_POS = 2 and EBANK_POS = 0

Logical Address

Number of bits defined by IBANK of SDRCR:	Number of bits defined by RSIZE of SDRCR:	Number of bits defined by EBANK of SDRCR:	Number of bits defined by IBANK of SDRCR:	Number of bits defined by PAGESIZE of SDRCR:
IBANK = 0 => 0 bits	RSIZE = 0 => 9 bits	EBANK = 0 => 0 bits	IBANK = 0 => 0 bits	PAGESIZE = 0 => 8 bits
IBANK = 1 => 0 bits	RSIZE = 1 => 10 bits	EBANK = 1 => 1 bit	IBANK = 1 => 1 bit	PAGESIZE = 1 => 9 bits
IBANK = 2 => 1 bits	RSIZE = 2 => 11 bits		IBANK = 2 => 1 bits	PAGESIZE = 2 => 10 bits
IBANK = 3 => 2 bit	RSIZE = 3 => 12 bits		IBANK = 3 => 1 bits	PAGESIZE = 3 => 11 bits
	RSIZE = 4 => 13 bits			
	RSIZE = 5 => 14 bits			
	RSIZE = 6 => 15 bits			

7.2.5.4 Address Mapping when IBANK_POS = 3 and EBANK_POS = 0

For IBANK_POS = 3 and EBANK_POS = 0 (see Table 7-7), the DDR2/3 controller cannot interleave banks within a device (per chip select). However, it can still interleave banks between the two chip selects. Thus, the DDR2/3 controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 2 of them.

Table 7-7. OCP Address to DDR2/3 Address Mapping for IBANK_POS = 3 and EBANK_POS = 0

	RSIZE = 4 => 13 bits		
	RSIZE = 5 => 14 bits		
	RSIZE = 6 => 15 bits		

7.2.5.5 Address Mapping when IBANK_POS = 0 and EBANK_POS = 1

For IBANK_POS = 0 and EBANK_POS = 1 (see Table 7-8), the DDR2/3 memory controller interleaves among all the banks within a device (per chip select). However, the memory controller cannot interleave banks between the two chip selects. Thus, the DDR2/3 memory controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 8 of them.

	RSIZE = 4 => 13 bits		
	RSIZE = 5 => 14 bits		
	RSIZE = 6 => 15 bits		

7.2.5.6 Address Mapping when IBANK_POS = 1 and EBANK_POS = 1

For IBANK_POS = 1 and EBANK_POS = 1 (see Table 7-9), the interleaving of banks within a device (per chip select) is limited to 4 banks. Also, the DDR2/3 memory controller cannot interleave banks between the two chip selects. Thus, the memory controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 4 of them.

	IBANK = 3 => 1 bit	RSIZE = 3 => 12 bits	IBANK = 3 => 2 bits	PAGESIZE = 3 => 11 bits
		RSIZE = 4 => 13 bits		
		RSIZE = 5 => 14 bits		
		RSIZE = 6 => 15 bits		

7.2.5.7 Address Mapping when IBANK_POS = 2 and EBANK_POS = 1

For IBANK_POS= 2 and EBANK_POS= 1 (see Table 7-10), the interleaving of banks within a device (per chip select) is limited to 2 banks. Also, the DDR2/3 memory controller cannot interleave banks between the two chip selects. Thus, the memory controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 2 of them.

		RSIZE = 4 => 13 bits		
		RSIZE = 5 => 14 bits		
		RSIZE = 6 => 15 bits		

7.2.5.8 Address Mapping when IBANK_POS = 3 and EBANK_POS = 1

For IBANK_POS= 3 and EBANK_POS= 1 (see Table 7-11), the DDR2/3 memory controller cannot interleave banks within a device (per chip select) or between the two chip selects. Thus, the memory controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but cannot interleave among any of them.

		RSIZE = 5 => 14 bits	
		RSIZE = 6 => 15 bits	

7.2.6 Performance Management

7.2.6.1 Command Ordering and Scheduling

The DDR2/3 memory controller performs command re-ordering and scheduling in an attempt to achieve efficient transfers with maximum throughput. The goal is to maximize the utilization of the data, address, and command buses while hiding the overhead of opening and closing DDR2/3 SDRAM rows. Command re-ordering takes place within the command FIFO.

The DDR2/3 memory controller examines all the commands stored in the command FIFO to schedule commands to the external memory. For each master, the DDR2/3 memory controller reorders the commands based on the following rules:

- Selects the oldest command
- A read command is advanced before an older write command if the read is to a different block address (2048 bytes) and the read priority is equal to or greater than the write priority.

The second bullet above may be viewed as an exception to the first bullet. This means that for an individual master, all of its commands complete from oldest to newest, with the exception that a read may be advanced ahead of an older, lower or equal priority write. Following this scheduling, each master may have one command ready for execution.

Next, the DDR2/3 memory controller examines each of the commands selected by the individual masters and performs the following reordering:

- Among all pending reads, selects reads to rows already open. Among all pending writes, selects writes to rows already open.
- Selects the highest priority command from pending reads and writes to open rows. If multiple commands have the highest priority, then the DDR2 memory controller selects the oldest command.

The DDR2/3 memory controller may now have a final read and write command. If the Read FIFO is not full, then the read command is performed before the write command; otherwise, the write command is performed first.

Besides commands received from on-chip resources, the DDR2/3 memory controller also issues refresh commands. The DDR2/3 memory controller attempts to delay refresh commands as long as possible to maximize performance while meeting the SDRAM refresh requirements. As the DDR2/3 memory controller issues read, write, and refresh commands to DDR2/3 SDRAM device, it follows the following priority scheme:

1. (Highest priority) SDRAM refresh request due to Refresh Must level of refresh urgency reached (see Section 7.2.6.4)
2. Request for a read or a write.
3. SDRAM Activate commands.
4. SDRAM Deactivate commands.
5. SDRAM Deep Power-Down request.
6. SDRAM clock stop or Power-Down request.
7. SDRAM refresh request due to Refresh May or Release level of refresh urgency reached (see Section 7.2.6.4)
8. (Lowest priority) SDRAM self-refresh request.

7.2.6.2 Command Starvation

The reordering and scheduling rules listed in Section 7.2.6.1 may lead to command starvation, which is the prevention of certain commands from being processed by the DDR2/3 memory controller. Command starvation results from the following conditions:

- A continuous stream of high-priority read commands can block a low-priority write command
- A continuous stream of DDR2/3 SDRAM commands to a row in an open bank can block commands to the closed row in the same bank.

To avoid these conditions, the DDR2/3 memory controller can momentarily raise the priority of the oldest command in the command FIFO after a set number of transfers have been made. The PR_OLD_COUNT field in the peripheral bus burst priority register (PBBPR) sets the number of the transfers that must be made before the DDR2/3 memory controller raises the priority of the oldest command.

7.2.6.3 Possible Race Condition

A race condition may exist when certain masters write data to the DDR2/3 memory controller. For example, if master A passes a software message via a buffer in DDR2/3 memory and does not wait for indication that the write completes, when master B attempts to read the software message it may read stale data and therefore receive an incorrect message. In order to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write completion status from the DDR2/3 memory controller before indicating to master B that the data is ready to be read. If master A does not wait for indication that a write is complete, it must perform the following workaround:

1. Perform the required write.
2. Perform a dummy write to the DDR2 memory controller module ID and revision register.
3. Perform a dummy read to the DDR2 memory controller module ID and revision register.
4. Indicate to master B that the data is ready to be read after completion of the read in step 3.

The completion of the read in step 3 ensures that the previous write was done.

For a list of the master peripherals that need this workaround, see the device-specific data sheet.

7.2.6.4 Refresh Scheduling

The DDR2/3 memory controller issues AUTO REFRESH commands to DDR2/3 SDRAM devices at a rate defined in the refresh rate (RR) field in the SDRAM refresh control register (SDRRCR). The controller uses two counters to schedule AUTO REFRESH commands: a 13-bit decrementing refresh interval counter and a 4-bit refresh backlog counter. The refresh interval counter is loaded with the value of the RR field and decrements by 1 each cycle until it reaches zero. Once the interval counter reaches zero, it reloads with the value of the RR field. Each time the interval counter expires, a refresh backlog counter increments by 1. Conversely, each time the DDR2/3 memory controller performs a AUTO REFRESH command, the backlog counter decrements by 1. This means the refresh backlog counter records the number of AUTO REFRESH commands the memory controller currently has outstanding. For the range of values that the backlog counter can take, there are three levels of urgency with which the controller should perform an auto refresh cycle as listed in Table 7-12.

The refresh counters do not operate when the memory controller is in self-refresh mode.

Table 7-12. Refresh Scheduling

Urgency Level	Description
Refresh May	Whenever the backlog count is greater than 0, to indicate that there is a refresh backlog, so if the controller is not busy and none of the SDRAM banks are open, it should perform an auto refresh cycle.
Refresh Release	Whenever the backlog count is greater than 4, to indicate that the refresh backlog is getting high, so if the controller is not busy it should perform an auto refresh cycle even if any banks are open.
Refresh Must	Whenever the backlog count is greater than 7, to indicate that the refresh backlog is getting excessive and the controller should perform an auto refresh cycle before servicing any new memory access requests. The controller starts servicing new memory accesses after Refresh Release level is cleared.

7.2.6.5 Performance Counters

The PRFCNT1 and PRFCNT2 registers are used to monitor or calculate the DDR2/DDR3 Controller bandwidth and efficiency. These counters are able to count events such as total SDRAM accesses, SDRAM activates, reads, writes, and other events. Each counter counts independent of the other counters. In addition to the ability to count events, the counters can also filter the events from a particular master or address space. The events counting and filter enabling are configured using the PRFCNTCFG register. The filter value used is configured through the PRFCNTSEL register. Each counter can be configured independently.

Table 7-13 lists all the events that can be counted and whether a filter can be applied to a particular event. A filter is applied to an event if the following bits are set to 0x1 for that event:

- For Performance Counter 1: PRFCNTCFG[15] CNTR1_MCONNID_EN and PRFCNTCFG[14] CNTR1_REGION_EN;
- For Performance Counter 2: PRFCNTCFG[31] CNTR2_MCONNID_EN and PRFCNTCFG[30] CNTR2_REGION_EN.

Table 7-13. Performance Counter Filter Configuration

CNTRn_CFG	CNTRn_REGION_EN	CNTRn_MCONNID_EN	Description
0x0	0x0	0x0 or 0x1	Count total SDRAM accesses
0x1	0x0	0x0 or 0x1	Count total SDRAM activates
0x2	0x0 or 0x1	0x0 or 0x1	Count total reads
0x3	0x0 or 0x1	0x0 or 0x1	Count total writes
0x4	0x0	0x0	Count the number of DDR2/DDR3 Controller functional clock cycles during which the L3 Command FIFO is full
0x5	0x0	0x0	Count the number of DDR2/DDR3 Controller functional clock cycles during which the L3 Write Data FIFO is full
0x6	0x0	0x0	Count the number of DDR2/DDR3 Controller functional clock cycles during which the L3 Read Data FIFO is full
0x7	0x0	0x0	Count the number of DDR2/DDR3 Controller functional clock cycles during which the L3 Return Command FIFO is full
0x8	0x0 or 0x1	0x0 or 0x1	Count the number of priotity elevations
0x9	0x0	0x0	Count the number of DDR2/DDR3 Controller functional clock cycles that a command was pending
0xA	0x0	0x0	Count the number of DDR2/DDR3 Controller functional clock cycles for which the memory data bus was transferring data.
0xB - 0xF	0x0	0x0	Reserved for future use.

7.2.6.5.1 Performance Counters General Examples

- **General Example for Counting All Write Accesses**
  PRFCNT1 register needs to count all write accesses from master with connection ID equal to 0xA (this is the system MMU). To enable the writes counting, the PRFCNTCFG[3:0] CNTR1_CFG bit field must be set to 0x3. The PRFCNTSEL[15:8] MCONNID1 bit field must be set to 0xA. Finally, to enable filtering, the PRFCNTCFG[15] CNTR1_MCONNID_EN bit must be set to 0x1. With this configuration PRFCNT1 will count every write made to the SDRAM from master 0xA to any address space. This will not include accesses from other masters and will not include commands other than writes.

- **General Example for Counting Total Access**
  PRFCNT2 register needs to count total accesses to the SDRAM regardless of the address space or master. To enable the counting of all accesses to the SDRAM, the PRFCNTCFG[19:16] CNTR2_CFG bit field must be set to 0x0. Finally, to disable filtering, both the PRFCNTCFG[31] CNTR2_MCONNID_EN and PRFCNTCFG[30] CNTR2_REGION_EN bits must be set to 0x0. With this configuration PRFCNT2 will count every access made to the SDRAM. This will include all accesses from all masters and to any address space.
- **General Example for Counting All Read Accesses**
  PRFCNT1 register needs to count all read accesses from master with connection ID equal to 0xA (this is the system MMU) to address space 0x0. To enable the reads counting, the PRFCNTCFG[3:0] CNTR1_CFG bit field must be set to 0x2. The PRFCNTSEL[15:8] MCONNID1bit field must be set to 0xA and the PRFCNTSEL[1:0] REGION_SEL1 bit field must be set to 0x0. Finally, to enable filtering, both the PRFCNTCFG[15] CNTR1_MCONNID_EN and the PRFCNTCFG[14] CNTR1_REGION_EN bits must be set to 0x1. With this configuration, PRFCNT1 will count every read made to the SDRAM from master 0xA to address space 0x0. This will not include accesses from other masters or accesses to other address spaces and will not include commands other than reads.

7.2.7 DDR3 Software Read-Write Leveling

The memory controller supports only software leveling. Software leveling is a procedure by which the time delays between DDR3 signals can be compensated by appropriate values programmed in the corresponding slave ratio registers of the DDR PHY. For description of these registers, see Table 7-35. Software leveling can be done independently for each data and command macro. When software leveling is used there is no need to enable the leveling feature of the external DDR3 SDRAM, which is controlled by one of its MR registers. However, during write leveling the ODT function must be on. Proper ODT values must be turned on at the external memory side by setting Rtt_Nom (A9,A6,A2) bits in external DDR3 MR1 register.

For more information about the concept of the software leveling, see http://processors.wiki.ti.com/index.php/TI814x-DDR3-Init-U-Boot.

7.2.8 PRCM Sequence for DDR2/3 Memory Controller

Following is the power, reset, and clock management (PRCM) module sequence to enable the clocks to the DDR2/3 memory controller:

1. Enable DDR2/3 clock by writing 2h to PRCM CM_DEFAULT_FW_CLKCTRL register.
2. Enable L3 interconnect fast clock by writing 2h to PRCM CM_DEFAULT_L3_FAST_CLKSTCTRL register.
3. Enable DDR2/3 controller 0 interface clocks by writing 2h to PRCM CM_DEFAULT_EMIF_0_CLKCTRL register.
4. Enable DDR2/3 controller 1 interface clocks by writing 2h to PRCM CM_DEFAULT_EMIF_1_CLKCTRL register.
5. Poll for 1 in CLKACTIVITY_L3_FAST_GCLK and CLKACTIVITY_DDR_GCLK bits of PRCM CM_DEFAULT_L3_FAST_CLKSTCTRL register (indicates clocks are active).
6. Poll for 0 in IDLEST bit of PRCM CM_DEFAULT_EMIF_0_CLKCTRL register (indicates module is fully functional including OCP).
7. Poll for 0 in IDLEST bit of PRCM CM_DEFAULT_EMIF_1_CLKCTRL register (indicates module is fully functional including OCP).
8. Enable DMM module clocks by writing 2h to PRCM CM_DEFAULT_DMM_CLKCTRL register.
9. Poll for 0 in IDLEST bit of PRCM CM_DEFAULT_DMM_CLKCTRL register (indicates module is fully functional including OCP).

Refer to the *Power, Reset, and Clock Management (PRCM) Module* chapter for the PRCM register details.

7.2.9 Interrupt Support

The DDR2/3 controller is compliant with Open Core Protocol Specification (OCP-IP 2.2). The controller supports only Idle, Write, Read, and WriteNonPost command types. Also, the controller supports only incrementing, wrapping, and 2-dimensional block addressing modes. The controller supports generations of an error interrupt, if an unsupported command or a command with unsupported addressing mode is received.

7.2.10 EDMA Event Support

The DDR2/3 memory controller is a DMA slave peripheral and therefore does not generate EDMA events. Data read and write requests may be made directly by masters including the EDMA controller.

7.2.11 Emulation Considerations

The DDR2/3 memory controller remains fully functional during emulation halts to allow emulation access to external memory.

7.2.12 Power Management

This section defines the power management capabilities and requirements.

7.2.12.1 Self-Refresh Mode

The DDR2/3 memory controller supports self-refresh mode for low power. The memory controller automatically puts the SDRAM into self-refresh after the memory controller is idle for SR_TIM number of DDR clock cycles and the LP_MODE field is set to 2h. The LP_MODE and SR_TIM fields are programmed in the power management control register (PMCR). The memory controller completes all pending refreshes before it puts the DRAM into self-refresh. Therefore, after the expiration of reg_sr_tim, the memory controller starts issuing refreshes to complete the refresh backlog, and then issues a SELF-REFRESH command to the SDRAM.

In self-refresh mode, the memory controller automatically stops the clocks DDR[x]_CLK[y] to the SDRAM. The memory controller maintains DDR[x]_CKE low to maintain the self-refresh state. When the SDRAM is in self-refresh, the memory controller services register accesses as normal. If the LP_MODE field is not equal to 2 or an SDRAM access is requested while it is in self-refresh, and T_CKE + 1 cycles have elapsed since the SELF-REFRESH command was issued, the memory controller brings the SDRAM out of self-refresh. The value of T_CKE is taken from the SDRAM timing 2 register (SDRTIM2).

The exit sequence of self-refresh mode for DDR2 devices. The memory controller:

- Enables clocks.
- Drives DDR[x]_CKE high.
- Waits for T_XSNR + 1 cycles. The value of T_XSNR is taken from SDRAM timing 2 register (SDRTIM2).
- If the DLL bit in the SDRAM configuration register (SDRCR) is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 with the DDR[x]_A[15:0] bits set as:

Bits	Value	Description
DDR[x]_A[15:13]	0	Reserved
DDR[x]_A[12]	0	Output buffer enabled
DDR[x]_A[11]	0	Reserved
DDR[x]_A[10]	!DDQS	Differential DQS enable value from SDRAM configuration register
DDR[x]_A[9:7]	0	Exit OCD calibration mode
DDR[x]_A[6]	DDRTERM[1]	DDR2 termination resistor value from SDRAM configuration register
DDR[x]_A[5:3]	0	Additive latency = 0
DDR[x]_A[2]	DDRTERM[0]	DDR2 termination resistor value from SDRAM configuration register
DDR[x]_A[1]	DRIVE	SDRAM drive strength from SDRAM configuration register
DDR[x]_A[0]	1	Disable DLL

- Starts an auto-refresh cycle in the next cycle.
- Enters its idle state and can issue any other commands except a write or a read. A write or a read is only issued after T_XSRD + 1 clock cycles have elapsed since DDR[x]_CKE is driven high. The value of T_XSRD is taken from SDRTIM2.

The exit sequence of self-refresh mode for DDR3 devices. The memory controller:

- Enables clocks.
- Drives DDR[x]_CKE high.
- Waits for T_XSNR + 1 cycles. The value of T_XSNR is taken from SDRAM timing 2 register (SDRTIM2).
- If the DLL bit in the SDRAM configuration register (SDRCR) is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 with the pad_a_o bits set as:

Bits	Value	Description
DDR[x]_A[15:13]	0	Reserved
DDR[x]_A[12]	0	Output buffer enabled
DDR[x]_A[11]	0	Reserved
DDR[x]_A[10]	0	Reserved
DDR[x]_A[9]	DDRTERM[2]	DDR3 termination resistor value from SDRAM configuration register
DDR[x]_A[8]	0	Reserved
DDR[x]_A[7]	0	Write leveling disabled
DDR[x]_A[6]	DDRTERM[1]	DDR3 termination resistor value from SDRAM configuration register
DDR[x]_A[5]	DRIVE[1]	SDRAM drive strength from SDRAM configuration register
DDR[x]_A[4:3]	0	Additive latency = 0
DDR[x]_A[2]	DDRTERM[0]	DDR3 termination resistor value from SDRAM configuration register
DDR[x]_A[1]	DRIVE[0]	SDRAM drive strength from SDRAM configuration register
DDR[x]_A[0]	1	Disable DLL

- Starts an auto-refresh cycle in the next cycle.
- Performs one write incremental leveling.
- Performs read DQS incremental training.
- Performs read data-eye incremental training.
- Enters its idle state and can issue any other commands except a write or a read. A write or a read is only issued after T_XSRD + 1 clock cycles have elapsed since DDR[x]_CKE is driven high. The value of T_XSRD is taken from SDRTIM2.

7.2.12.2 Power Down Mode

The memory controller also supports Power-Down mode for low power. The memory controller automatically puts the SDRAM into Power-Down after the memory controller is idle for PD_TIM number of DDR clock cycles and the LP_MODE field is set to 4h. The LP_MODE and PD_TIM fields are programmed in the power management control register (PMCR). If the Refresh Must Level is not reached before the entry into Power-Down, the memory controller does not precharge all banks before issuing the POWER-DOWN command. This results in SDRAM entering Active Power-Down mode.

If the Refresh Must Level is reached before the entry into Power-Down, the memory controller precharges all banks and issues refreshes until the Refresh Release Level is reached before issuing the POWER-DOWN command. This results in SDRAM entering Precharge Power-Down mode.

In Power-Down mode, the memory controller does not stop the clocks DDR[x]_CLK[y] to the SDRAM. The memory controller maintains DDR[x]_CKE low to maintain the Power-Down state.

When the SDRAM is in Power-Down, the memory controller services register accesses as normal. If the LP_MODE field is set not equal to 4h, or an SDRAM access is requested, or the Refresh Must level is reached while the SDRAM is in Power-Down, the memory controller brings the SDRAM out of Power-Down. For DDR3, the memory controller also exits Power-Down to perform incremental leveling.

Exit sequence of Power-Down mode for DDR2 and DDR3: The memory controller:

- Drives DDR[x]_CKE high after T_CKE + 1 cycles have elapsed since the POWER-DOWN command was issued. The value of T_CKE is taken from SDRAM timing 2 register (SDRTIM2).
- Waits for T_XP + 1 cycles. The value of T_XP is taken from SDRTIM2.
- Enters its idle state and can issue any commands.

7.2.12.3 Save and Restore Mode

The DDR2/3 memory controller supports a save and restore mechanism to completely switch off power to the DDR2/3 memory controller. The following operation puts the DDR2/3 memory controller in off mode:

- An external master reads the following memory-mapped registers and saves their value external to the DDR2/3 memory controller:
  - SDRAM configuration register (SDRCR)
  - SDRAM configuration register 2 (SDRCR2)
  - SDRAM refresh control shadow register (SDRRCSR)
  - SDRAM timing 1 register (SDRTIM1)
  - SDRAM timing 1 shadow register (SDRTIM1SR)
  - SDRAM timing 2 register (SDRTIM2)
  - SDRAM timing 2 shadow register (SDRTIM2SR)
  - SDRAM timing 3 register (SDRTIM3)
  - SDRAM timing 3 shadow register (SDRTIM3SR)
  - Power management control register (PMCR)
  - Power management control shadow register (PMCSR)
  - Peripheral bus burst priority register (PBBPR)
  - System OCP interrupt enable set register (SOIESR)
  - DDR PHY control register (DDRPHYCR)
  - DDR PHY control shadow register (DDRPHYCSR)
- Memory controller completes all pending transactions and drains all its FIFOs.
- Memory controller puts the SDRAM in self-refresh mode.
- Memory controller copies all shadow memory-mapped registers to its main registers. It is assumed that the shadow register always has the same value as its corresponding main register.
- Memory controller waits for all interrupts to be serviced.
- Memory controller acknowledges assertion of internal power down request.
- The internal module reset signal is asserted.
- The clocks and power to the memory controller can now be switched off.

To restore power to the memory controller, the following operation is followed:

- The power and clocks to the memory controller are switched on.
- The internal module reset signal is deasserted, indicating to the memory controller that it is waking up from off mode.
- The memory controller does not perform SDRAM initialization and forces its state machine to be in self-refresh mode.
- The external master restores all of the above memory-mapped registers.
- The memory controller exits self-refresh state.
- The system can now perform access to the external memory.

7.3 DDR PHY

7.3.1 Functional Overview

DDR PHY is a fully digital, flexible and advanced solution to get the ultimate performance from their memory interface. The DDR PHY supports:

- Bi-directional DQS
- Software read/write leveling.

For DDR3, while maintaining a backward compatibility with the DDR2 standard.

DDR PHY consists of 3 separate blocks:

- Address and command block
- Byte-wide data block
- Master DLL block

The data slices or macros contain the data signal path and the slave DLLs for write data, write DQS, and read DQS. The ratio logic functions are used to adjust the signal timing for each signal edge and these are controlled by the master DLL.

7.3.2 Data Slice Block

The data slice block contains all the logic required to support read and write interface for a single memory data slice of 8 bits. It handles the DQ, DM, DQS, and FIFO_WE signals. The block consists of the following modules:

- Data Macro
- Write Data/DQS Training FSM
- Read Data Eye Training FSM
- Read Gate Training FSM
- Multi-Rank Ratio Logic

7.3.3 Master DLL

The Master DLL measures the cycle period in terms of a number of taps and passes this number through the ratio logic to the slave delay lines. The DLL is comprised of a delay line, an FSM, a clock divider, a phase detector and output filter. The FSM sends different control values to the delay line until phase detector detects transition of crossed from 0 to 1. When cross is detected, control values are provided to output filter which generates dll lock as well as final full cycle delay value. The master DLL manages On-Chip Variation (OCV) and continuously monitors core clock over PVT.

7.3.4 Ratio Logic Block

The Ratio Logic takes the output from the master DLL, which indicates the number of delay taps required to form a full-cycle shift, and scales it by an input ratio value in the range of 0 to 511 in units of 1/256th of a clock cycle. The result from Ratio Logic is the number of delay taps for slave Delay line.

7.3.5 Address Command Write, Write and Read Operation

7.3.5.1 Address Command Write

DDR[x]_CLK[y] must be properly delayed with respect to DDR[x]_DQS[3:0] to start write leveling; otherwise, the write-leveling operation cannot be guaranteed. To ensure proper functionality, there is a feature for pushing out the DDR[x]_CLK[y] and the corresponding address/command by one half cycle, enabled by asserting CMD0/1/2_REG_PHY_INVERT_CLKOUT_0. There is no need configuring this register, if:

- there is no fly-by routing on the board
- there is no multiple fanout on DDR[x]_CLK[y] (multiple ranks)

7.3.5.2 Write Operation

On a write operation, the IDID accepts signals synchronous to the core or memory clock from controller. DDR[x]_CLK[y]/$\overline{\text{DDR[x]\_CLK[y]}}$ are generated inside the IDID and sent out edge-aligned with DDR[x]_CLK[y]/$\overline{\text{DDR[x]\_CLK[y]}}$ for DDR2 operation, and delayed from core clock by the write-leveling delay for DDR3 operation. DDR[x]_D[31:0] and DDR[x]_DQM[3:0] are phase shifted by approximately 90 degrees with respect to DDR[x]_DQS[3:0].

7.3.5.3 Read Operation

For a read operation, the DDR[x]_D[31:0] signal sent by memory is edge-aligned with DDR[x]_DQS[3:0], so DDR[x]_DQS[3:0] must be shifted by PHY data slice to center-align DDR[x]_D[31:0] with DDR[x]_DQS[3:0]. This is approximately a 90-degree phase shift, with the exact shift dependent on the result of read DQS eye training in DDR3 applications, or register programming for DDR2 applications. After DDR[x]_D[31:0] is sampled by DDR[x]_DQS[3:0] and converted from DDR to SDR domain, the sampled data is re-synchronized by the core clock through a FIFO. Read data is then sent to the controller along with a data-valid signal.

7.4 Electrical Characteristics Control

7.4.1 Output Impedance Calibration

The DDR2/3 controller supports automatic output impedance calibration for DDR3. The ZQ calibration is enabled per chip select by setting the CS0EN and CS1EN bits in the SDRAM output impedance calibration configuration register (ZQCR). The DDR2/3 memory controller supports the following three types of ZQ calibration commands:

- ZQINIT – ZQ calibration command during initialization
- ZQCS – ZQ calibration short command
- ZQCL – ZQ calibration long command

For DDR3, the memory controller automatically issues a ZQINIT command during initialization. The memory controller waits and blocks any other command for (ZQINITMULT + 1) × (ZQCLMULT + 1) × (T_ZQCS + 1) number of clock DDR3 clock cycles every time a ZQINIT command is issued.

The memory controller periodically issues a ZQCS command every time REFINTERVAL expires. In other words, the REFINTERVAL field defines the interval between ZQCS commands. The memory controller waits and blocks any other command for (T_ZQCS + 1) number of DDR3 clock cycles every time a ZQCS command is issued.

If SEFXITEN field is set to a 1, the memory controller issues a ZQCL command every time it exits Self-Refresh, Active Power-Down, and Precharge Power-Down. The memory controller waits and blocks any other command for (ZQCLMULT + 1) × (T_ZQCS + 1) number of clock DDR clock cycles every time a ZQCL command is issued.

If a separate calibration resistor is used per device, the ZQ calibration can be performed simultaneously over both the chip selects. To enable ZQ calibration to be performed simultaneously over both chip selects, the DUALCALEN bit must be set to 1. If the DUALCALEN bit is cleared to a 0, the EMIF performs ZQ calibration per chip select serially.

7.4.2 IO Configuration and Slew Rate Control

On this device, programmability is given to control the output driver strength/impedance and slew rate. Table 7-14 shows the programmable impedance settings, where Rext is the external resistor between device VTP pin and ground. Recommended value is 50 ohms with 1% tolerance.

The recommended IO buffer impedance settings are:

1. For all the command signals DDR[x]_A[14:0], DDR[x]_BA[2:0], $\overline{\text{DDR[x]\_CAS}}$, $\overline{\text{DDR[x]\_WE}}$, $\overline{\text{DDR[x]\_CS[1:0]}}$, and DDR[x]_CLK/$\overline{\text{DDR[x]\_CLK}}$: programmed to a constant value of 5h and are independent of board and DDR2/3 memory chip.
2. For all data signals DDR[x]_D[31:0] , DDR[x]_DQM[3:0] , DDR[x]_DQS[3:0]/$\overline{\text{DDR[x]\_DQS[3:0]}}$, and DQSGATE (internal signal) : programmed to a constant value of 4h and are independent of board and DDR2/3 memory chip.

Refer to Section 7.7.2.1 and Section 7.7.2.2 for address/command pad and clock pad configuration registers.

Refer to Section 7.7.2.7 and Section 7.7.2.8 for data pad and data strobe configuration registers.

Table 7-14. Programmable Impedance Settings

I2	I1	I0	Output Impedance (Ron)	Ron for Rext 50 Ohms	Drive Strength
0	0	0	2 × Rext	100 ohms	4 mA
0	0	1	Rext	50 ohms	8 mA
0	1	0	1.33 × Rext	66.7 ohms	6 mA
0	1	1	0.8 × Rext	40 ohms	10 mA
1	0	0	1.6 × Rext	80 ohms	5 mA
1	0	1	0.88 × Rext	44.4 ohms	9 mA
1	1	0	1.14 × Rext	57.1 ohms	7 mA
1	1	1	0.72 × Rext	36.4 ohms	11 mA

To achieve optimal noise/frequency trade off, the slew rate of the output signal can also be programmed using the slew rate control registers. The Fasted Slew Rate bit setting is recommended. Table 7-15 shows the programmable slew-rate settings.

Table 7-15. Programmable Slew-rate Settings

SR[1]	SR[0]	Description
0	0	Fastest Slew Rate
0	1	Fast Slew Rate
1	0	Slow Slew Rate
1	1	Slowest Slew Rate

7.4.3 ODT Control

The DDR2/3 controller supports ODT programming. ODT may be required for better system-level signal integrity and performance. ODT strength level is a function of output driver strength. 50-ohms termination programming is recommended for better system signal integrity. Table 7-16 shows the ODT settings.

Table 7-16. ODT Settings

ODT[1]	ODT[0]	Description
0	0	ODT off
0	1	ODT enable (50 ohms). Recommended for better signal integrity. For control lines: Rext For other than control lines: (0.88 x Rext)
1	0	ODT off
1	1	ODT enable (100 ohms) For control lines: 2 × Rext For other than control lines: (2 × 0.88 x Rext)

Refer to DDRPHYCR (Section 7.7.1.26) and DDRPHYCSR (Section 7.7.1.27) for register programming.

7.5 DDR2/3 SDRAM Memory Initialization

7.5.1 DDR2 SDRAM Memory Initialization

The DQSGATE signal on earlier devices (such as the TMS320DM648 processor) were looped back through the board. However, on this device the DQSGATE signal is looped back internally within the device. A delay line is used to adjust for the board round-trip delay. This is captured in the register. The delay value is represented in terms of DDR2 clock cycles and is 10 bits. A value of 100h implies a delay equal to one DDR2 clock cycle period. For example, if the round-trip delay on board is 1.25 ns for 400-MHz clock DDR2 operation (2.5 ns period), this would mean half a cycle delay and hence the value programmed would be 80h. This is board dependent.

The recommended IO buffer impedance settings are:

1. For all the command signals DDR[x]_A[14:0], DDR[x]_BA[2:0], $\overline{\text{DDR[x]\_CAS}}$, $\overline{\text{DDR[x]\_WE}}$, $\overline{\text{DDR[x]\_CS[1:0]}}$, and DDR[x]_CLK[y]/$\overline{\text{DDR[x]\_CLK[y]}}$: programmed to a constant value of 5h and are independent of board and DDR2 memory chip.
2. For all data signals DDR[x]_D[31:0], DDR[x]_DQM[3:0], DDR[x]_DQS[3:0]/$\overline{\text{DDR[x]\_DQS[3:0]}}$, and DQSGATE (internal signal): programmed to a constant value of 4h and are independent of board and DDR2 memory chip.

DDR2 SDRAM devices contain mode and extended mode registers that configure the mode of operation for the device. These registers control parameters such as burst type, burst length, and CAS latency. The DDR2/3 memory controller programs the mode and extended mode registers of the DDR2 memory by issuing MRS and EMRS commands during the initialization sequence. The initialization sequence performed by the DDR2/3 memory controller is compliant with the JESD79-2E specification for DDR2 operation.

The DDR2/3 memory controller performs the DDR2 initialization sequence under the following condition:

- DDR2 auto-initialization is not done after cold reset and is triggered by programming the INITREF_DIS bit to 0 in the SDRRCR.

At the end of the initialization sequence, the DDR2 memory controller performs an auto-refresh cycle, leaving the DDR2 memory controller in an idle state with all banks deactivated.

7.5.1.1 DDR2 SDRAM Device Mode Register Configuration Values

The DDR2 memory controller initializes the mode register, extended mode register 1, and extended mode register 2 of the memory device with the values shown in Table 7-17, Table 7-18, and Table 7-19. The DDR2 SDRAM extended mode registers 3 is configured with a value of 0.

Table 7-17. DDR2 SDRAM Mode Register Configuration

Mode Register Bit	Mode Register Field	Initial Value	Description
12	Power-down Mode	0	Active power-down exit time bit. Configured for Fast exit.
11-9	Write Recovery	SDRTIM1.T_WR	Write recovery bits for auto-precharge. Initialized using the T_WR bit if the SDRAM timing 1 register (SDRTIM1).
8	DLL Reset	1h	DLL reset bit
7	Mode	0	Operating mode bit. Normal operating mode is always selected.
6-4	CAS Latency	SDRCR.CL	CAS latency bit. Initialized using the CL bit in the SDRAM configuration register (SDRCR).
3	Burst Type	0	Burst type bit. Sequential burst mode is always used.
2-0	Burst Length	3h	Burst length bit. A burst length of 8 is always used.

Table 7-18. DDR2 SDRAM Extended Mode Register 1 Configuration

Mode Register Bit	Mode Register Field	Initial Value	Description
12	Output Buffer Enable	0	Output buffer enable bits. Output buffer is always enabled.
11	RDQS Enable	0	Always initialized to 0.
10	!DQS Enable	SDRCR.DDQS	DQS enable
9-7	OCD Operation	0	Off-chip driver impedance calibration bits. This bit is always initialized to 0.
6	ODT Value(Rtt) or DDRTERM[1]	SDRCR.DDRTERM[1]	On-die termination effective resistance (Rtt) bit.
5-3	Additive Latency	0	Additive latency bits. Always initialized to 0 (no additive latency).
2	ODT Value(Rtt) or DDRTERM[0]	SDRCR.DDRTERM[0]	On-die termination effective resistance (Rtt) bit.
1	Output Driver Impedance	SDRCR.DRIVE	Output driver impedance control bits. Initialized using the DRIVE bit in the SDRAM configuration register (SDRCR).
0	Enable DLL	0	DLL enable/disable bit. DLL is always enabled.

Table 7-19. DDR2 SDRAM Extended Mode Register 2 Configuration

Mode Register Bit	Mode Register Field	Initial Value	Description
7	Self-Refresh Temperature	0	Normal Operating Temperature range
6-4	Reserved	0	Reserved
3	DCC	0	DCC disable
2-0	Partial array self-refresh	0	Always initialized to 0

7.5.1.2 After Register Configuration

The initialization sequence can be initiated by programming INITREF_DIS bit in the SDRAM refresh control register (SDRRCR) to 0. Perform the following steps to start the initialization sequence:

1. Program the DDRPLL for the required DDR2 memory target frequency.
2. Write 1 to DDR_RCD to bring Reset Clock Distribution module out of reset.
3. Program PRCM to enable DDR2/3 memory controller clocks. See Section 7.2.8.
4. Program DDR PHY:
   (a) Write 1 to DATA0/1/2/3_REG_PHY_USE_RANK0_DELAYS register to use rank 0 delays for all ranks during read/write operation.
   (b) Write 0 to CMD0/1/2_REG_PHY_INVERT_CLKOUT_0 register to send non-inverted DDR Clock to DRAM.
   (c) Program CMD0/1/2_REG_PHY_CTRL_SLAVE_RATIO_0 register. If CMD0/1/2_REG_PHY_INVERT_CLKOUT_0 is cleared to 0, program to 80h; else, program to 100h.
   (d) Write 0 to WR_LEVEL bit of DDR_VTP_CTRL_0 register to select slave ratio support.
   (e) Calculate the Read DQS Gate, Read DQS, and Write DQS parameters (see the wiki page: DDR3 Initialization with SW Leveling):
      (i) Program DATA0/1/2/3_REG_PHY_FIFO_WE_SLAVE_RATIO_0 register with Read DQS Gate parameter.
      (ii) Program DATA0/1/2/3_REG_PHY_WR_DQS_SLAVE_RATIO_0 register with Write DQS parameter.
      (iii) Program DATA0/1/2/3_REG_PHY_WR_DATA_SLAVE_RATIO_0 register with (Write DQS parameter + 40h)
      (iv) Program DATA0/1/2/3_REG_PHY_RD_DQS_SLAVE_RATIO_0 register with Read DQS parameter.
   (f) Write 5h to CMD0/1/2_IO_CONFIG_I_0 register.
   (g) Write 5h to CMD0/1/2_IO_CONFIG_I_CLK_0 register.
   (h) Write 4h to DATA0/1/2/3_IO_CONFIG_I_0 register.
   (i) Write 4h to DATA0/1/2/3_IO_CONFIG_I_CLK_0 register.
5. Setup DMM registers DMM_LISA_MAP_0/1/2/3 to access DDR.
6. Program SDRTIM1 and SDRTIM1SR registers with the value needed to meet the DDR2 SDRAM device timings.
7. Program SDRTIM2 and SDRTIM2SR registers with the value needed to meet the DDR2 SDRAM device timings.
8. Program SDRTIM3 and SDRTIM3SR registers with the value needed to meet the DDR2 SDRAM device timings.
9. Program SDCFG register with the value needed to meet the DDR3 SDRAM.
10. Program the RL and RD_LODT bits in DDRPHYCR register to the desired value.
11. Program the RR bit in SDRRCR register to a value that meets the refresh requirements of the DDR3 SDRAM device.
12. Write 1 to the ASR bit in SDRRCR register to enable DDR3 auto self refresh.
13. Write 0 to the INITREF_DIS bit in SDRRCR register to enable DDR3 initialization.

7.5.2 DDR3 SDRAM Memory Initialization

7.5.2.1 Introduction

DDR3 supports the following modes to compute the slave delay lines:

- User Defined Delays as a Ratio of the DDR3 Clock. This mode ensures that the delays track the clock automatically. To calculate the Read DQS Gate, Read DQS, and Write DQS parameters, see the wiki page: DDR3 Initialization with SW Leveling.
- Automatic Mode: Use the results from Leveling state machines.

7.5.2.2 DDR3 SDRAM Device Mode Register Configuration Values

The DDR3 memory controller initializes the mode register, extended mode register 1, and extended mode register 2 of the memory device with the values shown in Table 7-20, Table 7-21, and Table 7-22.

Table 7-20. DDR3 SDRAM Mode Register Configuration

Mode Register Bit	Mode Register Field	Initial Value	Description
12	Power-down Mode	0	Active power-down exit time bit. Configured for Fast exit.
11-9	Write Recovery	SDRTIM1.T_WR	Write recovery bits for auto-precharge. Initialized using the T_WR bit in the SDRAM timing 1 register (SDRTIM1).
8	DLL Reset	1h	DLL reset bit
7	Mode	0	Operating mode bit. Normal operating mode is always selected.
6-4	CAS Latency	SDRCR.CL[3:1]	CAS latency bit. Initialized using the CL bit in the SDRAM configuration register (SDRCR).
3	Burst Type	0	Burst type bit. Sequential burst mode is always used.
2	CAS Latency	SDRCR.CL[0]	CAS latency bit. Initialized using the CL bit in the SDRAM configuration register (SDRCR).
1-0	Burst Length	0	Burst length bits. A burst length of 8 is always used.

Table 7-21. DDR3 SDRAM Extended Mode Register 1 Configuration

Mode Register Bit	Mode Register Field	Initial Value	Description
12	Output Buffer Enable	0	Output buffer enable bit. Output buffer is always enabled.
11	TDQS Enable	0	TDQS disable
10	Reserved	0	Reserved
9	ODT Value(Rtt) or DDRTERM[2	SDRCR.DDRTERM[2]	On-die termination effective resistance (Rtt) bit.
8	Reserved	0	Reserved
7	Write Leveling	1h	Write Leveling Enabled
6	ODT Value(Rtt) or DDRTERM[1]	SDRCR.DDRTERM[1]	On-die termination effective resistance (Rtt) bit.
5	Output Driver Impedance	SDRCR.DRIVE[1]	Output driver impedance control bits. Initialized using the DRIVE bit in the SDRAM configuration register (SDRCR).
4-3	Additive Latency	0	Additive latency bits. Always initialized to 0 (no additive latency).
2	ODT Value(Rtt) or DDRTERM[0]	SDRCR.DDRTERM[0]	On-die termination effective resistance (Rtt) bit.
1	Output Driver Impedance	SDRCR.DRIVE	Output driver impedance control bit. Initialized using the DRIVE bit in the SDRAM configuration register (SDRCR).
0	Enable DLL	0	DLL enable/disable bits. DLL is always enabled.

Table 7-22. DDR3 SDRAM Extended Mode Register 2 Configuration

Mode Register Bit	Mode Register Field	Initial Value	Description
10-9	Dynamic ODT	SDRCR.DYNODT	Dynamic ODT value from SDRAM configuration register (SDRCR).
8	Reserved	0	Reserved
7	Self-Refresh Range	0	Normal Self Refresh
6	Auto Self-Refresh Enable	SDRCR.ASR	Auto Self Refresh enable from SDRAM refresh control register (SDRRCR).
5	Reserved	0	Reserved
4-3	CAS Write Latency	SDRCR.CWL	CAS Write Latency from SDRAM configuration register (SDRCR).
2-0	Partial array self-refresh	0	Always initialized to 0

7.5.2.3 After Register Configuration

1. Program the DDRPLL for the required DDR3 memory target frequency.
2. Write 1 to DDR_RCD to bring Reset Clock Distribution module out of reset.
3. Program PRCM to enable DDR2/3 memory controller clocks. See Section 7.2.8.
4. Program DDR PHY:
   (a) Write 1 to DATA0/1/2/3_REG_PHY_USE_RANK0_DELAYS register to use rank 0 delays for all ranks during read/write operation.
   (b) Write 1 to CMD0/1/2_REG_PHY_INVERT_CLKOUT_0 register to send inverted DDR Clock to DRAM.
   (c) Program CMD0/1/2_REG_PHY_CTRL_SLAVE_RATIO_0 register. If CMD0/1/2_REG_PHY_INVERT_CLKOUT_0 is cleared to 0, program 80h; else, program to 100h.
   (d) Write 5h to CMD0/1/2_IO_CONFIG_I_0 register.
   (e) Write 5h to CMD0/1/2_IO_CONFIG_I_CLK_0 register.
   (f) Write 4h to DATA0/1/2/3_IO_CONFIG_I_0 register.
   (g) Write 4h to DATA0/1/2/3_IO_CONFIG_I_CLK_0 register.
5. Setup DMM registers DMM_LISA_MAP_0/1/2/3 to access DDR.
6. Program SDRTIM1 and SDRTIM1SR registers with the value needed to meet the DDR3 SDRAM device timings.
7. Program SDRTIM2 and SDRTIM2SR registers with the value needed to meet the DDR3 SDRAM device timings.
8. Program SDRTIM3 and SDRTIM3SR registers with the value needed to meet the DDR3 SDRAM device timings.
9. Program SDCFG register with the value needed to meet the DDR3 SDRAM.
10. Program the RL and RD_LODT bits in DDRPHYCR register to the desired value.
11. Program the RR bit in the SDRAM refresh control register (SDRRCR) to a value that meets the refresh requirements of the DDR3 SDRAM device.
12. Write 1 to the ASR bit in SDRRCR register to enable DDR3 auto self refresh.
13. Write 0 to the INITREF_DIS bit in SDRRCR register to enable DDR3 initialization.
14. Write 0 to the WR_LEVEL bit in DDR_VTP_CTRL_0 register to select slave ratio support.

15. Calculate the Read DQS Gate, Read DQS, and Write DQS parameters (see the wiki page: *DDR3 Initialization with SW Leveling*):
    (a) Program DATA0/1/2/3_REG_PHY_FIFO_WE_SLAVE_RATIO_0 register with Read DQS Gate parameter.
    (b) Program DATA0/1/2/3_REG_PHY_WR_DQS_SLAVE_RATIO_0 register with Write DQS parameter.
    (c) Program DATA0/1/2/3_REG_PHY_WR_DATA_SLAVE_RATIO_0 register with (Write DQS parameter + 40h)
    (d) Program DATA0/1/2/3_REG_PHY_RD_DQS_SLAVE_RATIO_0 register with Read DQS parameter.

7.6 Using the DDR2/3 Memory Controller

The following sections describe the architecture of the DDR2/3 memory controller and how to configure it to perform read and write operations to DDR2/3 SDRAM devices.

Not all memory topologies may be supported by your device. See your device-specific data manual for details of supported configurations and topologies.

Printed circuit board (PCB) layout rules and connection requirements between the processor and the memory device are described in the device-specific data manual.

7.6.1 Configuring DDR2/3 Memory Controller Registers to Meet DDR2 SDRAM Specifications

The DDR2/3 memory controller allows a high degree of programmability for shaping DDR2 accesses. This provides the DDR2/3 memory controller with the flexibility to interface with a variety of DDR2 devices. By programming the SDRAM configuration register (SDRCR), SDRAM refresh control register (SDRRCR), SDRAM timing 1 register (SDRTIM1), SDRAM timing 2 register (SDRTIM2), and SDRAM timing 3 register (SDRTIM3), the DDR2/3 memory controller can be configured to meet the data sheet specification for JESD79-2E compliant DDR2 SDRAM devices.

As an example, the following sections describe how to configure each of these registers for access to two 1Gb, 16-bit wide DDR2 SDRAM devices, where each device has the following configuration:

- Maximum data rate: 800 MHz
- Number of banks: 8
- Page size: 1024 words
- CAS latency: 5

Consider a data rate of 800 MHz for DDR2 controller configurations in the following example.

7.6.1.1 Programming the SDRAM Configuration Register (SDRCR)

The SDRAM configuration register (SDRCR) contains register fields that configure the DDR2 memory controller to match the data bus width, CAS latency, number of banks, and page size of the attached DDR2 memory. Table 7-23 shows the SDRCR configuration.

Table 7-23. SDRCR Configuration

Field	Value	Function Selection
MEMTYPE	2h	To select DDR2 Memory Type
DDRTERM	3h	To select 50 ohm termination register
DQS	1h	To select Differential Ended DQS
DLL	0h	To enable DLL for Normal Operation
DRIVE	0h	To select full drive strength
NM	0h	To configure the DDR2 memory controller for a 32-bit data bus width.
CL	5h	To select CAS latency of 5
IBANK	8h	To select 8 internal DDR2 banks
EBANK	0h	To select CS0
PAGESIZE	2h	To select 1024-word page size

7.6.1.2 Programming the SDRAM Refresh Control Register (SDRRCR)

The SDRAM refresh control register (SDRRCR) configures the DDR2 memory controller to meet the refresh requirements of the attached DDR2 device. SDRRCR also allows the DDR2 memory controller to enter and exit self refresh. In this example, we assume that the DDR2 memory controller is not is in self-refresh mode.

The RR field in SDRRCR is defined as the rate at which the attached DDR2 device is refreshed in DDR2 cycles. The value of this field may be calculated using the following equation:

RR = DDR2 clock frequency (in MHz) × DDR2 memory fresh rate (in µs)

The DDR2-800 refresh rate specification:

Symbol	Description	Value
tREF	Average Periodic Refresh Interval	7.8 µs

Therefore, the value for the refresh rate (RR) can be calculated as:

RR = 400 MHz x 7.8 µs = 2078.7 = C30h

Table 7-24 shows the SDRRCR configuration.

Table 7-24. SDRRCR Configuration

Field	Value	Function Selection
INITREF_DIS	0	To Enable DDR2 Initialization and Refreshes
ASR	1	To Enable auto self refresh
RR	C30h	Set to C30h DDR2 clock cycles to meet the DDR2 memory refresh rate requirement

7.6.1.3 Configuring SDRAM Timing Registers (SDRTIM1, SDRTIM2, and SDTIM3)

The SDRAM timing 1 register (SDRTIM1), SDRAM timing 2 register (SDRTIM2), and SDRAM timing 3 register (SDRTIM3) configure the DDR2 memory controller to meet the data sheet timing parameters of the attached DDR2 device. Each field in SDRTIM1, SDRTIM2, and SDTIM3 corresponds to a timing parameter in the DDR2 data sheet specification. Table 7-25, Table 7-26, and Table 7-27 lists the register field name and corresponding DDR2 data sheet parameter name along with the data sheet value. These tables also provide a formula to calculate the register field value and displays the resulting calculation. Each of the equations includes a minus 1 because the register fields are defined in terms of DDR2 clock cycles minus 1.

Table 7-25. SDRTIM1 Configuration

Register Field	DDR2 SDRAM Data Sheet Parameter	Description	Data Sheet Value	Unit	Formula (Register Field Must be ≥)	Field Value
T_RP	tRP	Precharge command to refresh or activate command	13.125	nS	(tRP × fDDR[x]_CLK) - 1	5
T_RCD	tRCD	Activate command to read/write command	13.125	nS	(tRCD × fDDR[x]_CLK) - 1	5
T_WR	tWR	Write recovery time	15	nS	(tWR × fDDR[x]_CLK) - 1	5
T_RAS	tRAS	Active to precharge command	45	nS	(tRAS × fDDR[x]_CLK) - 1	17
T_RC	tRC	Activate to Activate command in the same bank	58.125	nS	(tRC × fDDR[x]_CLK) - 1	23
T_RRD	tRRD/tFAW	Activate to Activate command in a different bank	45	nS	(tFAW × fDDR[x]_CLK/4) - 1 for 8 bank DDR2 memory	4
T_WTR	tWTR	Write to read command delay	7.5	nS	(tWTR × fDDR[x]_CLK) - 1	3

Table 7-26. SDRTIM2 Configuration

Register Field	DDR2 SDRAM Data Sheet Parameter	Description	Data Sheet Value	Unit	Formula (Register Field Must be ≥)	Field Value
T_XP	tXP	Exit precharge power-down to any non-read command	3	nS	(tXP × fDDR[y]_CLK) - 1	2
T_XSNR	tXSNR	Exit self-refresh to a non-read command	137.5	nS	(tXSNR × fDDR[y]_CLK) - 1	54
T_XSRD	tXSRD	Exit self-refresh to a read command	200	tCK	(tXSRD - 1)	199
T_RTP	tRTP	Read to precharge command delay	7.5	nS	(tRTP × fDDR[y]_CLK) - 1	2
T_CKE	tCKE	CKE minimum pulse width (high and low pulse width)	3	tCK	(tCKE - 1)	2

Table 7-27. SDRTIM3 Configuration

Register Field	DDR2 SDRAM Data Sheet Parameter	Description	Data Sheet Value	Unit	Formula (Register Field Must be ≥)	Field Value
T_RFC	tRFC	Auto-refresh to active/auto-refresh command time	127.5	nS	(tRFC × fDDR[y]_CLK) - 1	43
T_RASMAX		Maximum number of refresh rate intervals from Active to Precharge command				15

7.6.1.4 Configuring DDR PHY Control Register

The DDR2/3 memory controller control register (DDRPHYCR) contains a read latency (RL) field that helps the DDR2 memory controller determine when to sample read data.

Table 7-28. DDRPHYCR Configuration

Field	Value	Description
RD_LODT	3	Termination resistance during read access. For DDR2 control lines (Rext) For other than DDR2 control lines (0.88 x Rext). Where Rext is the VTP resistor value.
RL	11	Maximum RL = CL + 7 - 1 Minimum RL = CL + 1 - 1 CL = 5 is being used for 400 MHz DDR2 clock

7.6.2 Configuring DDR2/3 Memory Controller Registers to Meet DDR3 SDRAM Specifications

The DDR2/3 memory controller allows a high degree of programmability for shaping DDR3 accesses. This provides the DDR2/3 memory controller with the flexibility to interface with a variety of DDR3 devices. By programming the SDRAM Configuration Register (SDRCR), SDRAM Refresh Control Register (SDRRCR), SDRAM Timing 1 Register (SDRTIM1), SDRAM Timing 2 Register (SDRTIM2), and SDRAM Timing 3 Register (SDRTIM3), the DDR2/3 memory controller can be configured to meet the data sheet specification for JESD79-3C compliant DDR3 SDRAM devices.

As an example, the following sections describe how to configure each of these registers for access to two 1Gb, 16-bit wide DDR3 SDRAM devices, where each device has the following configuration:

- Maximum data rate: 1593 MHz
- Number of banks: 8
- Page size: 1024 words
- CAS latency: 11

Consider a data rate of 1593 MHz for DDR3 controller configurations in the following example.

7.6.2.1 Programming the SDRAM Configuration Register (SDRCR)

The SDRAM configuration register (SDRCR) contains register fields that configure the DDR3 memory controller to match the data bus width, CAS latency, number of banks, and page size of the attached DDR3 memory. Table 7-29 shows the resulting SDRCR configuration.

Table 7-29. SDRCR Configuration

Field	Value	Description
MEMTYPE	3h	To select DDR3 Operation
IBANKPOS	0h	If 0, RSIZE field value is ignored
DDRTERM	2h	240 (ZQ Value)/2, 120 Ohm termination resistance
DDQS	1h	Differential DQS. DDR3 supports only differential DQS
DYNODT	1h	To select 60 Ohm Dynamic ODT
DLL	0h	To enable DLL for Normal Operation
DRIVE	1h	To select 34 Ohm Output Driver Impedance
CWL	3h	To select CAS write latency of 8
NW	0h	To configure DDR2/3 memory controller for a 32-bit data bus width.
CL	Eh	To select CAS latency of 11
RSIZE	0h	If IBANKPOS = 0, RSIZE field does not have any effect
IBANK	3h	To select 8 internal DDR3 banks
EBANK	0h	To select 1 chip
PAGESIZE	2h	To select 1024-word page size

7.6.2.2 Programming the SDRAM Refresh Control Register (SDRRCR)

The SDRAM refresh control register (SDRRCR) configures the DDR3 memory controller to meet the refresh requirements of the attached DDR3 device. SDRRCR also allows the DDR3 memory controller to enter and exit self refresh. In this example, we assume that the DDR3 memory controller is not is in self-refresh mode.

The RR field in SDRRCR is defined as the rate at which the attached DDR3 device is refreshed in DDR3 cycles. The value of this field may be calculated using the following equation:

RR = DDR3 clock frequency (in MHz) x DDR3 memory fresh rate (in µs)

The DDR3-1600 refresh rate specification:

Symbol	Description	Value
tREF	Average Periodic Refresh Interval	7.8 µs

Therefore, the value for the Refresh Rate (RR) can be calculated as follows:

RR = 796.5 MHz x 7.8 µs = 6212.7= 1844h

Table 7-30 shows the resulting SDRRCR configuration.

Table 7-30. SDRRCR Configuration

Field	Value	Function Selection
INITREF_DIS	0	To Enable DDR3 Initialization and Refreshes
ASR	1	To Enable auto self refresh
RR	1844h	Set to 1844h DDR3 clock cycles to meet the DDR3 memory refresh rate requirement

7.6.2.3 Configuring SDRAM Timing Registers (SDRTIM1, SDRTIM2, and SDTIM3)

The SDRAM timing 1 register (SDRTIM1), SDRAM timing 2 register (SDRTIM2), and SDRAM timing 3 register (SDRTIM3) configure the DDR3 memory controller to meet the data sheet timing parameters of the attached DDR3 device. Each field in SDRTIM1, SDRTIM2, and SDTIM3 corresponds to a timing parameter in the DDR3 data sheet specification. Table 7-31, Table 7-32, and Table 7-33 lists the register field name and corresponding DDR3 data sheet parameter name along with the data sheet value. These tables also provide a formula to calculate the register field value and displays the resulting calculation. Each of the equations includes a minus 1 because the register fields are defined in terms of DDR3 clock cycles minus 1.

Table 7-31. SDRTIM1 Configuration

Register Field	DDR2 SDRAM Data Sheet Parameter	Description	Data Sheet Value	Unit	Formula (Register Field Must be ≥)	Field Value
T_RP	tRP	Precharge command to refresh or activate command	13.125	nS	(tRP × fDDR[x]_CLK) - 1	10
T_RCD	tRCD	Activate command to read/write command	13.125	nS	(tRCD x fDDR[x]_CLK) - 1	10
T_WR	tWR	Write recovery time	15	nS	(tWR x fDDR[x]_CLK) - 1	11
T_RAS	tRAS	Active to precharge command	35	nS	(tRAS x fDDR[x]_CLK) - 1	27
T_RC	tRC	Activate to Activate command in the same bank	48.125	nS	(tRC x fDDR[x]_CLK) - 1	38
T_RRD	tRRD/tFAW	Activate to Activate command in a different bank	30 (x8) 40 (x16)	nS	(tFAW x fDDR[x]_CLK/4) - 1 for 8 Bank DDR3	5 (×8) 7 (×16)

Table 7-31. SDRTIM1 Configuration (continued)

Register Field	DDR2 SDRAM Data Sheet Parameter	Description	Data Sheet Value	Unit	Formula (Register Field Must be ≥)	Field Value
T_WTR	tWTR	Write to read command delay	7.5	nS	(Max((T_WTR x fDDR[x]_CLK),4)) - 1	5

Table 7-32. SDRTIM2 Configuration

Register Field	DDR2 SDRAM Data Sheet Parameter	Description	Data Sheet Value	Unit	Formula (Register Field Must be ≥)	Field Value
T_XP	tXP	Exit precharge power-down to any non-read command	6	nS	MAX((T_XP x fDDR[x]_CLK),3) - 1	4
T_XSNR	tXSNR	Exit self-refresh to a non-read command	120	nS	(tXSNR x fDDR[x]_CLK) - 1	95
T_XSRD	tXSRD	Exit self-refresh to a read command	512	tCK	(tXSRD - 1)	511
T_RTP	tRTP	Read to precharge command delay	7.5	nS	(tRTP x fDDR[x]_CLK) - 1	5
T_CKE	tCKE	CKE minimum pulse width (high and low pulse width)	5	tCK	MAX((T_CKE × fDDR[x]_CLK), 3) - 1	3

Table 7-33. SDRTIM3 Configuration

Register Field	DDR2 SDRAM Data Sheet Parameter	Description	Data Sheet Value	Unit	Formula (Register Field Must be ≥)	Field Value
T_CKESR	tCKESR	Minimum CKE low pulse width for self refresh entry to self refresh exit timing	6.25	nS	MAX((T_CKESR × fDDR[x]_CLK), 3) - 1	5
T_ZQCS	tZQCS	Normal operation short calibration time	64	tCK	(T_ZQCS - 1)	63
T_RFC	tRFC	Auto-refresh to active/auto-refresh command time	110	nS	(T_RFC x fDDR[x]_CLK) - 1	87
T_RAS_MAX		Maximum number of refresh rate intervals from Active to Precharge command. This field should be programmed to 15.				15

7.6.2.4 Configuring DDR PHY Control Register

The DDR2/3 memory controller control register (DDRPHYCR) contains a read latency (RL) field that helps the DDR3 memory controller determine when to sample read data.

Table 7-34. DDRPHYCR Configuration

Field	Value	Description
RD_LODT	1	Termination resistance during read access. For DDR3 control lines (Rext) For other than DDR3 control lines (0.88 x Rext). Where Rext is the VTP resistor value.
RL	17	Maximum RL = CL + 7 - 1 Minimum RL = CL + 1 - 1 CL = 11 is being used for 800 MHz DDR3 clock

7.7 DDR2/3 Memory Controller Registers

7.7.1 DDR2/3 Memory Controller Registers

Table 7-35 lists the memory-mapped registers for the DDR2/3 memory controller. For the base address of these registers, see Table 1-11.

Table 7-35. DDR2/3 Memory Controller Registers

Address Offset	Acronym	Register Description	Section

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 7-39. SDRAM Refresh Control Register (SDRRCR) Field Descriptions

Bit	Field	Value	Description
31	INITREF_DIS		Initialization and Refresh Disable
		0	Enable SDRAM Initialization and Refreshes.
		1	Disable SDRAM Initialization and Refreshes but carries out SDRAM Write/Read transactions.
30	Reserved	0	Reserved
29	SRT		DDR2 and DDR3 Self Refresh Temperature Range. For DDR3, this bit must be cleared to 0 if ASR is set to 1. A write to this field causes the DDR2/3 to start the initialization sequence.
		0	Normal Operating Temperature range.
		1	Extended Operating Temperature range.
28	ASR		DDR3 Auto Self Refresh Enable. A write to this field causes the DDR3 to start the SDRAM initialization sequence.
		0	Reserved
		1	Auto Self Refresh Enable
27	Reserved	0	Reserved
26-24	PASR		Partial Array Self Refresh. Determines what portion of the array is refreshed with the external memory in partial array self refresh mode. These bits gets loaded into the EMR of the external DDR2/3 memory during initialization. If the external memory does not support partial array self refresh, this field should be cleared to 0. A write to this field causes the memory controller to start the SDRAM initialization sequence.
		0	Full array
		1h	1/2 array
		2h	1/4 array
		3h	1/8 array
		4h	3/4 array
		5h	1/2 array
		6h	1/4 array
		7h	1/8 array
23-16	Reserved	0	Reserved
15-0	RR	0-FFFFh	Refresh rate. Defines the rate at which the attached DDR2/3 devices are refreshed. The value of this field is calculated with the following equation:
			RR = DDR2/3 clock frequency (in MHz) x DDR2/3 fresh rate (in µs)
			Where DDR2/3 refresh rate is derived from DDR2/3 data sheet.

7.7.1.5 SDRAM Refresh Control Shadow Register (SDRRCSR)

The SDRRCSR is shown in Figure 7-8 and described in Table 7-40.

Figure 7-8. SDRAM Refresh Control Shadow Register (SDRRCSR)

31	16	15	0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 7-41. SDRAM Timing 1 Register (SDRTIM1) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reserved
28-25	T_RP	0-Fh	Specifies the minimum number of DDR[x]_CLK[y] cycles from a precharge command to a refresh or activate command, minus 1. Corresponds to tRP AC timing parameter in the DDR2/3 data sheet. Calculated by T_RP = (tRP/DDR[x]_CLK[y] period) - 1
24-21	T_RCD	0-Fh	Specifies the minimum number of DDR[x]_CLK[y] cycles from an activate command to read or write command, minus 1. Corresponds to tRCD AC timing parameter in the DDR2/3 data sheet. Calculated by T_RCD = (tRCD/DDR[x]_CLK[y] period) - 1
20-17	T_WR	0-Fh	Specifies the minimum number of DDR[x]_CLK[y] cycles from the last write transfer to a precharge command, minus 1. Corresponds to tWR AC timing parameter in the DDR2/3 data sheet. Calculated by T_WR = (tWR/DDR[x]_CLK[y] period) - 1
16-12	T_RAS	0-1Fh	Specifies the minimum number of DDR[x]_CLK[y] cycles from an active command to a precharge command, minus 1. Corresponds to tras AC timing parameter in the DDR2/3 data sheet. Calculated by T_RAS = (tRAS/DDR[x]_CLK[y] period) - 1
11-6	T_RC	0-3Fh	Specifies the minimum number of DDR[x]_CLK[y] cycles from an active command to an active command, minus 1. Corresponds to trc AC timing parameter in the DDR2/3 data sheet. Calculated by T_RC = (tRC/DDR[x]_CLK[y] period) - 1
5-3	T_RRD	0-7h	Specifies the minimum number of DDR[x]_CLK[y] cycles from an activate command to an activate command in a different bank, minus 1. Corresponds to tRRD AC timing parameter in the DDR2/3 data sheet. Calculated by T_RRD = (tRRD/DDR[x]_CLK[y] period) - 1 For an 8-ban DDR2 and DDR3, this field must be equal to ((tFAW/(4 × DDR[x]_CLK[y] period)) - 1)
2-0	T_WTR	0-7h	Specifies the minimum number of DDR[x]_CLK[y] cycles from the last write to a read command, minus 1. Corresponds to the tWTR AC timing parameter in the DDR2/3 data sheet. Calculated by T_WTR = (tWTR/DDR[x]_CLK[y] period) - 1

7.7.1.7 SDRAM Timing 1 Shadow Register (SDRTIM1SR)

The SDRTIM1SR is shown in Figure 7-10 and described in Table 7-42.

Figure 7-10. SDRAM Timing 1 Shadow Register (SDRTIM1SR)

Table 7-42. SDRAM Timing 1 Shadow Register (SDRTIM1SR) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reserved
28-25	T_RP_SHDW	0-Fh	Shadow field for T_RP in SDRTIMR1. This field is loaded into T_RP field in SDRAM Timing 1 Register when SIdleAck is asserted.
24-21	T_RCD_SHDW	0-Fh	Shadow field for T_RCD in SDRTIMR1. This field is loaded into T_RCD field in SDRAM Timing 1 Register when SIdleAck is asserted.
20-17	T_WR_SHDW	0-Fh	Shadow field for T_WR in SDRTIMR1. This field is loaded into T_WR field in SDRAM Timing 1 Register when SIdleAck is asserted.
16-12	T_RAS_SHDW	0-1Fh	Shadow field for T_RAS in SDRTIMR1. This field is loaded into T_RAS field in SDRAM Timing 1 Register when SIdleAck is asserted.
11-6	T_RC_SHDW	0-3Fh	Shadow field for T_RC in SDRTIMR1. This field is loaded into T_RC field in SDRAM Timing 1 Register when SIdleAck is asserted.
5-3	T_RRD_SHDW	0-7h	Shadow field for T_RRD in SDRTIMR1. This field is loaded into T_RRD field in SDRAM Timing 1 Register when SIdleAck is asserted.
2-0	T_WTR_SHDW	0-7h	Shadow field for T_WTR in SDRTIMR1. This field is loaded into T_WTR field in SDRAM Timing 1 Register when SIdleAck is asserted.

7.7.1.8 SDRAM Timing 2 Register (SDRTIM2)

SDRTIM2 is shown in Figure 7-11 and described in Table 7-43.

Figure 7-11. SDRAM Timing 2 Register (SDRTIM2)

Table 7-43. SDRAM Timing 2 Register (SDRTIM2) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved
30-28	T_XP	0-7h	Specifies the minimum number of DDR[x]_CLK[y] cycles from power down exit to any other command except read command, minus 1. For DDR2, this field must be greater than tXP or tCKE. Corresponds to tXP or tCKE AC timing parameter in the DDR2/3 data sheet.
27-25	Reserved	0	Reserved
24-16	T_XSNR	0-1FFh	Specifies the minimum number of DDR[x]_CLK[y] cycles from a self-refresh exit to any other command except a read command, minus 1. Corresponds to tXSNR/tXS AC timing parameter in the DDR2/3 data sheet. Calculated by T_XSNR = (tXSNR/DDR[x]_CLK[y] period) - 1
15-6	T_XSRD	0-3FFh	Specifies the mimimum number of DDR[x]_CLK[y] cycles from a self-refresh exit to a read command, minus 1. Corresponds to tXSRD/tXSDLL AC timing parameter in the DDR2/3 data sheet. Calculated by T_XSRD = (tXSRD or tXSDLL) - 1
5-3	T_RTP	0-7h	Specifies the mimimum number of DDR[x]_CLK[y] cycles from a last read command to a precharge command, minus 1. Corresponds to tRTP AC timing parameter in the DDR2/3 data sheet. Calculated by T_RTP = (tRTP/DDR[x]_CLK[y] period) - 1
2-0	T_CKE	0-7h	Specifies the minimum number of DDR[x]_CLK[y] cycles between transitions on the DDR[x]_CKE[y] pin, minus 1. Corresponds to the tCKE AC timing parameter in the DDR2 data sheet. Calculated by T_CKE = (tCKE/DDR[x]_CLK[y] period) - 1

7.7.1.9 SDRAM Timing 2 Shadow Register (SDRTIM2SR)

The SDRTIM2SR is shown in Figure 7-12 and described in Table 7-44.

Figure 7-12. SDRAM Timing 2 Shadow Register (SDRTIM2SR)

Table 7-45. SDRAM Timing 3 Register (SDRTIM3) Field Descriptions

Bit	Field	Value	Description
31-21	Reserved	4h	Reserved
20-15	T_ZQCS	0-3Fh	Specifies the minimum number of DDR[x]_CLK[y] cycles for ZQCS command, minus 1. This is applicable only for DDR3. Corresponds to T_ZQCS = (tZQCS - 1), where tZQCS is DDR Clock Cycles.
14-13	Reserved	0	Reserved
12-4	T_RFC	0-1FFh	Specifies the minimum number of DDR[x]_CLK[y] cycles from Refresh or Load mode to Refresh or Activate, minus 1. Corresponds to tRFC AC timing parameter in the DDR2/3 data sheet. Calculated by T_RFC = (tRFC/DDR[x]_CLK[y] period) - 1
3-0	T_RASMAX	0-Fh	Specifies the maximum number of refresh rate intervals from Active to Precharge command. This field must be programmed to Fh for DDR2/3 SDRAM types.

7.7.1.11 SDRAM Timing 3 Shadow Register (SDRTIM3SR)

The SDRTIM3SR is shown in Figure 7-14 and described in Table 7-46.

11	DP_DEN		Deep Power Down Enable
		0	Normal Operation
		1	Overrides LP_MODE field setting
10-8	LP_MODE		Automatic Power Management Enable
		1h	Clock Stop Mode
		2h	Self Refresh Mode
		4h	Power Down Mode
		0, 3h, 5h-7h	Disable Automatic power management

Table 7-47. Power Management Control Register (PMCR) Field Descriptions (continued)

Bit	Field	Value	Description
7-4	SR_TIM		Power Management timer for Self Refresh. The DDR controller puts the external SDRAM in Self Refresh Mode after the DDR controller is idle for these number of DDR clock cycles and if LP_MODE is set to 2h.
		0	Immediately enter Self Refresh Mode
		1h	Enter Self Refresh Mode after 16 DDR Clocks
		2h	Enter Self Refresh Mode after 32 DDR Clocks
		3h	Enter Self Refresh Mode after 64 DDR Clocks
		4h	Enter Self Refresh Mode after 128 DDR Clocks
		5h	Enter Self Refresh Mode after 256 DDR Clocks
		6h	Enter Self Refresh Mode after 512 DDR Clocks
		7h	Enter Self Refresh Mode after 1024 DDR Clocks
		8h	Enter Self Refresh Mode after 2048 DDR Clocks
		9h	Enter Self Refresh Mode after 4096 DDR Clocks
		Ah	Enter Self Refresh Mode after 8192 DDR Clocks
		Bh	Enter Self Refresh Mode after 16384 DDR Clocks
		Ch	Enter Self Refresh Mode after 32768 DDR Clocks
		Dh	Enter Self Refresh Mode after 65536 DDR Clocks
		Eh	Enter Self Refresh Mode after 131072 DDR Clocks
		Fh	Enter Self Refresh Mode after 262144 DDR Clocks
3-0	CS_TIM		Power Management timer for Clock Stop. The DDR controller puts the external SDRAM in clock stop mode after the DDR controller is idle for these number of DDR clock cycles and if LP_MODE field is set to 1.
		0	Immediately enter Clock Stop Mode
		1h	Enter Clock Stop Mode after 16 clocks
		2h	Enter Clock Stop Mode after 32 clocks
		3h	Enter Clock Stop Mode after 64 clocks
		4h	Enter Clock Stop Mode after 128 clocks
		5h	Enter Clock Stop Mode after 256 clocks
		6h	Enter Clock Stop Mode after 512 clocks
		7h	Enter Clock Stop Mode after 1024 clocks
		8h	Enter Clock Stop Mode after 2048 clocks
		9h	Enter Clock Stop Mode after 4096 clocks
		Ah	Enter Clock Stop Mode after 8192 clocks
		Bh	Enter Clock Stop Mode after 16384 clocks
		Ch	Enter Clock Stop Mode after 32768 clocks
		Dh	Enter Clock Stop Mode after 65536 clocks
		Eh	Enter Clock Stop Mode after 131072 clocks
		Fh	Enter Clock Stop Mode after 262144 clocks

7.7.1.13 Power Management Control Shadow Register (PMCSR)

The PMCSR is shown in Figure 7-16 and described in Table 7-48.

R-0		R/W-1h		R/W-3h	

15	0
REFINTERVAL	
R/W-4C00h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 7-60. SDRAM Output Impedance Calibration Configuration Register (ZQCR) Field Descriptions

Bit	Field	Value	Description
31	CS1EN	0-1	Writing a 1 enables ZQ calibration for CS1
30	CS0EN	0-1	Writing a 1 enables ZQ calibration for CS0
29	DUALCALEN	0-1	ZQ Dual Calibration Enable. Allows both ranks (chip selects) to be ZQ calibrated simultaneously. Setting this bit requires both chip selects to have a separate calibration resistor per device.
28	SEFXITEN	0-1	ZQCL on Self-Refresh, Active Power Down and Prechare Power-Down exit enable. Writing a 1 enables the issuing of ZQCL on Self-Refresh, Active Power-Down and Precharge Power Down exit.
27-20	Reserved	0	Reserved
19-18	ZQINITMULT	0-3h	Indicates number of ZQCL intervals that make up a ZQINIT interval, minus 1
17-16	ZQCLMULT	0-3h	Indicates number of ZQCS intervals that make up a ZQCL interval, minus 1
15-0	REFINTERVAL	0-FFFFh	Number of refresh periods between ZQCS commands. This field supports between 1 refresh period to 256 ms between ZQCS calibration commands. Refresh period is defined by RR field in SDRAM Refresh Control Register.

7.7.1.26 DDR PHY Control Register (DDRPHYCR)

The DDRPHYCR is shown in Figure 7-29 and described in Table 7-61.

Figure 7-29. DDR PHY Control Register (DDRPHYCR)

31	21	20	19	16
Reserved		EN_DYN _PWRDN	Reserved	
R-0		R/W-0	R-0	

15	10	9	8	7	5	4	0
Reserved		RD_LODT		Reserved		RL	
R-0		R/W-1		R-0		R/W-Bh	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 7-61. DDR PHY Control Register (DDRPHYCR) Field Descriptions

Bit	Field	Value	Description
31-21	Reserved	0	Reserved
20	EN_DYN_PWRDN		Enables dynamically powering down the IO Receiver when not performing a read.
			For PG1.x devices:
		0	IO Receiver for DQ, DQS always powered up
		1	IO Receiver for DQ, DQS powered up during a read
			For PG2.x devices:
		0	IO Receiver always powered up
		1	IO Receiver powered up during a read
19-10	Reserved	0	Reserved
9-8	RD_LODT		Select controller termination during read accesses.
		0	ODT off
		1h	ODT enable (50 ohms). Recommended for better signal integrity.
			For control lines: Rext
			For other than control lines: (0.88 x Rext)
		2h	ODT off
		3h	ODT enable (100 ohms)
			For control lines: 2 × Rext
			For other than control lines: (2 × 0.88 x Rext)
7-5	Reserved	0	Reserved
4-0	RL	0-1Fh	Defines the latency for read data from DDR SDRAM in number of 1x cycles. The value applied should be equal to the required value minus one. The maximum read latency supported by the DDR PHY is equal to CAS latency plus 7 clock cycles. The minimum read latency must be equal to CAS latency plus 1 clock cycles.

7.7.1.27 DDR PHY Control Shadow Register (DDRPHYCSR)

The DDRPHYCSR is shown in Figure 7-30 and described in Table 7-62.

Figure 7-30. DDR PHY Control Shadow Register (DDRPHYCSR)

31	21	20	19	16
Reserved		EN_DYN _PWRDN _SHDW	Reserved	
R-0		R/W-0	R-0

R-0		R/W-1		R-0		R/W-Bh	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 7-62. DDR PHY Control Shadow Register (DDRPHYCSR) Field Descriptions

Bit	Field	Value	Description
31-21	Reserved	0	Reserved
20	EN_DYN_PWRDN_SHDW	0-1	Shadow field for EN_DYN_PWRDN in DDRPHYCR. This bit is loaded into EN_DYN_PWRDN bit in DDR PHY Control Register when SIdleAck is asserted.
19-10	Reserved	0	Reserved
9-8	RD_LODT_SHDW	0-3h	Shadow field for RD_LODT in DDRPHYCR. This field is loaded into RD_LODT field in DDR PHY Control Register when SIdleAck is asserted.
7-5	Reserved	0	Reserved
4-0	RL_SHDW	0-1Fh	Shadow field for RL in DDRPHYCR. This field is loaded into RL field in DDR PHY Control Register when SIdleAck is asserted.

7.7.2 DDR2/3 PHY Registers

Table 7-63 lists the memory-mapped registers for the DDR2/3 PHY. For the base address of these registers, see Table 1-12.

Table 7-63. Memory Mapped Registers for DDR2/3 PHY

Address Offset	Acronym	Register Description	Section

General-Purpose I/O (GPIO) Interface

This chapter describes the general-purpose I/O (GPIO) interface.

Topic **Page**

8.1 Introduction

8.1.1 Purpose of the Peripheral

The general-purpose interface combines two general-purpose input/output (GPIO) banks. Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 64 (2 × 32) pins. These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.

8.1.2 Features

Each channel in the GPIO module has the following features:

- The output enable register (GPIO_OE) controls the output capability for each pin.
- The output line level reflects the value written in the data output register (GPIO_DATAOUT) through the peripheral bus.
- The input line can be fed in to the GPIO module through an optional and configurable debouncing cell.
- The input line value is sampled into the data input register (GPIO_DATAIN) and can be read from the peripheral bus.
- In Active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level (logical 0, logical 1, or both) to be used can be configured.

The global features of the GPIO module are:

- Two identical interrupt generation sub-modules process synchronous interrupt requests from each channel in order to be used independently in a bi-processor environment. Each sub-module controls its own synchronous interrupt request line and has its own interrupt enable and interrupt status registers. The interrupt enable register (GPIO_IRQENABLE_SET_x) selects the channel(s) considered for the interrupt request generation, and the interrupt status register (GPIO_IRQSTATUS_RAW_x) determines which channel(s) has/have activated the interrupt request. Event detection on GPIO channels is reflected into the interrupt status registers independently from the interrupt enable registers content.

The module provides an alternative to the atomic ‘Test and Set’ operations for the data output and interrupt enable registers. For these registers, the module implements the “Set and Clear protocol register update”.

8.1.3 Block Diagram

Figure 8-1 details the GPIO block diagram with its configuration registers and its main functional paths:

- The synchronous path (for Active mode operations), Figure 8-2, used to generate a synchronous interrupt request upon expected event detection on any input GPIO; the synchronous interrupt request lines 0 and 1 are active according to their respective interrupt enable 0 and 1 registers.
- The blocks handling the internal clock (clock gating) and managing the Sleep mode request/acknowledge protocol (enabling the Synchronous path in Active mode).

Figure 8-1. GPIO Block Diagram

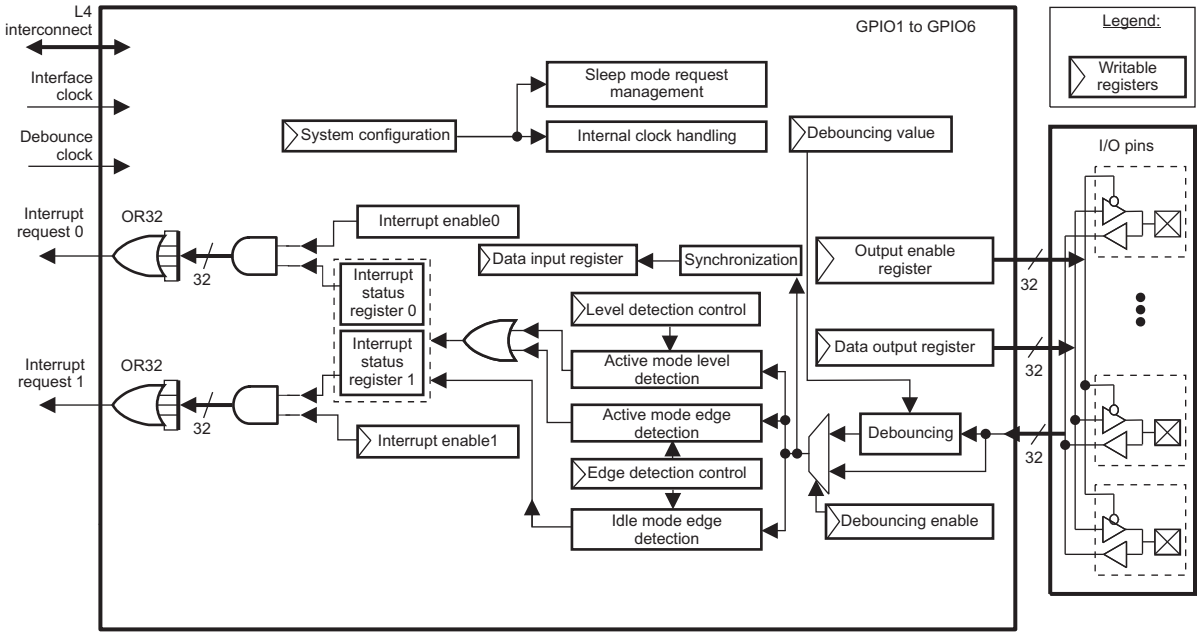

Figure 8-2. Synchronous Path Block Diagram

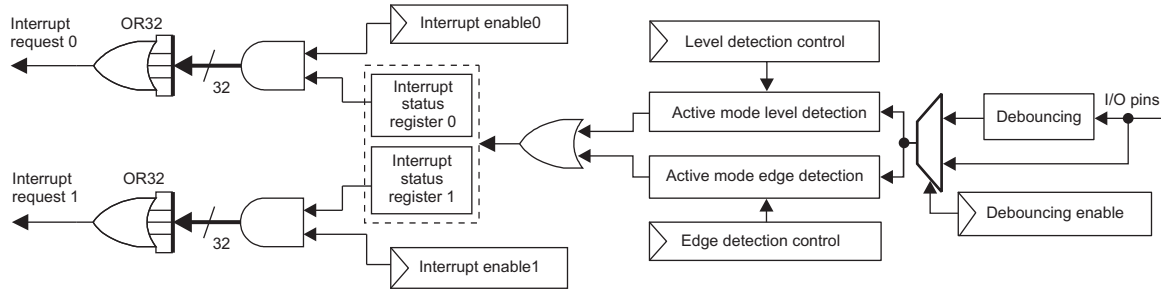


8.2 Architecture

This section discusses the operational details and basic functions of the GPIO peripheral.

8.2.1 Operating Modes

Four operating modes are defined for the module:

- **Active mode:** the module is running synchronously on the interface clock, interrupt can be generated according to the configuration and the external signals.
- **Idle mode:** the module is in a waiting state, interface clock can be stopped , no interrupt can be generated. Check the chip top-level functional specification for the availability of the debouncing clock while in Idle mode.
- **Inactive mode:** the module has no activity, interface clock can be stopped, no interrupt can be generated.
- **Disabled mode:** the module is not used, internal clock paths are gated, no interrupt request can be generated.

The Idle and Inactive modes are configured within the module and activated on request by the host processor through system interface sideband signals. The Disabled mode is set by software through a dedicated configuration bit. It unconditionally gates the internal clock paths not use for the system interface. All module registers are 8, 16 or 32-bit accessible through the OCP compatible interface (little endian encoding). In active mode, the event detection (level or transition) is performed in the GPIO module using the interface clock. The detection's precision is set by the frequency of this clock and the selected internal gating scheme.

8.2.2 Clocking and Reset Strategy

8.2.2.1 Clocks

GPIO module runs using two clocks:

- The debouncing clock is used for the debouncing sub-module logic (without the corresponding configuration registers). This module can sample the input line and filters the input level using a programmed delay.
- The interface clock provided by the peripheral bus (OCP compatible system interface). It is used through the entire GPIO module (except within the debouncing sub-module logic). It clocks the OCP interface and the internal logic. Clock gating features allow adapting the module power consumption to the activity.

8.2.2.2 Clocks, Gating and Active Edge Definitions

The interface clock provided by the peripheral bus (OCP compatible system interface) is used through the entire GPIO module. Two clock domains are defined: the OCP interface and the internal logic. Each clock domain can be controlled independently. Sampling operations for the data capture and for the events detection are done using the rising edge. The data loaded in the data output register (GPIO_DATAOUT) is set at the output GPIO pins synchronously with the rising edge of the interface clock.

Five clock gating features are available:

- Clock for the system interface logic can be gated when the module is not accessed, if the AUTOIDLE configuration bit in the system configuration register (GPIO_SYSCONFIG) is set. Otherwise, this logic is free running on the interface clock.
- Clock for the input data sample logic can be gated when the data in register is not accessed.
- Four clock groups are used for the logic in the synchronous events detection. Each 8 input GPIO_V2 pins group will have a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, then the corresponding clock will be gated. All channels are also gated using a 'one out of N' scheme. N can take the values 1, 2, 4 or 8. The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free running on the interface clock. When N is between 2 to 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

- In Inactive mode, all internal clock paths are gated.
- In Disabled mode, all internal clock paths not used for the system interface are gated. All GPIO registers are accessible synchronously with the interface clock.

8.2.2.3 Sleep Mode Request and Acknowledge

Upon a Sleep mode request issued by the host processor, the GPIO module goes to the Idle mode according to the IDLEMODE field in the system configuration register (GPIO_SYSCONFIG).

- IDLEMODE = 0 (Force-Idle mode): the GPIO goes in Inactive mode independently of the internal module state and the Idle acknowledge is unconditionally sent. In Force-Idle mode, the module is in Inactive mode.
- IDLEMODE = 1h (No-Idle mode): the GPIO does not go to the Idle mode and the Idle acknowledge is never sent.
- IDLEMODE = 2h (Smart-Idle mode) or IDLEMODE = 3h (Smart-Idle mode): the GPIO module evaluates its internal capability to have the interface clock switched off. Once there is no more internal activity (the data input register completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to GPIO_DEBOUNCINGTIME register pending to be synchronized), the Idle acknowledge is asserted and the GPIO enters Idle mode. When the system is awake, the Idle Request goes inactive, the Idle acknowledge signals are immediately de-asserted.

NOTE: Idle mode request and Idle acknowledge are system interface sideband signals. Once the GPIO acknowledges the Sleep mode request (Idle acknowledge has been sent), the interface clock can be stopped anytime.

Upon a Sleep mode request issued by the host processor, the GPIO module goes to the Idle mode only if there is no active bit in GPIO_IRQSTATUS_RAW_n registers.

8.2.2.4 Reset

The OCP hardware Reset signal has a global reset action on the GPIO. All configuration registers, all DFFs clocked with the Interface clock or Debouncing clock and all internal state machines are reset when the OCP hardware Reset is active (low level). The RESETDONE bit in the system status register (GPIO_SYSSTATUS) monitors the internal reset status: it is set when the Reset is completed on both OCP and Debouncing clock domains. The software Reset (SOFTRESET bit in the system configuration register) has the same effect as the OCP hardware Reset signal, and the RESETDONE bit in GPIO_SYSSTATUS is updated in the same condition.

8.2.3 Interrupt Features

8.2.3.1 Functional Description

In order to generate an interrupt request to a host processor upon a defined event (level or logic transition) occurring on a GPIO pin, the GPIO configuration registers have to be programmed as follows:

- Interrupts for the GPIO channel must be enabled in the GPIO_IRQENABLE_SET_0 and/or GPIO_IRQENABLE_SET_1 registers.
- The expected event(s) on input GPIO to trigger the interrupt request has to be selected in the GPIO_LEVELDETECT0, GPIO_LEVELDETECT1, GPIO_RISINGDETECT, and GPIO_FALLINGDETECT registers.

For instance, interrupt generation on both edges on input k is configured by setting to 1 the *k*th bit in registers GPIO_RISINGDETECT and GPIO_FALLINGDETECT along with the interrupt enabling for one or both interrupt lines (GPIO_IRQENABLE_SET_n).

NOTE: All interrupt sources (the 32 input GPIO channels) are merged together to issue two synchronous interrupt requests 0 and 1.

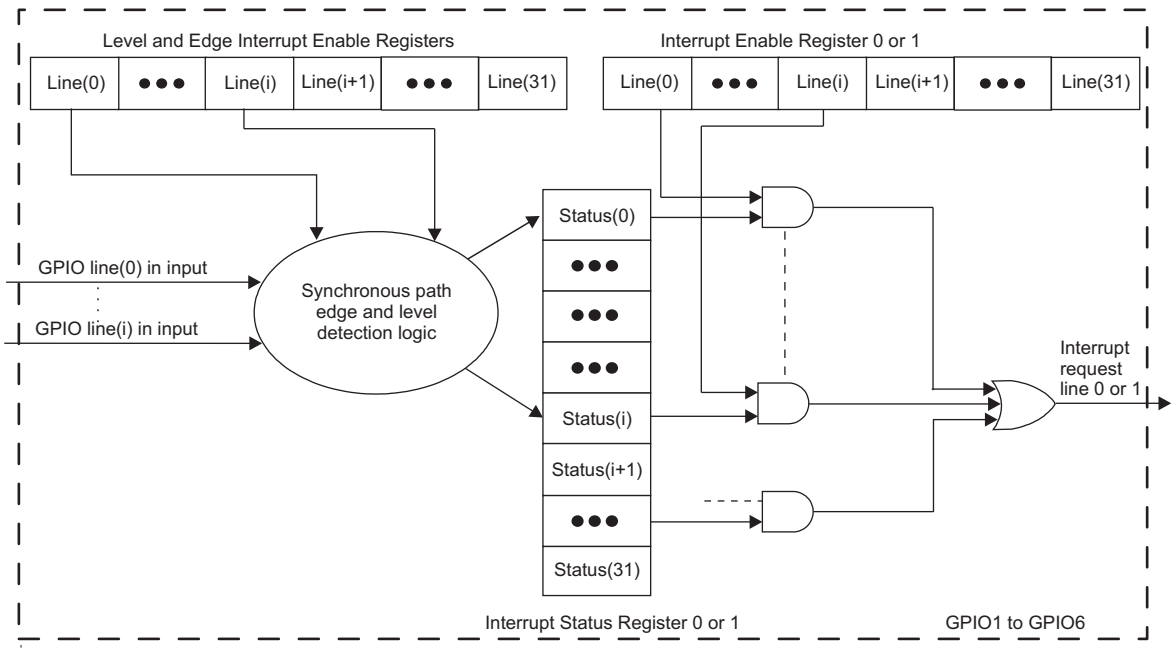
8.2.3.2 Synchronous Path: Interrupt Request Generation

In Active mode, once the GPIO configuration registers have been set to enable the interrupt generation, a synchronous path (Figure 8-3) samples the transitions and levels on the input GPIO with the internally gated interface clock. When an event matches the programmed settings, the corresponding bit in the GPIO_IRQSTATUS_RAW_n registers is set to 1 and, on the following interface clock cycle, the interrupt lines 0 and/or 1 are activated (depending on the GPIO_IRQENABLE_SET_n registers).

Due to the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period is equal to N times the interface clock period). This minimum pulse width has to be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

As the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This should not exceed 3 internally gated interface clock cycles + 2 interface clock cycles when the debouncing feature is not used. When the debouncing feature is active, the latency depends on the GPIO_DEBOUNCINGTIME register value and should be less than 3 internally gated interface clock cycles + 2 interface clock cycles + GPIO_DEBOUNCINGTIME value debouncing clock cycles + 3 debouncing clock cycles.

Figure 8-3. Interrupt Request Generation



8.2.3.3 Interrupt Line Release

When the host processor receives an interrupt request issued by the GPIO module, it can read the corresponding GPIO_IRQSTATUS_n register to find out which input GPIO has triggered the interrupt. After servicing the interrupt, the processor resets the status bit and releases the interrupt line by writing a 1 in the corresponding bit of the GPIO_IRQSTATUS_n register. If there is still a pending interrupt request to serve (all bits in the GPIO_IRQSTATUS_RAW_n register not masked by the GPIO_IRQENABLE_SET_n, which are not cleared by setting the GPIO_IRQENABLE_CLR_n), the interrupt line will be re-asserted.

8.2.4 General-Purpose Interface Basic Programming Model

8.2.4.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the registers:

- GPIO_LEVELDETECT0
- GPIO_LEVELDETECT1
- GPIO_RISINGDETECT
- GPIO_FALLINGDETECT

are set to 0101 0101h, then all clocks are active (power consumption is high);

are set to 0000 00FFh, then a single clock is active.

NOTE: When the clocks are enabled by writing to the GPIO_LEVELDETECT0, GPIO_LEVELDETECT1, GPIO_RISINGDETECT, and GPIO_FALLINGDETECT registers, the detection starts after 5 clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock has been started before a new setting is performed, the following is recommended: first, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

8.2.4.2 Set and Clear Instructions

The GPIO module implements the set-and-clear protocol register update for the data output and interrupt enable registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s).

Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

8.2.4.2.1 Clear Instruction

8.2.4.2.1.1 Clear Interrupt Enable Registers (GPIO_IRQENABLE_CLR_0 and GPIO_IRQENABLE_CLR_1):

- A write operation in the clear interrupt enable0 (or enable1) register clears the corresponding bit in the interrupt enable0 (or enable1) register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear interrupt enable0 (or enable1) register returns the value of the interrupt enable0 (or enable1) register.

8.2.4.2.1.2 Clear Data Output Register (GPIO_CLEARDATAOUT):

- A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear data output register returns the value of the data output register.

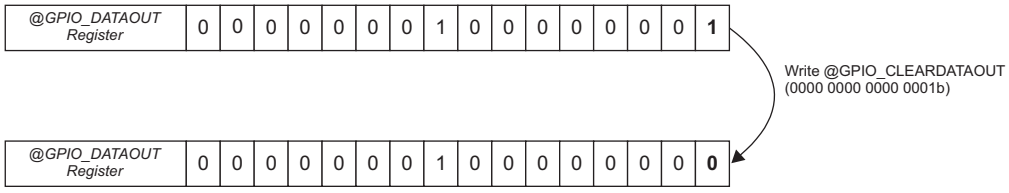
8.2.4.2.1.3 Clear Instruction Example

Assume the data output register (or one of the interrupt enable registers) contains the binary value, 0000 0001 0000 0001h, and you want to clear bit 0.

With the clear instruction feature, write 0000 0000 0000 0001h at the address of the clear data output register (or at the address of the clear interrupt enable register). After this write operation, a reading of the data output register (or the interrupt enable register) returns 0000 0001 0000 0000h; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32-bits wide, only the 16 least-significant bits are represented in this example.

Figure 8-4. Write @ GPIO_CLEARDATAOUT Register Example



8.2.4.2.2 Set Instruction

8.2.4.2.2.1 Set Interrupt Enable Registers (GPIO_IRQENABLE_SET_0 and GPIO_IRQENABLE_SET_1):

- A write operation in the set interrupt enable0 (or enable1) register sets the corresponding bit in the interrupt enable0 (or enable1) register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set interrupt enable0(or enable1) register returns the value of the interrupt enable0 (or enable1) register.

8.2.4.2.2.2 Set Data Output Register (GPIO_SETDATAOUT):

- A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set data output register returns the value of the data output register.

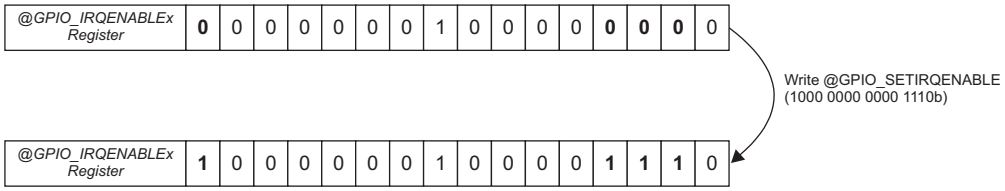
8.2.4.2.2.3 Set Instruction Example

Assume the interrupt enable0 (or enable1) register (or the data output register) contains the binary value, 0000 0001 0000 0000h, and you want to set bits 15, 3, 2, and 1.

With the set instruction feature, write 1000 0000 0000 1110h at the address of the set interrupt enable0 (or enable1) register (or at the address of the set data output register). After this write operation, a reading of the interrupt enable0 (or enable1) register (or the data output register) returns 1000 0001 0000 1110h; bits 15, 3, 2, and 1 are set.

NOTE: Although the general-purpose interface registers are 32-bits wide, only the 16 least-significant bits are represented in this example.

Figure 8-5. Write @ GPIO_SETIRQENABLEx Register Example



8.2.4.3 Data Input (Capture)/Output (Drive)

The output enable register (GPIO_OE) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module; its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in GPIO_OE), the value of the corresponding bit in the GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set and clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set data output register (GPIO_SETDATAOUT) or to the clear data output register (GPIO_CLEARDATAOUT) address. If the application uses a pin as an output and does not want interrupt generation from this pin, the application must properly configure the interrupt enable registers.

When configured as an input (the desired bit set to 1 in GPIO_OE), the state of the input can be read from the corresponding bit in the GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the interrupt enable registers to the interrupt as needed.

8.2.4.4 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

- The GPIO pin must be configured as input in the output enable register (write 1 to the corresponding bit of the GPIO_OE register).
- The debouncing time must be set in the debouncing value register (GPIO_DEBOUNCINGTIME). The GPIO_DEBOUNCINGTIME register is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31 microseconds long) to be used.

The following formula describes the required input stable time to be propagated to the debounced output:

Debouncing time = (DEBOUNCETIME + 1) × 31 µs

Where the DEBOUNCETIME field value in the GPIO_DEBOUNCINGTIME register is from 0 to 255.

- The debouncing feature must be enabled in the debouncing enable register (write 1 to the corresponding DEBOUNCEENABLE bit in the GPIO_DEBOUNCENABLE register).

8.2.4.5 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface (Figure 8-6). You can dedicate channels based on the keyboard matrix size. Figure 8-6 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pull-up. Column channels are configured as outputs and drive a low level.

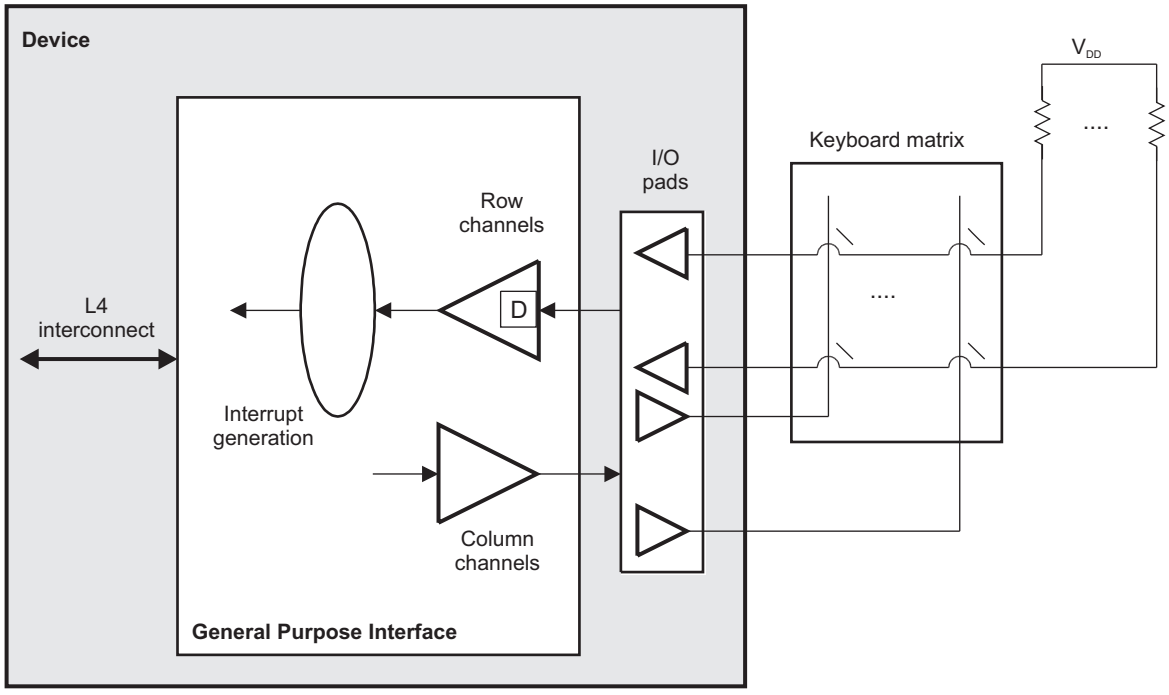
When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 8.2.3).

When the keyboard interrupt is received, the processor can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

Figure 8-6. General-Purpose Interface Used as a Keyboard Interface



8.3 GPIO Registers

All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little-endian encoding). Access to registers is direct; no shadow registers are implemented. For the base address of these registers, see .

Table 8-1. GPIO Registers

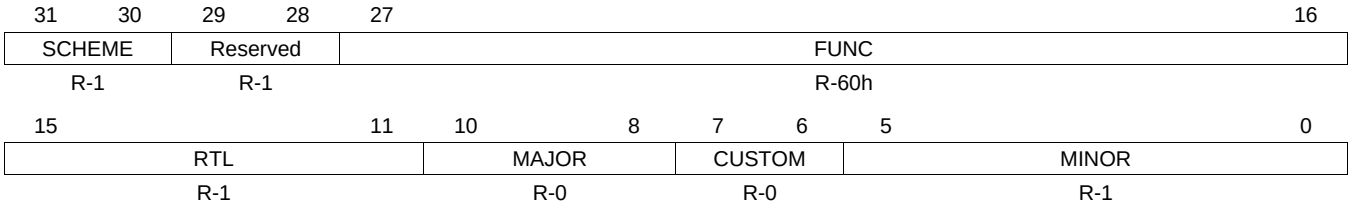
8.3.1 GPIO_REVISION Register

The GPIO revision register is a read only register containing the revision number of the GPIO module. A write to this register has no effect, the same as the reset.

Figure 8-7. GPIO_REVISION Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 8-2. GPIO_REVISION Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	Used to distinguish between old Scheme and current.
29-28	Reserved	R	1h	Reserved
27-16	FUNC	R	60h	Indicates a software compatible module family.
15-11	RTL	R	1Fh	RTL version
10-8	MAJOR	R	0h	Major Revision
7-6	CUSTOM	R	0h	Indicates a special version for a particular device.
5-0	MINOR	R	1Fh	Minor Revision

8.3.2 GPIO_SYSCONFIG Register

The GPIO_SYSCONFIG register controls the various parameters of the L4 interconnect.

NOTE: When the AUTOIDLE bit is set, the GPIO_DATAIN read command has a 3 OCP cycle latency due to the data in sample gating mechanism. When the AUTOIDLE bit is not set, the GPIO_DATAIN read command has a 2 OCP cycle latency.

8.3.4 GPIO_IRQSTATUS_RAW_0 Register

The GPIO_IRQSTATUS_RAW_0 register provides core status information for the interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit sets it to 1, that is, triggers the IRQ (mostly for debug). Writing a 0 has no effect, that is, the register value is not be modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

Figure 8-10. GPIO_IRQSTATUS_RAW_0 Register

8.3.5 GPIO_IRQSTATUS_RAW_1 Register

The GPIO_IRQSTATUS_RAW_1 register provides core status information for the interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit sets it to 1, that is, triggers the IRQ (mostly for debug). Writing a 0 has no effect, that is, the register value is not be modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

8.3.6 GPIO_IRQSTATUS_0 Register

The GPIO_IRQSTATUS_0 register provides core status information for the interrupt handling, showing all enabled events (enabled interrupts only). The fields are read-write. Writing a 1 to a bit clears the bit to 0, that is, clears the IRQ. Writing a 0 has no effect, that is, the register value is not modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

Figure 8-12. GPIO_IRQSTATUS_0 Register

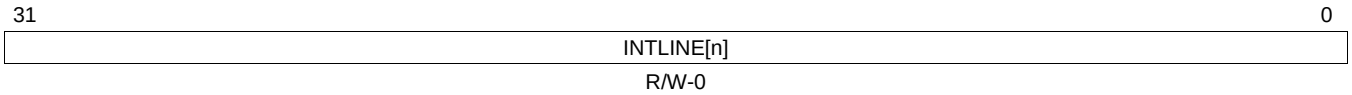
Table 8-8. GPIO_IRQSTATUS_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	INTLINE[*n*]	R/W1C	0h	Interrupt n status. 0 = No effect 1 = IRQ is triggered.

8.3.8 GPIO_IRQENABLE_SET_0 Register

All 1-bit fields in the GPIO_IRQENABLE_SET_0 register enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit enables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

Figure 8-14. GPIO_IRQENABLE_SET_0 Register



LEGEND: R/W = Read/Write; -*n* = value after reset

31-0	INTLINE[*n*]	R/W	0h	Interrupt n enable 0 = No effect 1 = Disable IRQ generation.

8.3.12 GPIO_SYSSTATUS Register

The GPIO_SYSSTATUS register provides the reset status information about the GPIO module. It is a read-only register; a write to this register has no effect.

Figure 8-18. GPIO_SYSSTATUS Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8.3.13 GPIO_CTRL Register

The GPIO_CTRL register controls the clock gating functionality. The DISABLEMODULE bit controls a clock gating feature at the module level. When set, this bit forces the clock gating for all internal clock paths. Module internal activity is suspended. System interface is not affected by this bit. System interface clock gating is controlled with the AUTOIDLE bit in the system configuration register (GPIO_SYSCONFIG). This bit is to be used for power saving when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

0	DISABLEMODULE	R/W	0h	Module Disable 0 = Module is enabled, clocks are not gated. 1 = Module is disabled, clocks are gated.

8.3.14 GPIO_OE Register

The GPIO_OE register is used to enable the pins output capabilities. At reset, all the GPIO related pins are configured as input and output capabilities are disabled. This register is not used within the module, its only function is to carry the pads configuration. When the application is using a pin as an output and does not want interrupt generation from this pin, the application can/has to configure properly the Interrupt Enable registers.

Figure 8-20. GPIO_OE Register

R/W-FFFF FFFFh	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 8-15. GPIO_OE Register Field Descriptions

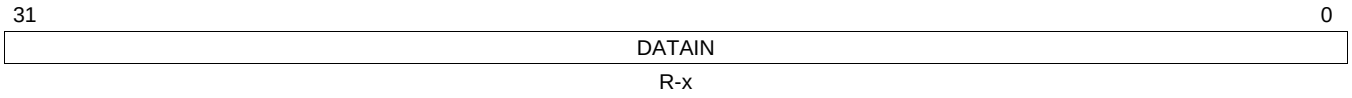
Bit	Field	Type	Reset	Description
31-0	OUTPUTEN[*n*]	R/W	FFFF FFFFh	Output Data Enable 0 = The corresponding GPIO port is configured as an output. 1 = The corresponding GPIO port is configured as an input.

8.3.15 GPIO_DATAIN Register

The GPIO_DATAIN register is used to register the data that is read from the GPIO pins. The GPIO_DATAIN register is a read-only register. The input data is sampled synchronously with the interface clock and then captured in the GPIO_DATAIN register synchronously with the interface clock. So, after changing, GPIO pin levels are captured into this register after two interface clock cycles (the required cycles to synchronize and to write the data).

NOTE: When the AUTOIDLE bit in the system configuration register (GPIO_SYSCONFIG) is set, the GPIO_DATAIN read command has a 3 OCP cycle latency due to the data in sample gating mechanism. When the AUTOIDLE bit is not set, the GPIO_DATAIN read command has a 2 OCP cycle latency.

Figure 8-21. GPIO_DATAIN Register



LEGEND: R = Read only; -*n* = value after reset

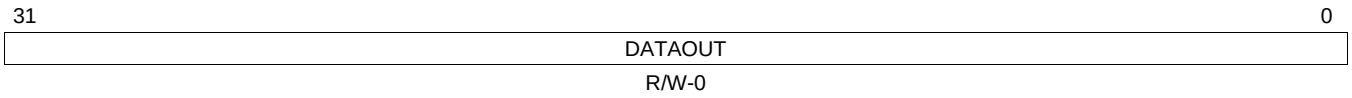
Table 8-16. GPIO_DATAIN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	DATAIN	R	x	Sampled Input Data

8.3.16 GPIO_DATAOUT Register

The GPIO_DATAOUT register is used for setting the value of the GPIO output pins. Data is written to the GPIO_DATAOUT register synchronously with the interface clock. This register can be accessed with direct read/write operations or using the alternate 'Set/Clear' feature. This feature enables to set or clear specific bits of this register with a single write access to the set data output register (GPIO_SETDATAOUT) or to the clear data output register (GPIO_CLEARDATAOUT) address.

Figure 8-22. GPIO_DATAOUT Register



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 8-17. GPIO_DATAOUT Register Field Descriptions

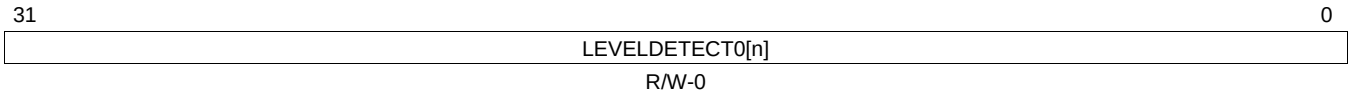
Bit	Field	Type	Reset	Description
31-0	DATAOUT	R/W	0	Data to set on output pins

8.3.17 GPIO_LEVELDETECT0 Register

The GPIO_LEVELDETECT0 register is used to enable/disable for each input lines the low-level (0) detection to be used for the interrupt request generation.

NOTE: Enabling at the same time high-level detection and low-level detection for one given pin makes a constant interrupt generator.

Figure 8-23. GPIO_LEVELDETECT0 Register



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 8-18. GPIO_LEVELDETECT0 Register Field Descriptions

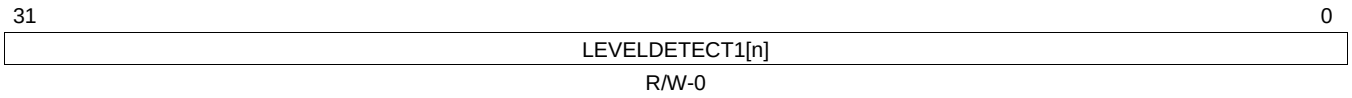
Bit	Field	Type	Reset	Description
31-0	LEVELDETECT0[*n*]	R/W	0h	Low Level Interrupt Enable 0 = Disable the IRQ assertion on low-level detect. 1 = Enable the IRQ assertion on low-level detect.

8.3.18 GPIO_LEVELDETECT1 Register

The GPIO_LEVELDETECT1 register is used to enable/disable for each input lines the high-level (1) detection to be used for the interrupt request generation.

NOTE: Enabling at the same time high-level detection and low-level detection for one given pin makes a constant interrupt generator.

Figure 8-24. GPIO_LEVELDETECT1 Register



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 8-19. GPIO_LEVELDETECT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	LEVELDETECT1[*n*]	R/W	0h	High Level Interrupt Enable 0 = Disable the IRQ assertion on high-level detect. 1 = Enable the IRQ assertion on high-level detect.

8.3.19 GPIO_RISINGDETECT Register

The GPIO_RISINGDETECT register is used to enable/disable for each input lines the rising-edge (transition 0 to 1) detection to be used for the interrupt request generation.

Figure 8-25. GPIO_RISINGDETECT Register

8.3.22 GPIO_DEBOUNCINGTIME Register

The GPIO_DEBOUNCINGTIME register controls debouncing time (the value is global for all ports). The debouncing cell is running with the debouncing clock (32 kHz), this register represents the number of the clock cycle(s) (31µs long) to be used.

Figure 8-28. GPIO_DEBOUNCINGTIME Register

8.3.23 GPIO_CLEARDATAOUT Register

Writing a 1 to a bit in the GPIO_CLEARDATAOUT register clears to 0 the corresponding bit in the GPIO_DATAOUT register; writing a 0 has no effect. A read of the GPIO_CLEARDATAOUT register returns the value of the data output register (GPIO_DATAOUT).

Figure 8-29. GPIO_CLEARDATAOUT Register

General-Purpose Memory Controller (GPMC)

This chapter describes the general-purpose memory controller (GPMC).

Topic **Page**

9.1 Introduction

9.1.1 Overview

The general-purpose memory controller (GPMC) is an unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-multiplexed mode) burst NOR flash devices
- NAND Flash
- Pseudo-SRAM devices

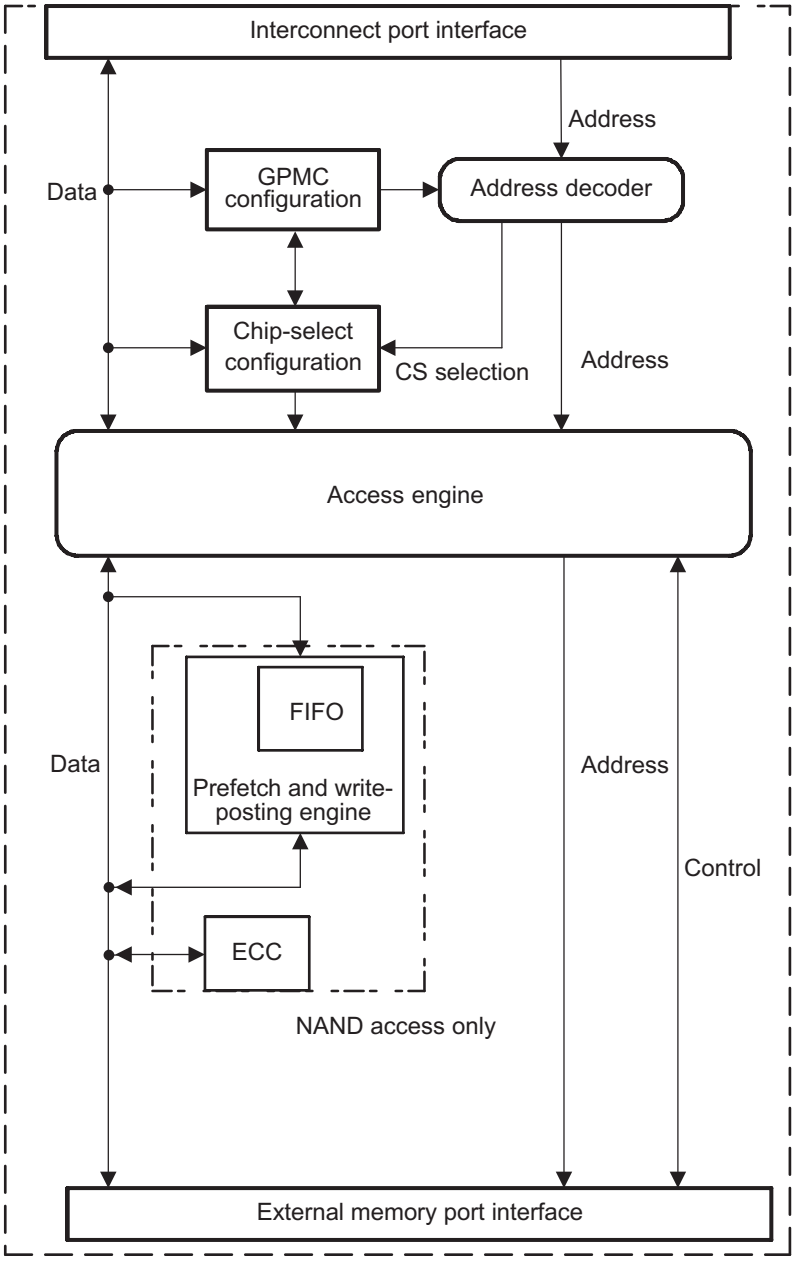
9.1.2 Block Diagram

The GPMC can access various external devices through the L3 Slow Interconnect. The flexible programming model allows a wide range of attached device types and access schemes. Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type. Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

Figure 9-1 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 9-1. GPMC Block Diagram



9.2 Architecture

9.2.1 GPMC Signals

Table 9-1 lists the GPMC subsystem I/O pins.

NOTE: In this chapter, the i in GPMC_CONFIGx_i represents GPMC chip-select i, where i = 0 to 5.

Table 9-1. GPMC I/O Description

Pin Name	I/O	Description
GPMC_A[27:0]	O	Address
GPMC_D[15:0]	I/O	Data
GPMC_CS[5:0]	O	Chip-selects (active low).
GPMC_CLK	O	Clock generated for the external memory or device
GPMC_ADV_ALE	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
GPMC_OE_RE	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
GPMC_WE	O	Write enable (active low)
GPMC_BE0_CLE	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
GPMC_BE1	O	Upper-byte enable (active low)
GPMC_WP	O	Write protect (active low). Not all devices pin out the Write protect signal. See the device specific data manual to determine if the Write protect pin is supported.
GPMC_WAIT[1:0]	I	External wait signals for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-selects. Not all devices pin out both External wait signals. See the device specific data manual to determine the number of External wait signals supported.
GPMC_DIR	O	GPMC_D[15:0] signals direction control: Low during transmit (for write access: data OUT from GPMC to memory) High during receive (for read access: data IN from memory to GPMC) Not all devices pin out the direction control signal. See the device specific data manual to determine if the direction control signal is supported.

Table 9-2 shows the use of address and data GPMC controller pins based on the type of external device.

GPMC_D[1]	D1	D1	A2/D1	D1	D1
GPMC_D[0]	D0	D0	A1/D0	D0	D0

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i MUXADDDATA field (i = 0 to 5).
- Asynchronous page mode is not supported for multiplexed address and data devices.

9.2.2 GPMC Modes

This section shows three GPMC external connections options:

- Figure 9-2 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol use less address pins) external memory device.
- Figure 9-3 shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device .
- Figure 9-4 shows a connection between the GPMC and a 8-bit NAND device

NOTE: If ROM boot from a NOR device is required, some high-order address lines must be driven low by external hardware during ROM operation. See Section 25.7.2 for details.

Figure 9-2. GPMC to 16-Bit Address/Data-Multiplexed Memory

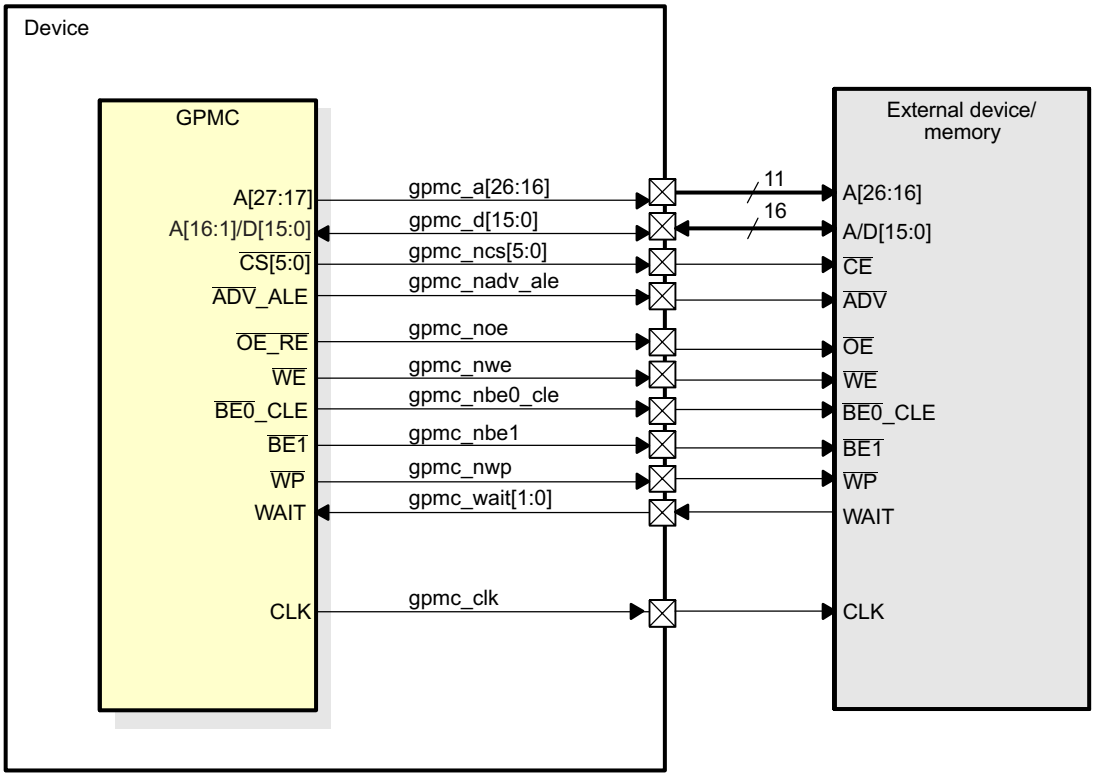

Figure 9-3. GPMC to 16-Bit Nonmultiplexed Memory

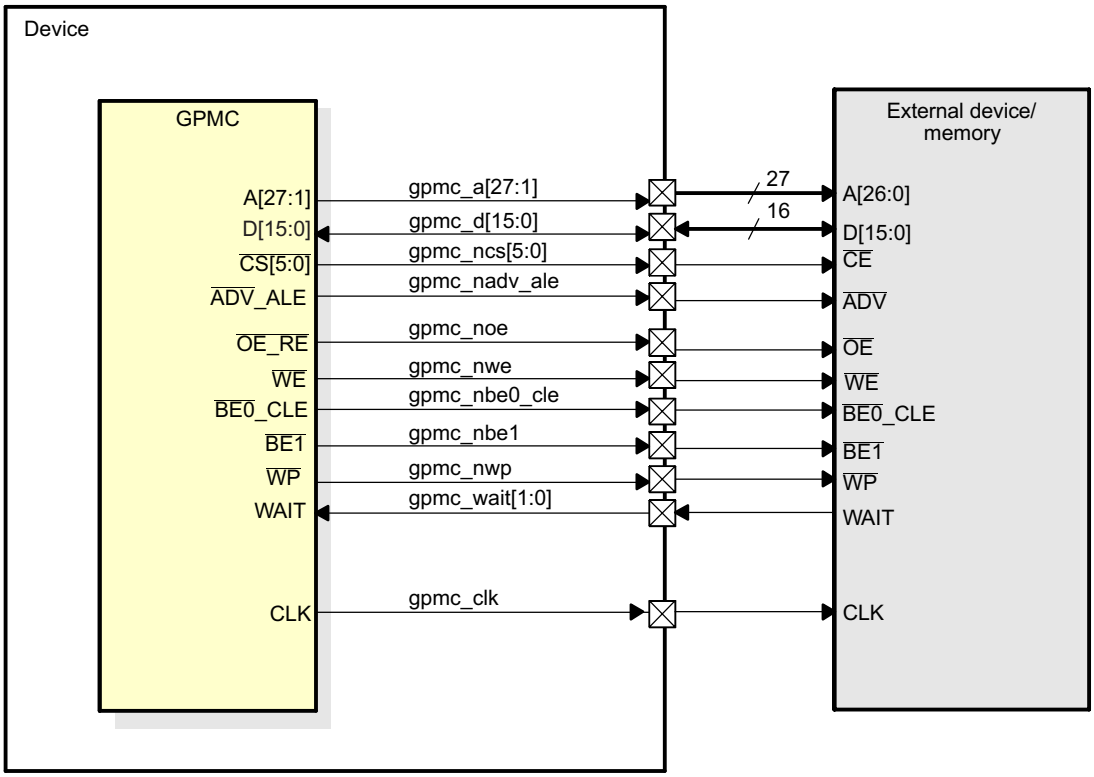

Figure 9-4. GPMC to 8-Bit NAND Device

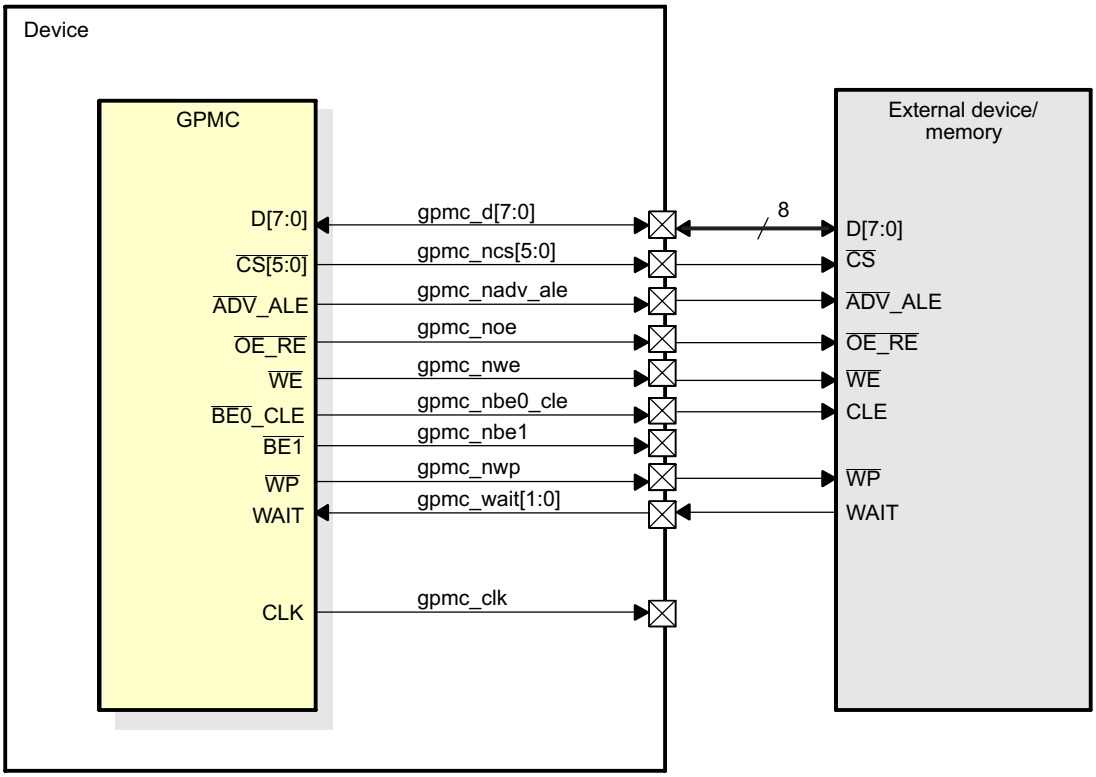

9.2.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No STANDBY hardware handshake
- No wake-up request
- One system direct memory access (eDMA) request
- One interrupt request to the Cortex-A8 MPU Interrupt Controller (MA_IRQ)
- One clock for functional and interface domains

Figure 9-5 shows GPMC integration. Table 9-3 through Table 9-5 summarize the integration of the module in the device.

Figure 9-5. GPMC Integration

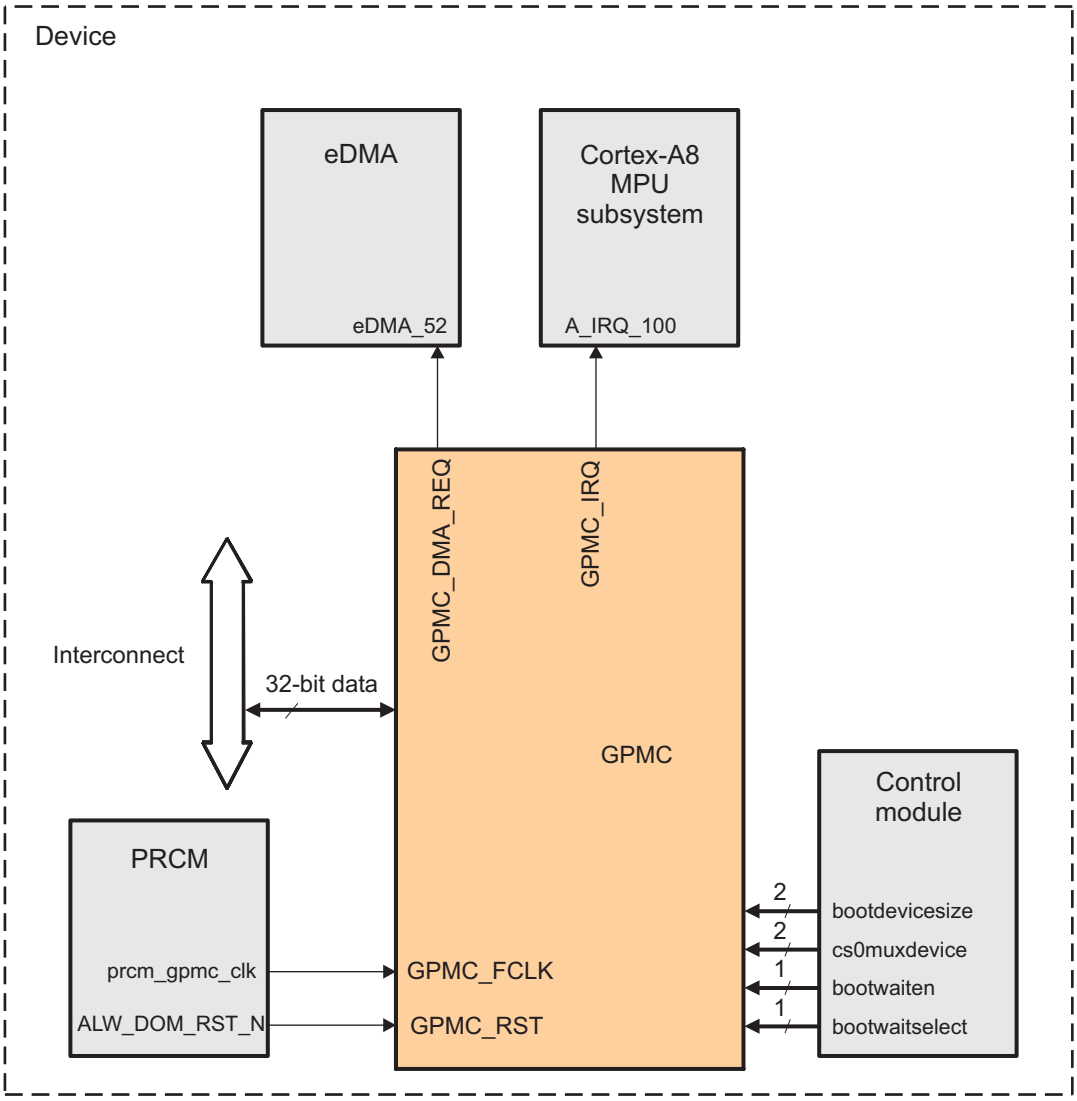

Table 9-3. GPMC Integration Attributes

Module Instance	Attribute		
	Power Domain	Wake-up Capability	Interconnect
GPMC	ALWAYS_ON	No	L3_Slow

Table 9-4. GPMC Clocks and Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description

DMA Requests				
GPMC	GPMC_DMA_REQ	e_DMA_52	eDMA	GPMC request from Prefetch Engine to eDMA

9.2.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

9.2.4.1 GPMC Clock Configuration

Table 9-6 describes the GPMC clocks.

Table 9-6. GPMC Clocks

Signal	I/O	Description
GPMC_FCLK	I	Functional and interface clock
GPMC_CLK	O	External clock provided to synchronous external memory devices.

The GPMC_CLK is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in Table 9-4. The GPMC_CLK is configured via the GPMC_CONFIG1_i GPMCFCLKDIVIDER field (for i = 0 to 3) as shown in Table 9-7.

Table 9-7. GPMC_CONFIG1_i Configuration

Source Clock	GPMC_CONFIG1_i GPMCFCLKDIVIDER Field	GPMC_CLK Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

9.2.4.2 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS RESETDONE bit indicates that the software reset is complete when its value is 1. The software must ensure that the software reset completes before doing GPMC operations.

9.2.4.3 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines. Table 9-8 describes power-management features available for the GPMC module.

Table 9-8. GPMC Local Power Management Features

Feature	GPMC_SYSCONFIG Register	Description
Clock Auto Gating	AUTOIDLE bit	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave Idle Modes	SIDLEMODE field	Force-idle, No-idle and Smart-idle wakeup modes are available
Clock Activity	N/A	Feature not available
Master Standby Modes	N/A	Feature not available
Global Wake-up Enable	N/A	Feature not available
Wake-up Sources Enable	N/A	Feature not available

9.2.4.4 GPMC Interrupt Requests

The GPMC generates one interrupt event as shown in Figure 9-5.

- The interrupt request goes from GPMC (GPMC_IRQ) to the Cortex-A8 MPU subsystem: A_IRQ_100

Table 9-9 lists the event flags, and their mask, that can cause module interrupts.

Table 9-9. GPMC Interrupt Events

GPMC_IRQSTATUS Event Flag	GPMC_IRQENABLE Event Mask	Sensitivity	Map to	Description
WAIT1EDGEDETECTION STATUS	WAIT1EDGEDETECTION ENABLE	Edge	A_IRQ_100	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through GPMC_CONFIG WAIT1PINPOLARITY bit.
WAIT0EDGEDETECTION STATUS	WAIT0EDGEDETECTION ENABLE	Edge	A_IRQ_100	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through GPMC_CONFIG WAIT0PINPOLARITY bit.
TERMINALCOUNT STATUS	TERMINALCOUNT ENABLE	Level	A_IRQ_100	Terminal count event: Triggered on prefetch process completion, that is when the number of currently remaining data to be requested reaches 0.
FIFOEVENT STATUS	FIFOEVENT ENABLE	Level	A_IRQ_100	FIFO event interrupt: Indicates FIFO levels availability for in Write-Posting mode and prefetch mode. GPMC_PREFETCH_CONFIG DMAMODE bit shall be cleared to 0.

9.2.4.5 GPMC DMA Requests

The GPMC generates one DMA event as shown in Figure 9-5.

- From GPMC (GPMC_DMA_REQ) to the eDMA: e_DMA_53

9.2.4.6 L3 Slow Interconnect Interface

The GPMC L3 Slow interconnect interface is a pipelined interface including an 16 × 32-bit word write buffer. Any system host can issue external access requests through the GPMC. The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32 or 16 × 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the GPMC_CONFIG1_i ATTACHEDDEVICEPAGELENGTH field according to the effective attached device page length and to enable the GPMC_CONFIG1_i WRAPBURST bit if the attached device supports wrapping burst. However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

9.2.4.7 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: GPMC_D[15-8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: GPMC_A[27-0].
- 8-bit wide NAND devices do not use GPMC I/O: GPMC_A[27-0] and GPMC I/O: GPMC_D[15-8].

9.2.4.7.1 GPMC I/O Configuration Setting

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i DEVICETYPE field = 10
- GPMC_CONFIG1_i MUXADDDATA field = 00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i DEVICETYPE field = 00
- GPMC_CONFIG1_i MUXADDDATA field = 10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i DEVICETYPE field = 00
- GPMC_CONFIG1_i MUXADDDATA field = 01

To select an address/data-nonmultiplexed device , program the following register fields:

- GPMC_CONFIG1_i DEVICETYPE field = 00
- GPMC_CONFIG1_i MUXADDDATA field = 00

9.2.4.8 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). Section 9.5 provides the GPMC register locations. For the map of GPMC memory locations, see Table 9-55.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

9.2.4.8.1 Chip-Select Base Address and Region Size

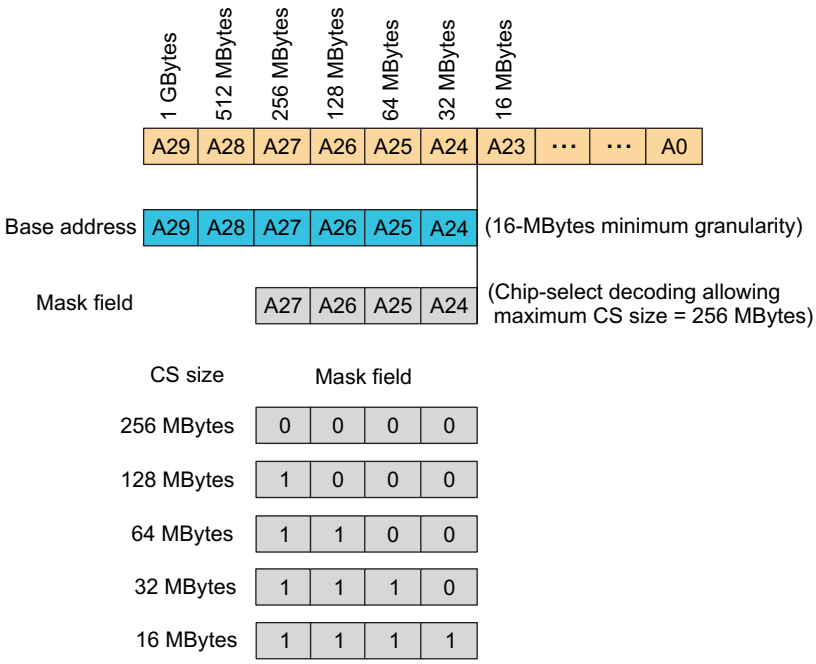
Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-Mbyte contiguous address space. For details, see Table 9-55.

The GPMC 512 Mbyte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16 Mbytes to 256 Mbytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in Figure 9-6 (with A0 as the device system byte-address line). Base address is programmed through the GPMC_CONFIG7_i BASEADDRESS field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field cleared to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i MASKADDRESS field.

Figure 9-6. Chip-Select Address Mapping and Decoding Mask



Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i CSVALID bit (i = 0 to 5). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select. Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

Although the GPMC interface can drive up to eight chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

9.2.4.8.2 Access Protocol

9.2.4.8.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i DEVICETYPE parameter (where i = 0 to 5) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

For more information about the NAND flash GPMC basic programming model and NAND support, see Section 9.2.4.12 and Section 9.2.4.12.1.

9.2.4.8.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i DEVICESIZE field (where i = 0 to 5) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

9.2.4.8.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i MUXADDDATA field (where i = 0 to 5). The $\overline{\text{ADV}}$ signal must be used as the external device address latch control signal. For the associated chip-select configuration, $\overline{\text{ADV}}$ assertion and deassertion time and $\overline{\text{OE}}$ assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device (see Section 9.2.3).

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol (see Section 9.2.4.12).

9.2.4.8.3 External Signals

9.2.4.8.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC features two input wait pin:gpmc_wait1, and gpmc_wait0. This pin allow control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC_CONFIG1_i WAITPINSELECT field (where i = 0 to 5) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured per CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC_CONFIG1_i WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC_CONFIG1_i WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i READTYPE and GPMC_CONFIG1_i WRITETYPE bits).

9.2.4.8.3.2 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

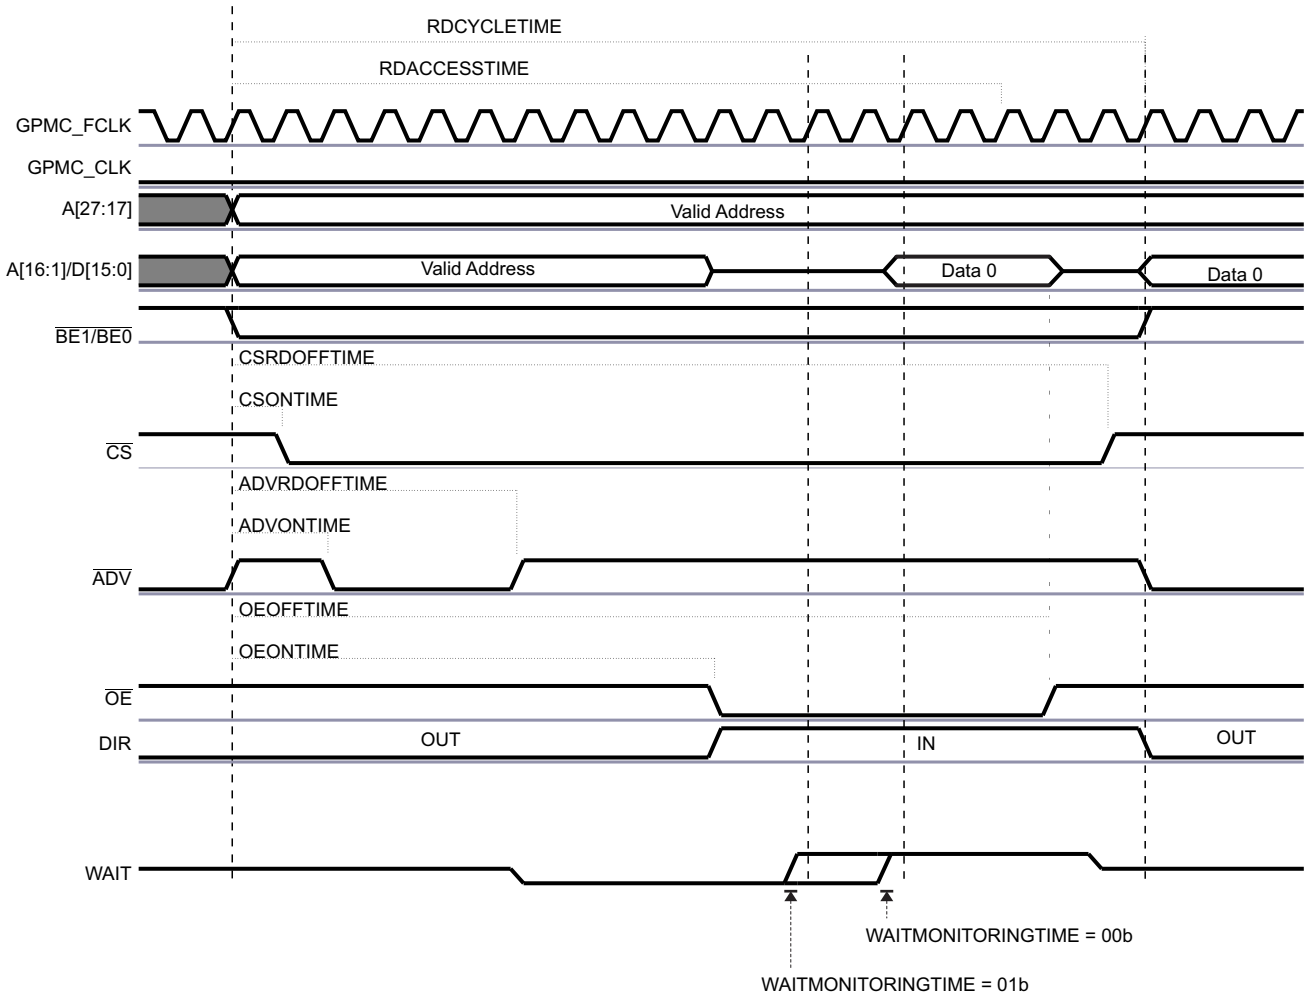
- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i WAITMONITORINGTIME field (i = 0 to 5).

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 9-7 shows wait behavior during an asynchronous single read access.

Figure 9-7. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)



The WAIT signal is active low. GPMC_CONFIG1_i WAITMONITORINGTIME field = 00 or 01.

9.2.4.8.3.3 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC_CONFIG1_i WAITWRITEMONITORING bit = 1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i WAITMONITORINGTIME field (i = 0 to 5).

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, GPMC_CONFIG1_i GPMCFCLKDIVIDER field is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

9.2.4.8.3.4 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC_CONFIG1_i WAITMONITORINGTIME field (i = 0 to 5), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC_CONFIG1_i WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

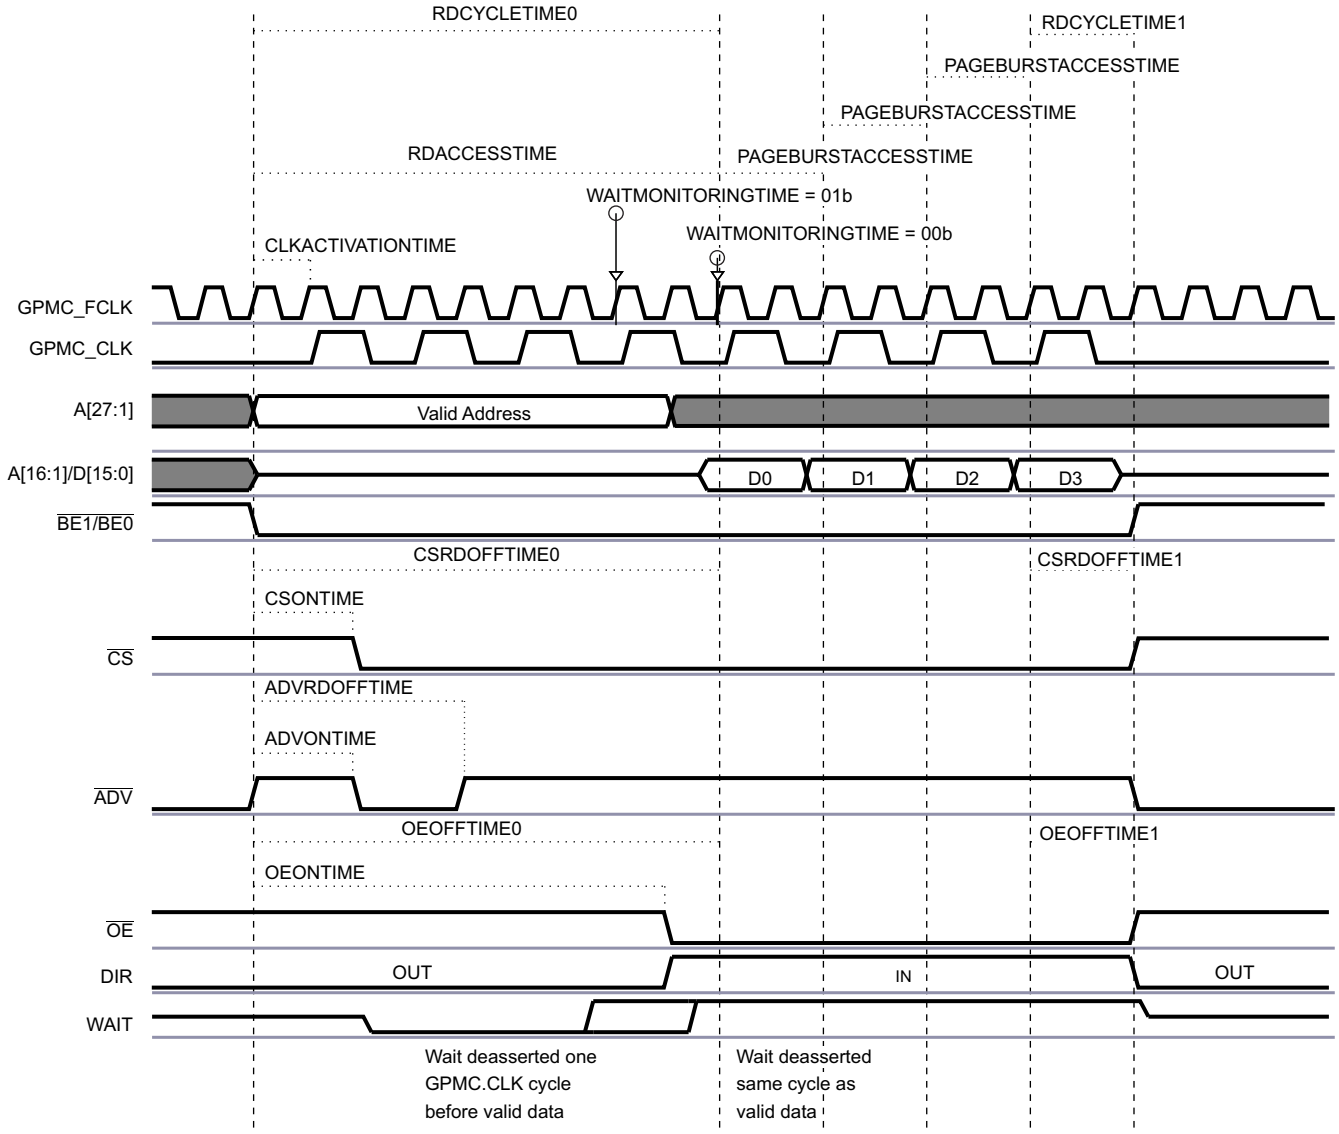
- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 9-8 shows wait behavior during a synchronous read burst access.

Figure 9-8. Wait Behavior During a Synchronous Read Burst Access



The WAIT signal is active low. WAITMONITORINGTIME field = 00 or 01.

9.2.4.8.3.5 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to delay the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

Wait monitoring is supported for all configurations except for GPMC_CONFIG1_i WAITMONITORINGTIME field = 0 (where i = 0 to 3) for write bursts with a clock divider of 1 or 2 (GPMC_CONFIG1_i GPMCFCLKDIVIDER field is equal to 0 or 1, respectively).

9.2.4.8.3.6 WAIT with NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see Section 9.2.4.12.2.

9.2.4.8.3.7 Idle Cycle Control Between Successive Accesses

9.2.4.8.3.7.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the $\overline{CS}$/$\overline{OE}$ de-assertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after $\overline{CS}$ or $\overline{OE}$ de-assertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i BUSTURNAROUND field (i = 0 to 5).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus will not have enough time to go into high-impedance even though it could be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i CYCLE2CYCLEDELAY delays. It should be noted that BUSTURNAROUND is a timing parameter for the ending chip-select access while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access. See Figure 9-9 to Figure 9-11.

Another way to prevent bus contention is to define an earlier $\overline{CS}$ or $\overline{OE}$ deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

Figure 9-9. Read to Read for an Address-Data Multiplexed Device, On Different CS, Without Bus Turnaround ($\overline{CS0}$ Attached to Fast Device)

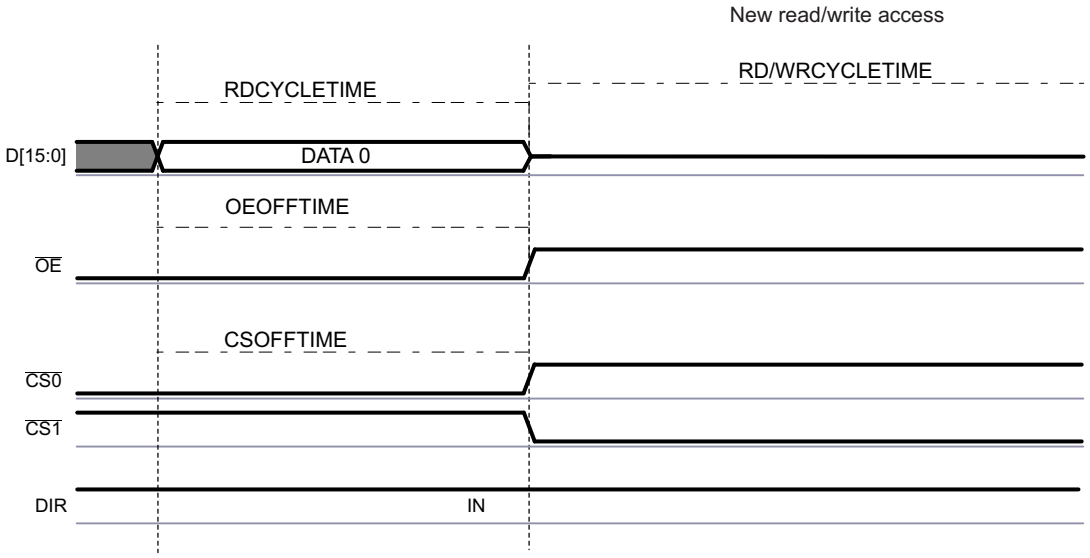


Figure 9-10. Read to Read / Write for an Address-Data Multiplexed Device, On Different CS, With Bus Turnaround

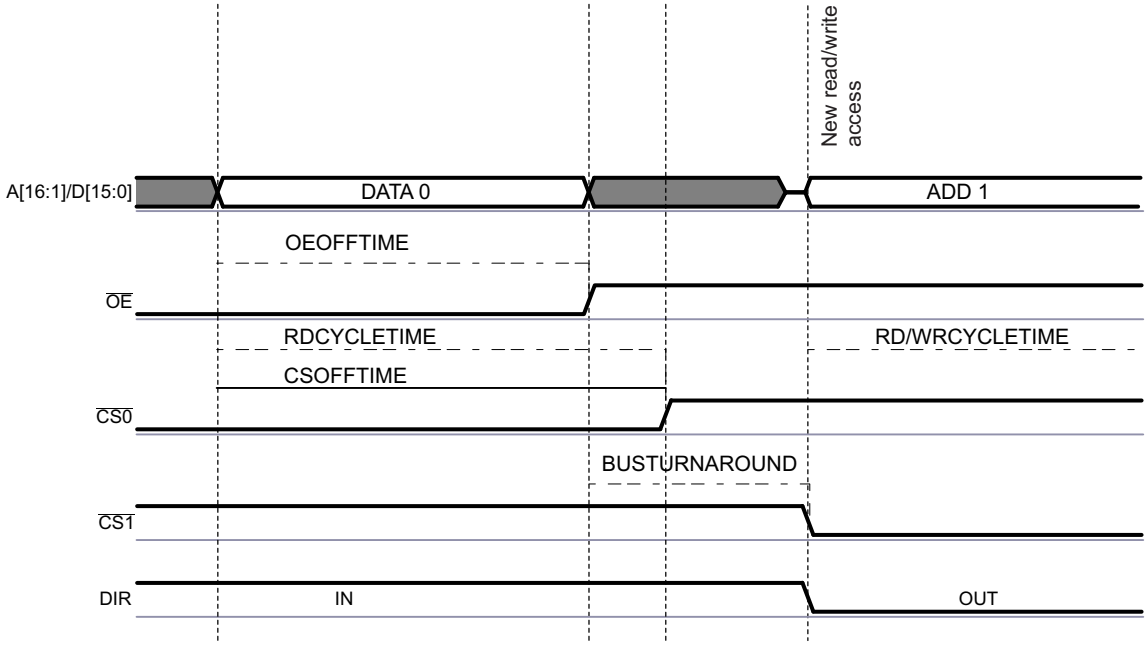

Figure 9-11. Read to Read / Write for a Address-Data or AAD-Multiplexed Device, On Same CS, With Bus Turnaround

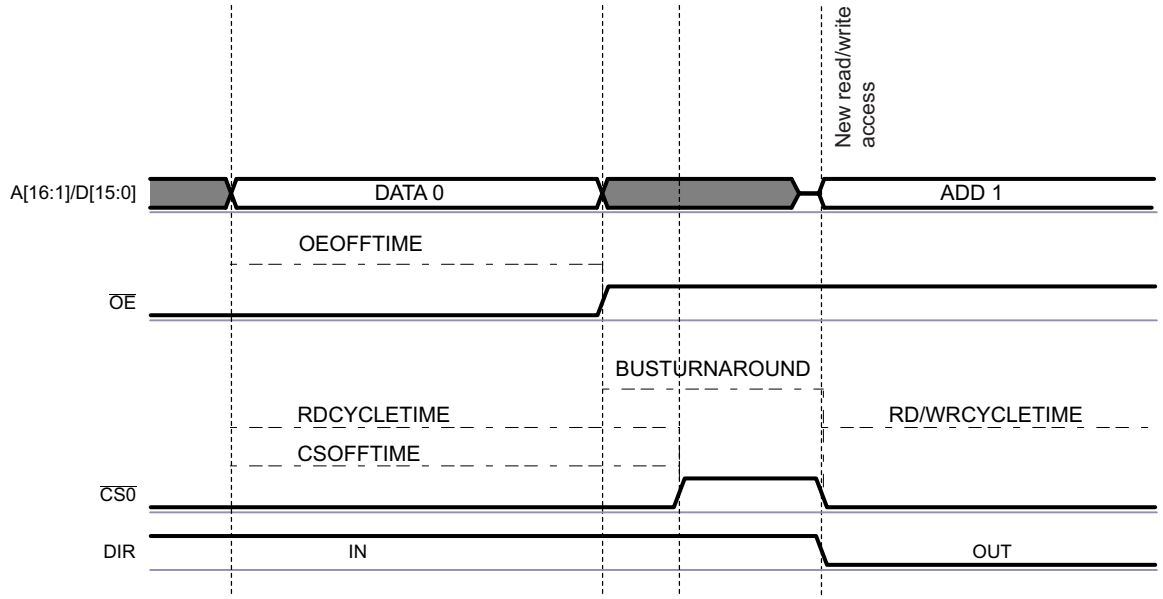


9.2.4.8.3.7.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i CYCLE2CYCLESAMECSEN bit (i = 0 to 5) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i READMULTIPLE = 0 or GPMC_CONFIG1_i WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

9.2.4.8.3.7.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals ($\overline{CS}$, $\overline{ADV}$_ALE, $\overline{BE0}$_CLE, $\overline{OE\_RE}$, $\overline{WE}$) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals ($\overline{WE}$, $\overline{OE\_RE}$) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If GPMC_CONFIG6_i CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See Section 9.2.4.8.3.7.1 for more details on bus turnaround.

Table 9-10 describes the configuration required for idle cycle insertion.

Table 9-10. Idle Cycle Insertion Configuration

First Access Type	BUSTURNAROUND Timing Parameter	Second Access Type	Chip-Select	Addr/Data Multiplexed	CYCLE2CYCLE SAMECSEN Parameter	CYCLE2CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	>0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	>0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	>0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	>0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	>0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	>0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	>0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

9.2.4.8.3.8 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i TIMEPARAGRANULARITY bit (where i = 0 to 5). Increasing all access timing parameters allows support of slow devices.

9.2.4.8.3.9 GPMC_DIR Pin

The GPMC_DIR pin is used to control I/O direction on the GPMC data bus GPMC_D[15-0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required. The GPMC_DIR pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the GPMC_DIR pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the GPMC_DIR pin goes from OUT to IN at $\overline{OE}$ assertion time and stays IN until:

- BUSTURNAROUND is enabled
  - The GPMC_DIR pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled
  - After an asynchronous read access, the GPMC_DIR pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the GPMC_DIR pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the GPMC_DIR pin is OUT (see Section 9.2.4.9.10). In nonmultiplexed devices, the GPMC_DIR pin stays IN between two successive read accesses to prevent unnecessary toggling.

9.2.4.8.3.10 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see *Power, Reset, and Clock Management (PRCM) Module* chapter.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

9.2.4.8.3.11 Write Protect Signal ($\overline{WP}$)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory. The $\overline{GPMC\_WP}$ output pin value is controlled through the GPMC_CONFIG WRITEPROTECT bit, which is common to all CS.

9.2.4.8.3.12 Byte Enable ($\overline{BE1}$/$\overline{BE0}$)

Byte enable signals ($\overline{BE1}$/$\overline{BE0}$) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

9.2.4.8.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.

- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 Slow interconnect interface
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the

9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at the interconnect level.

9.2.4.9 Timing Setting

The GPMC offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information on GPMC_CLK and GPMC_FCLK see Section 9.2.4.9.6.

In the following sections, the start access time refer to the time at which the access begins.

9.2.4.9.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i RDCYCLETIME and GPMC_CONFIG5_i WRCYCLETIME fields (i = 0 to 5) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. RDCYCLETIME and WRCYCLETIME fields can be set with a granularity of 1 or 2 throught GPMC_CONFIG1_i TIMEPARAGRANULARITY.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals ($\overline{CS}$, $\overline{ADV}$_ALE, $\overline{OE}$_$\overline{RE}$, $\overline{WE}$, and $\overline{BE0}$_CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC_CONFIG6_i CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals ($\overline{CS}$, $\overline{ADV}$_ALE, $\overline{BE0}$_CLE, $\overline{WE}$, and $\overline{OE}$_$\overline{RE}$) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

9.2.4.9.2 $\overline{CS}$: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i CSONTIME field (where i = 0 to 5) defines the $\overline{CS}$ signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i CSRDOFFTIME (read access) and GPMC_CONFIG2_i CSWROFFTIME (write access) fields define the $\overline{CS}$ signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

$\overline{CS}$ signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG2_i CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the $\overline{CS}$ assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters controlling $\overline{CS}$ transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME fields to be greater than the $\overline{CS}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

9.2.4.9.3 $\overline{ADV}$_ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY / ADVAADMUXONTIME / ADVAADMUXRDOFFTIME / ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i ADVONTIME field (where i = 0 to 5) defines the $\overline{ADV}$_ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i ADVRDOFFTIME (read access) and GPMC_CONFIG3_i ADVWROFFTIME (write access) fields define the $\overline{ADV}$_ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before $\overline{ADV}$_ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after $\overline{ADV}$_ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

$\overline{ADV}$_ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG3_i ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{ADV}$_ALE assertion and deassertion time to assure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling $\overline{ADV}$_ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME fields to be greater than $\overline{ADV}$_ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

The GPMC_CONFIG3_i ADVAADMUXONTIME, GPMC_CONFIG3_i ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. It is the user responsibility to make sure ADVAADMUXxxOFFTIME is programmed to a value lower than or equal to ADVxxOFFTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high $\overline{ADV}$ pulse is needed between the two AAD-mux address phases, which is the typical case in synchronous mode. In this configuration, $\overline{ADV}$ is kept low until it reaches the correct ADVxxOFFTIME.

See Section 9.2.4.12 for more details on ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME, ADVAADMUXWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

9.2.4.9.4 $\overline{OE\_RE}$: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i OEONTIME field (where i = 0 to 5) defines the $\overline{OE\_RE}$ signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC_CONFIG4_i OEOFFTIME field defines the $\overline{OE\_RE}$ signal deassertion time relative to start access time. It is applicable only to read accesses. $\overline{OE\_RE}$ is not asserted during a write cycle.

OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before $\overline{OE\_RE}$ assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after $\overline{OE\_RE}$ assertion.

OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. It is the user responsibility to make sure OEAADMUXOFFTIME is programmed to a value lower than OEONTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME shall never be equal to OEONTIME because the AAD-mux protocol requires a second address phase with the $\overline{OE}$ signal de-asserted before $\overline{OE}$ can be asserted again to define a read command.

The $\overline{OE\_RE}$ signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{OE\_RE}$ assertion and deassertion time to assure proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling $\overline{OE\_RE}$ transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than $\overline{OE\_RE}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time.

9.2.4.9.5 $\overline{WE}$: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i WEONTIME field (where i = 0 to 3) defines the $\overline{WE}$ signal-assertion time relative to start access time. The GPMC_CONFIG4_i WEOFFTIME field defines the $\overline{WE}$ signal-deassertion time relative to start access time. These bit fields only apply to write accesses. $\overline{WE}$ is not asserted during a read cycle.

WEONTIME can be used to control an address and byte enable valid setup time control before $\overline{WE}$ assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after $\overline{WE}$ assertion.

$\overline{WE}$ signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{WE}$ assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling $\overline{WE}$ transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the $\overline{WE}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

9.2.4.9.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i GPMCFCLKDIVIDER field (where i = 0 to 5), with an assured 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i CLKACTIVATIONTIME field (i = 0 to 5) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.

To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME - CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

9.2.4.9.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i CLKACTIVATIONTIME field (i = 0 to 5) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

9.2.4.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently through GPMC_CONFIG5_i RDACCESSTIME and GPMC_CONFIG6_i WRACCESSTIME fields (i = 0 to 5). This allows $\overline{OE}$ and GPMC data capture timing parameters to be independent of $\overline{WE}$ and memory device data capture timing parameters. RDACCESSTIME and WRACCESSTIME fields can be set with a granularity of 1 or 2 through GPMC_CONFIG1_i TIMEPARAGRANULARITY.

9.2.4.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, GPMC_CONFIG5_i RDACCESSTIME field (i = 0 to 5) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK, which is sent to the memory device for synchronization with the GPMC controller, is internally timed to correctly latch the returned data. GPMC_CONFIG5_i RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally timed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see Section 9.2.4.8.1.

9.2.4.9.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see Section 9.2.4.8.1.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see Section 9.2.4.8.1.

9.2.4.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

GPMC_CONFIG5_i PAGEBURSTACCESSTIME field (i = 0 to 5) can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i TIMEPARAGRANULARITY.

9.2.4.9.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the GPMC_CONFIG5_i PAGEBURSTACCESSTIME field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see Section 9.2.4.8.1.

9.2.4.9.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. GPMC_CONFIG5_i PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see Section 9.2.4.8.1.

9.2.4.9.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

9.2.4.10 NOR Access Description

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC_CONFIG1_i READTYPE bit (i = 0 to 5). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC_CONFIG1_i WRITETYPE bit (i = 0 to 5).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

The address bus and $\overline{\text{BE}}$[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

9.2.4.10.1 Asynchronous Access Description

This section describes:

- Asynchronous single read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

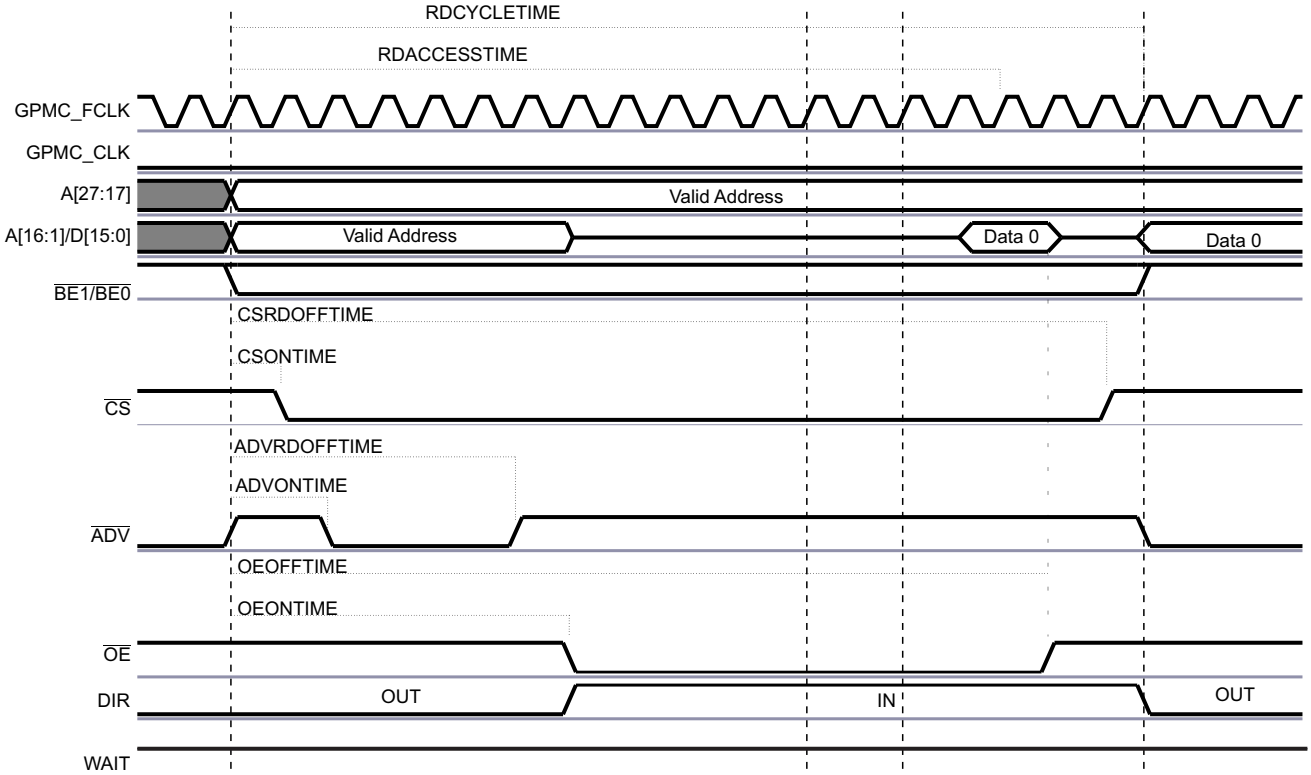
In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

9.2.4.10.1.1 Access on Address/Data Multiplexed Devices

9.2.4.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 9-12 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 9-12. Asynchronous Single Read Operation on an Address/Data Multiplexed Device



9.2.4.10.1.1.2 Asynchronous Single Read on an Address/Data-Multiplexed Device

See Section 9.3.6.1 for formulas to calculate timing parameters.

Table 9-41 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time. For details, see Section 9.2.4.8.2.3.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits GPMC_A[25:16] are placed on the address bus. The address phase ends at $\overline{OE}$ assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal $\overline{CS}$
  - $\overline{CS}$ assertion time is controlled by the GPMC_CONFIG2_i CSONTIME field. It controls the address setup time to $\overline{CS}$ assertion.
  - $\overline{CS}$ deassertion time is controlled by the GPMC_CONFIG2_i CSRDOFFTIME field. It controls the address hold time from $\overline{CS}$ deassertion
- Address valid signal $\overline{ADV}$
  - $\overline{ADV}$ assertion time is controlled by the GPMC_CONFIG3_i ADVONTIME field.
  - $\overline{ADV}$ deassertion time is controlled by the GPMC_CONFIG3_i ADVRDOFFTIME field.

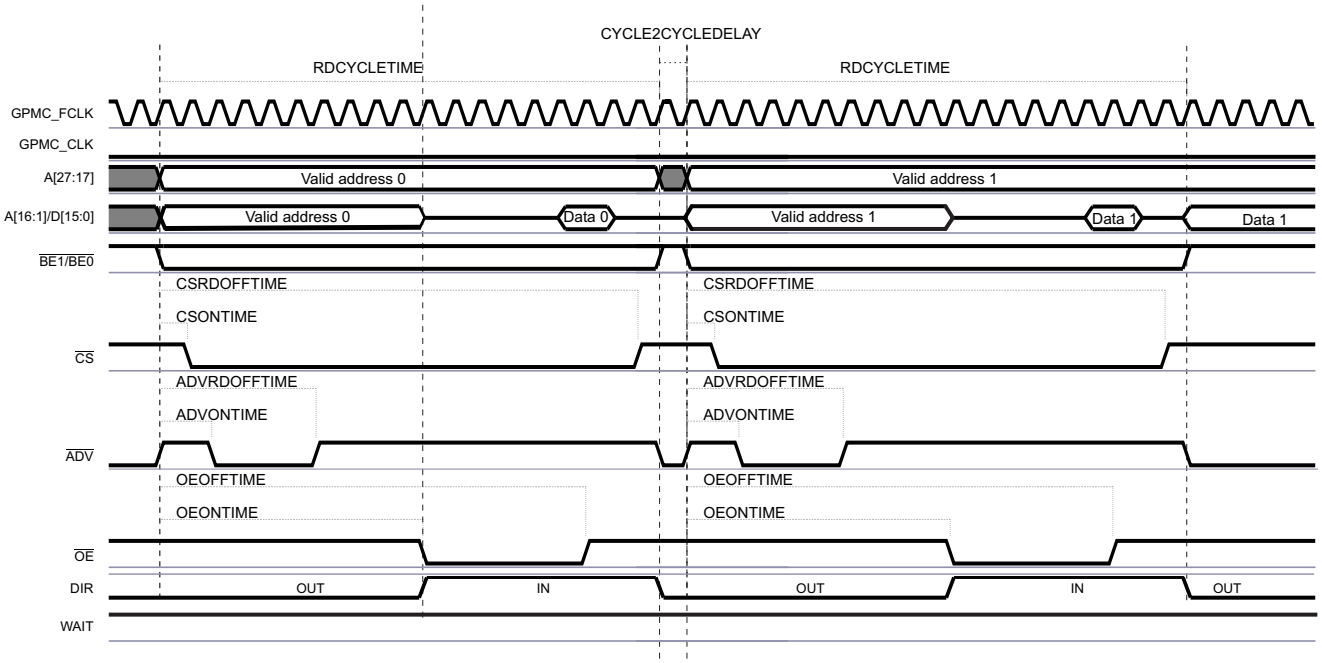
- Output enable signal $\overline{OE}$
  - $\overline{OE}$ assertion indicates a read cycle.
  - $\overline{OE}$ assertion time is controlled by the GPMC_CONFIG4_i OEONTIME field.
  - $\overline{OE}$ deassertion time is controlled by the GPMC_CONFIG4_i OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i RDACCESSTIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that $\overline{OE}$ is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 9.2.4.10.5. Between two successive accesses, if an $\overline{CS}$ pulse is needed:

- The GPMC_CONFIG6_i CYCLE2CYCLEDELAY field can be programmed with GPMC_CONFIG6_i CYCLE2CYCLESAMECSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

Figure 9-13 shows two asynchronous single-read accesses on an address/data-multiplexed devices.

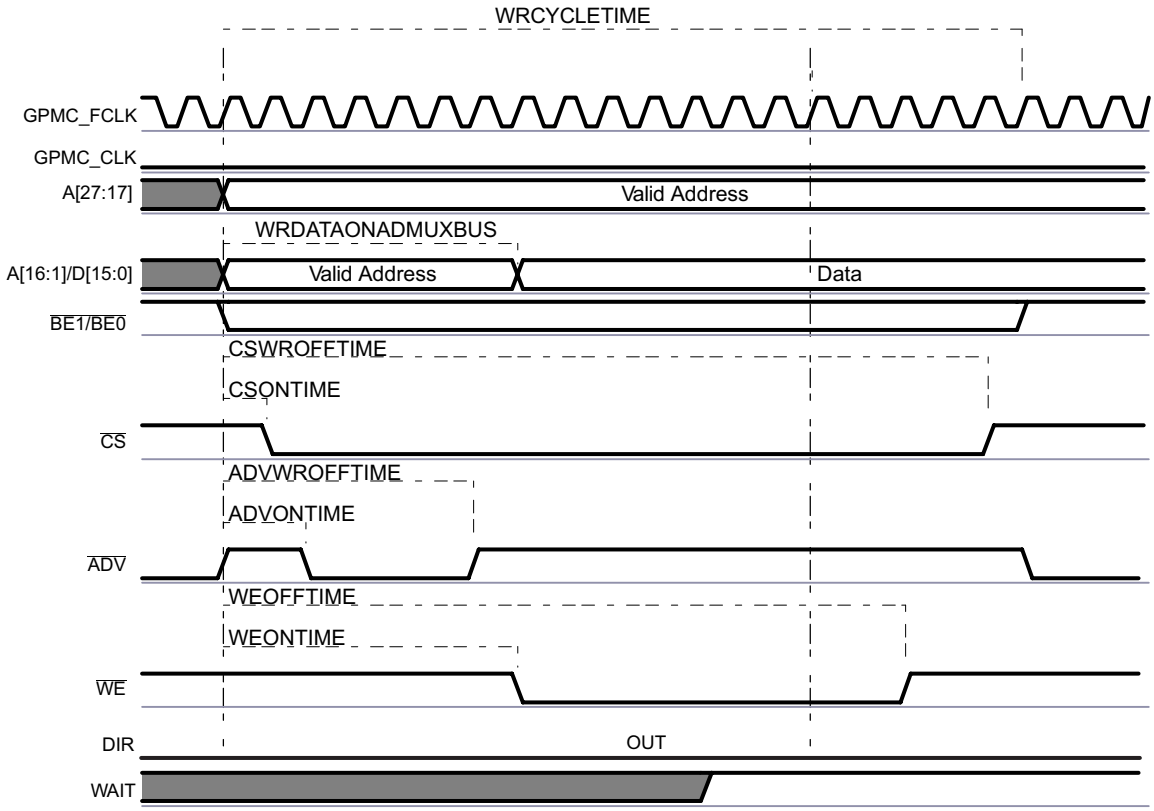
Figure 9-13. Two Asynchronous Single Read Accesses on an Address/Data Multiplexed Device (32-Bit Read Split Into 2 × 16-Bit Read)



9.2.4.10.1.1.3 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 9-14 shows an asynchronous single write operation on an address/data-multiplexed device.

Figure 9-14. Asynchronous Single Write on an Address/Data-Multiplexed Device



9.2.4.10.1.1.4 Asynchronous Single Write on an Address/Data-Multiplexed Device

See Section 9.3.6.1 for formulas to calculate timing parameters.

Table 9-41 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode. When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until $\overline{WE}$ assertion time. For more information, see Section 9.2.4.8.2.3.

The $\overline{CS}$ and $\overline{ADV}$ signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Write enable signal $\overline{WE}$
  - $\overline{WE}$ assertion indicates a write cycle.
  - $\overline{WE}$ assertion time is controlled by the GPMC_CONFIG4_i WEONTIME field.
  - $\overline{WE}$ deassertion time is controlled by the GPMC_CONFIG4_i WEOFFTIME field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i WRDATAONADMUXBUS time.

Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 9.2.4.9.10.

9.2.4.10.1.1.5 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices. If GPMC_CONFIG1_i WRITEMULTIPLE bit is enabled (1) with GPMC_CONFIG1_i WRITETYPE bit as asynchronous (0), the GPMC processes single asynchronous accesses.

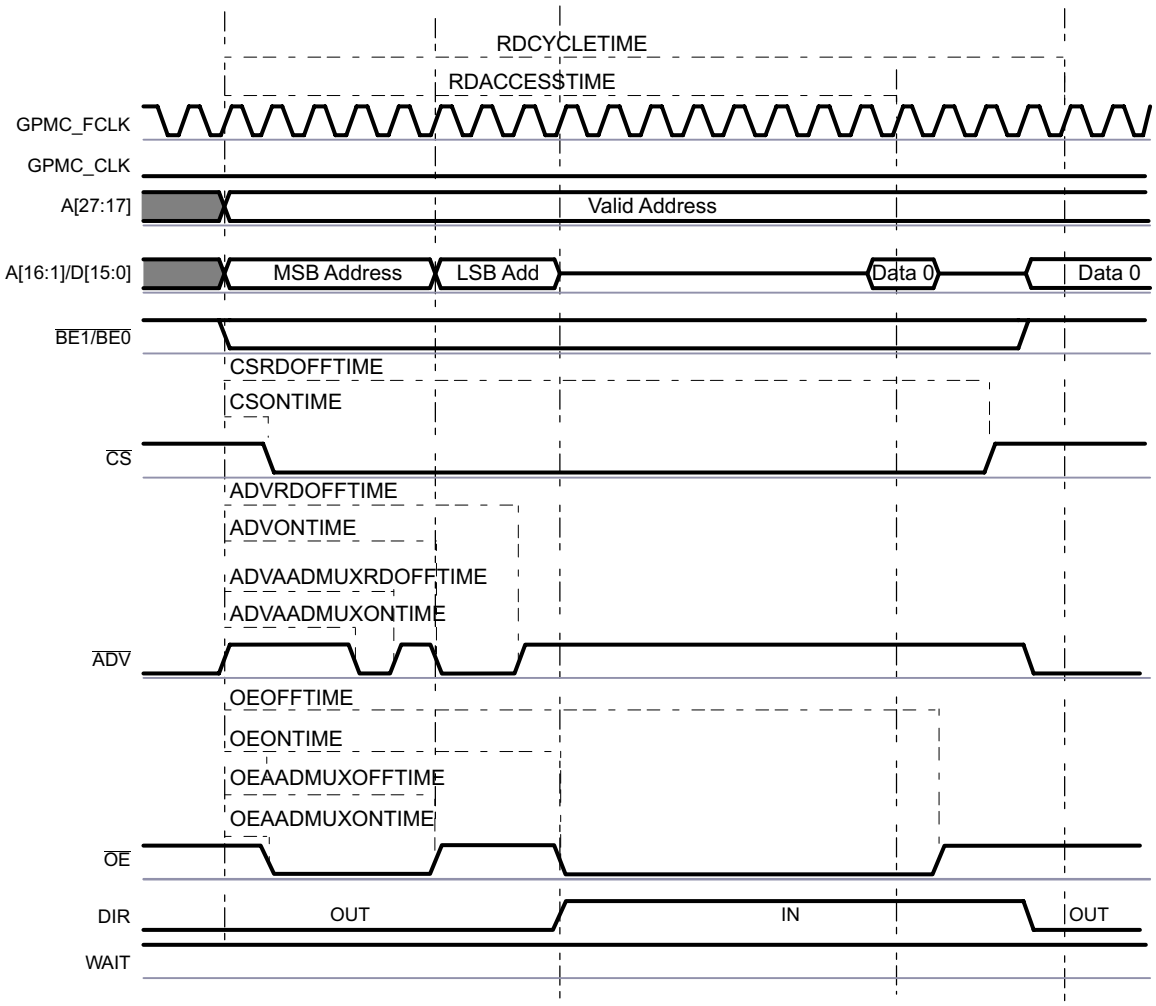
For accesses on non-multiplexed devices, see Section 9.2.4.10.3.

9.2.4.10.1.2 Access on Address/Address/Data (AAD) Multiplexed Devices

9.2.4.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 9-15 shows an asynchronous single read operation on an AAD-multiplexed device.

Figure 9-15. Asynchronous Single-Read on an AAD-Multiplexed Device



9.2.4.10.1.2.2 Asynchronous Single Read on an AAD-Multiplexed Device

See Section 9.3.6.1 for formulas to calculate timing parameters.

Table 9-41 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The first address phase ends at the first $\overline{OE}$ deassertion time. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The second address phase ends at the second $\overline{OE}$ assertion time, when the DIR signal goes from OUT to IN.

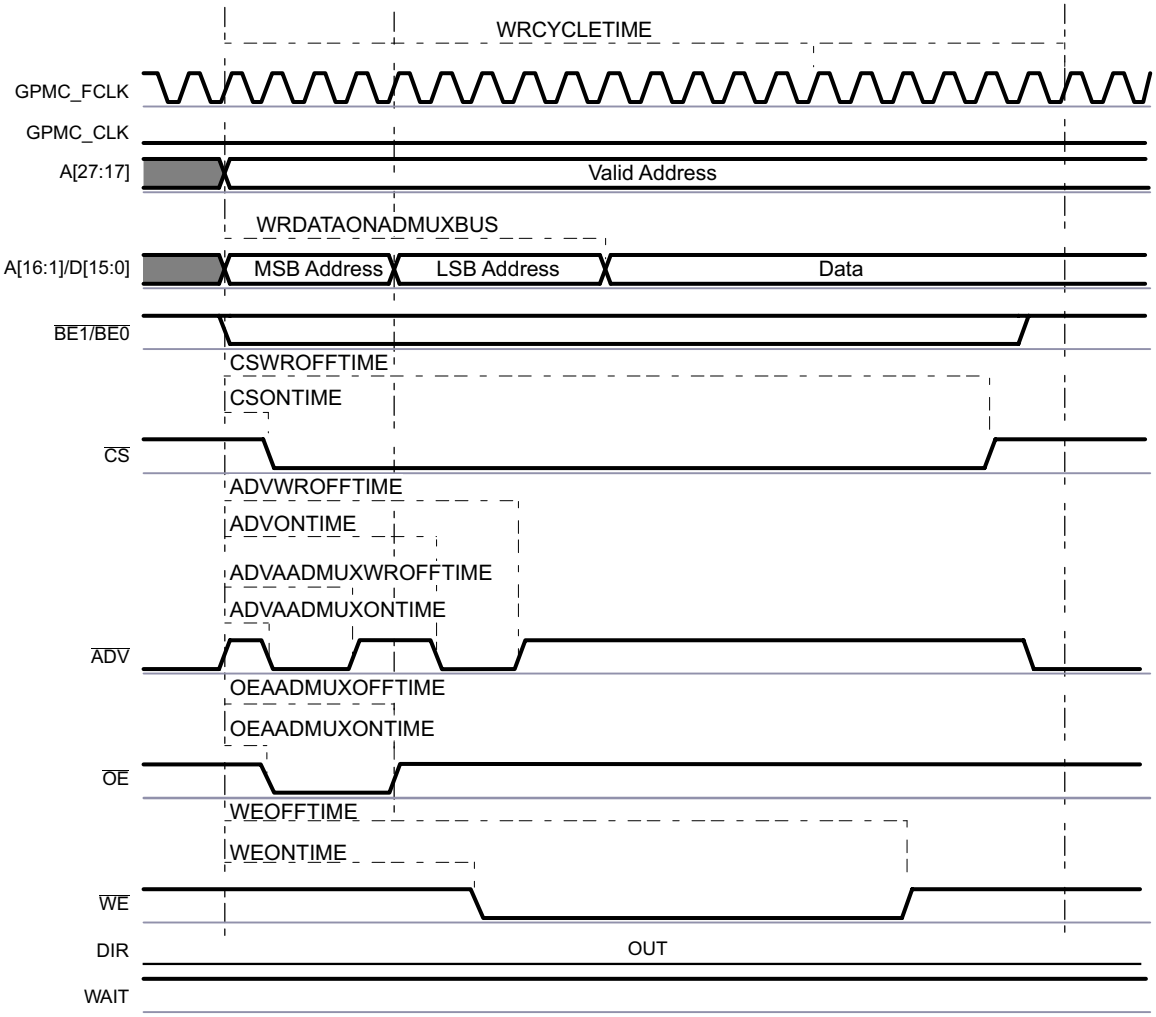
The $\overline{CS}$ and DIR signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Address valid signal $\overline{ADV}$. $\overline{ADV}$ is asserted and deasserted twice during a read transaction:
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i ADVAADMUXRDOFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i ADVRDOFFTIME field.
- Output Enable signal $\overline{OE}$. $\overline{OE}$ is asserted and deasserted twice during a read transaction ($\overline{OE}$ second assertion indicates a read cycle):
  - $\overline{OE}$ first assertion time is controlled by the GPMC_CONFIG4_i OEAADMUXONTIME field.
  - $\overline{OE}$ first deassertion time is controlled by the GPMC_CONFIG4_i OEAADMUXOFFTIME field.
  - $\overline{OE}$ second assertion time is controlled by the GPMC_CONFIG4_i OEONTIME field.
  - $\overline{OE}$ second deassertion time is controlled by the GPMC_CONFIG4_i OEOFFTIME field.

9.2.4.10.1.2.3 Asynchronous Single Write Operation on an AAD-Multiplexed Device

Figure 9-16 shows an asynchronous single write operation on an AAD-multiplexed device.

Figure 9-16. Asynchronous Single Write on an AAD-Multiplexed Device



See Section 9.3.6.1 for formulas to calculate timing parameters.

Table 9-41 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The address phase ends at $\overline{WE}$ assertion time.

The $\overline{CS}$, $\overline{WE}$, and DIR signals are controlled in the same way as for asynchronous single write operation on an address/data-multiplexed device.

- Address valid signal $\overline{ADV}$ is asserted and deasserted twice during a write transaction
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i ADVAADMUXWROFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i ADVWROFFTIME field.
- Output Enable signal $\overline{OE}$ is asserted during the address phase of a write transaction
  - $\overline{OE}$ assertion time is controlled by the GPMC_CONFIG4_i OEAADMUXONTIME field.
  - $\overline{OE}$ deassertion time is controlled by the GPMC_CONFIG4_i OEAADMUXOFFTIME field.

The address bits for the first address phase are driven onto the data bus until $\overline{OE}$ deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i WRDATAONADMUXBUS parameter.

9.2.4.10.1.2.4 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If GPMC_CONFIG1_i WRITEMULTIPLE bit is enabled (1) with GPMC_CONFIG1_i WRITETYPE bit as asynchronous (0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see Section 9.2.4.10.3.

9.2.4.10.2 Synchronous Access Description

This section details read and write synchronous accesses on address/data multiplexed. All information in this section can be applied to any type of memory - non-multiplexed, address and data multiplexed or AAD-multiplexed - with a difference limited to the address phase. For accesses on non-multiplexed devices, see Section 9.2.4.10.3.

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i GPMCFCLKDIVIDER field. In the following section, i stands for the chip-select number, i = 0 to 3.
- The GPMC_CONFIG1_i CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completion.

9.2.4.10.2.1 Synchronous Single Read

Figure 9-17 and Figure 9-18 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 9-17. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

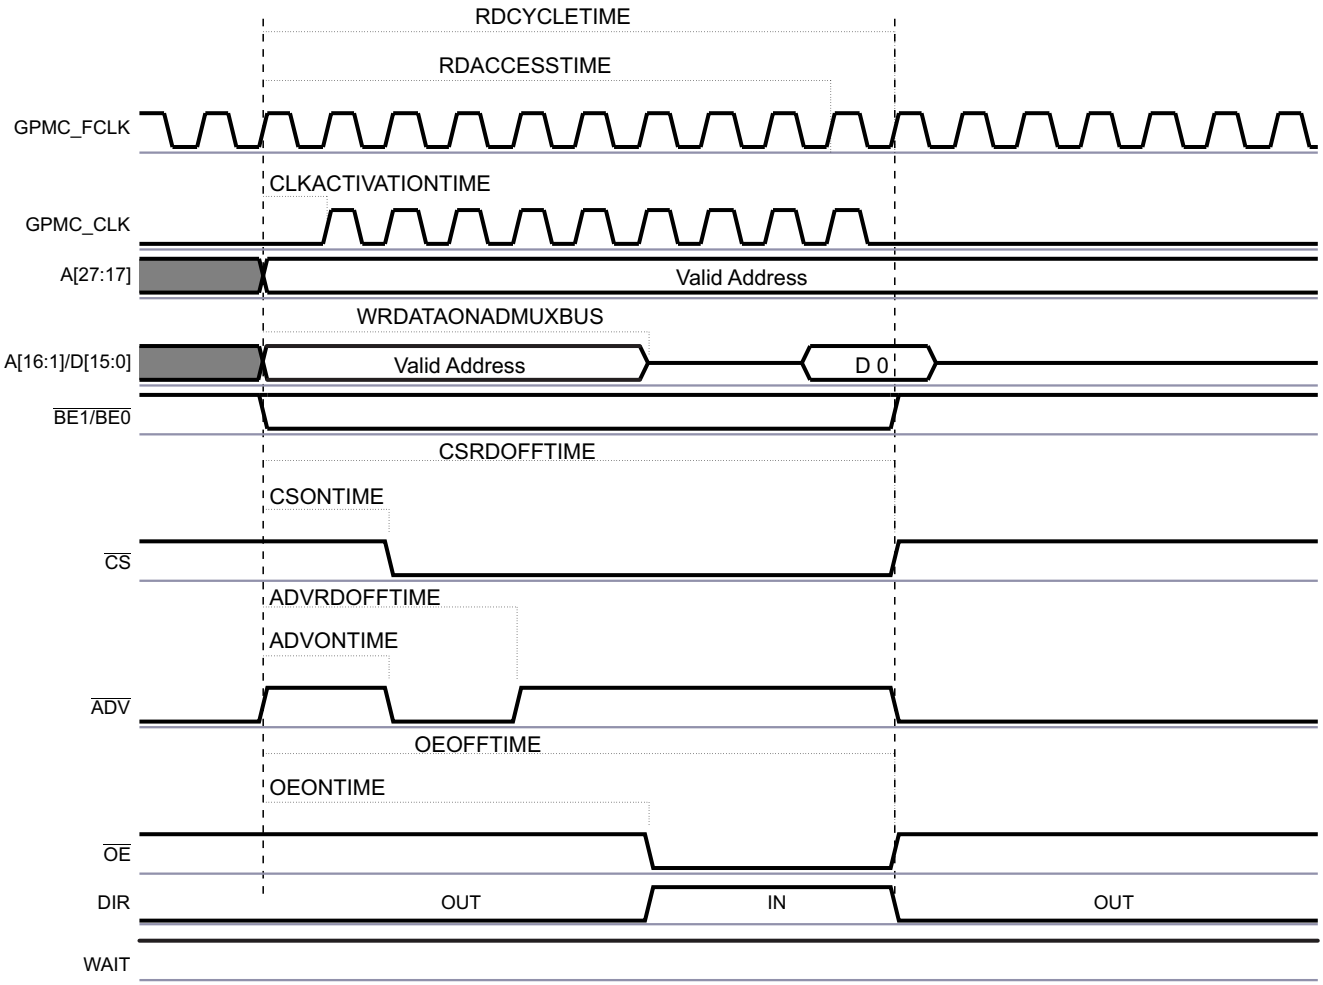


Figure 9-18. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

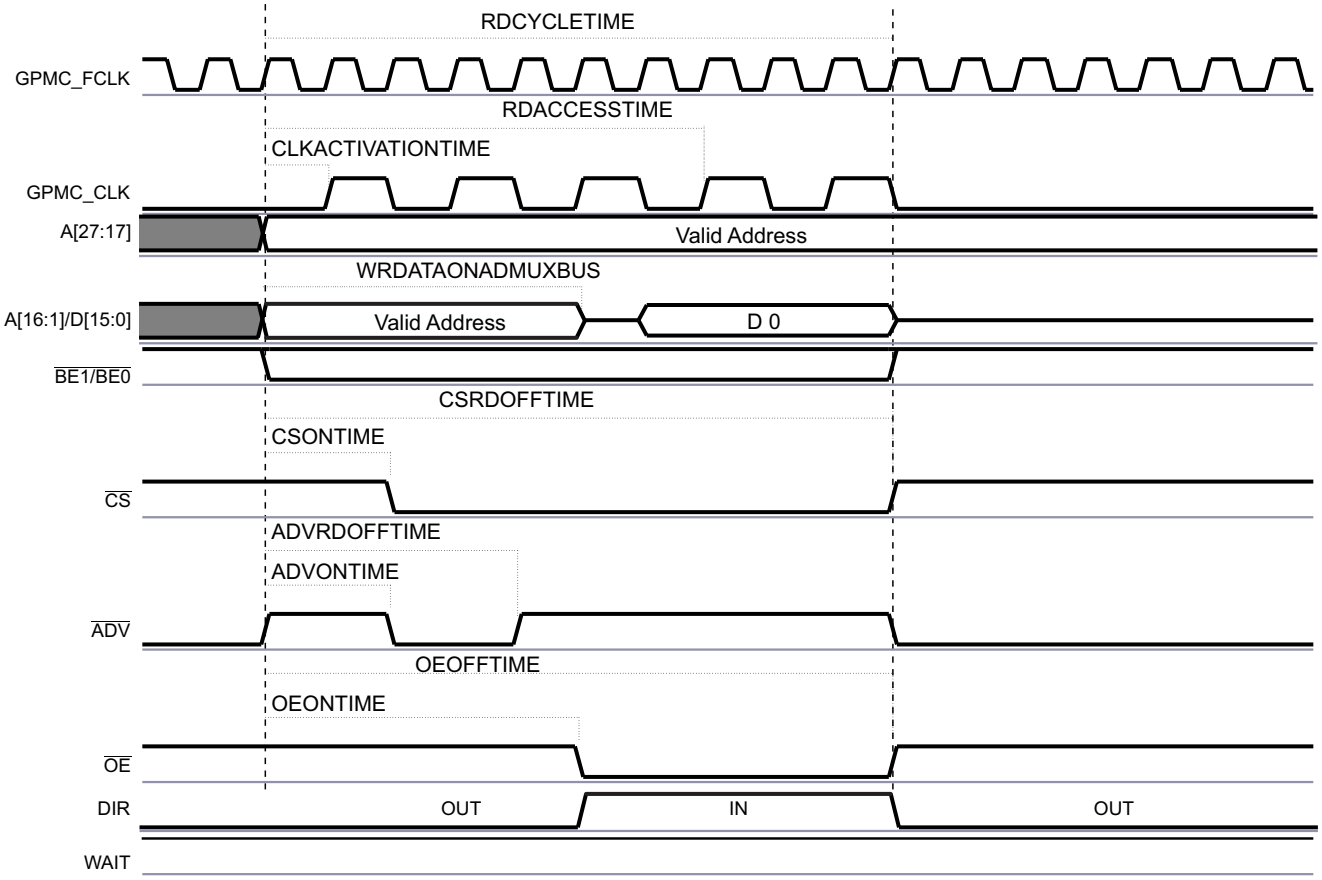

See Section 9.3.6.1 for formulas to calculate timing parameters.

Table 9-41 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time. For details, see Section 9.2.4.8.2.3.

- Chip-select signal $\overline{CS}$
  - $\overline{CS}$ assertion time is controlled by the GPMC_CONFIG2_i CSONTIME field and ensures address setup time to $\overline{CS}$ assertion.
  - $\overline{CS}$ deassertion time is controlled by the GPMC_CONFIG2_i CSRDOFFTIME field and ensures address hold time to $\overline{CS}$ deassertion.
- Address valid signal $\overline{ADV}$
  - $\overline{ADV}$ assertion time is controlled by the GPMC_CONFIG3_i ADVONTIME field.
  - $\overline{ADV}$ deassertion time is controlled by the GPMC_CONFIG3_i ADVRDOFFTIME field.
- Output enable signal $\overline{OE}$
  - $\overline{OE}$ assertion indicates a read cycle.
  - $\overline{OE}$ assertion time is controlled by the GPMC_CONFIG4_i OEONTIME field.
  - $\overline{OE}$ deassertion time is controlled by the GPMC_CONFIG4_i OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i RDACCESSTIME field or by monitoring the WAIT signal.
- Total access time (GPMC_CONFIG5_i RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from $\overline{CS}$ deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

- Direction signal DIR: DIR goes from OUT to IN at the same time as $\overline{OE}$ assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The address phase ends at $\overline{WE}$ assertion time.

The $\overline{CS}$ and DIR signals are controlled in the same way as for synchronous single read operation on an address/data-multiplexed device.

- Address valid signal $\overline{ADV}$ is asserted and deasserted twice during a read transaction
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i ADVAADMUXRDOFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i ADVRDOFFTIME field.
- Output Enable signal $\overline{OE}$ is asserted and deasserted twice during a read transaction ($\overline{OE}$ second assertion indicates a read cycle)
  - $\overline{OE}$ first assertion time is controlled by the GPMC_CONFIG4_i OEAADMUXONTIME field.
  - $\overline{OE}$ first deassertion time is controlled by the GPMC_CONFIG4_i OEAADMUXOFFTIME field.
  - $\overline{OE}$ second assertion time is controlled by the GPMC_CONFIG4_i OEONTIME field.
  - $\overline{OE}$ second deassertion time is controlled by the GPMC_CONFIG4_i OEOFFTIME field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 9.2.4.9.10.

9.2.4.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 9-19 and Figure 9-20 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 9-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

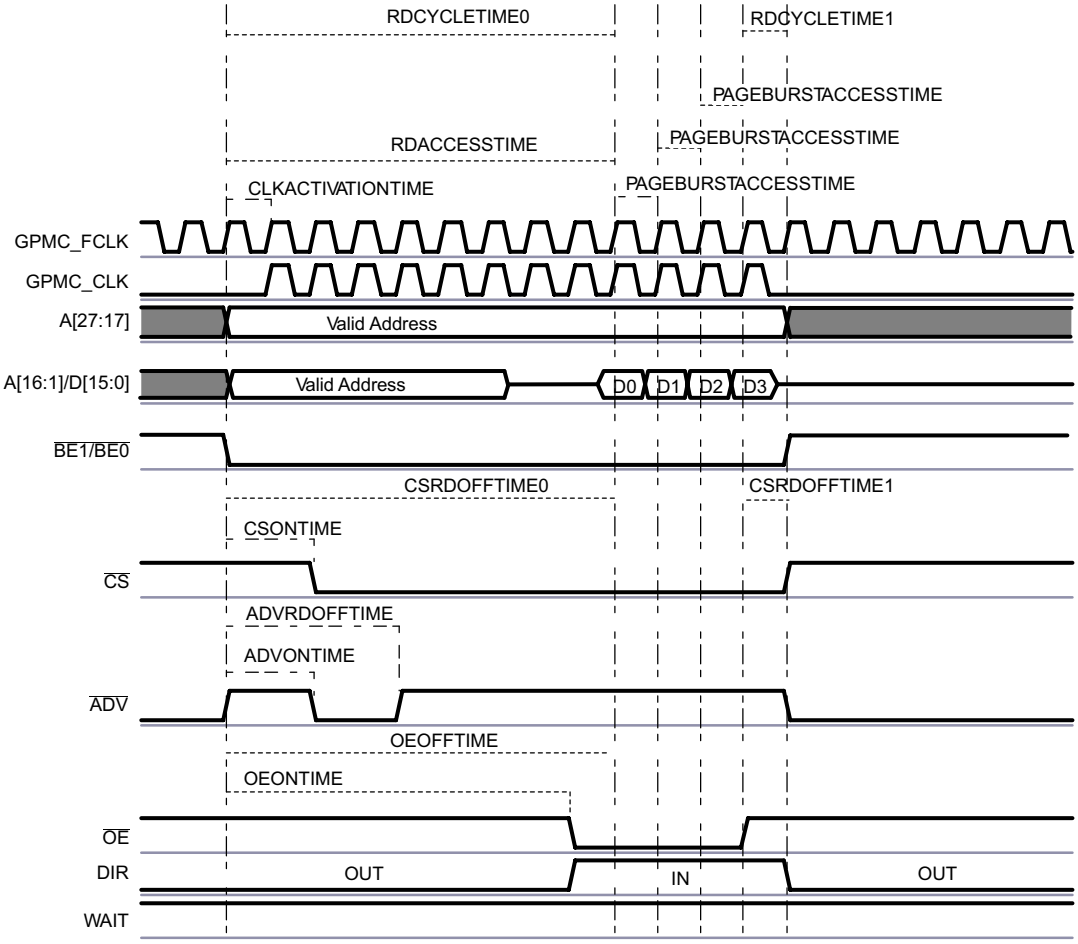

Figure 9-20. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

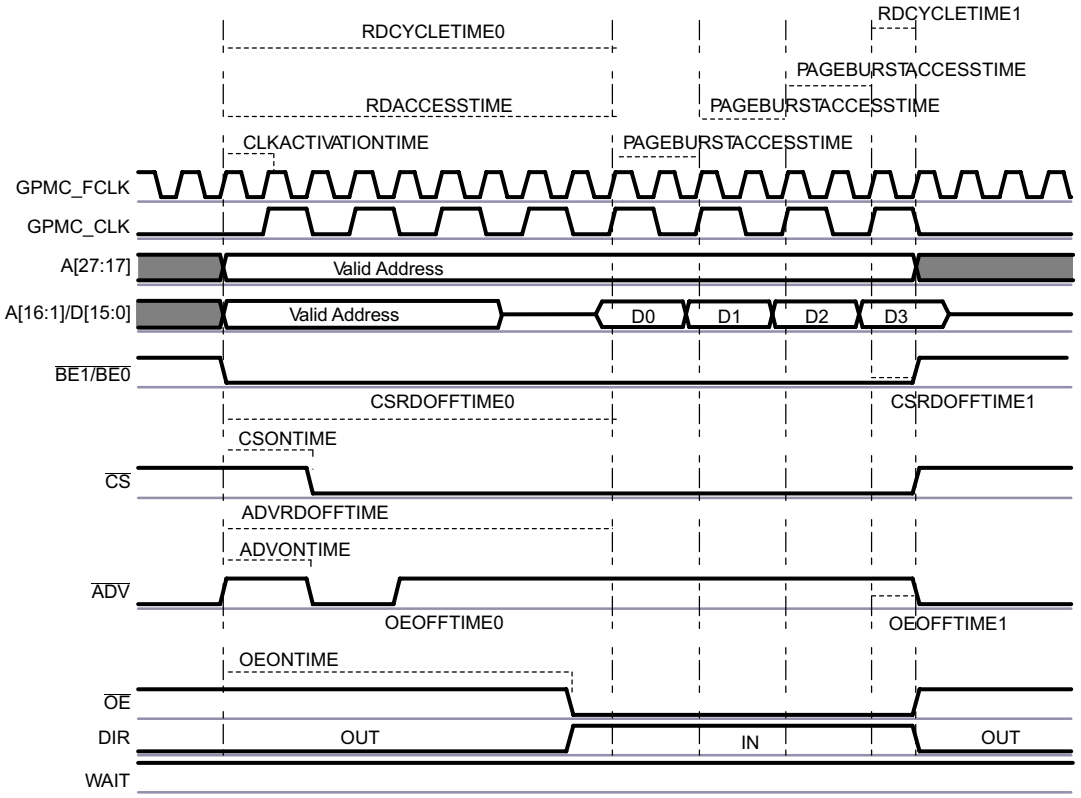


When GPMC_CONFIG5_i RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to GPMC_CONFIG5_i PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

The $\overline{CS}$, $\overline{ADV}$, $\overline{OE}$ and DIR signals are controlled in the same way as for synchronous single read operation. See Section 9.2.4.10.2.1.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMC_CONFIG1_i GPMCFCLKDIVIDER and the memory-device internal configuration. Depending on the device page length, the GPMC checks device page crossing during a new burst request and purposely insert initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from $\overline{CS}$ deassertion. In Figure 9-19, RDCYCLETIME programmed value equals to RDCYCLETIME0 + RDCYCLETIME1.

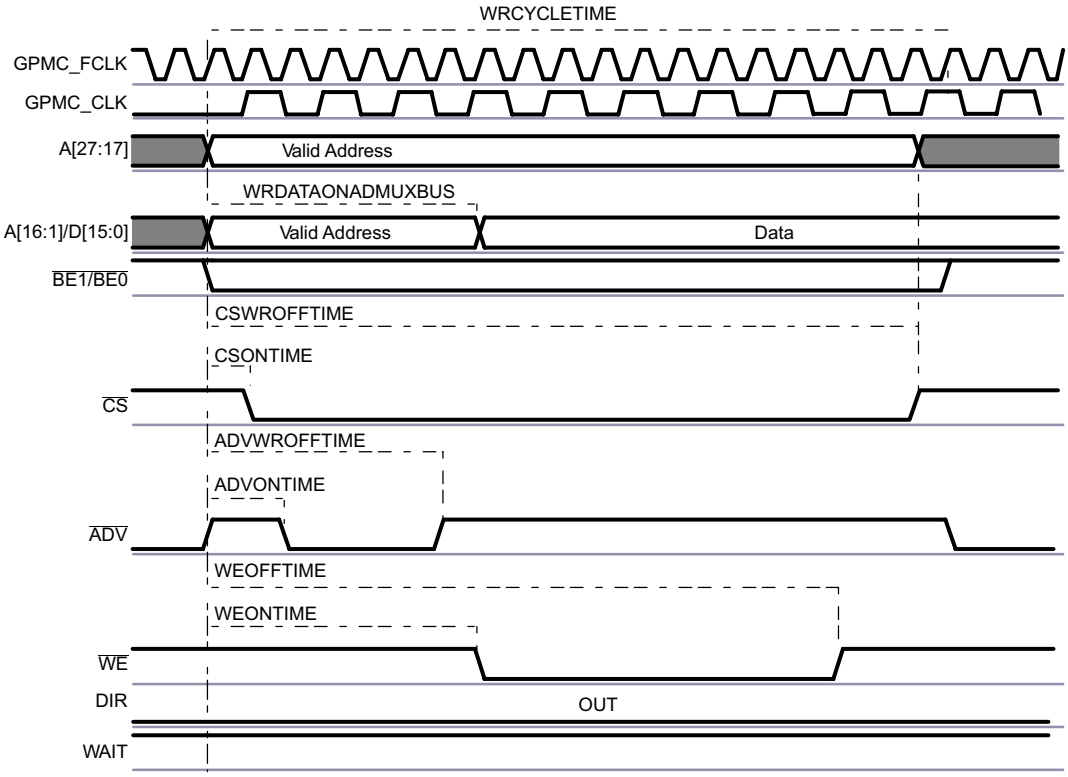
After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 9.2.4.9.10.

Burst wraparound is enabled through the GPMC_CONFIG1_i WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through GPMC_CONFIG1_i ATTACHEDDEVICEPAGELENGTH.

9.2.4.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses (see Figure 9-21).

Figure 9-21. Synchronous Single Write on an Address/Data-Multiplexed Device



When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until GPMC_CONFIG6_i WRDATAONADMUXBUS time. First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

9.2.4.10.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses. Figure 9-22 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 9-22. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

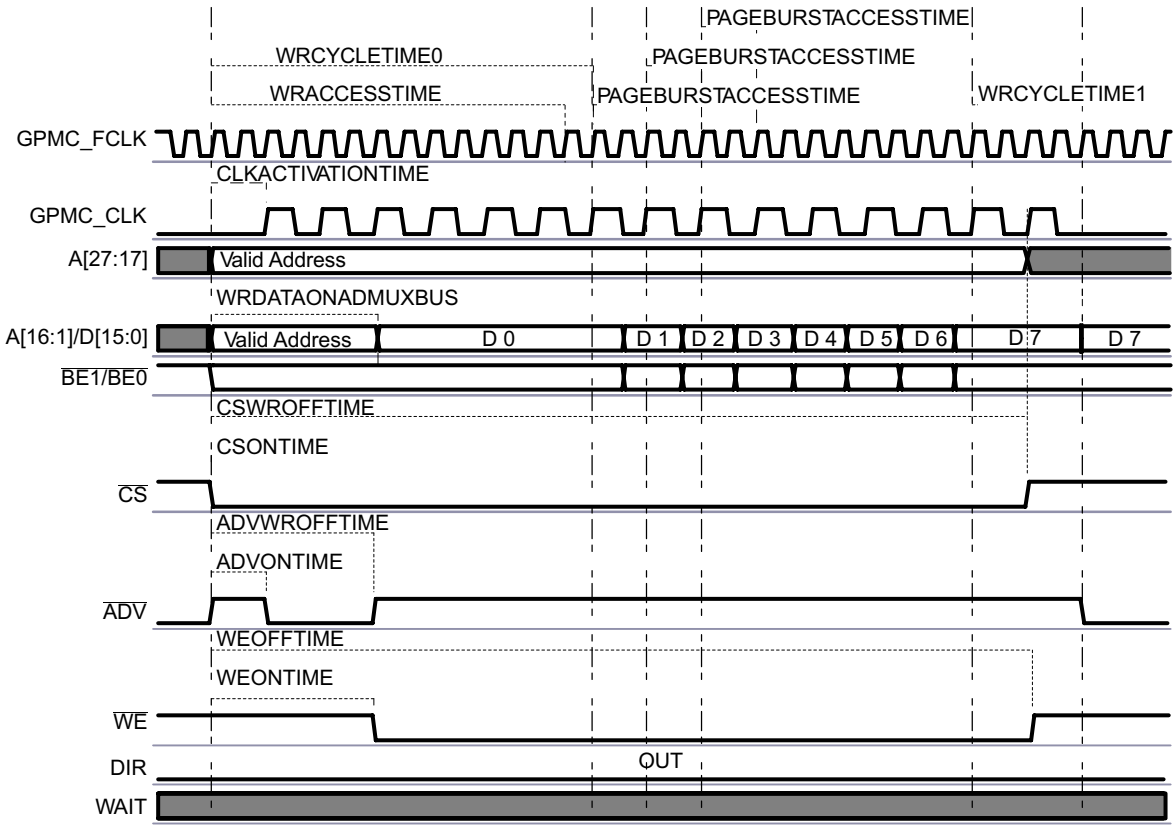


Figure 9-23 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

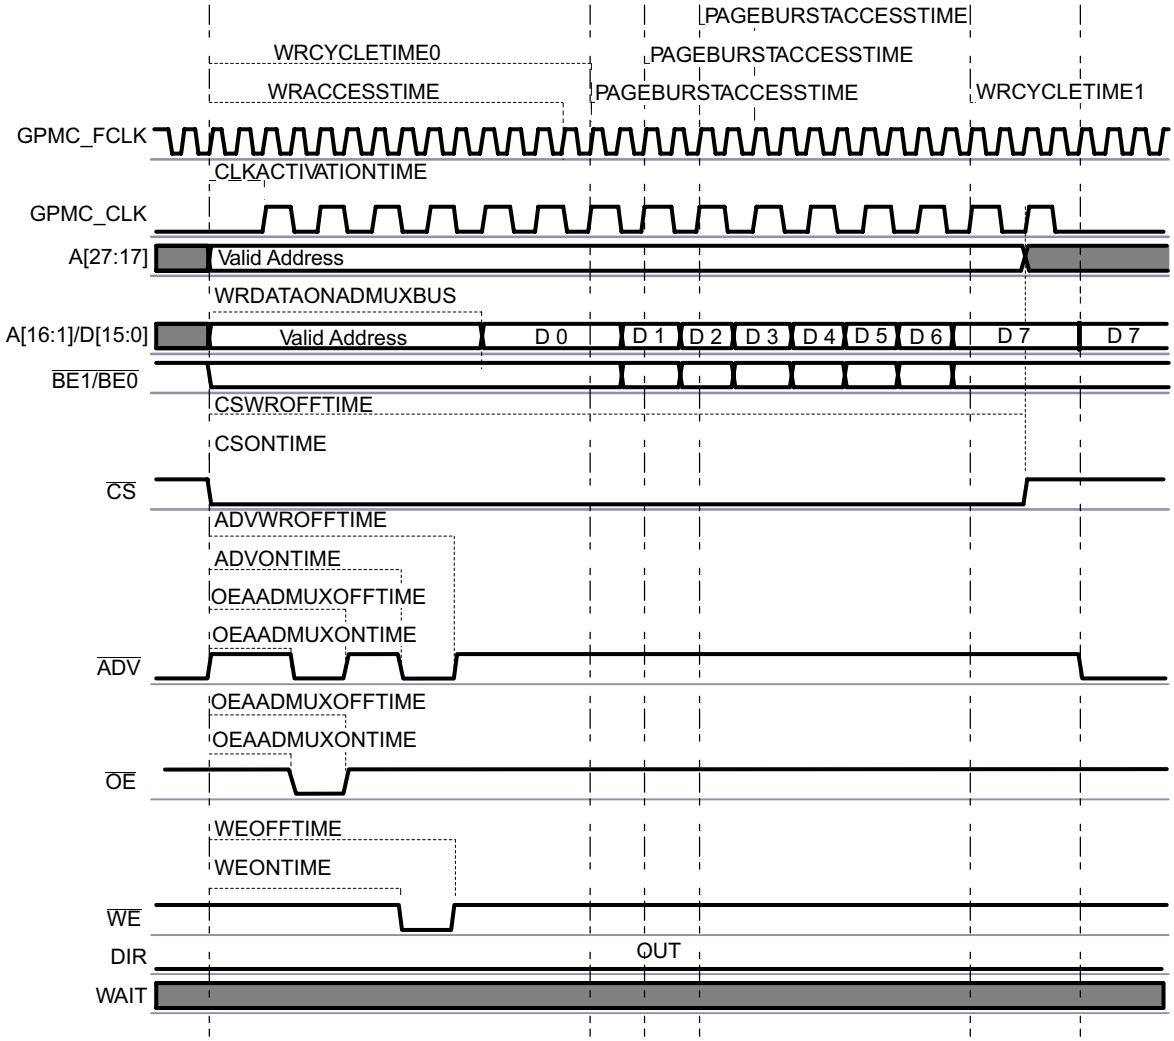
Figure 9-23. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode



The first data of the burst is driven on the A/D bus at GPMC_CONFIG6_i WRDATAONADMUXBUS.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time. For details, see Section 9.2.4.8.2.3.

- Chip-select signal $\overline{CS}$
  - $\overline{CS}$ assertion time is controlled by the GPMC_CONFIG2_i CSONTIME field (i = 0 to 5) and ensures address setup time to $\overline{CS}$ assertion.
  - $\overline{CS}$ deassertion time controlled by the GPMC_CONFIG2_i CSWROFFTIME field and ensures address hold time to $\overline{CS}$ deassertion.
- Address valid signal $\overline{ADV}$
  - $\overline{ADV}$ assertion time is controlled by the GPMC_CONFIG3_i ADVONTIME field.
  - $\overline{ADV}$ deassertion time is controlled by the GPMC_CONFIG3_i ADVWROFFTIME field.

- Write enable signal $\overline{WE}$
  - $\overline{WE}$ assertion indicates a read cycle.
  - $\overline{WE}$ assertion time is controlled by the GPMC_CONFIG4_i WEONTIME field.
  - $\overline{WE}$ deassertion time is controlled by the GPMC_CONFIG4_i WEOFFTIME field.

  The $\overline{WE}$ falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the $\overline{WE}$ signal at low during the address phase.
- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The address phase ends at $\overline{WE}$ assertion time.

The $\overline{CS}$ and DIR signals are controlled as detailed above.

- Address valid signal $\overline{ADV}$ is asserted and deasserted twice during a read transaction
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i ADVAADMUXRDOFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i ADVRDOFFTIME field.
- Output Enable signal $\overline{OE}$ is asserted and deasserted twice during a read transaction ($\overline{OE}$ second assertion indicates a read cycle)
  - $\overline{OE}$ first assertion time is controlled by the GPMC_CONFIG4_i OEAADMUXONTIME field.
  - $\overline{OE}$ first deassertion time is controlled by the GPMC_CONFIG4_i OEAADMUXOFFTIME field.
  - $\overline{OE}$ second assertion time is controlled by the GPMC_CONFIG4_i OEONTIME field.
  - $\overline{OE}$ second deassertion time is controlled by the GPMC_CONFIG4_i OEOFFTIME field.

First write data is driven by the GPMC at GPMC_CONFIG6_i WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from $\overline{CS}$ deassertion. In Figure 9-23 the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 9.2.4.9.10.

9.2.4.10.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

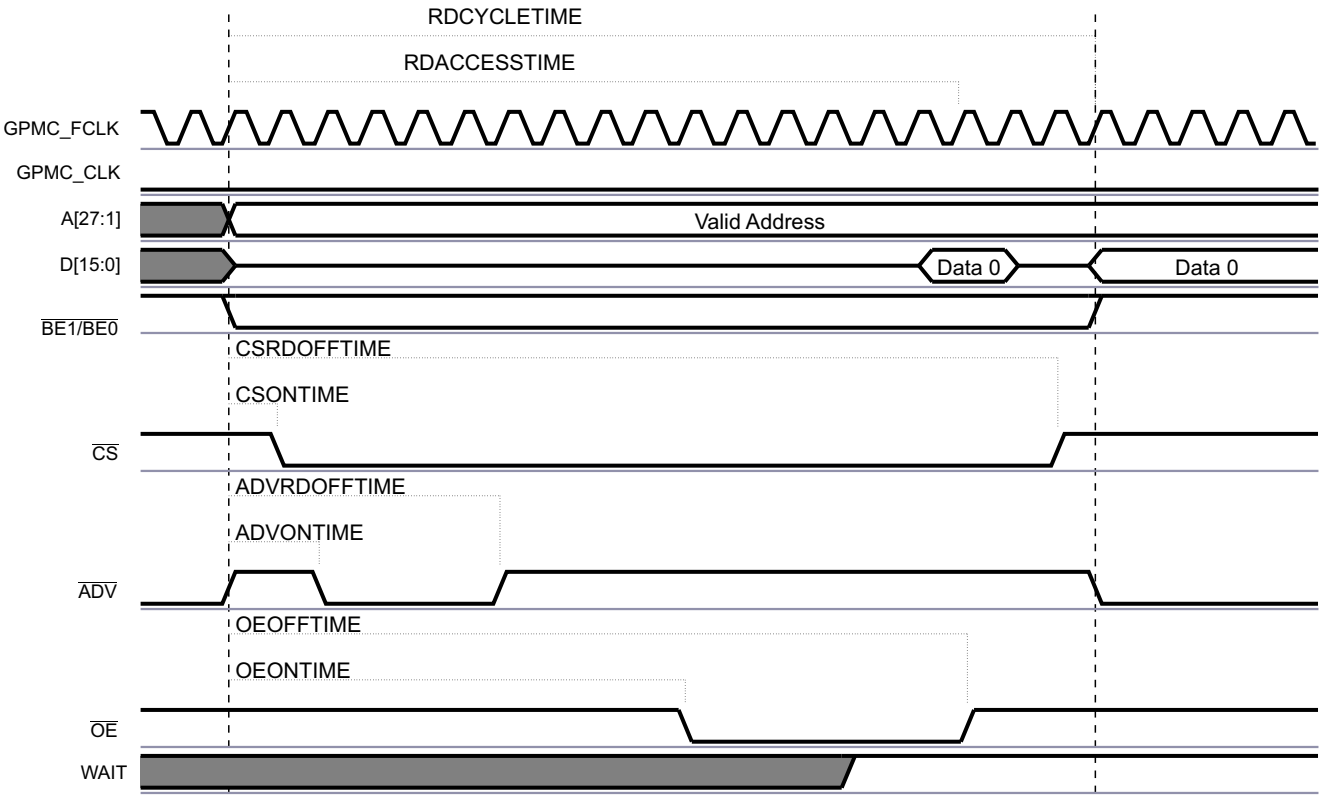
Page mode is only available in non-multiplexed mode.

- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

9.2.4.10.3.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 9-24 shows an asynchronous single read operation on a nonmultiplexed device.

Figure 9-24. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device



The 27-bit address is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

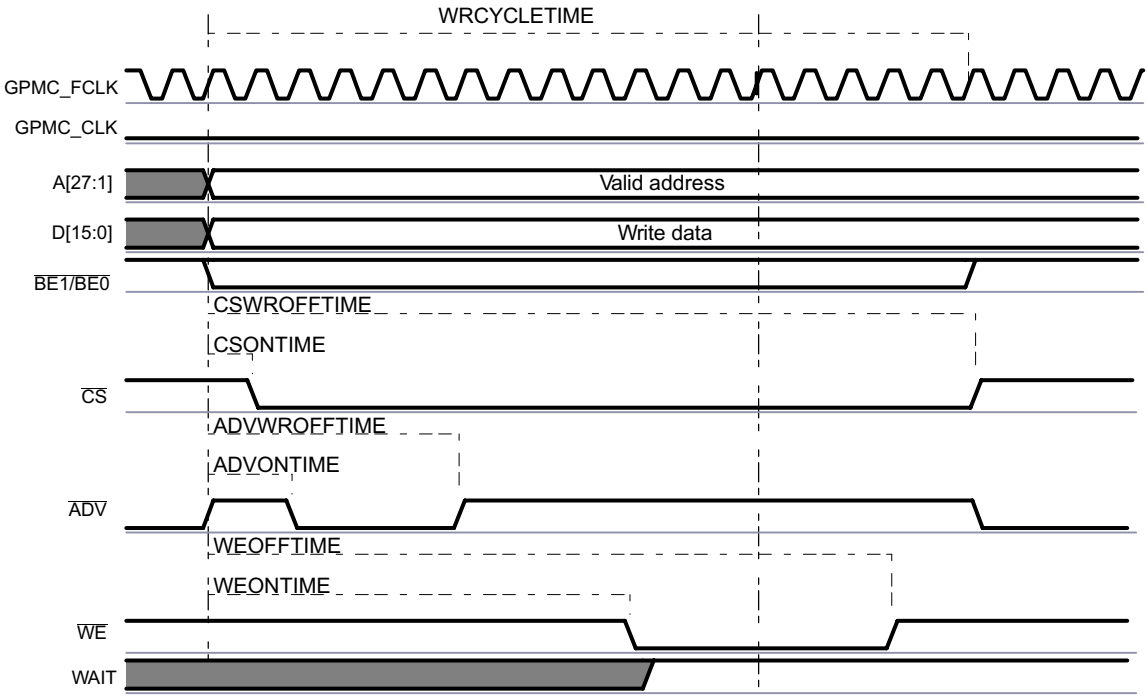
Read data is latched at GPMC_CONFIG1_5 RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5 RDCYCLETIME parameter.

$\overline{CS}$, $\overline{ADV}$, $\overline{OE}$ and DIR signals are controlled in the same way as address/data multiplexed accesses, see Section 9.2.4.10.1.1.2.

9.2.4.10.3.2 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 9-25 shows an asynchronous single write operation on a nonmultiplexed device.

Figure 9-25. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device



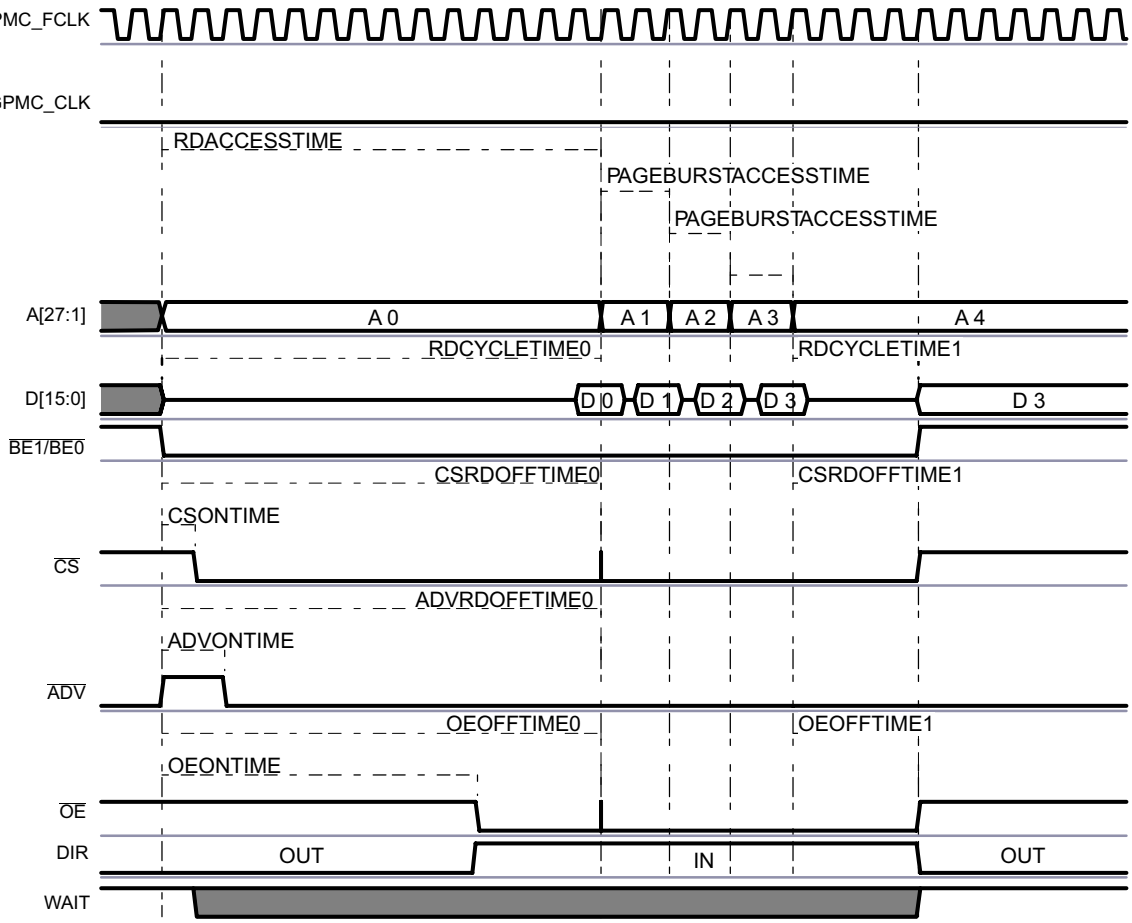
The 27-bit address is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

$\overline{CS}$, $\overline{ADV}$, $\overline{WE}$ and DIR signals are controlled in the same way as address/data multiplexed accesses, see Section 9.2.4.10.1.1.3.

9.2.4.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

Figure 9-26 shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two 32-word host read accesses to the GPMC are split into one multiple (page mode of four 16-word) read access to the attached device.

Figure 9-26. Asynchronous Multiple (Page Mode) Read



The WAIT signal is active low.

CS, ADV, OE and DIR signals are controlled in the same way as address/data multiplexed accesses, see Section 9.2.4.10.1.1.2.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i RDACCESSTIME completion time (i = 0 to 5). The end of the access is defined by the GPMC_CONFIG5_i RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the CS deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i RDCYCLETIME field.
- In Figure 9-26, the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

9.2.4.10.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 9.3.3.

9.2.4.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i READMULTIPLE and GPMC_CONFIG1_i WRITMULTIPLE bits (i = 0 to 5) are associated with the READTYPE and WRITETYPE parameters.

- Asynchronous write page mode is not supported.
- 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

9.2.4.10.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the GPMC_CONFIG1_i ATTACHEDDEVICEPAGELENGTH field (i = 0 to 5). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i WRAPBURST bit (i = 0 to 5) must be set to 1. Similarly, DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word 16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word 16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

9.2.4.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i DEVICETYPE field (i = 0 to 3) shall be cleared to 00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum $\overline{CS}$ high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

9.2.4.12 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be de-asserted if accesses to other chip-selects are requested.

9.2.4.12.1 NAND Memory Device in Byte or 16-Bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the $\overline{ADV}$_ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the $\overline{BE0}$_CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

9.2.4.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 5) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in Table 9-11. Failure to comply with these settings corrupts the NAND interface protocol.

The GPMC_CONFIG1_i to GPMC_CONFIG4_i register (where i = 0 to 5) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

Table 9-11. Chip-Select Configuration for NAND Interfacing

GPMC_CONFIG1_i Bit Field	Value	Comments
WRAPBURST	0	No wrap
READMULTIPLE	0	Single access
READTYPE	0	Asynchronous mode
WRITEMULTIPLE	0	Single access
WRITETYPE	0	Asynchronous mode
CLKACTIVATIONTIME	0b00	
ATTACHEDDEVICEPAGELENGTH	Don't care	Single-access mode
WAITREADMONITORING	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT		Select which wait is monitored by edge detectors
DEVICESIZE	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	0b10	NAND device in stream mode
MUXADDDATA	0b00	Nonmultiplexed mode
TIMEPARAGRANULARITY	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	Don't care	Asynchronous mode

9.2.4.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) register locations with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with $\overline{OE}$ and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) register locations must be posted for faster operations. The GPMC_CONFIG NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- A GPMC_STATUS EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) registers are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to a GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i can be used, and any of the four byte locations of the registers are valid.

The same applies to GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid

9.2.4.12.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i (where i = 0 to 5) register location places the data as the NAND command value on the bus, using a regular asynchronous write access.

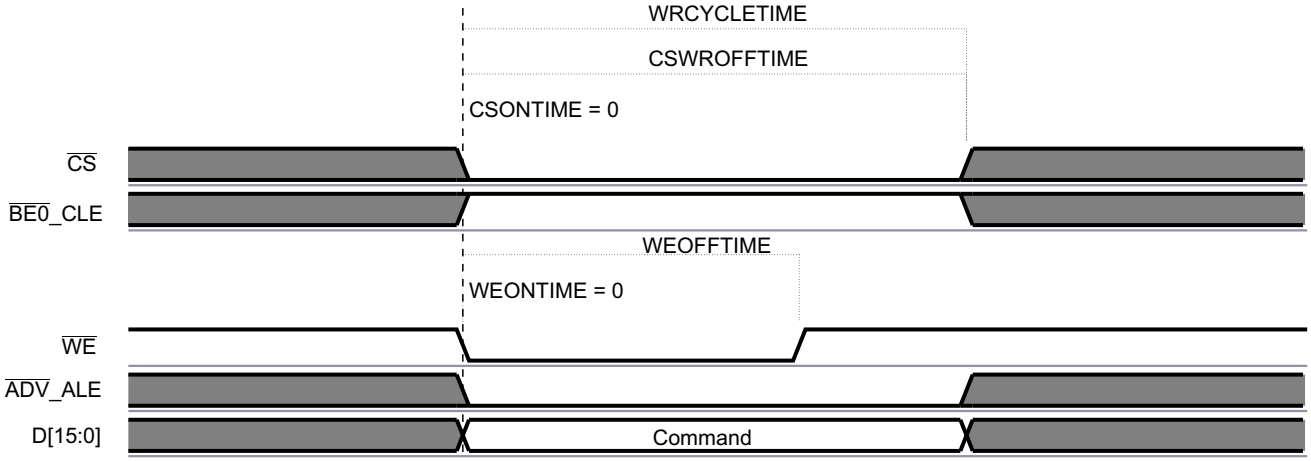
- $\overline{CE}$ is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- WE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and $\overline{RE}$ ($\overline{OE}$) are maintained inactive.

Figure 9-27 shows the NAND command latch cycle.

CLE is shared with the $\overline{BE0}$ output signal and has an inverted polarity from $\overline{BE0}$. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, $\overline{BE0}$ (also $\overline{BE1}$) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

Figure 9-27. NAND Command Latch Cycle



9.2.4.12.1.4 Address Latch Cycle

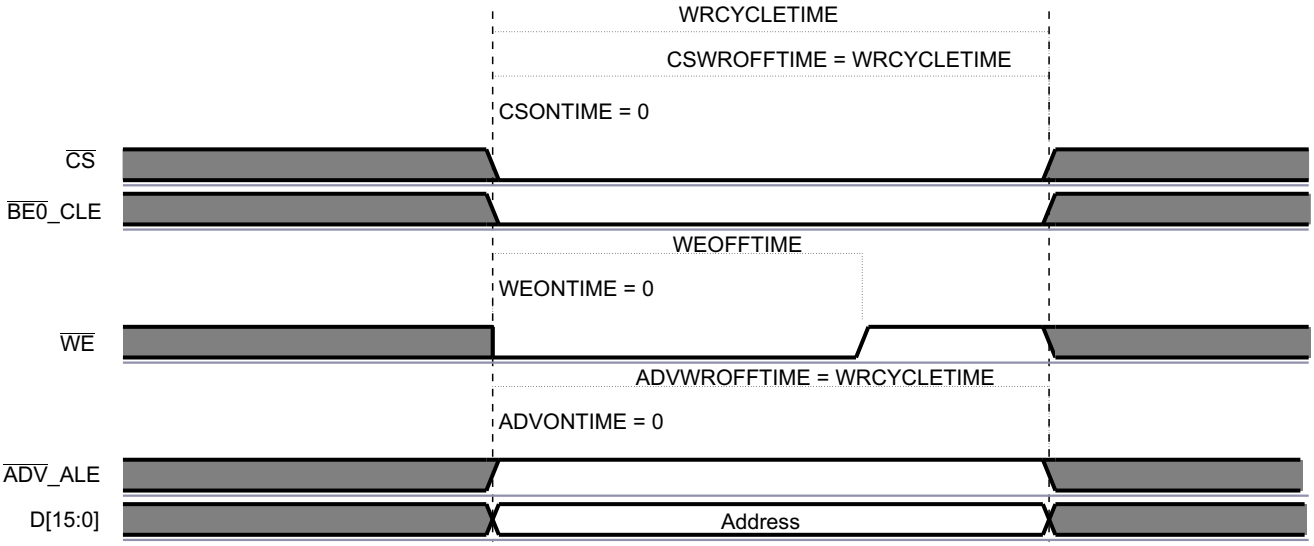
Writing data at the GPMC_NAND_ADDRESS_i (where i = 0 to 5) register location places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- $\overline{CS}$ is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- $\overline{WE}$ is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and $\overline{RE}$ ($\overline{OE}$) are maintained inactive.

Figure 9-28 shows the NAND address latch cycle.

ALE is shared with the $\overline{ADV}$ output signal and has an inverted polarity from $\overline{ADV}$. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

Figure 9-28. NAND Address Latch Cycle



9.2.4.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i (where i = 0 to 5) register location mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable $\overline{RE}$ or $\overline{WE}$ signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

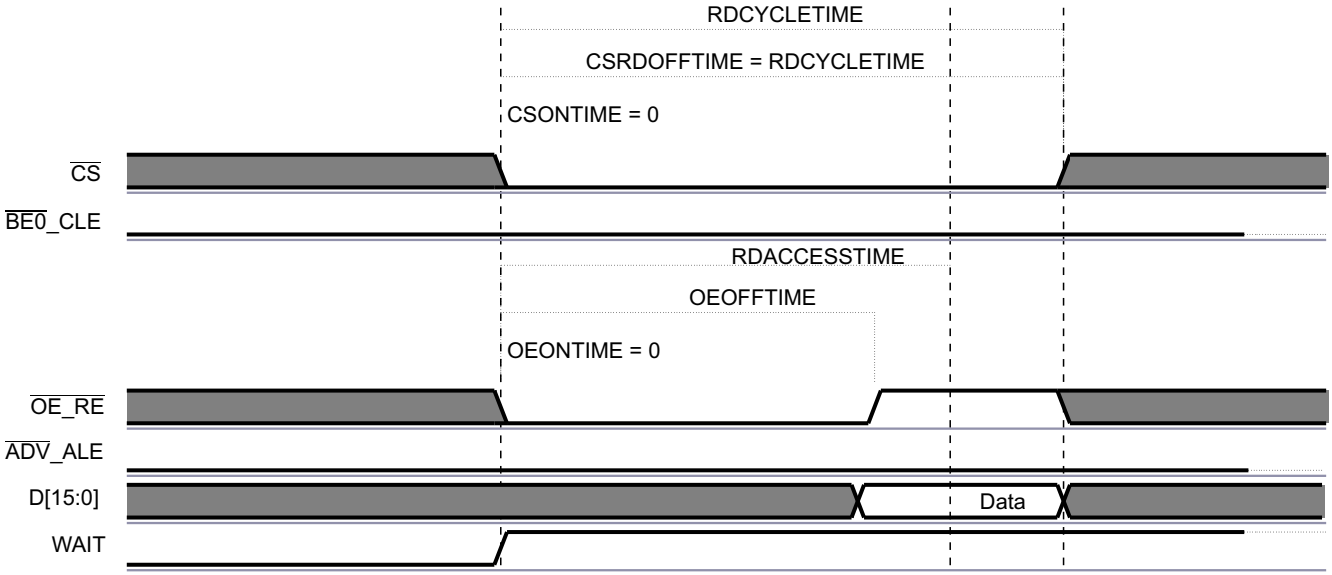
Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- $\overline{CS}$ is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- $\overline{RE}$ is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of $\overline{RE}$ high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after $\overline{RE}$ deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and $\overline{WE}$ are maintained inactive.

Figure 9-29 shows the NAND data read cycle.

Figure 9-29. NAND Data Read Cycle

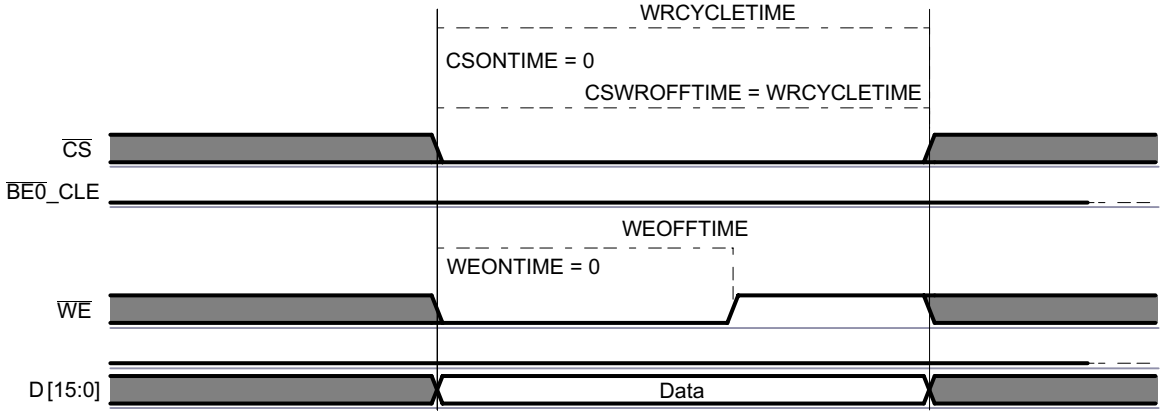


Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- $\overline{CS}$ is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- $\overline{WE}$ is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and $\overline{RE}$ ($\overline{OE}$) are maintained inactive.

Figure 9-30 shows the NAND data write cycle.

Figure 9-30. NAND Data Write Cycle



9.2.4.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by $\overline{CS}$-to-data-valid timing and has faster $\overline{RE}$-to-data-valid timing. Successive accesses with $\overline{CS}$ deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that $\overline{CS}$ always stays low between two accesses to the same chip-select. Moreover, an $\overline{CS}$ deassertion time between the same chip-select NAND accesses is likely to be required as follows: the $\overline{CS}$ deassertion requires programming CYCLETIME and RDACCESSTIME according to the $\overline{CS}$-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum $\overline{CS}$ high pulse width between accesses. For more information about optimal prefetch engine access, see Section 9.2.4.12.4.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum $\overline{CS}$ high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important $\overline{RE}$ high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

9.2.4.12.1.7 Read and Write Access Size Adaptation

9.2.4.12.1.7.1 8-Bit Wide NAND Device

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

9.2.4.12.1.7.2 16-Bit Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FFh is applied to the ECC engine) and is set to FFh on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

9.2.4.12.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 µs) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i WAITWRITEMONITORING and GPMC_CONFIG1_i WAITREADMONITORING bits to 0, where i = 0 to 5), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit (n = 0 to 1) of the GPMC_STATUS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE [9-8] bits).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

9.2.4.12.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (x = 0 or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

9.2.4.12.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (x = 0 or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (x = 0 or 1) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

9.2.4.12.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG ECCALGORITHM bit:

- Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
- BCH (Bose-Chaudhurl-Hocquenghem) code for 4- to 16-bit error correction

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG ECCCS field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

9.2.4.12.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

9.2.4.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPOINTER can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each register, j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZE bits are cleared to 0, and the ECC9RESULTSIZE bit is set to 1.

9.2.4.12.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG ECCCS field selects the allocated chip-select. The GPMC_ECC_CONFIG ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZE (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 9-12 describes the ECC enable settings.

Table 9-12. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-3h	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0-1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0-7h	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0-7h	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0-FFh	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0-FFh	Defines ECCSIZE0
ECCjRESULTSIZE	GPMC_ECC_SIZE_CONFIG	0-1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

9.2.4.12.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 9-31 and Figure 9-32. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

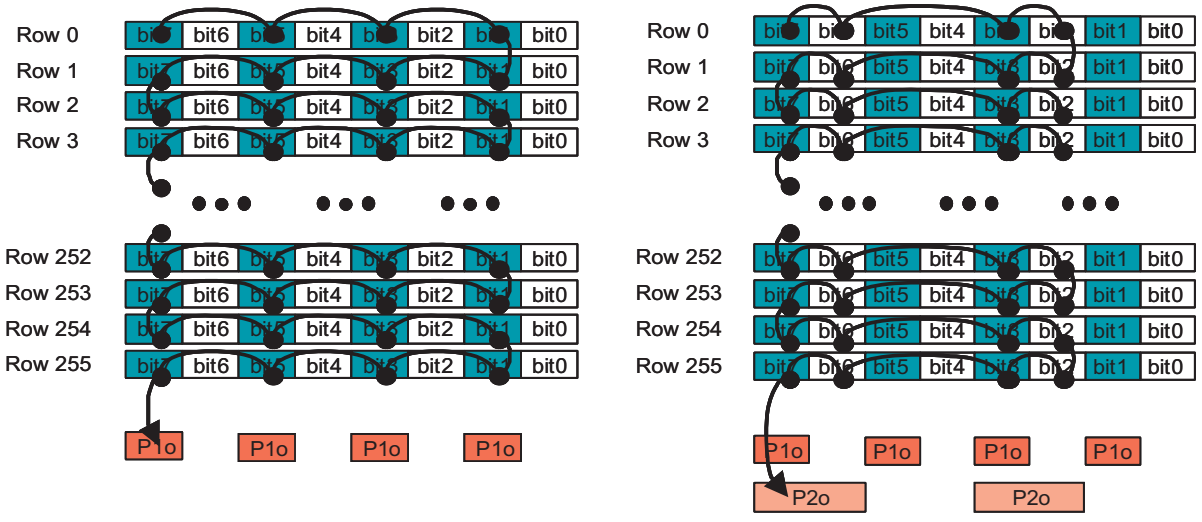
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 9-31. Hamming Code Accumulation Algorithm (1 of 2)



For line parities, the bits of each new data are XORed together, and line parity bits are computed as:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254

P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

Unused parity bits in the result registers are cleared to 0.

Figure 9-32. Hamming Code Accumulation Algorithm (2 of 2)

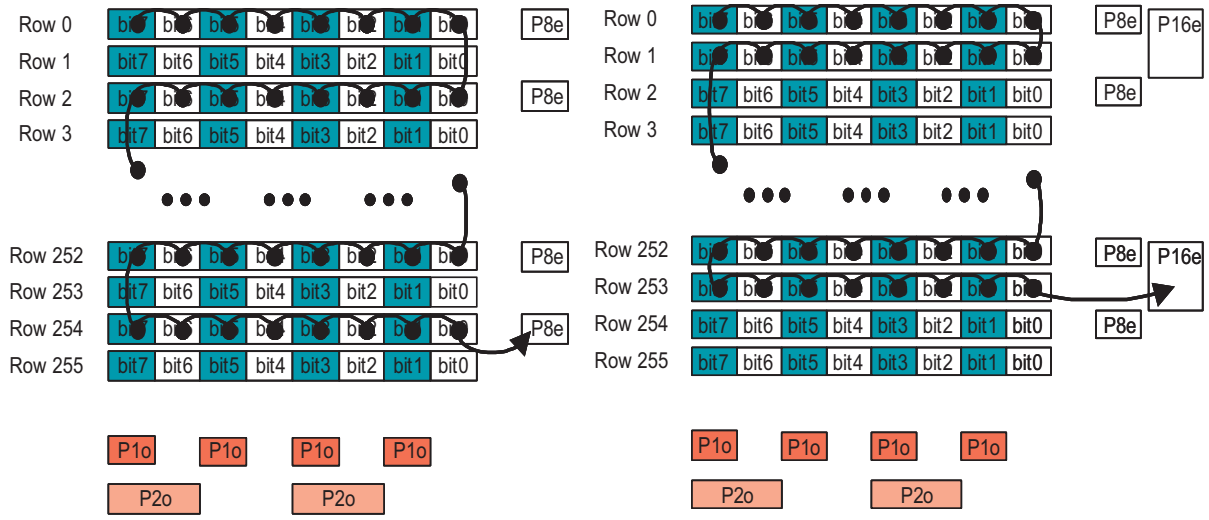


Figure 9-33 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 9-33. ECC Computation for a 256-Byte Data Stream (Read or Write)

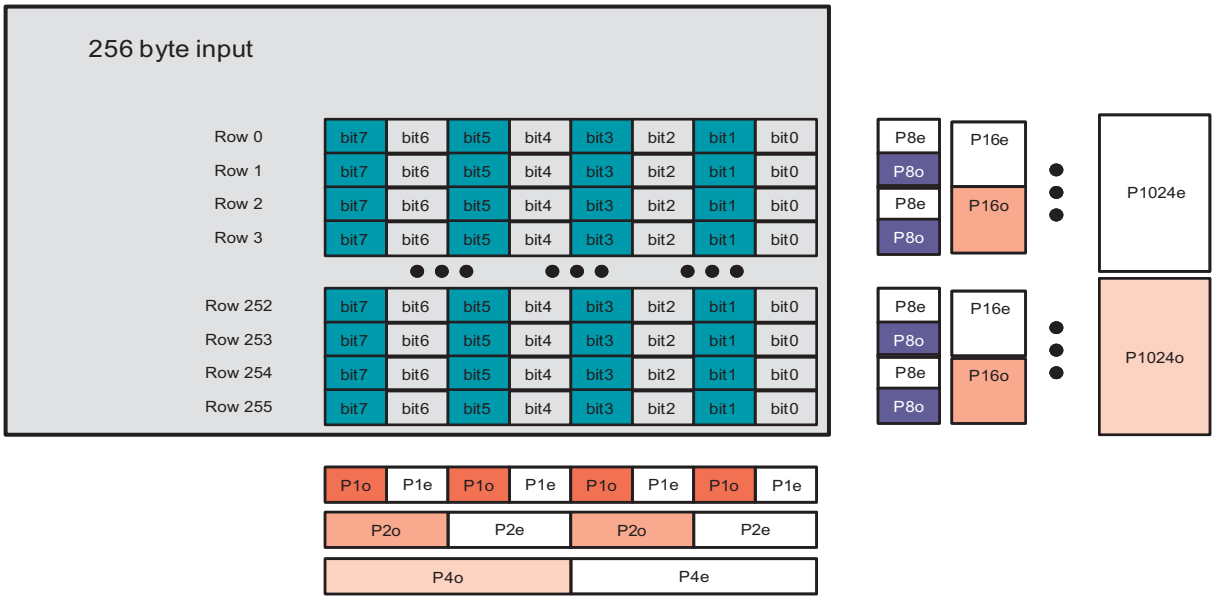

Figure 9-34 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

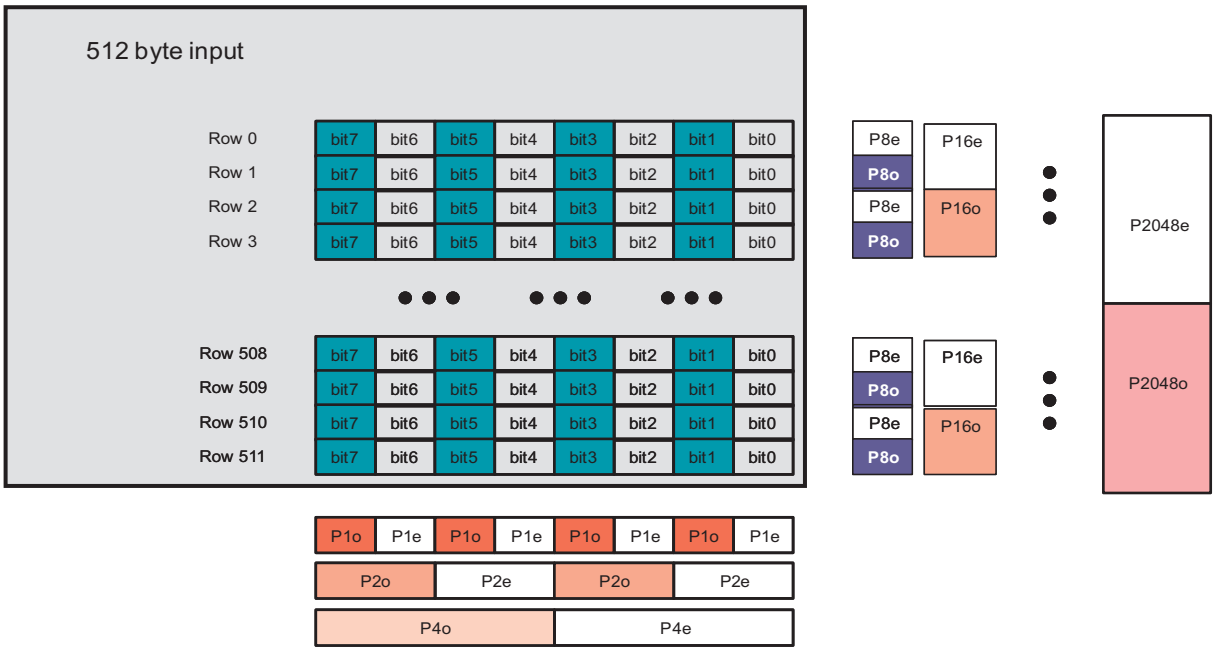
For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (j = 1 to 9).

Figure 9-34. ECC Computation for a 512-Byte Data Stream (Read or Write)



9.2.4.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

9.2.4.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

9.2.4.12.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the GPMC_ECC_CONFIG ECC16B bit must be cleared to 0 when interfacing an 8-bit wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. Figure 9-35 and Figure 9-36.

Figure 9-35. 128 Word16 ECC Computation

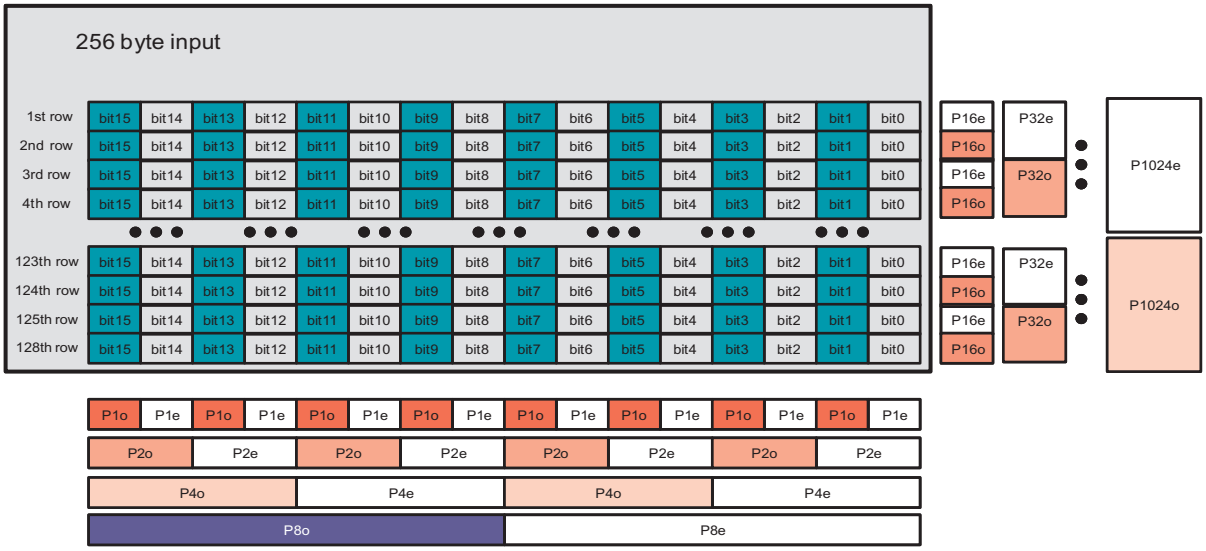


Figure 9-36. 256 Word16 ECC Computation

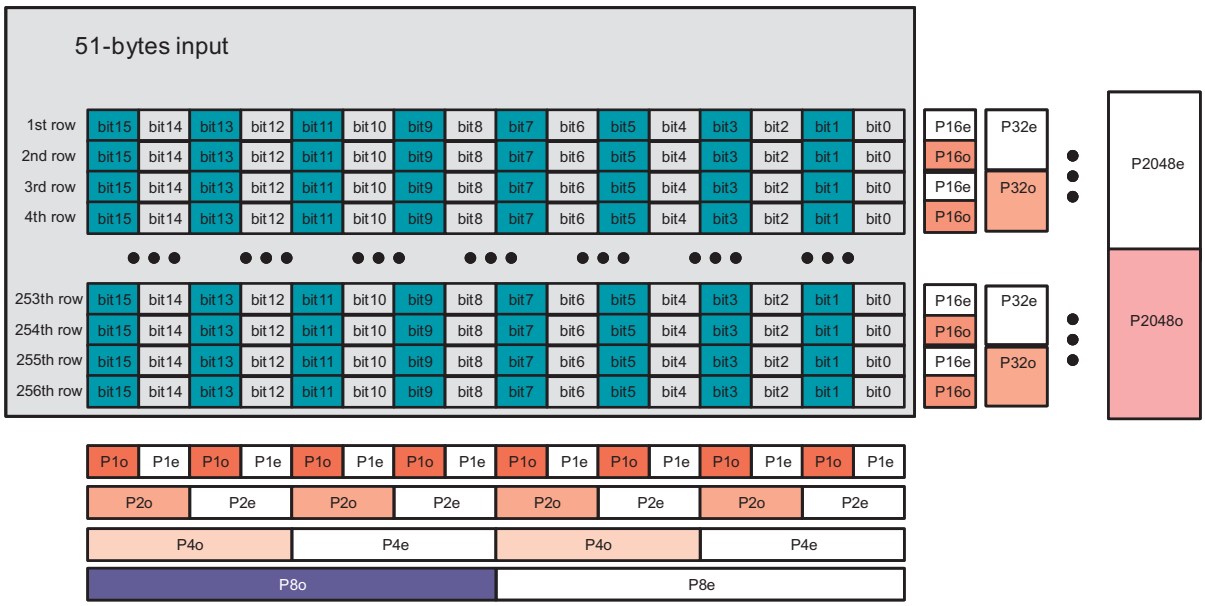


9.2.4.12.3.2 BCH Code (Bose-Chaudhurl-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

9.2.4.12.3.2.1 Requirements

Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.

Typical page write sequence:

- Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array

Typical page read sequence:

- Sequential read of a page. ECC is calculated on the fly.
- ECC module buffers status determines the presence of errors.
- Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
- Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 × 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.

- NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
- The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

9.2.4.12.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In our standard case, 512 bytes of data (that is, 2 bits = 4096 bits) are seen as a polynomial of degree 2 - 1 = 4095, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x) as shown in Table 9-13.

Table 9-13. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)	ECC R(x)				
Bit number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) - 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in , , , and (where i = 0 to 5).

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

9.2.4.12.3.2.3 Memory Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LS bit) represents a segment of polynomial (b7 × x) + (b6 × x) + ... + (b0 × x
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described in the following.

Table 9-14 and Table 9-15 show the mapping of the same 512-byte vector (typically a BCH message) in the NAND memory space. Note that the byte 'address' is only an offset modulo 512 (200h), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and M(2^12-1) of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

Table 9-14. Aligned Message Byte Mapping in 8-bit NAND

Byte Offset	8-Bit Word
0	(msb) Byte 511 (1FFh)
1h	Byte 510 (1FEh)
⋮	⋮
1FFh	Byte 0 (0) (LSB)

Table 9-15. Aligned Message Byte Mapping in 16-bit NAND

Byte Offset	16-Bit Words MSB	16-Bit Words LSB
0	Byte 510 (1FEh)	(msb) Byte 511 (1FFh)
2h	Byte 508 (1FCh)	Byte 509 (1FDh)
⋮	⋮	⋮
1FEh	Byte 0 (0)	(lsb) Byte 1 (1)

Table 9-16 and Table 9-17 show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

Table 9-16. Aligned Nibble Mapping of Message in 8-bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Less Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
⋮	⋮	⋮
S/2 - 2	Nibble 3	Nibble 2
S/2 - 1	Nibble 1	Nibble 0 (LSB)

Table 9-17. Misaligned Nibble Mapping of Message in 8-bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Less Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
⋮	⋮	⋮
(S+1)/2 - 2	Nibble 2	Nibble 1
(S+1)/2 - 1	Nibble 0 (LSB)	

Table 9-18. Aligned Nibble Mapping of Message in 16-bit NAND

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
⋮	⋮	⋮	⋮	⋮
S/2 - 4	Nibble 5	Nibble 4	Nibble 7	Nibble 6
S/2 - 2	Nibble 1	Nibble 0 (LSB)	Nibble 3	Nibble 2

Table 9-19. Misaligned Nibble Mapping of Message in 16-bit NAND (1 Unused Nibble)

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
⋮	⋮	⋮	⋮	⋮
(S+1)/2 - 4	Nibble 4	Nibble 3	Nibble 6	Nibble 5
(S+1)/2 - 2	Nibble 0 (LSB)		Nibble 2	Nibble 1

Table 9-20. Misaligned Nibble Mapping of Message in 16-bit NAND (2 Unused Nibble)

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
⋮	⋮	⋮	⋮	⋮
(S+2)/2 - 4	Nibble 3	Nibble 2	Nibble 5	Nibble 4
(S+2)/2 - 2			Nibble 1	Nibble 0 (LSB)

Table 9-21. Misaligned Nibble Mapping of Message in 16-bit NAND (3 Unused Nibble)

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
⋮	⋮	⋮	⋮	⋮
(S+3)/2 - 4	Nibble 2	Nibble 1	Nibble 4	Nibble 3
(S+3)/2 - 2			Nibble 0 (LSB)	

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

9.2.4.12.3.2.4 Memory Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a software controlled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

9.2.4.12.3.2.5 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see Section 9.2.4.12.3.3.

For each mode:

- A sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

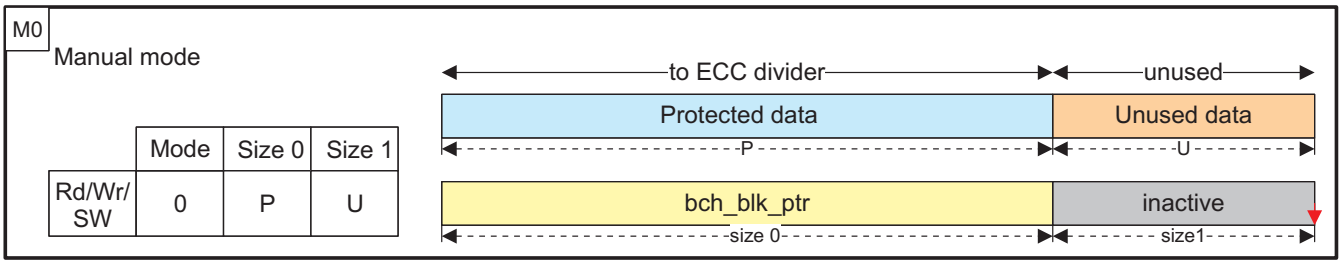
9.2.4.12.3.2.6 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 × 16-bit accesses: we must program size0 = 5, size1 = 3).

Figure 9-37 shows the manual mode sequence and mapping. In this figure, size and size0 are the same parameter.

Figure 9-37. Manual Mode Sequence and Mapping



Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

9.2.4.12.3.2.7 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.2.4.12.3.2.8 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

9.2.4.12.3.2.9 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.2.4.12.3.2.10 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

9.2.4.12.3.2.11 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

9.2.4.12.3.2.12 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1 + size1))

9.2.4.12.3.2.13 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

9.2.4.12.3.2.14 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1 + size1))

9.2.4.12.3.2.15 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.2.4.12.3.2.16 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

9.2.4.12.3.2.17 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.2.4.12.3.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 9.2.4.12.3.2.3.

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 9-38 to Figure 9-40, tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of n = 2 - 1 = 8191 bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (Figure 9-38: see M1-M2-M3-M9-M10):
  - all sectors: (512) + P + E
- Spares pooled and protected by sector 0 (Figure 9-38: see M5-M6):
  - sector 0 codeword: (512) + P + E
  - other sectors: (512) + E
- Unprotected spares (Figure 9-38: see M4-M7-M8-M11-M12):
  - all codewords (512) + E

9.2.4.12.3.3.1 Per-Sector Spare Mappings

In these schemes (Figure 9-38), each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

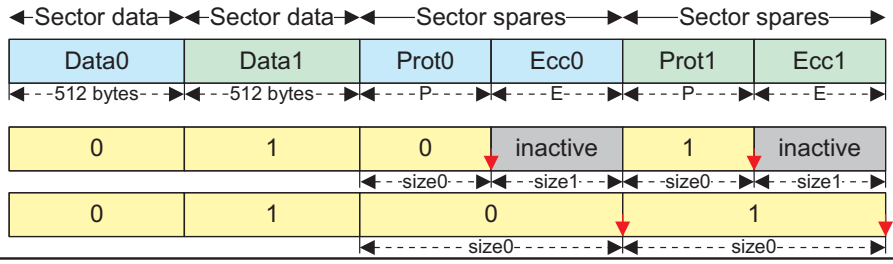
- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 9-38. NAND Page Mapping and ECC: Per-Sector Schemes

M1

Per-sector spares
Spares covered by sector ECC per sector ECC mapping.

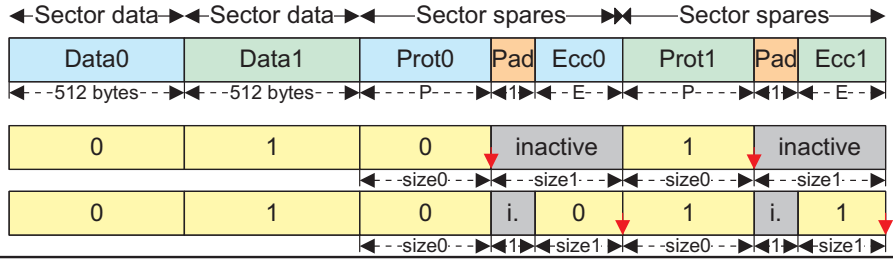
	Mode	Size0	Size1
Write	1	P	E
Read	1	P+E	0



M2

Per-sector spares
Spares covered by sector ECC per sector, left-padded ECC.

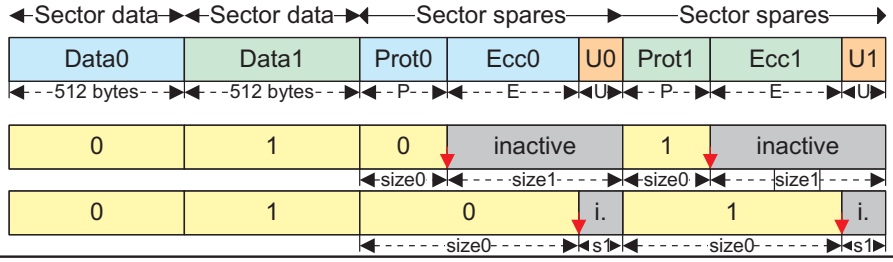
	Mode	Size0	Size1
Write	1	P	1+E
Read	10	P	E



M3

Per-sector spares
Spares covered by sector ECC, ECC not right-aligned.

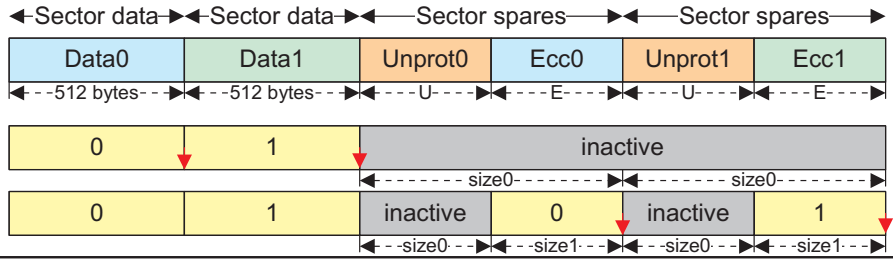
	Mode	Size0	Size1
Write	1	P	E+U
Read	1	P+E	U



M4

Per-sector spares
Spares not covered by ECC, ECC right-aligned per sector.

	Mode	Size0	Size1
Write	2	U+E	0
Read	2	U	E



9.2.4.12.3.3.2 Pooled Spare Mapping

In these schemes (Figure 9-39), the spare area is pooled for the page.

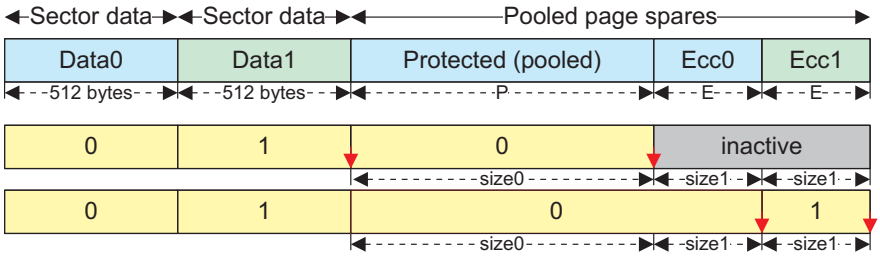
- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

Figure 9-39. NAND Page Mapping and ECC: Pooled Spare Schemes

M5

Pooled spares
Spares covered by ECC0.
All ECC at the end (of page).

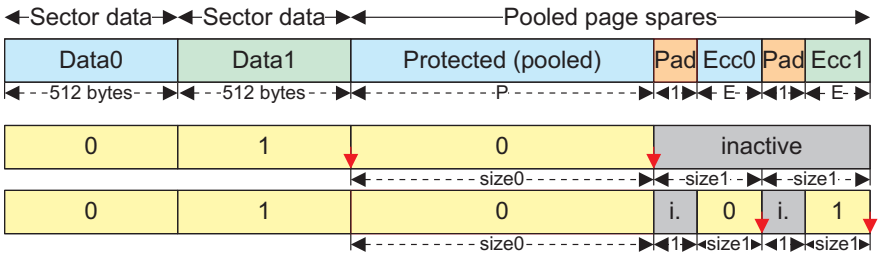
	Mode	Size0	Size1
Write	7	P	E
Read	3	P	E



M6

Pooled spares
Spares covered by ECC0.
All ECC at the end, left-padded.

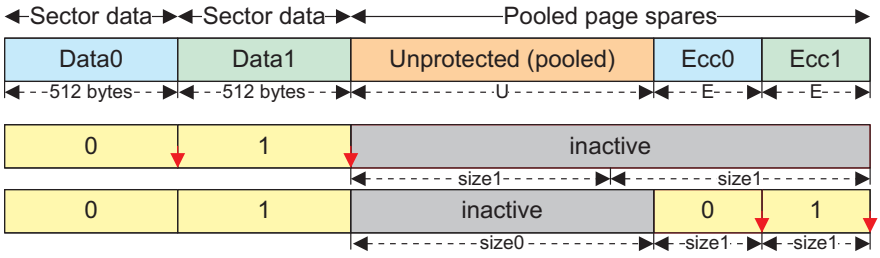
	Mode	Size0	Size1
Write	7	P	1+E
Read	8	P	E



M7

Pooled spares
Spares not covered by ECC.
All ECC at the end.

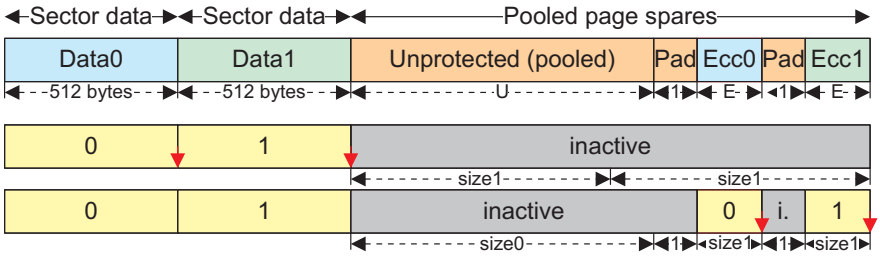
	Mode	Size0	Size1
Write	6	0	U/S +E
Read	4	U	E



M8

Pooled spares
Spares not covered by ECC.
All ECC at the end, left-padded.

	Mode	Size0	Size1
Write	6	0	U/S +1+E
Read	9	U	E

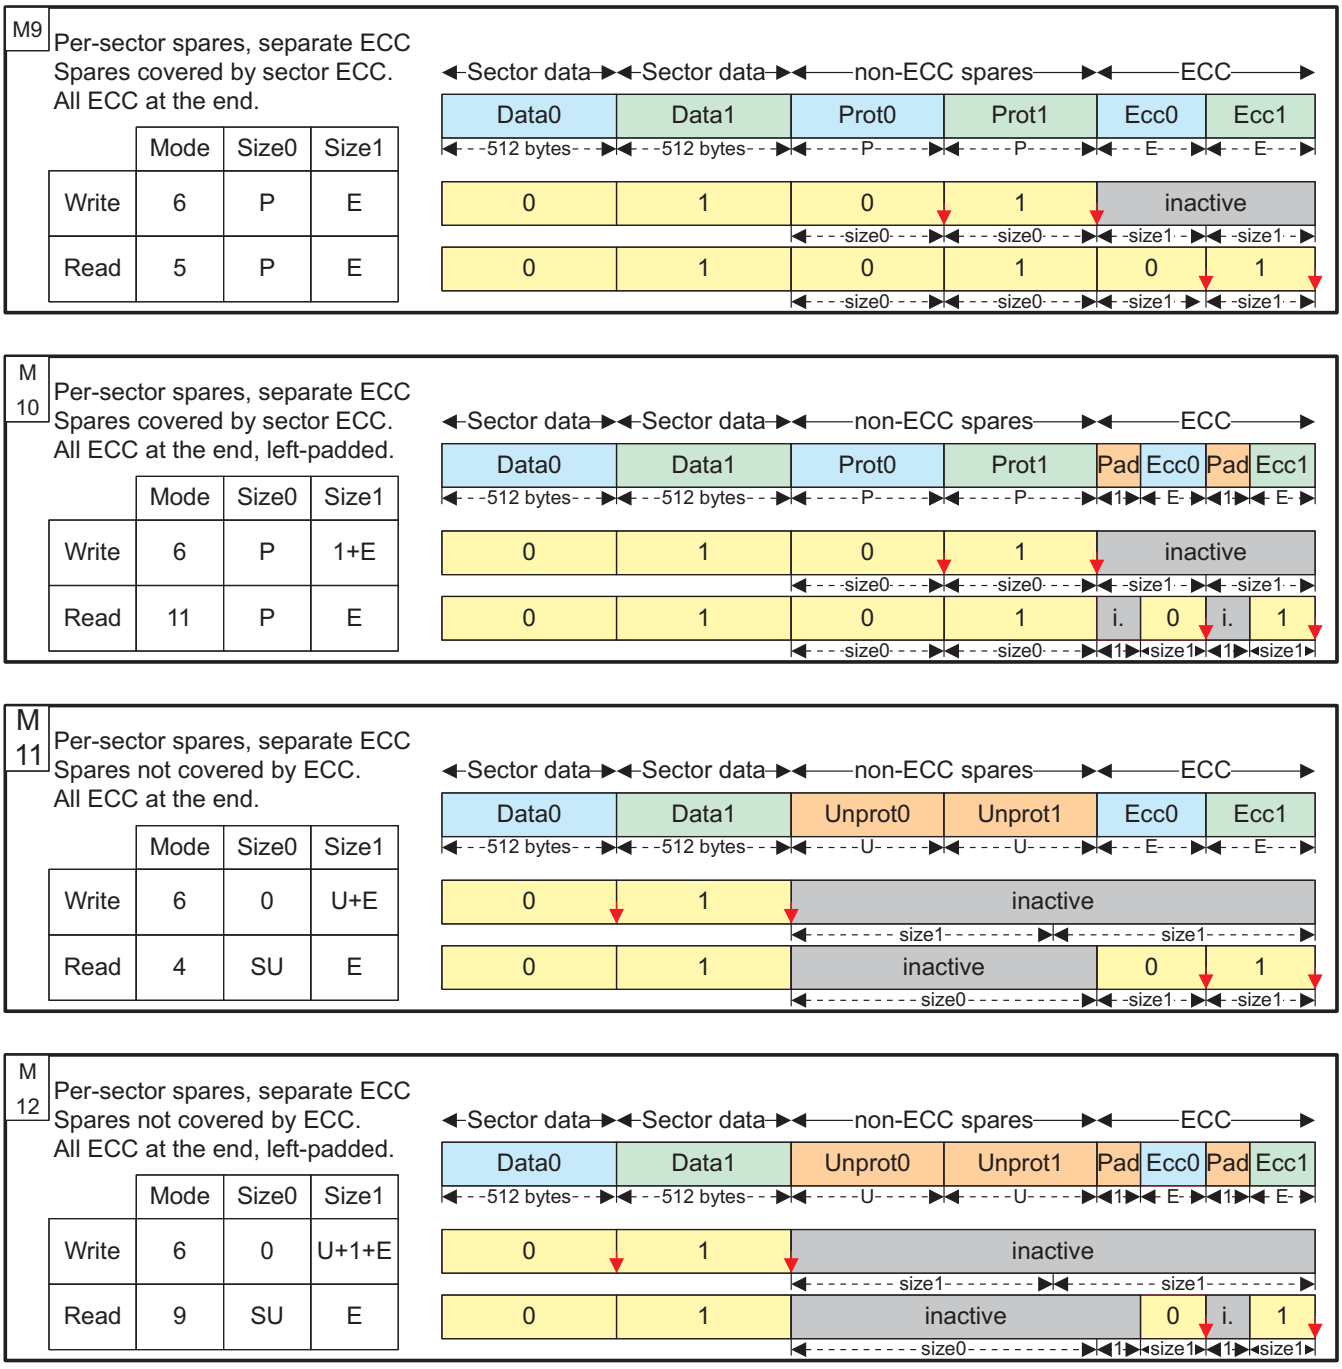


9.2.4.12.3.3.3 Per-Sector Spare Mapping, With ECC Separated at the End of the Page

In these schemes (Figure 9-40), each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 9-40. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC



9.2.4.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1 PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1 PFPWWEIGHTEDPRIO field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

9.2.4.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1 ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine, respectively, uses byte or 16-bit word access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of 16-bit word.

When the GPMC_PREFETCH_CONFIG1 ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through these registers (where i = 0 to 5):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the L3 interconnect port can be accessed with Byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS FIFOPOINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC_PREFETCH_STATUS COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

9.2.4.12.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1 ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1 SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see Section 9.2.4.12.2.2. The GPMC_PREFETCH_CONFIG1 WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by GPMC_PREFETCH_CONFIG2 TRANSFERCOUNT field.

Table 9-22 describes the prefetch mode configuration.

Table 9-22. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL	0	Prefetch engine can be configured only if STARTENGINE is cleared to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1	0 to 3h	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG1		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1 SYNCHROMODE = 1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1	0/1	See Section 9.2.4.12.4.6
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONFIG1	1	Starts the prefetch engine

9.2.4.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an eDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS FIFOPOINTER field or through the GPMC_PREFETCH_STATUS FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1 DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

9.2.4.12.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1 ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1 SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2 TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 9-23. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL	0	Write-posting engine can be configured only if STARTENGINE is cleared to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1	0 to 3h	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1	0/1	See Section 9.2.4.12.4.6
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL	1	Starts the prefetch engine

9.2.4.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit

The posting completion can be monitored through the GPMC_PREFETCH_STATUS COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the GPMC_PREFETCH_CONFIG1 DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

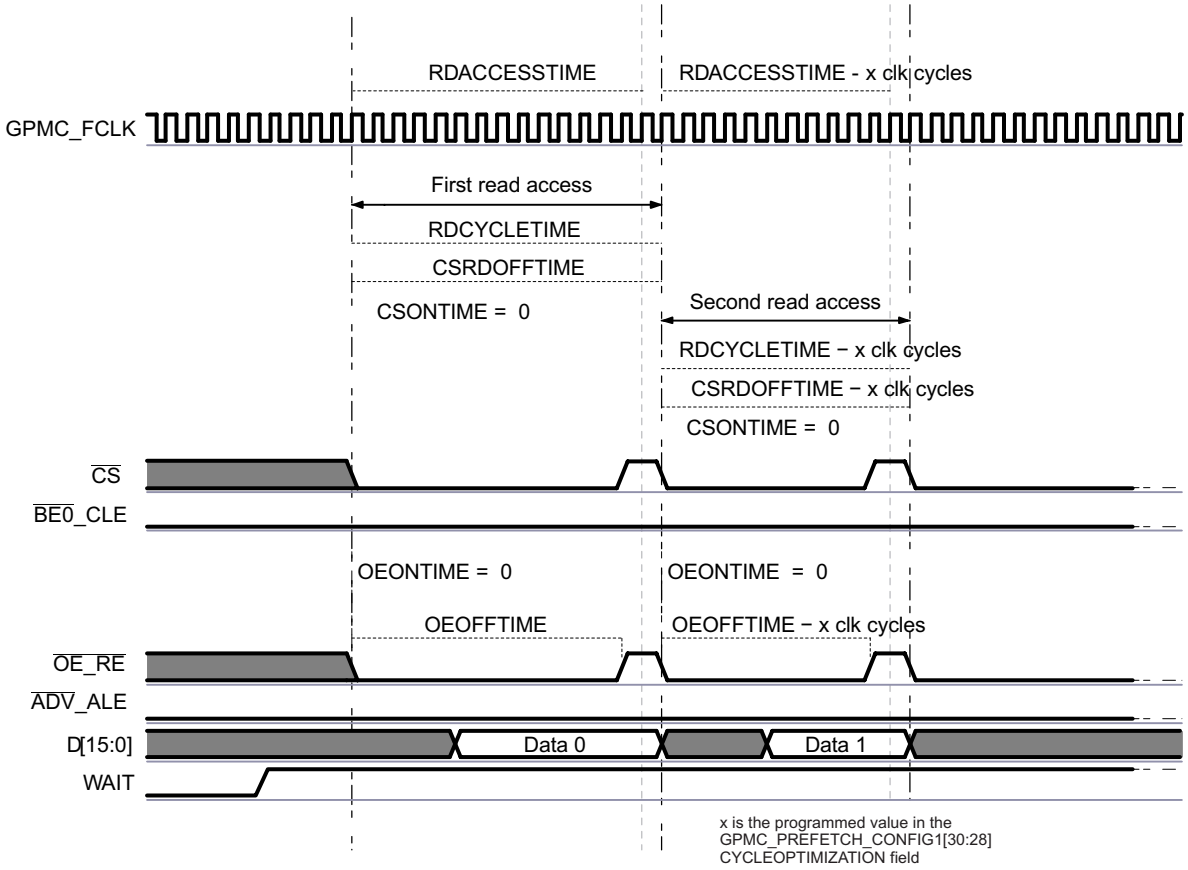
9.2.4.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated $\overline{CS}$ signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i (where , i = 0 to 5) are never optimized.

The GPMC_PREFETCH_CONFIG1 ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1 CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 9-41, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1 CYCLEOPTIMIZATION field.

Figure 9-41. NAND Read Cycle Optimization Timing Description



9.2.4.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1 PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1 PFPWWEIGHTEDPRIO field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 2h. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

9.3 Basic Programming Model

9.3.1 GPMC High-Level Programming Model Overview

The high-level programming model introduces a top-down approach for users that need to configure the GPMC module. Figure 9-42 shows a programming model top-level diagram for the GPMC. Each block of the diagram is described in one of the following subsections through a set of registers to configure. Table 9-24 and Table 9-25 list each step in the model.

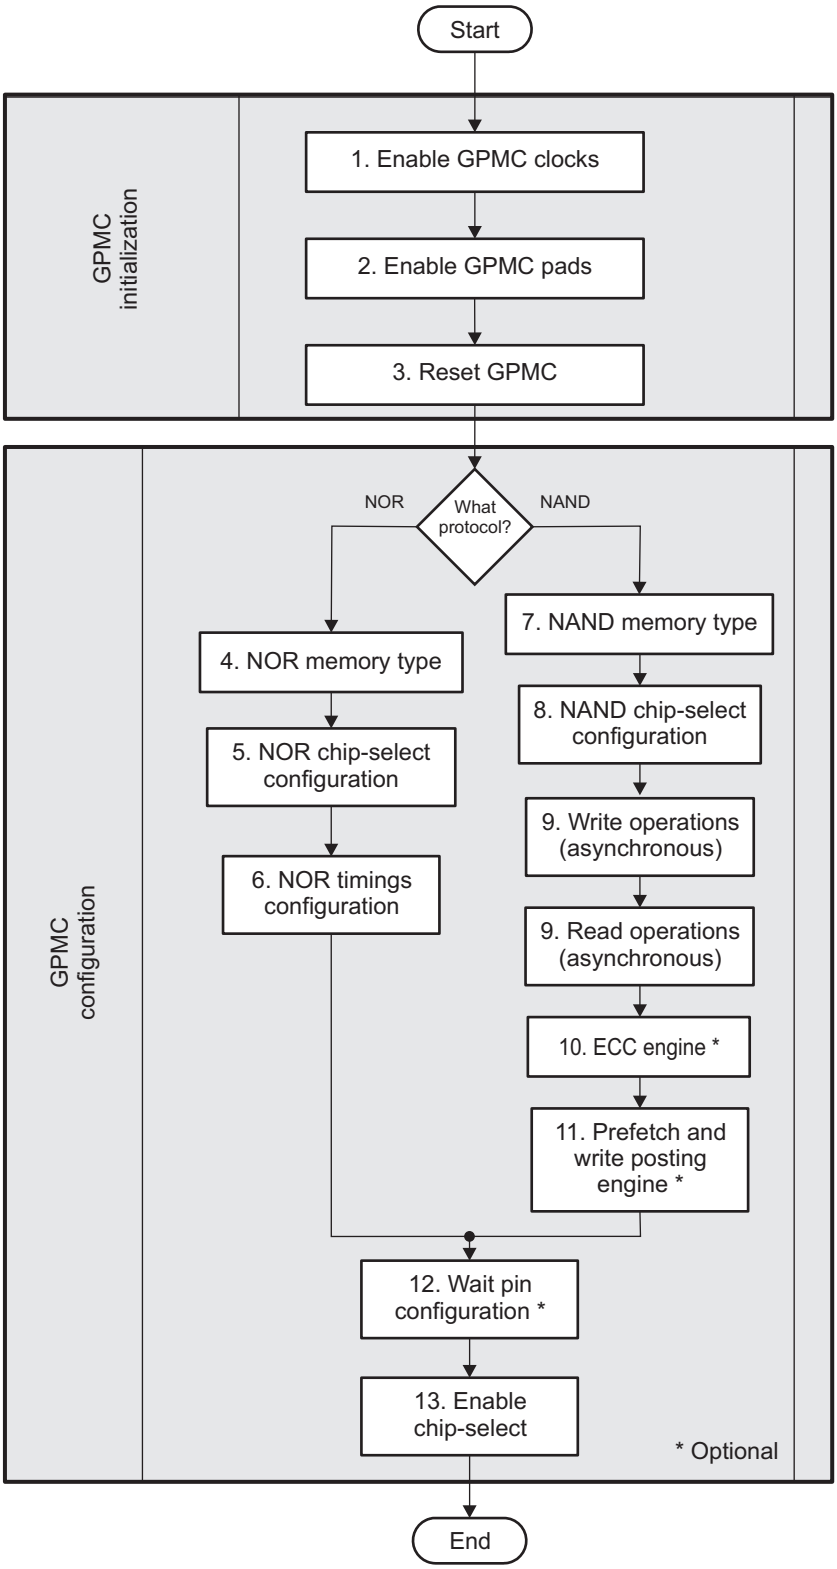
Table 9-24. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 9-27
NOR Chip-Select Configuration	See Table 9-28
NOR Timings Configuration	See Table 9-29
Wait Pin Configuration	See Table 9-30
Enable Chip-Select	See Table 9-31

Table 9-25. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 9-32
NAND Chip-Select Configuration	See Table 9-33
Write Operations (Asynchronous)	See Table 9-34
Read Operations (Asynchronous)	See Table 9-34
ECC Engine	See Table 9-35
Prefetch and Write-Posting Engine	See Table 9-36
Wait Pin Configuration	See Table 9-37
Enable Chip-Select	See Table 9-38

Figure 9-42. Programming Model Top-Level Diagram



9.3.2 GPMC Initialization

Table 9-26 describes the settings required to reset the GPMC.

Table 9-26. Reset GPMC

Sub-process Name	GPMC_SYSCONFIG Register Bit	Value
Start a software reset	SOFTRESET	1
Wait until	RESETDONE	1

9.3.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC. Table 9-27 through Table 9-31 list the steps to configure the GPMC in NOR mode.

NOTE: In the tables of this section, 'x' in Value column stands for 'depends on configuration'.

Table 9-27. NOR Memory Type

Sub-process Name	GPMC_CONFIG1_i Register Bitfield	Value
Set the NOR protocol	DEVICETYPE	0
Set a device size	DEVICESIZE	x
Select an address and data multiplexing protocol	MUXADDDATA	x
Set the attached device page length	ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities	WRAPBURST	x
Select a timing signals latencies factor	TIMEPARAGRANULARITY	x
Select an output clock frequency	GPMCFCLKDIVIDER	x
Choose an output clock activation time	CLKACTIVATIONTIME	x
Set a single or multiple access for read operations	READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations	READTYPE	x
Set a single or multiple access for write operations	WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations	WRITETYPE	x

Table 9-28. NOR Chip-Select Configuration

Sub-process Name	GPMC_CONFIG7_i Register Bitfield	Value
Select the chip-select base address	BASEADDRESS	x
Select the chip-select mask address	MASKADDRESS	x

Table 9-29. NOR Timings Configuration

Sub-process Name	Register Bitfield	Value
Configure adequate timing parameters in various memory modes	See Section 9.3.6	

Table 9-30. WAIT Pin Configuration

Sub-process Name	GPMC_CONFIG1_i Register Bitfield	Value
Enable or disable wait pin monitoring for read operations	WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations	WAITWRITEMONITORING	x
Select a wait pin monitoring time	WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select	WAITPINSELECT	x

Table 9-31. Enable Chip-Select

Sub-process Name	GPMC_CONFIG7_i Register Bitfield	Value
When all parameters are configured, enable the chip-select	CSVALID	x

9.3.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to NAND memory connected to the GPMC.

Table 9-32. NAND Memory Type

Sub-process Name	GPMC_CONFIG1_i Register Bitfield	Value
Set the NAND protocol	DEVICETYPE	2h
Set a device size	DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device	MUXADDDATA	0
Select a timing signals latencies factor	TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations	See Section 9.3.5	x

Table 9-33. NAND Chip-Select Configuration

Sub-process Name	GPMC_CONFIG7_i Register Bitfield	Value
Select the chip-select base address	BASEADDRESS	x
Select the chip-select minimum granularity (16M bytes)	MASKADDRESS	x

Table 9-34. Asynchronous Read and Write Operations

Sub-process Name	Register Bitfield	Value
Configure adequate timing parameters in asynchronous modes	See Section 9.3.6	

Table 9-35. ECC Engine

Sub-process Name	Register Bitfield	Value
Select the ECC result register where the first ECC computation is stored (Only applies to Hamming)	GPMC_ECC_CONTROL ECCPOINTER	x
Clear all ECC result registers	GPMC_ECC_CONTROL ECCCLEAR	Write 1 to clear
Define ECCSIZE0 and ECCSIZE1	GPMC_ECC_SIZE_CONFIG ECCSIZE0 and ECCSIZE1	x
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1)	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE, where j = 1 to 9	x
Select the chip-select where ECC is computed	GPMC_ECC_SIZE_CONFIG ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use	GPMC_ECC_SIZE_CONFIG ECCALGORITHM	x
Select word size for ECC calculation	GPMC_ECC_SIZE_CONFIG ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process	GPMC_ECC_SIZE_CONFIG ECCBCHTSEL and ECCTOPSECTOR	x
Enable the ECC computation	GPMC_ECC_SIZE_CONFIG ECCENABLE	1

Table 9-36. Prefetch and Write-Posting Engine

Sub-process Name	Register Bitfield	Value
Disable the engine before configuration	GPMC_PREFETCH_CONTROL STARTENGINE	0
Select the chip-select associated with a NAND device where the prefetch engine is active	GPMC_PREFETCH_CONFIG1 ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1 ACCESSMODE	x
Select the threshold used to issue a DMA request	GPMC_PREFETCH_CONFIG1 FIFOTHRESHOLD	x
Select either DMA synchronized mode or SW manual mode.	GPMC_PREFETCH_CONFIG1 DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1 SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1 WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (For all back-to-back accesses to the NAND flash but not the first one)	GPMC_PREFETCH_CONFIG1 CYCLEOPTIMIZATION	x
Enable the prefetch postwite engine	GPMC_PREFETCH_CONFIG1 ENABLEENGINE	1
Select the number of bytes to be read or written by the engine to the selected chip-select	GPMC_PREFETCH_CONFIG2 TRANSFERCOUNT	x
Start the prefetch engine	GPMC_PREFETCH_CONTROL STARTENGINE	1

Table 9-37. WAIT Pin Configuration

Sub-process Name	GPMC_PREFETCH_CONFIG1 Register Bitfield	Value
Selects when the engine starts the access to CS	SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	WAITPINSELECTOR	x

Table 9-38. Enable Chip-Select

Sub-process Name	GPMC_CONFIG7_i Register Bitfield	Value
When all parameters are configured, enable the chip-select	CSVALID	x

9.3.5 Set Memory Access

This section details the bit field to configure to set the GPMC in various memory modes.

Table 9-39. Mode Parameters Check List Table

GPMC_CONFIG1_i Register Bitfield	Asynchronous				Synchronous			
	Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
READMULTIPLE	0	-	1	N/S	0	-	1	-
READTYPE	0	-	0	N/S	1	-	1	-
WRITEMULTIPLE	-	0		N/S	-	0	-	1
WRITETYPE	-	0		N/S	-	1	-	1

9.3.6.1 GPMC Timing Parameters Formulas

This section intends to help the user to calculate the GPMC timing bit fields values. Formulas are not listed exhaustively.

The section details:

- NAND Flash Interface Timing Parameters Formulas
- Synchronous NOR Flash Timing Parameters Formulas
- Asynchronous NOR Flash Timing Parameters Formulas

9.3.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to use in order to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i DEVICETYPE = 2h. Table 9-42 details NAND timing parameters.

Table 9-42. NAND Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - GPMC_WE valid time
B	ns	Delay time - GPMC_CS valid to GPMC_WE valid
C	ns	Delay time - GPMC_BE0_CLE/GPMC_ADV_ALE high to GPMC_WE valid
D	ns	Delay time - GPMC_AD[15:0] valid to GPMC_WE valid
E	ns	Delay time - GPMC_WE invalid to GPMC_AD[15:0] invalid
F	ns	Delay time - GPMC_WE invalid to GPMC_BE0_CLE/GPMC_ADV_ALE invalid
G	ns	Delay time - GPMC_WE invalid to GPMC_CS invalid
H	ns	Cycle time - Write cycle time
I	ns	Delay time - GPMC_CS valid to GPMC_OE valid
J	ns	Setup time - GPMC_AD[15:0] valid to GPMC_OE invalid
K	ns	Pulse duration - GPMC_OE valid time
L	ns	Cycle time - Read cycle time
M	ns	Delay time - GPMC_OE invalid to GPMC_CS invalid

The configuration parameters are calculated through the following formulas.

A = (WEOffTime - WEOnTime) × (TimeParaGranularity + 1) × GPMC_FCLK period

B = ((WEOnTime - CSOnTime) × (TimeParaGranularity + 1) + 0.5 × (WEExtraDelay - CSExtraDelay)) × GPMC_FCLK period

C = ((WEOnTime - ADVOnTime) × (TimeParaGranularity + 1) + 0.5 × (WEExtraDelay - ADVExtraDelay)) × GPMC_FCLK period

D = (WEOnTime × (TimeParaGranularity + 1) + 0.5 × WEExtraDelay) × GPMC_FCLK period

E = (WrCycleTime - WEOffTime × (TimeParaGranularity + 1) - 0.5 × WEExtraDelay) × GPMC_FCLK period

F = (ADVWrOffTime - WEOffTime × (TimeParaGranularity + 1) + 0.5 × (ADVExtraDelay - WEExtraDelay) × GPMC_FCLK period

G = (CSWrOffTime - WEOffTime × (TimeParaGranularity + 1) + 0.5 × (CSExtraDelay - WEExtraDelay) × GPMC_FCLK period

H = WrCycleTime × (1 + TimeParaGranularity) × GPMC_FCLK period

I = ((OEOnTime - CSOnTime) × (TimeParaGranularity + 1) + 0.5 × (OEExtraDelay - CSExtraDelay)) × GPMC_FCLK period

J = ((RdAccessTime - OEOffTime) × (TimeParaGranularity + 1) - 0.5 × OEExtraDelay)) × GPMC_FCLK period

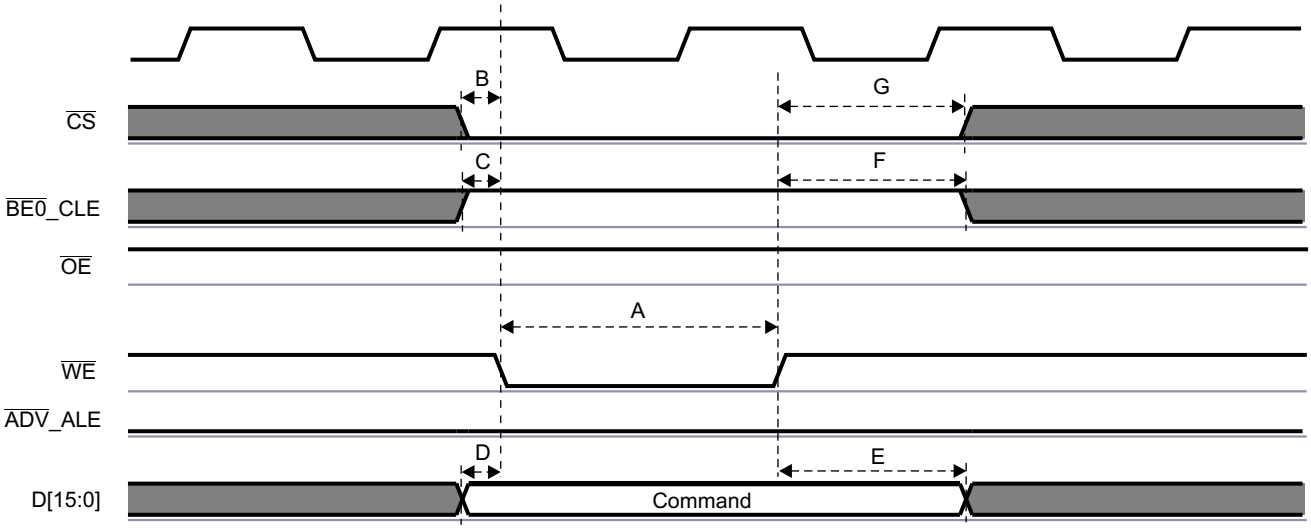
K = (OEOffTime - OEOnTime) × (1 + TimeParaGranularity) × GPMC_FCLK period

L = RdCycleTime × (1 + TimeParaGranularity) × GPMC_FCLK period

M = (CSRdOffTime - OEOffTime × (TimeParaGranularity + 1) + 0.5 × (CSExtraDelay - OEExtraDelay) × GPMC_FCLK period

Figure 9-44 shows a command latch cycle timing simplified example where formulas are associated with signal waves.

Figure 9-44. NAND Command Latch Cycle Timing Simplified Example



9.3.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i DEVICETYPE = 0 and when READTYPE or WRITETYPE are set to synchronous mode.

Table 9-43. Synchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - GPMC_CS low
B	ns	Delay time - address bus valid to GPMC_CLK first edge
		Delay time - GPMC_BE0_CLE/GPMC_BE1 valid to GPMC_CLK first edge
C	ns	Pulse duration - GPMC_BE0_CLE/GPMC_BE1 low
D	ns	Delay time - GPMC_CLK rising edge to GPMC_BE0_CLE/GPMC_BE1 invalid
		Delay time - GPMC_CLK rising edge to GPMC_ADV_ALE invalid
E	ns	Delay time - GPMC_CLK rising edge to GPMC_CS invalid
		Delay time - GPMC_CLK rising edge to GPMC_OE invalid
F	ns	Delay time - GPMC_CLK rising edge to GPMC_CS transition
G	ns	Delay time - GPMC_CLK rising edge to GPMC_ADV_ALE transition
H	ns	Delay time - GPMC_CLK rising edge to GPMC_OE transition
I	ns	Delay time - GPMC_CLK rising edge to GPMC_WE transition
J	ns	Delay time - GPMC_CLK rising edge to GPMC_AD data bus transition
		Delay time - GPMC_CLK rising edge to GPMC_BE0_CLE/GPMC_BE1 transition
K	ns	Pulse duration - GPMC_ADV_ALE low
L	ns	Delay time - GPMC_WAIT invalid to first data latching GPMC_CLK edge

The configuration parameters are calculated through the following formulas.

For single read accesses:

A = (CSRDOFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

C = RDCYCLETIME × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

D = (RDCYCLETIME - RDACCESSTIME) × GPMC_FCLK period

E = (CSRDOFFTIME - RDACCESSTIME) × GPMC_FCLK period

For burst read accesses (where n is the page burst access number):

A = (CSRDOFFTIME - CSONTIME + (n - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

C = (RDCYCLETIME + (n - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

D = (RDCYCLETIME - (RDACCESSTIME + (n - 1) × PAGEBURSTACCESSTIME)) × GPMC_FCLK period

E = (CSRDOFFTIME - (RDACCESSTIME + (n - 1) × PAGEBURSTACCESSTIME)) × GPMC_FCLK period

For burst write accesses (where n is the page burst access number):

A = (CSWROFFTIME - CSONTIME + (n - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

C = (WRCYCLETIME + (n - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

D = (WRCYCLETIME - (WRACCESSTIME + (n - 1) × PAGEBURSTACCESSTIME)) × GPMC_FCLK period

E = (CSWROFFTIME - (WRACCESSTIME + (n - 1) × PAGEBURSTACCESSTIME)) × GPMC_FCLK period

For all accesses:

For $\overline{CS}$ falling edge ($\overline{CS}$ activated):

- Case where GPMC_CONFIG1_i GPMCFCLKDIVIDER = 0

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2h

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{CS}$ rising edge ($\overline{CS}$ de-activated) in reading mode:

- Case where GPMC_CONFIG1_i GPMCFCLKDIVIDER = 0

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2h

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{CS}$ rising edge ($\overline{CS}$ de-activated) in writing mode:

- Case where GPMC_CONFIG1_i GPMCFCLKDIVIDER = 0

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2h

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{ADV}$ falling edge ($\overline{ADV}$ activated):

- Case where GPMC_CONFIG1_i GPMCFCLKDIVIDER = 0

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2h

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{ADV}$ rising edge ($\overline{ADV}$ de-activated) in reading mode:

- Case where GPMC_CONFIG1_i GPMCFCLKDIVIDER = 0

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2h

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{ADV}$ rising edge ($\overline{ADV}$ de-activated) in writing mode:

- Case where GPMC_CONFIG1_i GPMCFCLKDIVIDER = 0

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2h

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{OE}$ falling edge ($\overline{OE}$ activated):

- Case where GPMC_CONFIG1_i GPMCFCLKDIVIDER = 0

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)

  H = (1 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2h

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME) is a multiple of 3

  H = (1 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  H = (2 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{OE}$ rising edge ($\overline{OE}$ de-activated):

- Case where GPMC_CONFIG1_i GPMCFCLKDIVIDER = 0

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)

  H = (1 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2h

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  H = (1 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  H = (2 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{WE}$ falling edge ($\overline{WE}$ activated):

- Case where GPMC_CONFIG1_i GPMCFCLKDIVIDER = 0

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)

  I = (1 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2h

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME) is a multiple of 3

  I = (1 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  I = (2 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{WE}$ rising edge ($\overline{WE}$ de-activated):

- Case where GPMC_CONFIG1_i GPMCFCLKDIVIDER = 0

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)

  I = (1 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 2h

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  I = (1 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  I = (2 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For GPMC_$\overline{ADV}$ low pulse duration:

- Read operation

  K = (ADVRDOFFTIME - ADVONTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period
- Write operation

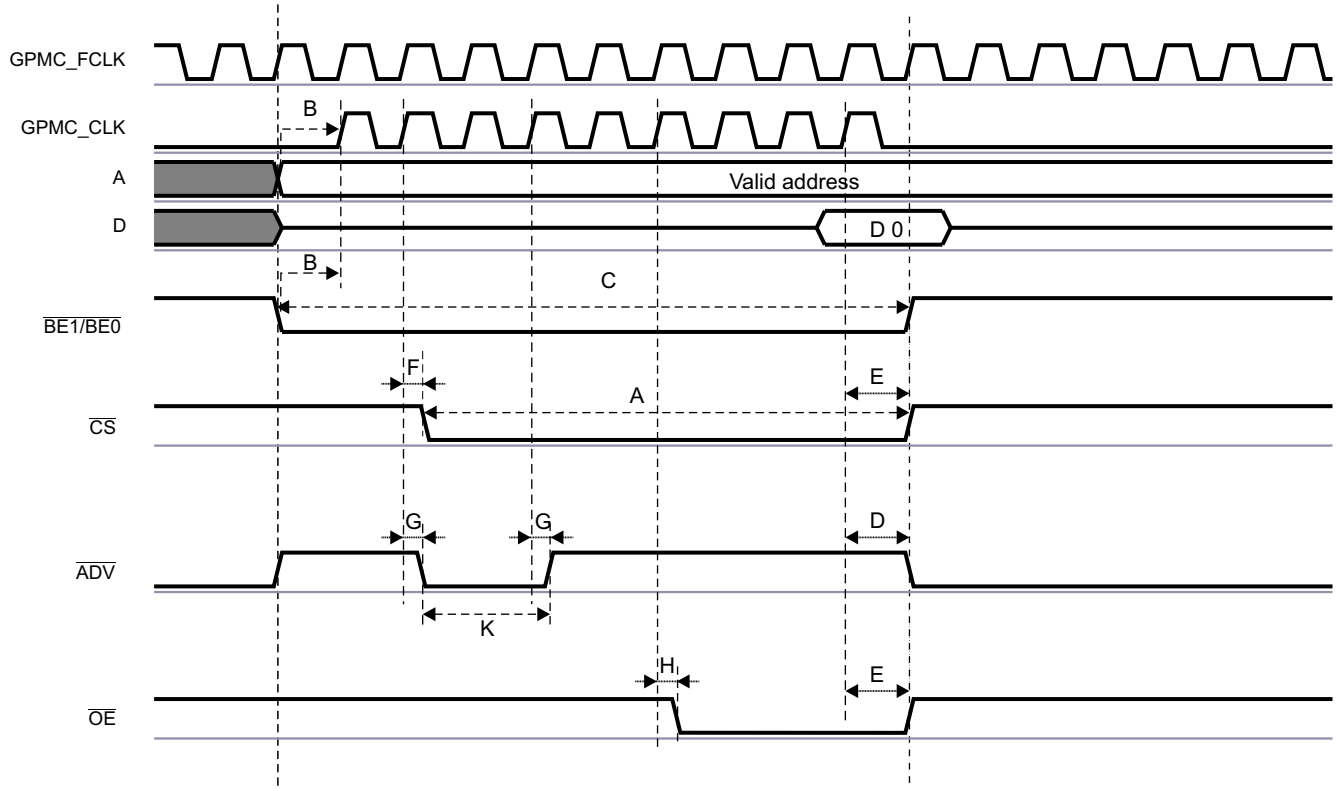
  K = (ADVWROFFTIME - ADVONTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

For GPMC_WAIT invalid to first data latching GPMC_CLK edge:

L = WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) × GPMC_FCLK period + GPMC_CLK period

Figure 9-45 shows a synchronous NOR single read simplified example where formulas are associated with signal waves.

Figure 9-45. Synchronous NOR Single Read Simplified Example



9.3.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate asynchronous NOR timing parameters. This is the case when [11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode.

Table 9-44. Asynchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - GPMC_CS low
B	ns	Delay time - GPMC_CS valid to GPMC_ADV_ALE invalid
C	ns	Delay time - GPMC_CS valid to GPMC_OE invalid (single read)
D	ns	Pulse duration - address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time - GPMC_CS valid to GPMC_WE valid
F	ns	Delay time - GPMC_CS valid to GPMC_WE invalid
G	ns	Address invalid duration between 2 successive R/W accesses
H	ns	Setup time - read data valid before GPMC_OE high
I	ns	Delay time - GPMC_CS valid to GPMC_OE invalid (burst read)
J	ns	Delay time - address bus valid to GPMC_CS valid
		Delay time - data bus valid to GPMC_CS valid
		Delay time - GPMC_BE0_CLE/GPMC_BE1 valid to GPMC_CS valid
K	ns	Delay time - GPMC_CS valid to GPMC_ADV_ALE valid
L	ns	Delay time - GPMC_CS valid to GPMC_OE valid
M	ns	Delay time - GPMC_CS valid to first data latching edge
N	ns	Pulse duration - GPMC_BE0_CLE/GPMC_BE1 valid time
O	ns	Delay time - GPMC_CS valid to GPMC_ADV_ALE valid

The configuration parameters are calculated through the following formulas. Note that these formulas are not exhaustive.

GPMC_CS low pulse:

For single read: A = (CSRDOFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

For burst read: A = (CSRDOFFTIME - CSONTIME + (N - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period, where N = page burst access number

For single write: A = (CSWROFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

For burst write: A = (CSWROFFTIME - CSONTIME + (N - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period, where N = page burst access number

GPMC_CS valid to GPMC_ADV_ALE invalid delay:

For reading: B = ((ADVRDOFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (ADVEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

For writing: B = ((ADVWROFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (ADVEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

C = ((OEOFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (OEEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

D = PAGEBURSTACCESSTIME × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

E = ((WEONTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (WEEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

F = ((WEOFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (WEEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

G = CYCLE2CYCLEDELAY × GPMC_FCLK period

H = ((OEOFFTIME - RDACCESSTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × OEEXTRADELAY) × GPMC_FCLK period

I = ((OEOFFTIME + (N - 1) × PAGEBURSTACCESSTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (OEEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period, where N = page burst access number

J = (CSONTIME × (TIMEPARAGRANULARITY + 1) + 0.5 × CSEXTRADELAY) × GPMC_FCLK period

K = ((ADVONTIME - × (TIMEPARAGRANULARITY + 1) + 0.5 × (ADVEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

L = ((OEONTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (OEEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period M = ((RDACCESSTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) - 0.5 × CSEXTRADELAY) × GPMC_FCLK period

GPMC_$\overline{BE0}$_CLE/$\overline{GPMC_BE1}$ pulse:

For single read: N = RDCYCLETIME × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

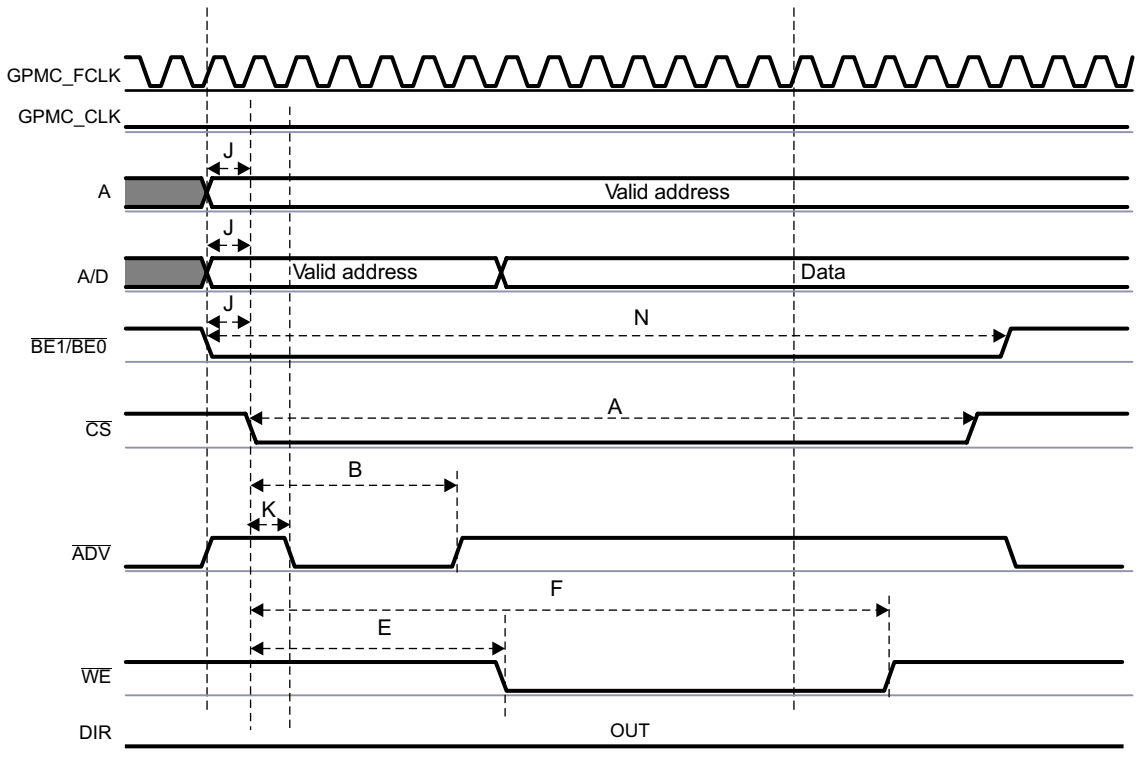
For burst read: N = (RDCYCLETIME + (N - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period, where N = page burst access number

For burst write: N = (WRCYCLETIME + (N - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period, where N = page burst access number

O = ((WRCYCLETIME + (N - 1) × PAGEBURSTACCESSTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (ADVEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

Figure 9-46 shows an asynchronous NOR single write simplified example where formulas are associated with signal waves.

Figure 9-46. Asynchronous NOR Single Write Simplified Example



Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

9.4 Use Cases And Tips

9.4.1 How to Set GPMC Timing Parameters for Typical Accesses

9.4.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 125 MHz clock frequency
- Read access time: 80 ns

9.4.1.2 Typical GPMC Setup

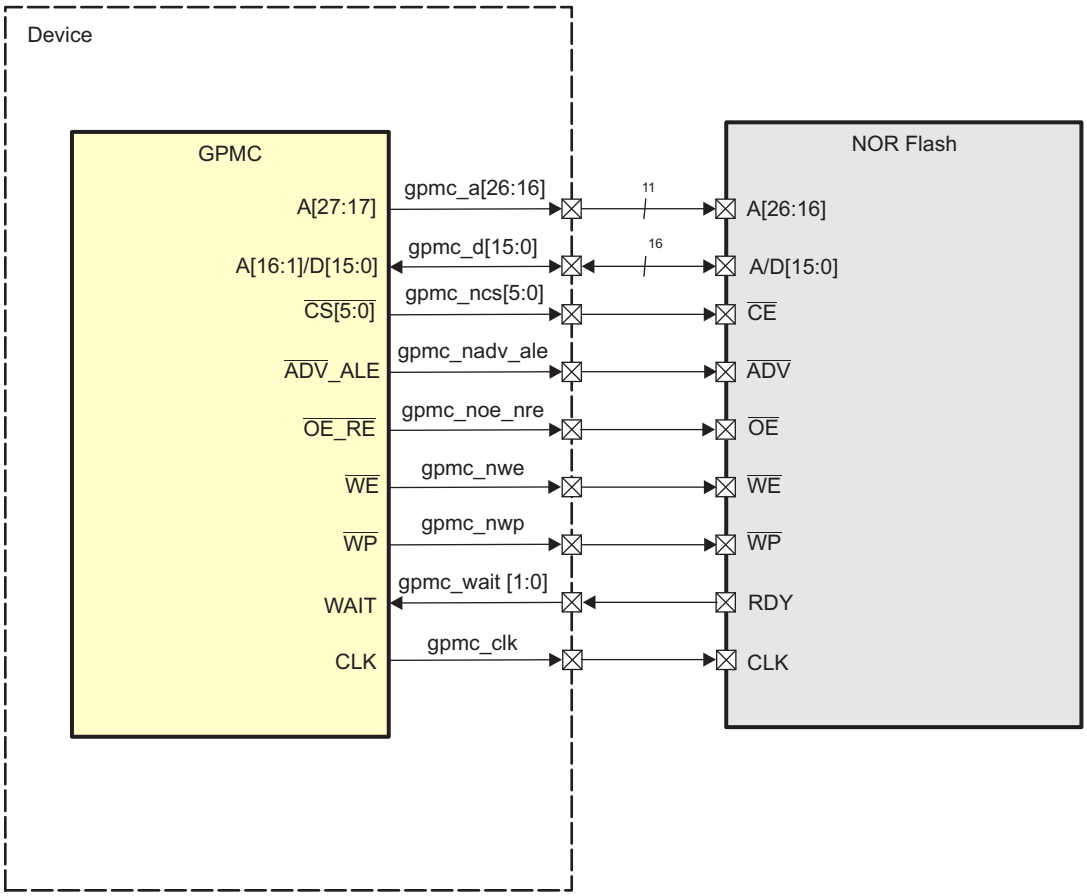
Table 9-45 lists some of the I/Os of the GPMC module.

Table 9-45. GPMC Signals

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
GPMC_CLK	O	External clock provided to the external device for synchronous operations
GPMC_A[27:17]	O	Address
GPMC_D[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
$\overline{\text{GPMC\_CSx}}$	O	Chip-select (where x = 0, or 1)
GPMC_$\overline{\text{ADV}}$_ALE	O	Address valid enable
$\overline{\text{GPMC\_OE\_RE}}$	O	Output enable (read access only)
$\overline{\text{GPMC\_WE}}$	O	Write enable (write access only)
GPMC_WAIT	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 9-47 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 9-47. GPMC Connection to an External NOR Flash Memory



The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

9.4.1.3 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 125 MHz (f = 125 MHz; T = 8 ns).

Table 9-46 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 9-47 shows how to calculate timings for the GPMC using the memory parameters.

Figure 9-48 shows the synchronous burst read access.

Table 9-46. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	$\overline{CS}$ setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Impedance	7
tOEZ	Output enable to High-Impedance	7
tAVC	$\overline{ADV}$ setup time	6
tAVD	$\overline{AVD}$ pulse	6
tACH	Address hold time from clock	3

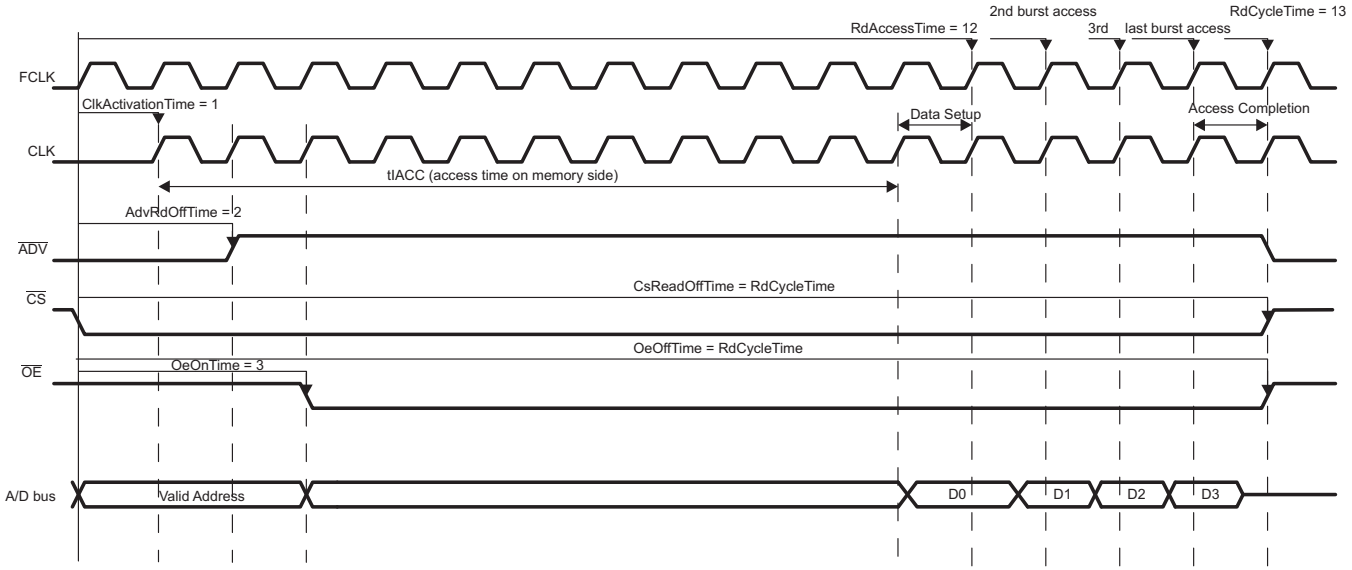
The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 8 ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 2,8 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: $\overline{CS}$/$\overline{OE}$ hold time ($\overline{CS}$ and $\overline{OE}$ must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 9-47. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 125 MHz)	GPMC Register Configurations
GPMC FCLK Divider	-	-	-	GPMCFCLKDIVIDER = 0
ClkActivationTime	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	90,8: (8 + 80 + 2,8)	12 : roundmax (90,8 / 8)	RDACCESSTIME = Ch
PageBurstAccessTime	roundmax (tBACC)	roundmax (5,2)	1	PAGEBURSTACCESSTIME = 1
RdCycleTime	RdAccessTime + max (tCEZ, tOEZ)	97,8: (90,8 + 7)	13	RDCYCLETIME = Dh
CsOnTime	tCES	0	0	CSONTIME = 0
CsReadOffTime	RdCycleTime	-	13	CSRDOFFTIME = Dh
AdvOnTime	tAVC	0	0	ADVONTIME = 0
AdvRdOffTime	tAVD + tAVC	12	2	ADVRDOFFTIME = 2h
OeOnTime	(ClkActivationTime + tACH) < OeOnTime < (ClkActivationTime + tIACC)	-	3, for instance	OEONTIME = 3h
OeOffTime	RdCycleTime	-	13	OEOFFTIME = Dh

Figure 9-48. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)



9.4.1.4 GPMC Configuration for Asynchronous Read Access

The clock runs at 125 MHz (f = 125 MHz; T = 8 ns).

Table 9-48 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 9-49 shows how to calculate timings for the GPMC using the memory parameters.

Figure 9-49 shows the asynchronous read access.

Table 9-48. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from $\overline{CS}$ low	80
tAAVDS	Address setup time to rising edge of $\overline{ADV}$	3
tAVDP	$\overline{ADV}$ low time	6
tCAS	$\overline{CS}$ setup time to $\overline{ADV}$	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Impedance	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 9-49: the number of clock cycles between the address capture ($\overline{ADV}$ rising edge) and the data valid on the output bus.

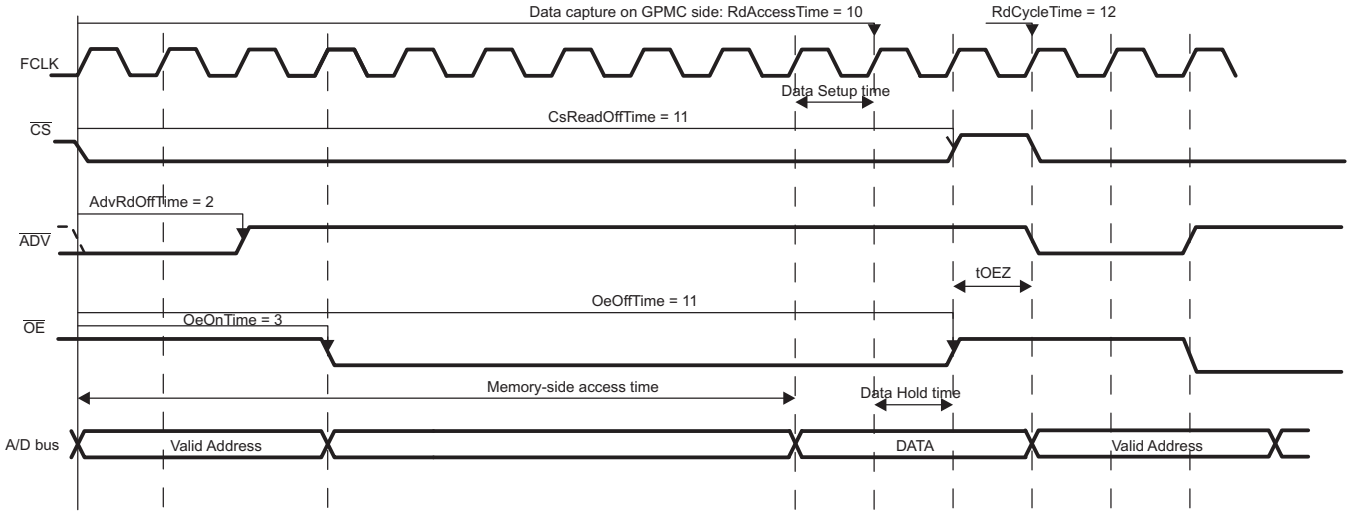
The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

- To read the data correctly, the GPMC must be configure to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no $\overline{OE}$/$\overline{CS}$ deassertion while reading the data). This data hold time is 1 clock cycle (that is, RdAccessTime + 1).
- To complete the access, $\overline{OE}$/$\overline{CS}$ signals are driven to high-impedance. RdAccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

Table 9-49. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 125 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = Ah
PageBurstAccessTime	n/a (single access)			
RdCycleTime	RdAccessTime + 1cycle + tOEZ	95	12	RDCYCLETIME = Ch
CsOnTime	tCAS	0	0	CSONTIME = 0
CsReadOffTime	RdAccessTime + 1 cycle	88	11	CSRDOFFTIME = Bh
AdvOnTime	tAAVDS	3	1	ADVONTIME = 1
AdvRdOffTime	tAAVDS + tAVDP	9	2	ADVRDOFFTIME = 2
OeOnTime	OeOnTime ≥ AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 3h
OeOffTime	RdAccessTime + 1cycle	88	11	OEOFFTIME = Bh

Figure 9-49. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)



9.4.1.5 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 125 MHz: (f = 125 MHz; T = 8 ns).

Table 9-50 shows how to calculate timings for the GPMC using the memory parameters.

Table 9-51 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 9-50 shows the synchronous burst write access.

Table 9-50. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	$\overline{ADV}$ low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	$\overline{CS}$ setup time to $\overline{WE}$	3
tCAS	$\overline{CS}$ setup time to $\overline{ADV}$	0
tAVSC	$\overline{ADV}$ setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires 1 cycle of data hold time ($\overline{CS}$ de-assertion).

Table 9-51. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 125 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	n/a (single access)			
WrCycleTime	WeOffTime + AccessCompletion	56	7	WRCYCLETIME = 7h
CsOnTime	tCAS	0	0	CSONTIME = 0
CsWrOffTime	WeOffTime + 1	56	7	CSWROFFTIME = 7h
AdvOnTime	tAVSC	3	1	ADVONTIME = 1
AdvWrOffTime	tAVSC + tAVDP	9	2	ADVWROFFTIME = 2
WeOnTime	tCS	3	1	WEONTIME = 2
WeOffTime	tCS + tWP + tWPH	48	6	WEOFFTIME = 6h

9.4.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

9.4.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, , ...)
- 8- and 16-bit NAND flash device

9.4.2.2 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories (see Table 9-52).

Table 9-52. Supported Memory Interfaces

9.4.2.3 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 9-53 summarizes the NAND interface signals level applied to external device or memories.

Table 9-53. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	$\overline{CE}$	$\overline{WE}$	$\overline{RE}$	$\overline{WP}$
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H	H	H	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L

9.4.2.4 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 9-54 summarizes the NOR interface signals level applied to external device or memories.

Table 9-54. NOR Interface Bus Operations Summary

Bus Operation	CLK	$\overline{ADV}$	$\overline{CS}$	$\overline{OE}$	$\overline{WE}$	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

9.4.2.5 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND Flash is a high-density and low-power memory device. It is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

9.4.2.6 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

9.4.2.7 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 3.3V
- Maximum GPMC addressing capability: 256 MBytes divided into eight chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

9.5 GPMC Registers

Table 9-55 provides a summary of the GPMC registers. For the base address of these registers, see Table 1-11. All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except the GPMC_NAND_DATA_i register, are little-endian. If the GPMC_NAND_DATA_i register is accessed, the endianness is access-dependent.

In this section, i corresponds to the chip-select number, i = 0 to 5.

Table 9-63. GPMC_ERR_TYPE Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	Reserved
10-8	ILLEGALMCMD	0-7h	System Command of the transaction that caused the error
7-5	Reserved	0	Reserved
4	ERRORNOTSUPPADD		Not supported Address error
		0	No error occurs
		1	The error is due to a non supported Address
3	ERRORNOTSUPPMCMD		Not supported Command error
		0	No error occurs
		1	The error is due to a non supported Command
2	ERRORTIMEOUT		Time-out error
		0	No error occurs
		1	The error is due to a time out
1	Reserved	0	Reserved
0	ERRORVALID		Error validity status - Must be explicitly cleared with a write 1 transaction
		0	All error fields no longer valid
		1	Error detected and logged in the other error fields

9.5.9 GPMC_CONFIG

The configuration register allows global configuration of the GPMC.

Figure 9-59. GPMC_CONFIG

31	16
Reserved	
R-0	

15	10	9	8
Reserved		WAIT1PIN POLARITY	WAIT0PIN POLARITY
R-0		R/W-0	R/W-0

7	5	4	3	2	1	0
Reserved		WRITE PROTECT	Reserved		LIMITED ADDRESS	NANDFORCE POSTEDWRITE
R-0		R/W-0	R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-64. GPMC_CONFIG Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	WAIT1PINPOLARITY		Selects the polarity of input pin WAIT1
		0	WAIT1 active low
		1	WAIT1 active high
8	WAIT0PINPOLARITY		Selects the polarity of input pin WAIT0
		0	WAIT0 active low
		1	WAIT0 active high
7-5	Reserved	0	Reserved
4	WRITEPROTECT		Controls the $\overline{WP}$ output pin level
		0	$\overline{WP}$ output pin is low
		1	$\overline{WP}$ output pin is high
3-2	Reserved	0	Reserved
1	LIMITEDADDRESS	0-1	Limited Address device support
0	NANDFORCEPOSTEDWRITE		Enables the Force Posted Write feature to NAND Cmd/Add/Data location
		0	Disables Force Posted Write
		1	Enables Force Posted Write

9.5.10 GPMC_STATUS

The status register provides global status bits of the GPMC.

Figure 9-60. GPMC_STATUS

31	16
Reserved

Table 9-66. GPMC_CONFIG1_i Field Descriptions

Bit	Field	Value	Description
31	WRAPBURST		Enables the wrapping burst capability. Must be set if the attached device is configured in wrapping burst
		0	Synchronous wrapping burst not supported
		1	Synchronous wrapping burst supported
30	READMULTIPLE		Selects the read single or multiple access
		0	single access
		1	multiple access (burst if synchonous, page if asynchronous)
29	READTYPE		Selects the read mode operation
		0	Read Asynchronous
		1	Read Synchronous
28	WRITEMULTIPLE		Selects the write single or multiple access
		0	Single access
		1	Multiple access (burst if synchronous, considered as single if asynchronous)
27	WRITETYPE		Selects the write mode operation
		0	Write Asynchronous
		1	Write Synchronous
26-25	CLKACTIVATIONTIME		Output GPMC.CLK activation time
		0	First rising edge of GPMC_CLK at start access time
		1h	First rising edge of GPMC_CLK one GPMC_FCLK cycle after start access time
		2h	First rising edge of GPMC_CLK two GPMC_FCLK cycles after start access time
		3h	Reserved
24-23	ATTACHEDDEVICEPAGELENGTH		Specifies the attached device page (burst) length (1 Word = Interface size)
		0	4 Words
		1h	8 Words
		2h	16 Words
		3h	Reserved

Table 9-66. GPMC_CONFIG1_i Field Descriptions (continued)

Bit	Field	Value	Description
22	WAITREADMONITORING		Selects the Wait monitoring configuration for Read accesses (Reset value is BOOTWAITEN input pin sampled at IC reset)
		0	WAIT pin is not monitored for read accesses
		1	WAIT pin is monitored for read accesses
21	WAITWRITEMONITORING		Selects the Wait monitoring configuration for Write accesses
		0	WAIT pin is not monitored for write accesses
		1	WAIT pin is monitored for write accesses
20	Reserved	0	Reserved
19-18	WAITMONITORINGTIME		Selects input pin Wait monitoring time
		0	WAIT pin is monitored with valid data
		1h	WAIT pin is monitored one GPMC_CLK cycle before valid data
		2h	WAIt pin is monitored two GPMC_CLK cycle before valid data
		3h	Reserved
17-16	WAITPINSELECT		Selects the input WAIT pin for this chip select (Reset value is BOOTWAITSELECT input pin sampled at IC reset for CS0 and 0 for CS1-5)
		0	WAIT input pin is WAIT0
		1h	WAIT input pin is WAIT1
		2h	Reserved
		3h	Reserved
15-14	Reserved	0	Reserved
13-12	DEVICESIZE		Selects the device size attached (Reset value is BOOTDEVICESIZE input pin sampled at IC reset for $\overline{CS}$[0] and 01 for $\overline{CS}$[1-5])
		0	8 bit
		1h	16 bit
		2h	Reserved
		3h	Reserved
11-10	DEVICETYPE		Selects the attached device type
		0	NOR Flash like, asynchronous and synchronous devices
		1h	Reserved
		2h	NAND Flash like devices, stream mode
		3h	Reserved
9-8	MUXADDDATA		Enables the Address and data multiplexed protocol (Reset value is CS0MUXDEVICE input pin sampled at IC reset for $\overline{CS}$[0] and 0 for $\overline{CS}$[1-5])
		0	Non-multiplexed attached device
		1h	AAD-multiplexed protocol device
		2h	Address and data multiplexed attached device
		3h	Reserved
7-5	Reserved	0	Reserved
4	TIMEPARAGRANULARITY		Signals timing latencies scalar factor (Rd/WRCycleTime, RdAccessTime, PageBurstAccessTime, CSOnTime, CSRd/WrOffTime, ADVOnTime, ADVRd/WrOffTime, OEOnTime, OEOffTime, WEOnTime, WEOffTime, Cycle2CycleDelay, BusTurnAround, TimeOutStartValue)
		0	×1 latencies

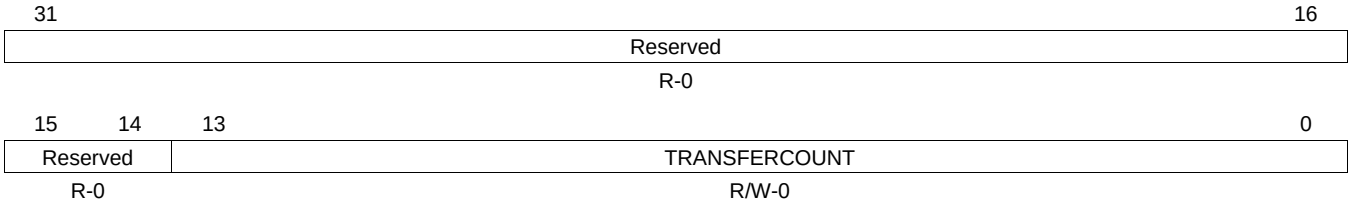
		1h	The two next accesses are granted to the PFPW engine
		⋮	⋮
		Fh	The 16 next accesses are granted to the PFPW engine
15	Reserved	0	Reserved

Table 9-76. GPMC_PREFETCH_CONFIG1 Field Descriptions (continued)

Bit	Field	Value	Description
14-8	FIFOTHRESHOLD		Selects the maximum number of bytes read from the FIFO or written to the FIFO by the host on a DMA or interrupt request
		0	0 byte
		1h	1 byte
		⋮	⋮
		40h	64 bytes
7	ENABLEENGINE		Enables the Prefetch Postwite engine
		0	Prefetch Postwrite engine is disabled
		1	Prefetch Postwrite engine is enabled
6	Reserved	0	Reserved
5-4	WAITPINSELECTOR		Select which WAIT pin edge detector should start the engine in synchronized mode
		0	Selects Wait0EdgeDetection
		1h	Selects Wait1EdgeDetection
		2h	Reserved
		3h	Reserved
3	SYNCHROMODE		Selects when the engine starts the access to CS
		0	Engine starts the access to CS as soon as STARTENGINE is set
		1	Engine starts the access to CS as soon as STARTENGINE is set AND wait to non wait edge detection on the selected wait pin
2	DMAMODE		Selects interrupt synchronization or DMA request synchronization
		0	Interrupt synchronization is enabled. Only interrupt line will be activated on FIFO threshold crossing.
		1	DMA request synchronization is enabled. A DMA request protocol is used.
1	Reserved	0	Reserved
0	ACCESSMODE		Selects pre-fetch read or write posting accesses
		0	Prefetch read mode
		1	Write-posting mode

9.5.22 GPMC_PREFETCH_CONFIG2

Figure 9-72. GPMC_PREFETCH_CONFIG2



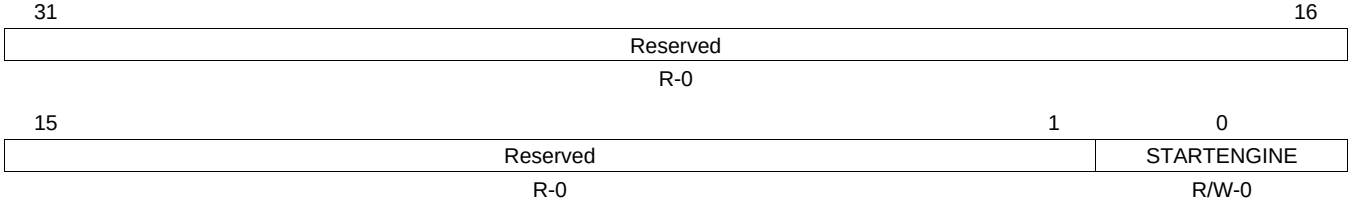
LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-77. GPMC_PREFETCH_CONFIG2 Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved
13-0	TRANSFERCOUNT		Selects the number of bytes to be read or written by the engine to the selected $\overline{CS}$
		0	0 byte
		1h	1 byte
		⋮	⋮
		2000h	8 Kbytes

9.5.23 GPMC_PREFETCH_CONTROL

Figure 9-73. GPMC_PREFETCH_CONTROL



LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-78. GPMC_PREFETCH_CONTROL Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	STARTENGINE		Resets the FIFO pointer and starts the engine
		R0	Engine is stopped
		W0	Stops the engine
		R1	Engine is running
		W1	Resets the FIFO pointer to 0 in prefetch mode and 40h in postwrite mode and starts the engine

High-Definition Multimedia Interface (HDMI)

This chapter describes the high-definition multimedia interface (HDMI) module.

Topic **Page**

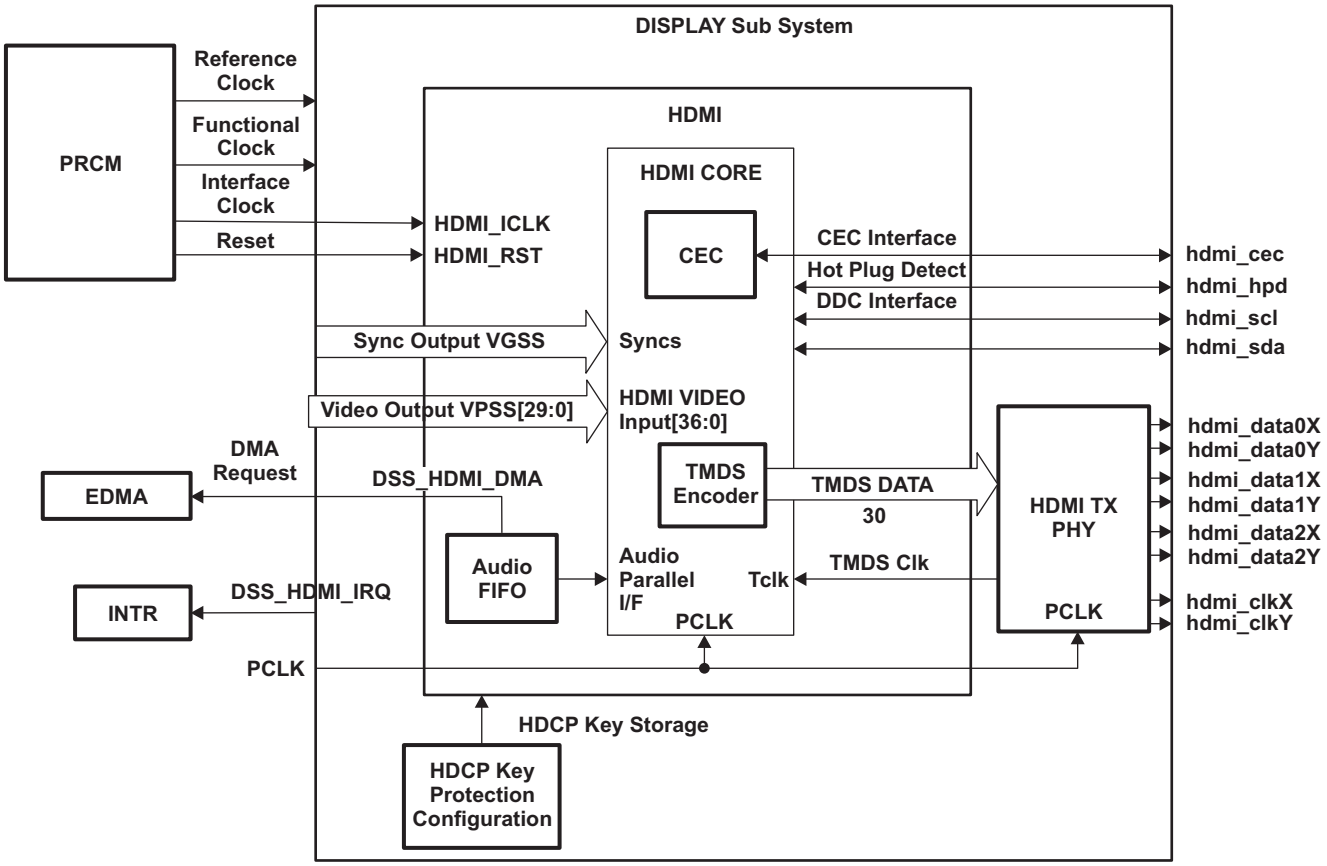
10.1 Introduction

10.1.1 Overview

The high-definition multimedia interface wrapper (HDMI_WP) module is used to encapsulate the HDMI, providing compatibility and interface to the HDMI TXPHY module. The HDMI_WP module contains the support logic for the HDMI IP, including the HDMI core (HDMI_CORE) and CEC core. The major additional parts comprise a slave interface port for configuration and buffering for the audio data streams.

Figure 10-1 is an overview of the HDMI module.

Figure 10-1. HDMI Overview



10.1.2 Main Features

The HDMI module provides the following main features:

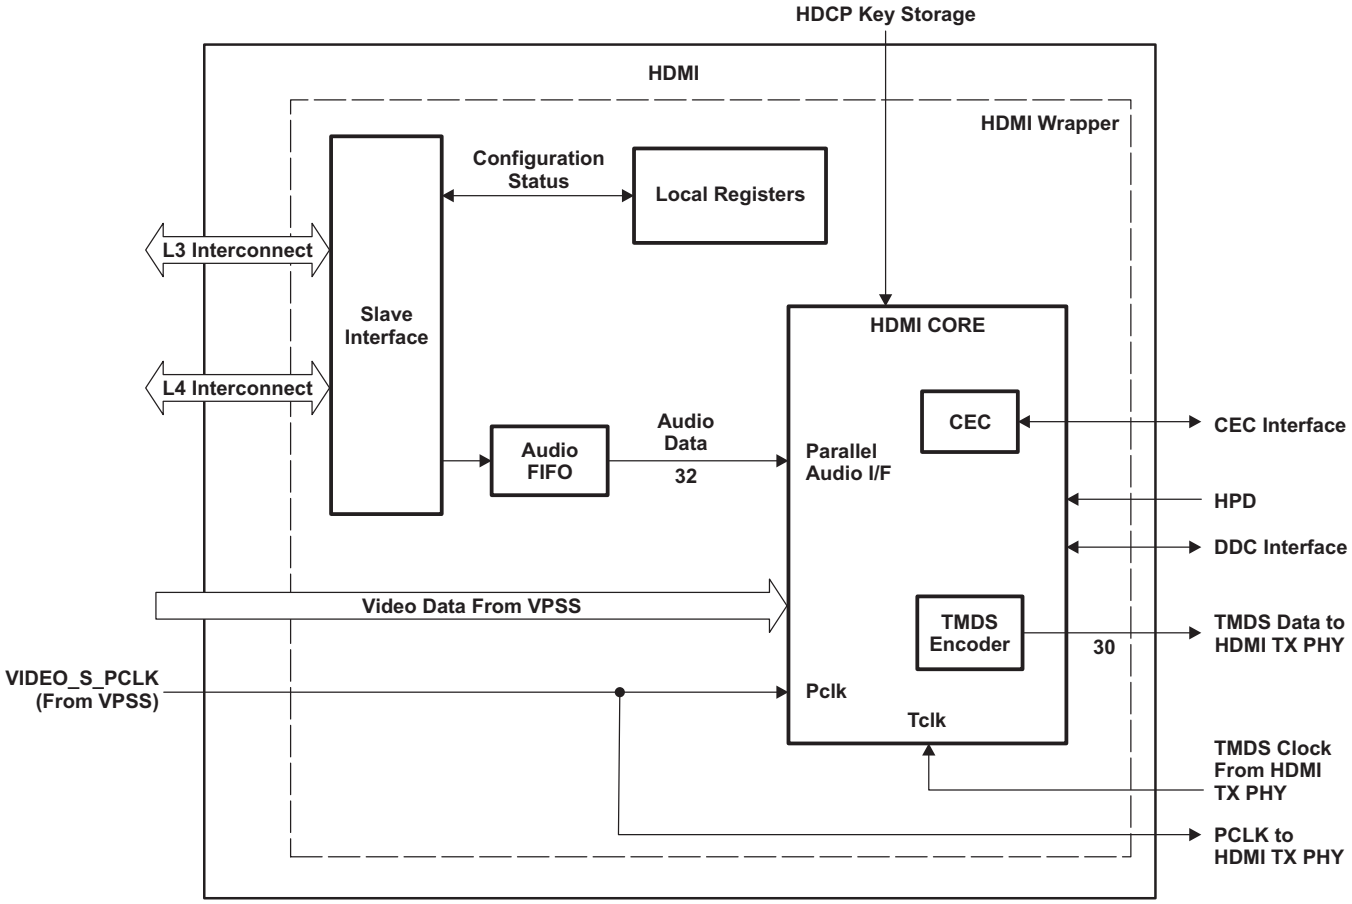
- HDMI 1.3, HDCP 1.2, and DVI 1.0 compliant
- EIA/CEA-861-D video format support
- VESA Display Monitor Timing (DMT) video format support
- Support for deep-color mode:
  - 10-bit/component color depth up to 1080p at 60 Hz
  - 12-bit/component color depth up to 720p/1080i at 60 Hz
- Supports up to 165-MHz pixel clock (1920 × 1080p at 60 Hz)
- Video formats: 24-bit RGB
- Uncompressed multichannel (up to eight channels) audio (L-PCM) support
- Master inter-intergrated circuit (I2C) interface for display data channel (DDC) connection

- Consumer Electronic Control (CEC) interface
- Integrated High-bandwidth Digital Content Protection (HDCP) encryption engine for transmitting protected audio and video content (authentication performed by software)
- Integrated Transition Minimized Differential Signaling (TMDS) and TER4 encoders for data island support
- Integrated TMDS physical layer (PHY) (three TMDS differential data lanes + TMDS differential clock lane)
  - Up to 1.85625 Gbps per lane at (1080p at 60 Hz at 10 bits/component, lower resolutions at 12 bits/component)
  - 928.125 Mbps per lane at (720p/1080i at 60 Hz 10 bits/component, lower resolutions at 12 bits/component)
  - 337.5 Mbps at (576p at 50 Hz/480p at 60 Hz 10 bits/component)

10.1.3 Functional Block Diagram

Figure 10-2 is a functional block diagram of the HDMI module.

Figure 10-2. HDMI Block Diagram



10.1.4 Video Formats and Timings

Table 10-1 lists the video timings supported by the HDMI module, according to the CEA-861-D standard.

Table 10-2 lists the video timings supported by the HDMI module, according to the VESA DMT standard.

Table 10-1. HDMI Video Timings (CEA-861-D)

Refresh Rate	Resolution
24 Hz (low-field rate)	1920 x 1080p
50 Hz	1920 x 1080p
	1920 x 1080i
	1280 x 720p
	2880 x 576p
	1440 x 576p
	1440 x 576i
	720 x 576p
59.94 Hz	1920 x 1080p
	2880 x 480p
	1440 x 480p

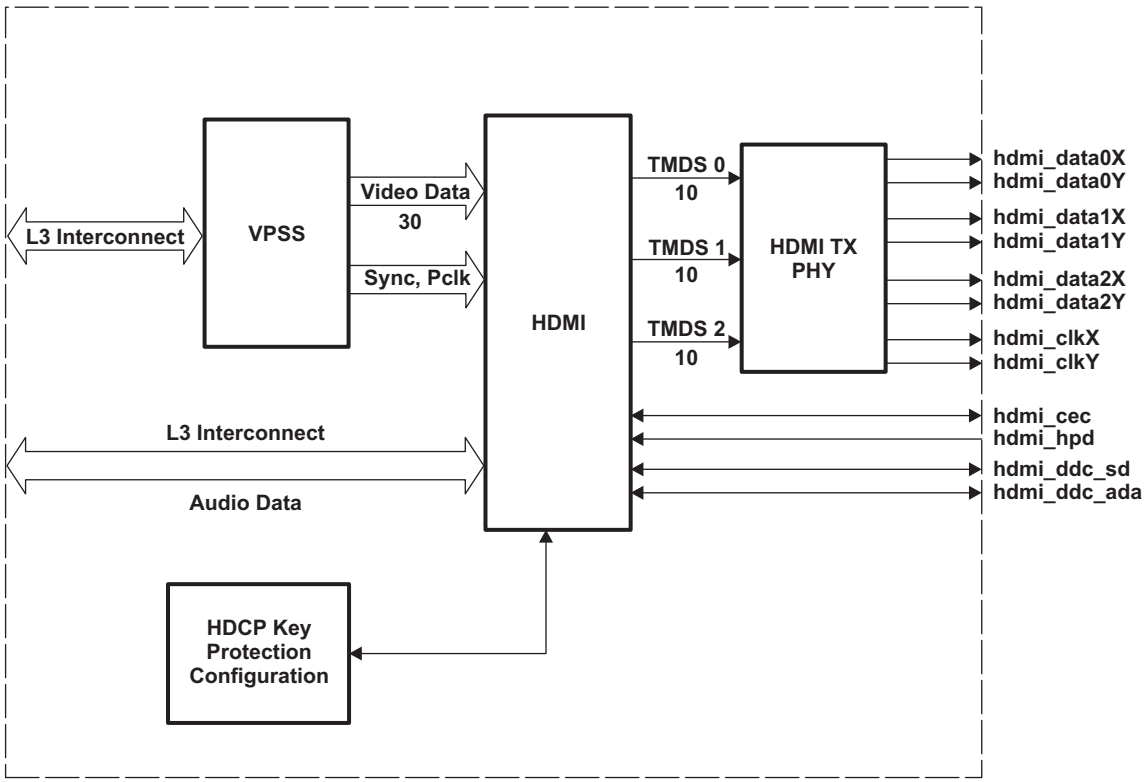
	1440 x 900p
	1680 x 1050p
	1920 x 1080p
60 Hz (reduced blanking)	1280 x 768p
	1280 x 800p
	1400 x 1050p
	1440 x 900p
	1680 x 1050p

10.1.5 Environment

This section describes the HDMI application fields from an environment point of view (external connections). It describes HDMI connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

Figure 10-3 shows the external connections and simplified data path for the HDMI module.

Figure 10-3. HDMI Environment



The following paths are used to transmit video and audio data through the HDMI link:

- Video data path:
  - Video Processing Sub System (VPSS)
  - HDMI module
  - HDMI complex input/output (I/O) (HDMI_TXPHY)

The VPSS module provides synchronization signals to the HDMI and synchronously sends 30 bits of pixel data to the HDMI with these signals. The digital output of the VPSS is always a 30-bit RGB value .For more information about the connection between the VPSS and HDMI, see Section 1.4.7.1, HDMI Video Interface. For more information about the VPSS settings and features, see the Video Processing Sub System chapter in the device TRM. The video data received on the HDMI video slave port is always a 30-bit RGB value. The HDMI module performs pixel processing that allows manipulation of the pixels received on the video interface. The processed data is sent to the HDCP for encryption, or directly to the HDMI_TXPHY module after TDMS encoding, if there is no HDCP encryption enabled.

- Audio data path:
  - Level 3 (L3) interconnect
  - HDMI module
  - HDMI complex I/O (HDMI_TXPHY)

The audio data is received on the buffered HDMI audio port through the L3 Interconnect using a direct memory access (DMA) request to the device system DMA (EDMA) module, or interrupt request (IRQ) to the device microprocessor unit (MPU) interrupt controllers (INTCs). In the HDMI, the data is packed, formatted, and sent to the HDMI_TXPHY module.

Additionally, the HDMI module provides universal remote control capability through the CEC protocol on the hdmi_cec pin, which allows common communication between different pieces of consumer electronics when the device is connected to them by HDMI cable.

The HDMI module can drive the display data channel (DDC) bus, which supports a variety of I2C commands, on the hdmi_ddc_scl and hdmi_ddc_sda pins. This allows the TV-set/monitor to provide information to the host device, such as supported resolutions.

Hot plug detection (HPD) capability is supported by the HDMI module on the hdmi_hpd pin. It allows detection of the presence of an attached TV display.

10.2 Architecture

This section describes the HDMI configuration.

10.2.1 Clock Configuration

10.2.1.1 Clock Domains

There are three main clock domains within the HDMI module:

- L3 clock domain: Runs at the frequency of the DSS_L3_ICLK clock, generated by the device PRCM module, and is asynchronous with the other clocks
- TCLK clock domain: Runs at the frequency of the TMDS clock (TMDS_CLK) generated by the HDMI_TXPHY module
- PCLK clock domain: VPSS to HDMI_WP input runs at PCLK generated by VPSS Venc.

10.2.1.2 CEC Interface Clock Configuration

The clock for the CEC interface module (CEC_DDC_CLK) is generated inside the HDMI module from the DSS_HDMI clock (48 MHz) by division. The divider value is set through the HDMI_WP_CLK[5:0] CEC_DIV bit field, as defined in Table 10-3. The clock frequency required by the CEC protocol is 2 MHz, and is achieved by setting the CEC_DIV bit field to 18h.

Table 10-3. CEC Clock Generation

Reference Clock	HDMI_WP_CLK[5:0] CEC_DIV Value	CEC Clock
DSS_HDMI	0	Gated
-	1	Free running
-	...	...
-	18h	2-MHz clock
-	...	...

10.2.1.3 Time-Out Capability

The HDMI module provides time-out capability to the DSS_HDMI clock. The OCP_TIME_OUT_INTR interrupt is generated, if the HDMI_WP_CLK[16] OCP_TIME_OUT_DIS bit is cleared to 0 and the DSS_HDMI clock is not provided to the HDMI module. For more information about the OCP_TIME_OUT_INTR interrupt, see Section 10.2.6. The time-out capability can be disabled by writing 1 to the HDMI_WP_CLK[16] OCP_TIME_OUT_DIS bit. By default, this option is enabled.

10.2.2 Signals

Table 10-4 describes the HDMI module signals.

Table 10-4. HDMI I/O Signal Description

Signal	I/O[1]	Description	Function
hdmi_data0x hdmi_data0y	O	Transmit data lane 0	TMDS serial data output
hdmi_data1x hdmi_data1y	O	Transmit data lane 1	TMDS serial data output
hdmi_data2x hdmi_data2y	O	Transmit data lane 2	TMDS serial data output
hdmi_clockx hdmi_clocky	O	Transmit clock lane	TMDS clock output
hdmi_cec	I/O	CEC interface line	CEC interface input/output
hdmi_hpd	I	Monitor charge input	Used to connect to the HDMI hot plug pin to detect the presence of an attached monitor
hdmi_ddc_scl	I/O	DDC I2C clock line	DDC clock input/output
hdmi_ddc_sda	I/O	DDC I2C clock line	DDC clock input/output

(1) I = Input; O = Output

10.2.3 Integration

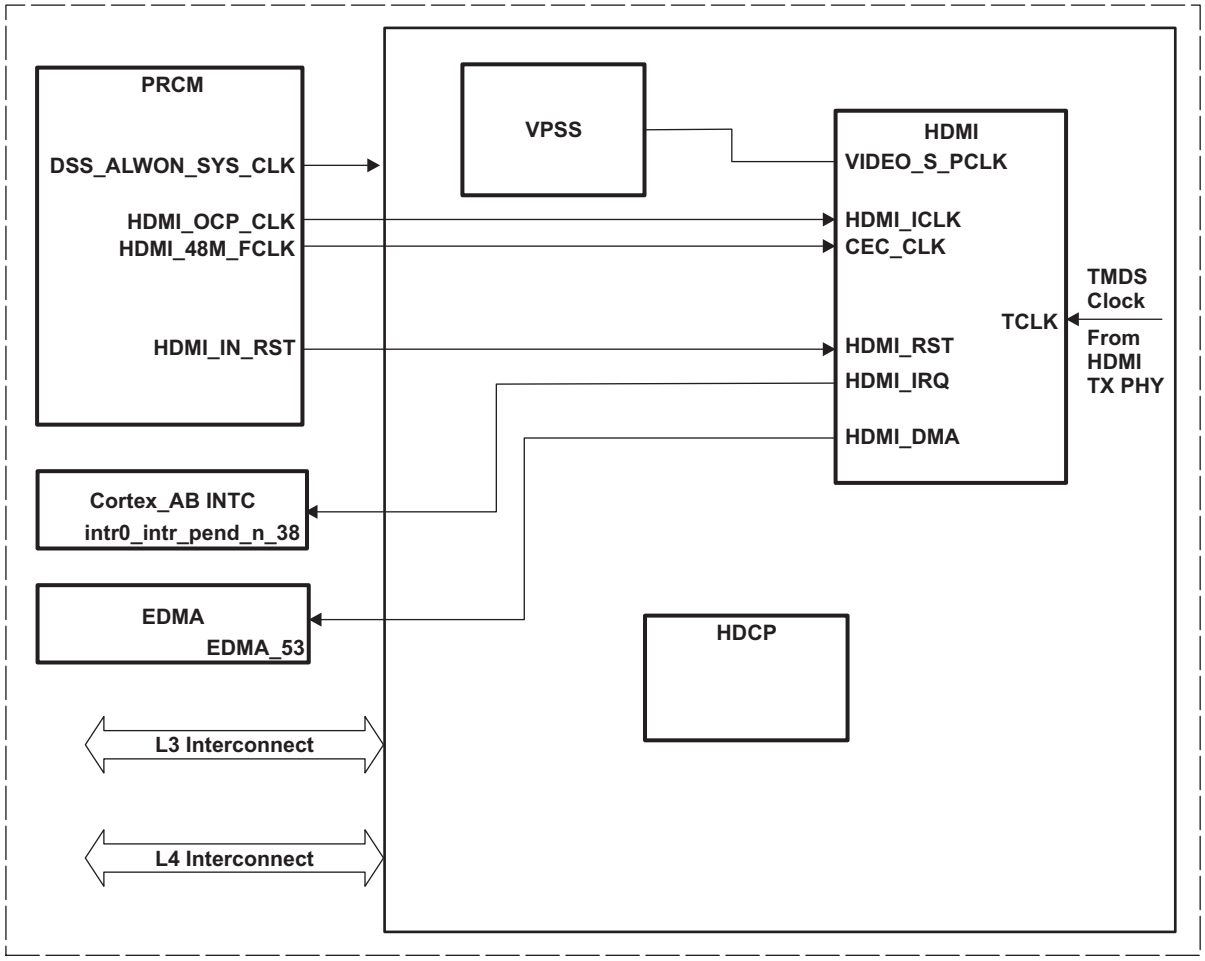
This section describes the module integration in the device (see Figure 10-4), including information about clocks, resets, and hardware requests.

Table 10-5, Table 10-6, and Table 10-7 summarize the integration of the module in the device.

10.2.4 Software Reset

Global reset of the module is done at the PRCM module level. The HDMI module can be reset by software. This has the same effect as a hardware reset. The HDMI module can be reset by setting the HDMI_WP_SYSCONFIG[0] SOFTRESET bit to 1. Software can monitor this bit to wait for the reset to complete.

Figure 10-4. HDMI Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Sleep (Idle) and Wake-Up Management, in Power, Reset, and Clock Management.

Table 10-5. Integration Attributes

Module Instance	Attributes
HDMI	Power Domain — Interconnect Active Domain —L3 for Data; L4 for Configuration

Table 10-6. Clocks and Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Destination
		Clocks		
HDMI	DSS_HDMI	HDMI_PHY_48_S_FCLK	PRCM	The CEC/DDC clock is derived from this clock. Also reference clock for HDMI_TXPHY module.
	HDMI_ICLK	DSS_L3_ICLK	PRCM	Interface clock
	TCLK	TMDS_CLK	HDMI_TXPHY	The TMDS encoded data is sent to the HDMI_TXPHY module on this clock.
VPSS	VIDEO_S_PCLK	HDMI_CLK	VPSS	HDMI
		Resets		
HDMI	HDMI_RST	HDMI_IN_RST	PRCM	Nonretention reset

Table 10-7. Hardware Requests

Module Instance	Desination Signal Name	Source Signal Name	Destination	Description
HDMI	DSS_HDMI_IRQ	intr0_intr_pend_n_38	CortexA8	HDMI Interrupt Request
HDMI	DSS_HDMI_DMA	EDMA_53	EDMA	HDMI audio DMA request

10.2.5 Power Management

Table 10-8 describes the power-management features available to the HDMI module.

NOTE: For information about source clock gating and a description of the sleep/wake-up transitions, see the Sleep (Idle) and Wake-Up Management section in the Power, Reset, and Clock Management..

For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see the AutoIDLE Clock Control section in the Power, Reset, and Clock Management.

Table 10-8. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	HDMI_WP_SYSCONFIG[3:2] IDLEMODE bit field	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.

10.2.6 Interrupt Requests

One external interrupt line is generated by the HDMI module: DSS_HDMI_IRQ (for more information, see Table 10-7). Table 10-9 lists the event flags, and their masks, that can cause internal module interrupts that are mapped to DSS_HDMI_IRQ.

Table 10-9. HDMI Interrupt Events

Event Flag	Event Mask	Map To	Description
HDMI_WP_IRQSTATUS[10] AUDIO_FIFO_SAMPLE_REQ_INTR	HDMI_WP_IRQENABLE_SET[10] ENABLE_SET_AUDIO_FIFO_ SAMPLE_REQ_INTR	AUDIO_FIFO_SAMPLE_ REQ_INTR	Audio FIFO requests some data in IRQ mode
HDMI_WP_IRQSTATUS[9] AUDIO_FIFO_OVERFLOW_INTR	HDMI_WP_IRQENABLE_SET[9] ENABLE_SET_AUDIO_FIFO_ OVERFLOW_INTR	AUDIO_FIFO_ OVERFLOW_INTR	Audio FIFO overflow
HDMI_WP_IRQSTATUS[8] AUDIO_FIFO_UNDERFLOW_INTR	HDMI_WP_IRQENABLE_SET[8] ENABLE_SET_AUDIO_FIFO_ UNDERFLOW_INTR	AUDIO_FIFO_ UNDERFLOW_INTR	Audio FIFO underflow
HDMI_WP_IRQSTATUS[4] OCP_TIME_OUT_INTR	HDMI_WP_IRQENABLE_SET[4] OCP_TIME_OUT_INTR	OCP_TIME_OUT_INTR	Time-out interrupt in case the DSS_HDMI clock is not provided
HDMI_WP_IRQSTATUS[0] CORE_INTR	HDMI_WP_IRQENABLE_ SET[0] ENABLE_SET_CORE_INTR	CORE_INTR	HDMI core has generated internally an interrupt. Software must read the interrupt status register in the HDMI core to identify the interrupt event(s).

NOTE: The HDMI_WP_IRQENABLE_SET register is used to enable the interrupt event(s), by writing 1 in the desired bit field(s). To disable the interrupt event(s), the HDMI_WP_IRQENABLE_CLR register must used, by writing 1 in the respective bit field(s).

10.2.7 DMA Requests

The HDMI module generates one DMA request for audio data: DSS_HDMI_DMA (for more information, see Section 10.2.8.2.2.1).

10.2.8 Wrapper Functions

10.2.8.1 Wrapper Video Interface

10.2.8.1.1 Video Interface Features

- Video slave port with 30 bit RGB data format (deep color mode)
- Slave operational mode:
  - Synchronization signals, pixel clock, data-enable and data pixels are provided to the HDMI module
- CEA 861-D video timings support at 50 Hz, 59.94 Hz, and 60 Hz (low field rate 24 Hz included)
- VESA DMT video timings support at 60 Hz (reduced blanking included)
  - 10 bits per color component for 1080p/60fps and 1080p/50fps – 12 bits per color component otherwise
- Support for TCLK up to 185.625 MHz (TCLK derived from PCLK)

10.2.8.1.2 Video Interface Description

NOTE: The signals described in this section are internal and not bounded outside the device.

The HDMI module receives synchronization signals, pixel clock, and 30 bits of pixel data on its video slave port from VPSS module (Table 10-10). The digital output of the VPSS is always a 30-bit RGB value. This is extended to 36 bits by adding LSB zeroes, as listed in Table 10-11.

Table 10-10. Video Port Signals

Signal Name	Width	Direction	Description
VIDEO_S_PCLK	---	IN	Input pixel clock (PCLK)
VIDEO_S_DATA	35:0	IN	Video data input bus
VIDEO_S_DE	---	IN	Data Enable
VIDEO_S_HS	---	IN	Horizontal sync
VIDEO_S_VS	---	IN	Vertical sync
VIDEO_S_FID	---	IN	Field identifier

10.2.8.1.3 Video Interface Configuration

The slave port is connected to the HDMI module. Always clear the HDMI_WP_VIDEO_CFG[1:0] Mode bit field to 0.

According to the video data bus connection and pixel format, packing mode must be selected. The format supported by the HDMI module is 36-bit RGB. The packing can be selected through the HDMI_WP_VIDEO_CFG[10:8] PACKING_MODE bit field:

- HDMI_WP_VIDEO_CFG[10:8] PACKING_MODE = 0: If 10-bit deep-color mode is selected and

RGB format is used on the video port data bus:

- HDMI_WP_VIDEO_CFG[10:8] PACKING_MODE = 1: If 8-bit deep-color mode is not selected and

RGB format is used on the video port data bus:

- HDMI_WP_VIDEO_CFG[10:8] PACKING_MODE = 7h: If 12-bit deep-color mode is selected and

RGB format is used on the video port data bus. No change on input video data lines. The VIDEO_S_DATA[35:0] data is provided without any change in it.

Video Timing is controlled by VENC module inside VPSS which drives HDMI module. Please refer VPSS PRG for information about timing for different resolutions.

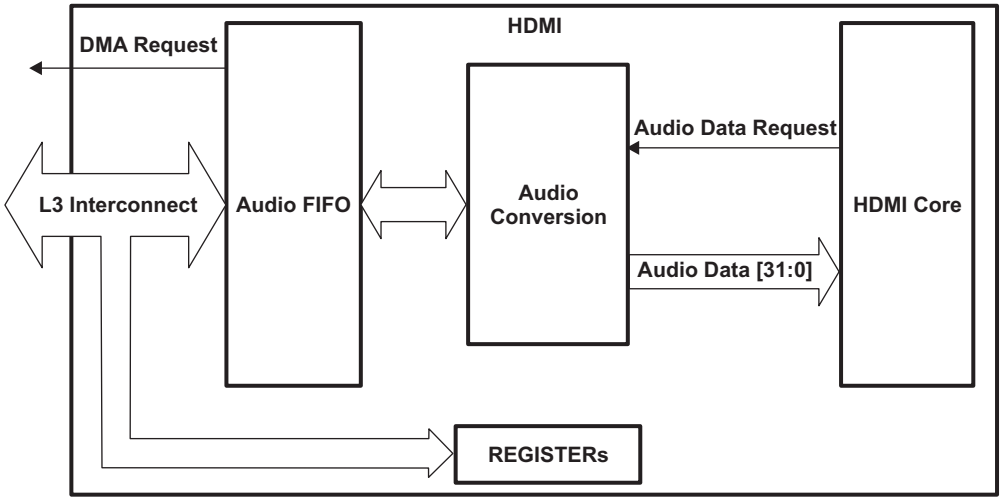
10.2.8.2 Wrapper Audio Interface

10.2.8.2.1 Audio Interface Description

The HDMI module supports parallel interface that is based on a filling of the audio FIFO through the L3 interconnect. The audio data and register configuration is received through the L3 interconnect on a request to the device EDMA module. Each 32-bit access is split into four consecutive accesses to the HDMI Core 8-bit registers of the 32-bit access, starting with the least-significant bit (LSB) to the MSB.

Figure 10-5 is an overview of the audio interface to the HDMI core.

Figure 10-5. HDMI Audio Interface Overview



10.2.8.2.2 Audio FIFO Overview

The audio FIFO provides buffering to ensure that audio samples can always be delivered to the HDMI core exactly when required, despite the L3 interconnect latency.

10.2.8.2.2.1 Audio Data Request

By default, the audio FIFO is filled by the device EDMA using a standard DMA request signal mapped to DSS_HDMI_DMA on the display subsystem level. For additional mapping information, see Table 10-7.

The FIFO can also use an IRQ signal (AUDIO_FIFO_SAMPLE_REQ_INTR) to request audio data, instead of a DMA request, using the same threshold. The IRQ status can be read in the HDMI_WP_IRQSTATUS[10] AUDIO_FIFO_SAMPLE_REQ_INTR bit. For more information about the audio IRQ, see Table 10-9.

The selection between DMA or IRQ request can be done through the HDMI_WP_AUDIO_CTRL[9] DMA_OR_IRQ bit.

The audio data is written in the HDMI_WP_AUDIO_DATA[31:0] FIFO_DAT bit field.

The request is made based on comparison of fullness with register programmable thresholds. The DMA/IRQ is generated when the number of samples (24- or 16-bit) in the FIFO is less than or equal to the threshold value.

- The size of samples is selected through the HDMI_WP_AUDIO_CFG[0] SAMPLE_SIZE bit.
- The valid number of samples can be read from the HDMI_WP_AUDIO_CTRL[25:16].

NUMBER_OF_SAMPLE bit field:

- The threshold value can be set in the HDMI_WP_AUDIO_CTRL[8:0] TRESHOLD_VALUE bit field.

The DSS_HDMI_DMA signal is released (deactivated) when the last transfer of the DMA burst is performed in the FIFO. An internal counter is used to do this. The reset value of this counter is set to 16 and the maximum value is set to 64. In this case, the maximum length of the DMA transfer is 64 (32-bit interface access). The counter can be configured through the HDMI_WP_AUDIO_CFG2[15:8] DMA_TRANSFER bit field.

The threshold value and the DMA burst size must be set to ensure the filling of the FIFO to four samples. The minimum level (otherwise, underflow occurs) is four audio samples, which can be 2 × 32-bit data (in case of two samples per word) or 4 × 32-bit data (IEC or one sample per word). The interconnect latency must be considered. The number of samples is controlled through the HDMI_WP_AUDIO_CFG[1] SAMPLE_NBR bit.

10.2.8.2.2.2 Audio FIFO Error (Underflow and Overflow)

The underflow and overflow status are required and highlighted by sending interrupt requests IRQs).

The FIFO underflow condition occurs when the HDMI core is requesting data from the FIFO when the FIFO is empty. The status can be read through the HDMI_WP_IRQSTATUS[8] AUDIO_FIFO_UNDERFLOW_INTR bit.

The underflow IRQ may happen during a sequence only if one of the following occurs:

- The audio data path is not set correctly. In this case, the device EDMA cannot fill the FIFO fast enough.
- It is the end of the sequence and the number of samples is not a multiple of two times the value in the HDMI_WP_AUDIO_CFG2[7:0] BLOCK_SIZE bit field (384 samples by default).

The FIFO filling must be ensured by the system before the HDMI core is enabled; this means that in steady state the filling of the FIFO is always four words of 32 bits (except at the end).

The FIFO overflow condition occurs when an audio data is written (by the device EDMA or MPU modules) while the FIFO is full. The status can be read through the HDMI_WP_IRQSTATUS[9] AUDIO_FIFO_OVERFLOW_INTR bit.

The overflow IRQ may happen only if:

- The device EDMA module does not respect the DMA transfer length.
- The threshold is not set to the correct value in the HDMI_WP_AUDIO_CTRL[8:0] TRESHOLD_VALUE bit field.
- The device MPU module does not check the filling of the FIFO when the audio data is requested through an IRQ.

10.2.8.2.2.3 Audio FIFO Reset

The audio sample in the FIFO can be flushed by writing 0 in the HDMI_WP_AUDIO_CTRL[31] WRAPPER_ENABLE bit. As soon as the enable signal is deactivated (set to 0),the following occur: 1. The audio FIFO is reset. 2. The read and write pointers are reset. 3. The DSS_HDMI_DMA signal is deasserted. 4. Only the threshold value in the HDMI_WP_AUDIO_CTRL[8:0] TRESHOLD_VALUE bit field is kept.

10.2.8.2.3 Audio FIFO Data Formats

The format of the audio data in the audio FIFO can be configured through the HDMI_WP_AUDIO_CFG[4] IEC bit field.

- IEC = 0: The audio format is L-PCM.
- IEC = 1: The audio format is IEC 60958/IEC 61937.

10.2.8.2.3.1 L-PCM Format in Audio FIFO

Table 10-12 describes the 16-bit data format in the audio FIFO.

Table 10-12. PCM, 16-Bit Format

Order	Bits [31:16]	Bits [15:0]
---	16 bits, 2 channels (stereo)	---
1	Right - Channel 2	Left - Channel 1
---	16 bits, 4 channels	---
1	Right - Channel 2	Left - Channel 1
2	Right - Channel 4	Left - Channel 3
3	Right - Channel 2	Left - Channel 1
4	Right - Channel 4	Left - Channel 3
---	16 bits, 8 channels	---
1	Right - Channel 2	Left - Channel 1

Table 10-12. PCM, 16-Bit Format (continued)

Order	Bits [31:16]	Bits [15:0]
2	Right - Channel 4	Left - Channel 3
3	Right - Channel 6	Left - Channel 5
4	Right - Channel 8	Left - Channel 7

Table 10-13 describes the 24-bit data format in the audio FIFO. For the following formats, if less than 24 bits are valid, the data can be MSB- or LSB-justified. This is controlled through the HDMI_WP_AUDIO_CFG[3] JUSTIFY bit field.

Table 10-13. PCM, 24-Bit Format

Order	Bits [31:24]	Bits [23:0]
---	24 bits, 2 channels (stereo right - justified)	---
1	Unused	Left - Channel 1
2	Unused	Right - Channel 2
---	24 bits, 2 channels stereo left - justified	---
1	Left - Channel 1	Unused
2	Right - Channel 2	Unused
---	24 bits, 3 channels stereo right - justified	---
1	Unused	Left - Channel 1
2	Unused	Right - Channel 2
3	Unused	Center - Channel 3
4	Unused	Left - Channel 1
5	Unused	Right - Channel 2
6	Unused	Center - Channel 3
---	24 bits, 8 channels (right-justified)	---
1	Unused	Left - Channel 1
2	Unused	Right - Channel 2
3	Unused	Left - Channel 3
4	Unused	Right - Channel 4
5	Unused	Left - Channel 5
6	Unused	Right - Channel 6
7	Unused	Left - Channel 7
8	Unused	Right - Channel 8

NOTE: Left justification for three- and eight-channel data formats is also possible.

10.2.8.2.3.2 Speaker Mapping and Channel Ordering in the Audio FIFO

The speaker mapping in the eight channels is defined by the CEA-861-D specification and is described in Table 10-14. The CEA code is used to program the Packet Byte 4 of the Audio Info FRAME register inside the HDMI core (for more information, see the HDMI standard v1.3).

Table 10-14. Speaker Mapping Versus Channel

CEA Code	8	7	6	5	4	3	2	1
0h	-	-	-	-	-	-	FR	FL
1h	-	-	-	-	-	LFE	FR	FL
2h	-	-	-	-	FC	-	FR	FL

Table 10-14. Speaker Mapping Versus Channel (continued)

CEA Code	8	7	6	5	4	3	2	1

2Fh	FRH	FLH	RR	RL	FC	LFE	FR	FL
30h	FRW	FLW	RR	RL	FC	-	FR	FL
31h	FRW	FLW	RR	RL	FC	LFE	FR	FL

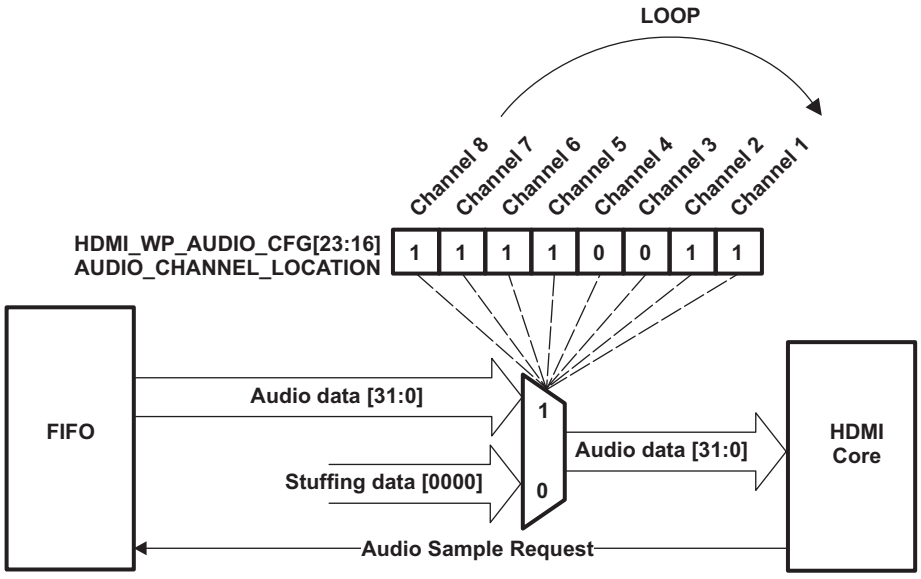
In Table 10-14, the following acronym definitions are used:

- FL: Front left
- FC: Front center
- FR: Front right
- FLC: Front left center
- FRC: Front right center
- RL: Rear left
- RC: Rear center
- RR: Rear right
- RLC: Rear left center
- RRC: Rear right center
- LFE: Low-frequency effect
- FLW: Front left wide
- FRW: Front right wide
- FLH: Front left high
- FCH: Front center high
- FRH: Front right high
- TC: Top center

The audio FIFO can be filled from two to eight channels, but the HDMI core supports only an even number of channels (the missing sample must be filled with 0, depending on the audio format).

The HDMI_WP_AUDIO_CFG[23:16] AUDIO_CHANNEL_LOCATION bit field indicates the location and the active channels. The AUDIO_CHANNEL_LOCATION field contains 8-bit fields, each corresponding to one channel. The HDMI_WP_AUDIO_CFG[26:24] STEREO_CHANNEL_ENABLE bit field indicates the number of stereo channels used. In Figure 10-6, the registers are filled accordingly with the CEA channel/speaker allocation code 10h received from the HDMI core. Upon a data request from the HDMI core, the data coming from the audio FIFO or the stuffing (filling zeros) data are sent.

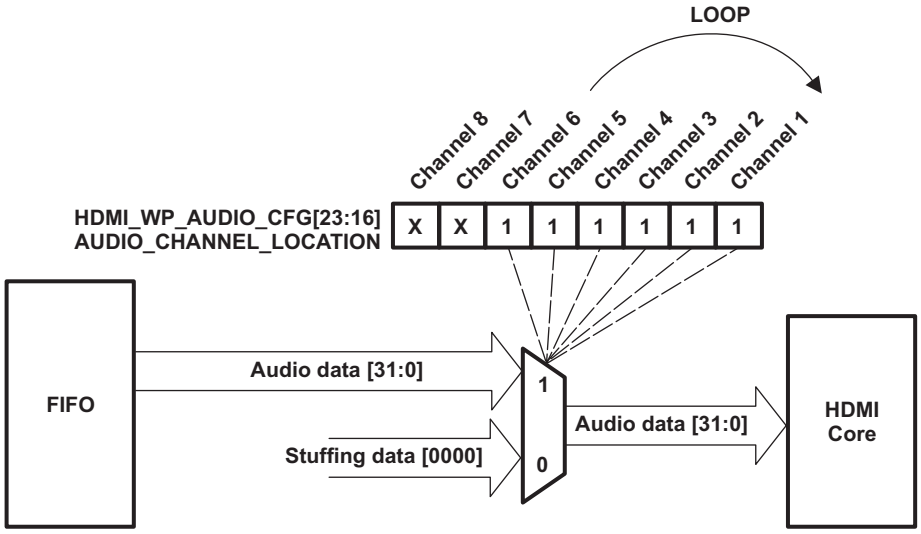
Figure 10-6. Audio Data Stuffing Behavior



If only three stereo channels are set in the HDMI wrapper, the loop can be optimized and set to 6. If three stereo channels are enabled in the HDMI core module, the function must be set to 3h in the HDMI_WP_AUDIO_CFG[26:24] STEREO_CHANNEL_ENABLE bit field.

Figure 10-7 shows an example with the CEA channel/speaker allocation code 7h and only three stereo channels enabled in the HDMI core. This format is also supported with the four channels enabled, but channel 7/8 must be cleared to 0.

Figure 10-7. Audio Data Stuffing Behavior with Only Three Stereo Channels Active



10.2.8.2.3.3 IEC 61958 Format

In the IEC 61958 format (Table 10-15), the channel status and user data bits are supplied with the audio data.

The valid bits are supplied with the audio data but may be overridden based on the audio FIFO operation(forced to invalid, if FIFO data is invalid). They may also be forced to valid or invalid.

This format supports only two channels (stereo) or two monophonic channels.

The audio FIFO can be filled directly with data aligned with the 60958 format. In this case, the VUCP and the preamble data are available.

Table 10-15. IEC 60958 Sample Format

Order	Bits [31:28]	Bits [27:4]	Bits [3:0]
1	VUCP	Left - Channel 1	Preamble
2	VUCP	Right - Channel 2	Preamble

10.2.8.2.3.4 IEC 61937 Format

The IEC 61937 format (Table 10-16) is similar to the IEC 61958 format, with multichannel supported.

Table 10-16. IEC 60937 Format

Order	Bits [31:28]	Bits [27:4]	Bits [3:0]
1	VUCP	Left - Channel 1	Preamble
2	VUCP	Right - Channel 2	Preamble
3	VUCP	Left - Channel 3	Preamble
4	VUCP	Right - Channel 4	Preamble
5	VUCP	Left - Channel 5	Preamble
6	VUCP	Right - Channel 6	Preamble

Table 10-16. IEC 60937 Format (continued)

Order	Bits [31:28]	Bits [27:4]	Bits [3:0]
7	VUCP	Left - Channel 7	Preamble
8	VUCP	Right - Channel 8	Preamble

NOTE: The compressed formats are supported only if software can stuff the missing data with zeros to reach the bandwidth defined in the IEC 60958 format.

10.2.8.2.4 AUDIO FIFO Data Adaptation

The HDMI core supports only the IEC 60958 format, or similar formats. Between the audio FIFO and the HDMI core, a format adaptation is done to optimize the audio data transfer.

There are three different formats in the audio FIFO:

- Two L-PCM samples on 16 bits in a 32-bit container
- One L-PCM sample on 24 bits in a 32-bit container
- IEC 61937 or IEC 60958 sample format compliant

The audio formats supported include 16- and 24-bit modes for stereo (two channels) and 8-channel modes.

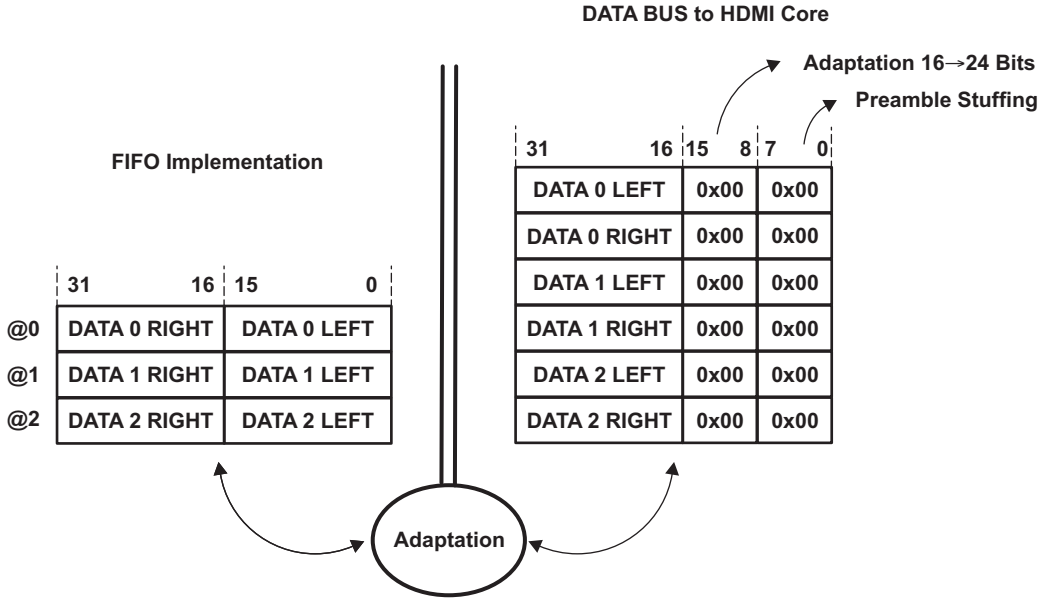
10.2.8.2.4.1 IEC 61937 and IEC 60958 Format Adaptation

The IEC 61937 and IEC 60958 formats are fully compatible with the HDMI core. In this case, data in the FIFO is sent to the HDMI core without adaptation. This is true for 16- and 24-bit modes and it is channel-number independent.

10.2.8.2.4.2 L-PCM 16-Bit Format Adaptation

When the audio FIFO is filled with 16-bit samples on the 32-bit container, the data is adapted to be similar to the IEC 61937/IEC 60958 format, as shown in Figure 10-8.

Figure 10-8. L-PCM 16-Bit Format Adaptation



10.2.8.2.4.3 L-PCM 24-bit Format Adaptation

When the audio FIFO is filled with a 24-bit sample on the 32-bit container, it is already in a format similar to IEC 61937/IEC 60958, left- or right-justified, depending on the FIFO filling (the HDMI_WP_AUDIO_CFG[3] JUSTIFY bit). In this case, the data in the audio FIFO is sent directly to the HDMI core without adaptation. However, the 8 dummy bits (MSB or LSB, depending on the justification) are filled with 0 data.

10.2.9 TXPHY Functions

10.2.9.1 TXPHY Overview

NOTE: The HDMI_TXPHY module must be configured before any transfer on the HDMI link. The HDMI module is fully functional only when the TMDS clock is provided. It has an internal PLL which will take in PCLK as an input and provide the required TCLK based on register configuration.

The HDMI_TXPHY receives 30 bits of TMDS parallel encoded data from the HDMI module and then prepares the data for transmission by serializing it. HDMI_TXPHY is a complex I/O with four unidirectional lane modules. This includes three data lane modules and one clock lane module. Each lane module has two data pads (DX and DY), which form a differential pair. These correspond to the HDMI serial output transmit signals, as described in Table 10-4. The data pads are connected with a complementary lane module on the external HDMI receiver device using a point-to-point interconnect.

The maximum data rate supported is 1.85625 Gbps per data lane. The lane module function and position are configurable. That is, any lane module can be chosen as a clock or a data lane module, and the DX/DY data pad for each lane module can be configured as a positive polarity (DP) or negative polarity (DN) pin.

10.2.9.2 TXPHY Clock Domains

The HDMI_TXPHY module has the following clock domains:

- TMDS clock domain: This is the data interface clock to the HDMI module. The data received on the HDMI_TXPHY inputs are sampled on this clock.
- HFBITCLK clock domain: This is the high frequency clock on which the transmit of the serialized data occurs.
- REFCLK clock domain: This is the 48-MHz free-running clock (DSS_HDMI) that is used as a reference for the switched capacitor circuit.

10.2.9.3 TXPHY RX Connection Detect

The HDMI_TXPHY can detect a pullup to 3.3 V on any clock and data lines. This situation occurs when an external HDMI receiver is connected to the device.

The information can be read by reading TMDS_CNTL2[0], RSEN.

10.2.9.4 TXPHY Data Interface

10.2.9.4.1 Input Interface

The HDMI_TXPHY module receives the 30-bit parallel data on its D0 to D2 inputs. The data is sampled on the rising edge of the TMDS clock.

10.2.9.4.2 Output Interface

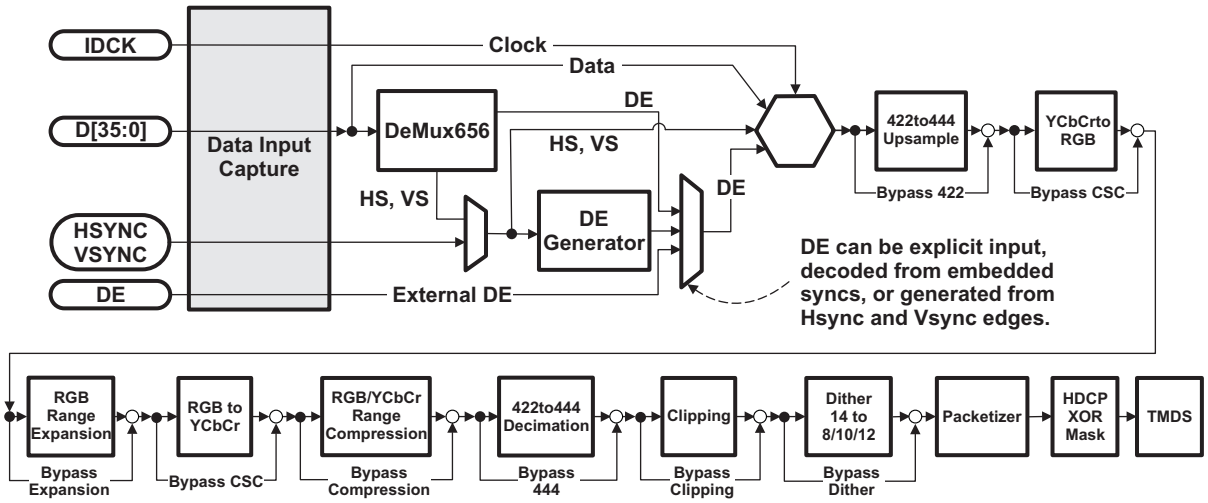
The serialized data on differential output lines DX/DY has the order LSB first and MSB last. The TMDS clock on the clock lane has a falling edge at the start of the 10-bit serial data word on the line.

10.2.10 Programming Video Input Mode and Video Output Mode

Specific registers in the HDMI Transmitter must be programmed according to the selection of input video bus mode and output video format. See Figure 10-9.

- The DE parameters need to be programmed only when the DE Generator is enabled. It is not recommended to enable the DE Generator.
- Set RANGE to 1 whenever converting YCbCr data and outputting full-range (0-255) RGB (PC mode) data across HDMI. When outputting limited-range (16-235) RGB (CE mode) data across the link, clear RANGE to 0.
- Set WIDE_BUS to the number of bits per input video channel.
- Set DITHER_MODE to the number of bits per output video channel supported by the Sink. By default, the HDMI Transmitter dithers the input (if DITHER is enabled) or truncates the input (if DITHER is disabled) to 8 bits.
- PB_CTRL1 and PB_CTRL2 should be programmed once the core is powered up only.
- Always clear (set to 0) the DE_ADJ field in IADJUST register when DE is not enabled (Recommended usage).
- DIV_ENC_BYP field in TEST_TXCTRL register should always be programmed to zero.
- ten_bit_bypass in TMDS_CNTL9 register and enc_byp in BIST_CNTL register should always be set to 1.
- Program the HDMI registers and then enable the VENC on VPSS side. All timings are provided by the VENC module in VPSS.

Figure 10-9. Transmitter Video Data Processing Path



10.3 HDMI Registers

Table 10-17 shows the base address offset for the HDMI registers. For the base address of the wrapper and core registers, see Table 1-11. For the base address of the PHY registers, see Table 1-12.

Table 10-17. HDMI Registers

Base Address Offset	Module	Section
0000h	HDMI Wrapper Registers	Section 10.3.1
0400h	HDMI Core System Registers	Section 10.3.2
0800h	HDMI IP Core Gamut Registers	Section 10.3.3
0900h	HDMI IP Core Audio Video Registers	Section 10.3.4
0D00h	HDMI IP Core CEC Registers	Section 10.3.5
2000h	HDMI PHY Registers	Section 10.3.6

10.3.1 HDMI Wrapper Registers

Table 10-18 lists the HDMI wrapper registers.

Table 10-18. HDMI Wrapper Registers

Address Offset	Acronym	Register Name
00h	HDMI_WP_REVISION	IP Revision Identifier
10h	HDMI_WP_SYSCONFIG	Clock management configuration
24h	HDMI_WP_IRQSTATUS_RAW	Raw Interrupt Status
28h	HDMI_WP_IRQSTATUS	Interrupt Status
2Ch	HDMI_WP_IRQENABLE_SET	Interrupt Enable
30h	HDMI_WP_IRQENABLE_CLR	Interrupt Disable
44h	HDMI_WP_DEBOUNCE	Glitch filter
50h	HDMI_WP_VIDEO_CFG	Configuration of HDMI Wrapper video
70h	HDMI_WP_CLK	Configuration of clocks
80h	HDMI_WP_AUDIO_CFG	Audio Configuration in FIFO
84h	HDMI_WP_AUDIO_CFG2	Audio configuration of DMA
88h	HDMI_WP_AUDIO_CTRL	Audio FIFO control
8Ch	HDMI_WP_AUDIO_DATA	TX Data of FIFO

10.3.1.1 IP Revision Identifier Register (HDMI_WP_REVISION)

The IP revision identifier register is shown in Figure 10-10 and described in Table 10-19.

Figure 10-10. IP Revision Identifier Register (HDMI_WP_REVISION)

31	0
Revision	
R-5003 0200h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

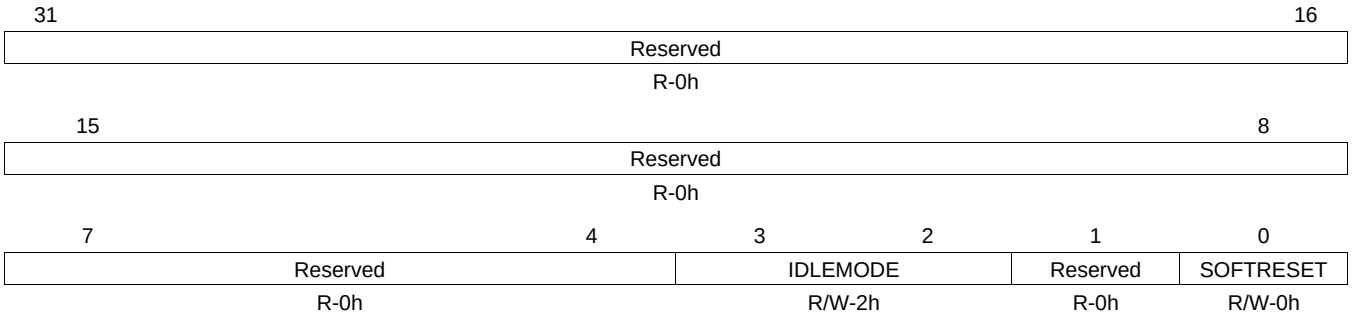
Table 10-19. IP Revision Identifier Register (HDMI_WP_REVISION) Field Descriptions

Bit	Field	Description
31-0	Revision	IP Revision

10.3.1.2 Clock Management Configuration Register (HDMI_WP_SYSCONFIG)

The Clock management configuration register is shown in Figure 24-23 and described in Table 10-20.

Figure 10-11. Clock Management Configuration Register (HDMI_WP_SYSCONFIG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-20. Clock Management Configuration Register (HDMI_WP_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3-2	IDLEMODE		Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. Default = 2h.
		0	Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, that is regardless of the IP module's internal requirements. Backup mode, for debug only.
		1h	No-idle mode: local target never enters idle state. Used in case Audio is transferred (to avoid DSS_L3_ICLK clock to be shut down)
		2h	Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module should not generate (IRQ- or DMA-request-related) wakeup events. To be used, if only Video is transmitted (since the DSS_L3_ICLK clock is not required)
		3h	Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.
1	Reserved	0	Reserved
0	SOFTRESET		Software reset. (Optional)
		R0	Software reset done, no pending action
		W0	No action
		R1	Software reset ongoing
		W1	Initiate software reset

10.3.1.3 Raw Interrupt Status Register (HDMI_WP_IRQSTATUS_RAW)

The raw interrupt status register is shown in Figure 10-12 and described in Table 10-21.

Figure 10-12. Raw Interrupt Status Register (HDMI_WP_IRQSTATUS_RAW)

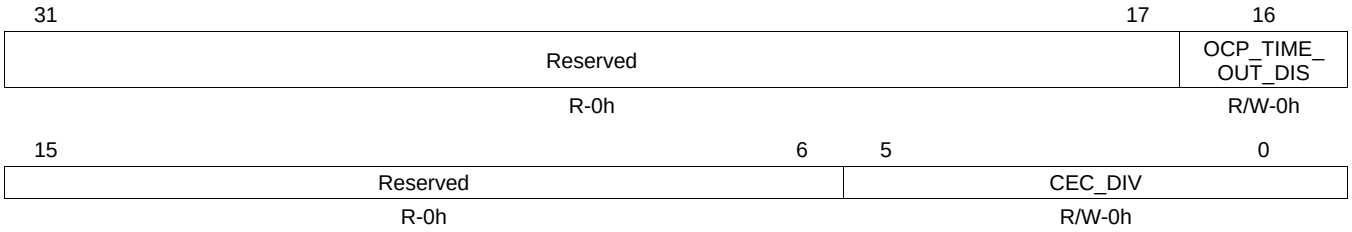
31-11	Reserved	20h	Reserved
10-8	PACKING_MODE	0	Used to pack 10-bits RGB or YUV444 input data in case the video input is not already packed. Will pack video_data[35:26] - video_data[23:14] - video_data[11:2]
		1h	Used to pack 24-bits RGB, 24-bit YUV444, 16-bit YUV422 or 24-bit YUV422 input data in case the video input is not already packed. Will pack video_data[35:28] - video_data[23:16] - video_data[11:4]
		2h	Used to pack 20-bits YUV422 input data in case the video input is not already packed. Will pack video_data[35:28] - video_data[23:16] - video_data[11:10] - video_data[7:6]
		3h-6h	Reserved
		7h	No change on input video_data lines. The video_data[35:0] is provided to the core without any change on it.
7-6	Reserved	0	Reserved
5	CORE_VSYNC_INV		Enables to invert or not the VSYNC signal provided to the HDMI core
		0	VSYNC is unchanged
		1	VSYNC is inverted
4	CORE_HSYNC_INV		Enables to invert or not the HSYNC signal provided to the HDMI core
		0	HSYNC is unchanged
		1	HSYNC is inverted
3-2	Reserved	0	Reserved
1-0	MODE	0	Always program to 0

10.3.1.9 Configuration of Clocks Register (HDMI_WP_CLK)

The configuration of clocks register is shown in Figure 10-18 and described in Table 10-27.

Figure 10-18. Configuration of Clocks Register (HDMI_WP_CLK)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-27. Configuration of Clocks Register (HDMI_WP_CLK) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	OCP_TIME_OUT_DIS		Timeout in case CEC_DDC_CLK not provided.
		0	Timeout after 4095 OCP clock cycles after inactivity. HDMI Core register interface (due to CEC_DDC_CLK not provided to HDMI). An interrupt is generated. No error response is provided on the OCP interface.
		1	No timeout capability
15-6	Reserved	0	Reserved
5-0	CEC_DIV		Defines the divisor value to be used for the generation of the CEC clock (1 MHz) from the input CEC_DDC clock (48 MHz). If 48 MHz is provided, the division by 24 is required (18h) to get the expected CEC clock speed (2 MHz) The valid values are from 0 to 63.
		0	Gated
		1	Free-running

10.3.1.10 Audio Configuration in FIFO Register (HDMI_WP_AUDIO_CFG)

The audio configuration in FIFO register is shown in Figure 10-19 and described in Table 10-28.

Table 10-28. Audio Configuration in FIFO Register (HDMI_WP_AUDIO_CFG) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reserved
26-24	STEREO_CHANNEL_ENABLE		This field contains the number of stereo channels enabled in the HDMI_CORE module. Must be set by the software and aligned with the register set in the HDMI_core.
		0	No stereo channel enabled in the HDMI_core module
		1h	1 stereo channel enabled in the HDMI_core module
		2h	2 stereo channels enabled in the HDMI_core module
		3h	3 stereo channels enabled in the HDMI_core module
		4h	4 stereo channels enabled in the HDMI_core module
		5h-7h	Reserved
23-16	AUDIO_CHANNEL_LOCATION	3h	This field contains which channels are active. It is used also to define which registers are stuffed with zero.
15-6	Reserved	0	Reserved
5	BLOCK_START_END_DISABLE		This field disables or not the block end start generation. This field does not affect the pcm format.
		0	Block signals are generated.
		1	Block signals are not generated; Block start is set to high and block end to low
4	IEC		Indicate if the format of the FIFO is compliant with the IEC format.
		0	Audio format is L-PCM; Format not aligned with IEC
		1	Audio format is IEC 60 958/61937; Format is aligned with IEC format
3	JUSTIFY		This field shows the justification (not applicable if IEC format)
		0	Justify left
		1	Justify right
2	LEFT_BEFORE		DO NOT USE—Software always uses LEFT_BEFORE = 1
		0	The first sample is the right
		1	The first sample is the left
1	SAMPLE_NBR		This field indicates the number of sample per word (32 bits) (not applicable if IEC format)
		0	1 sample per word, 32 bit
		1	2 samples per word, 32 bits (only compatible with sample on 16 bits)

Table 10-28. Audio Configuration in FIFO Register (HDMI_WP_AUDIO_CFG) Field Descriptions (continued)

Bit	Field	Value	Description
0	SAMPLE_SIZE		Audio sample size, 16 bits or 24 bits (not applicable if IEC format)
		0	Sample is on 16 bits
		1	Sample is on 24 bits

10.3.1.11 Audio Configuration of DMA Register (HDMI_WP_AUDIO_CFG2)

The audio configuration of DMA register is shown in Figure 10-20 and described in Table 10-29.

Bit	Field	Value	Description
31	WRAPPER_ENABLE		This filed enable the audio wrapper. When disable the audio path is under reset Register setting are not affected by the enable.
		0	Wrapper is disabled
		1	Wrapper is enabled
30	CORE_REQ_ENABLE	0	Enables the Audio data request generated by the core. This is used to start the audio data transmission from the wrapper to the core. This must be enabled only after the 5th VSYNC is generated to ensure that the Audio and Video are in Sync.
29-26	Reserved	0	Reserved
25-16	NUMBER_OF_SAMPLE	0	Shows the number of valid sample (16 or 24 bits) in the FIFO (depends of the FIFO format setting)
15-10	Reserved	0	Reserved
9	DMA_OR_IRQ		Indicated if the threshold generates a DMA or an IRQ
		0	When the threshold is reached a DMA req will be generated
		1	When the threshold is reached an IRQ will be generated
8-0	THRESHOLD_VALUE	10h	The DMA/IRQ is generated if the number of sample (24 or 16 bit) in the FIFO is less or equal to the threshold value. The maximum threshold is 511 and the minimum is 0.

10.3.1.13 TX Data of FIFO Register (HDMI_WP_AUDIO_DATA)

The TX data of FIFO register is shown in Figure 10-22 and described in Table 10-31.

Figure 10-22. TX Data of FIFO Register (HDMI_WP_AUDIO_DATA)

31	0
FIFO_DATA	
W-0h	

LEGEND: W = Write only; *-n* = value after reset

Table 10-31. TX Data of FIFO Register (HDMI_WP_AUDIO_DATA) Field Descriptions

Bit	Field	Description
31-0	FIFO_DATA	Audio TX DATA. Can be accessed in 32-bit mode only. Read returns 0.

10.3.2 HDMI Core System Registers

Table 10-32 lists the HDMI core system registers.

Table 10-32. HDMI Core System Registers

Address Offset	Acronym	Register Name
00h	VND_IDL	Vendor ID Register
04h	VND_IDH	Vendor ID Register
08h	DEV_IDL	Device ID Register
0Ch	DEV_IDH	Device ID Register
10h	DEV_REV	Device Revision Register
14h	SRST	Software Reset Register
20h	SYS_CTRL1	System Control Register 1
24h	SYS_STAT	System Status Register
28h	SYS_CTRL3	Legacy Registers
34h	DCTL	Data Control Register
3Ch	HDCP_CTRL	HDCP Control Register
40h-50h	BKSV__0 - BKSV__4	HDCP BKSV Register
54h-70h	AN__0 - AN__7	HDCP AN Register
74h-84h	AKSV__0 - AKSV__4	HDCP AKSV Register
88h	RI1	HDCP Ri Register
8Ch	RI2	HDCP Ri Register
90h	RI_128_COMP	HDCP Ri 128 Compare Register
94h	I_CNT	HDCP I Counter Register
98h	RI_STAT	Ri Status Register
9Ch	RI_CMD	Ri Command Register
A0h	RI_START	Ri Line Start Register
A4h	RI_RX_L	Ri From RX Registers
A8h	RI_RX_H	Ri From RX Registers
ACh	RI_DEBUG	Ri Debug Registers
C8h	DE_DLY	VIDEO DE Delay Register
C8h	DE_DLY	VIDEO DE Delay Register
CCh	DE_CTRL	VIDEO DE Control Register
D0h	DE_TOP	VIDEO DE Top Register
D8h	DE_CNTL	VIDEO DE Count Register
DCh	DE_CNTH	VIDEO DE Count Register
E0h	DE_LINL	VIDEO DE Line Register
E4h	DE_LINH_1	VIDEO DE Line Register
E8h	HRES_L	Video H Resolution Register
ECh	HRES_H	Video H Resolution Register
F0h	VRES_L	Video V Resolution Register
F4h	VRES_H	Video V Resolution Register
F8h	IADJUST	Video Interlace Adjustment Register
FCh	POL_DETECT	Video SYNC Polarity Detection Register
100h	HBIT_2HSYNC1	Video Hbit to HSYNC Register
104h	HBIT_2HSYNC2	Video Hbit to HSYNC Register
108h	FLD2_HS_OFSTL	Video Field2 HSYNC Offset Register
10Ch	FLD2_HS_OFSTH	Video Field2 HSYNC Offset Register
110h	HWIDTH1	Video HSYNC Length Register
114h	HWIDTH2	Video HSYNC Length Register
118h	VBIT_TO_VSYNC	Video Vbit to VSYNC Register

Table 10-32. HDMI Core System Registers (continued)

Address Offset	Acronym	Register Name
11Ch	VWIDTH	Video VSYNC Length Register
120h	VID_CTRL	Video Control Register
124h	VID_ACEN	Video Action Enable Register
128h	VID_MODE	Video Mode1 Register
12Ch	VID_BLANK1	Video Blanking Registers
130h	VID_BLANK2	Video Blanking Registers
134h	VID_BLANK3	Video Blanking Registers
138h	DC_HEADER	Deep Color Header Register
13Ch	VID_DITHER	Video Mode2 Register
140h	RGB2XVYCC_CT	RGB_2_xvYCC control Register
144h	R2Y_COEFF_LOW	RGB_2_xvYCC Conversion R_2_Y Register
148h	R2Y_COEFF_UP	RGB_2_xvYCC Conversion R_2_Y Register
14Ch	G2Y_COEFF_LOW	RGB_2_xvYCC Conversion G_2_Y Register

3BCh	DDC_OFFSET	DDC I2C Target Offset Address Register
3C0h	DDC_COUNT1	DDC I2C Data Count Register
3C4h	DDC_COUNT2	DDC I2C Data Count Register
3C8h	DDC_STATUS	DDC I2C Status Register
3CCh	DDC_CMD	DDC I2C Command Register
3D0h	DDC_DATA	DDC I2C Data Register
3D4h	DDC_FIFOCNT	DDC I2C FIFO Count Register
3E4h	EPST	ROM Status Register
3E8h	EPCM	ROM Command Register

10.3.2.1 Vendor IDL Register (VND_IDL)

The vendor IDL register is shown in Figure 10-23 and described in Table 10-33.

Figure 10-23. Vendor ID Register (VND_IDL)

31	8	7	0
Reserved		VND_IDL	
R-0h		R-1h	

LEGEND: R = Read only; -*n* = value after reset

Table 10-33. Vendor ID Register (VND_IDL) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	VND_IDL	Vendor ID low byte. Provides unique vendor identification through I2C.

10.3.2.2 Vendor IDH Register (VND_IDH)

The vendor IDH register is shown in Figure 10-24 and described in Table 10-34.

Figure 10-24. Vendor ID Register (VND_IDH)

31	8	7	0
Reserved		VND_IDH	
R-0h		R-0h	

LEGEND: R = Read only; -*n* = value after reset

Table 10-34. Vendor ID Register (VND_IDH) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	VND_IDH	Vendor ID high byte. Provides unique vendor identification through I2C.

10.3.2.3 Device IDL Register (DEV_IDL)

The device IDL register is shown in Figure 10-25 and described in Table 10-35.

Figure 10-25. Device IDL Register (DEV_IDL)

31	8	7	0
Reserved		DEV_IDL	
R-0h		R-36h	

LEGEND: R = Read only; -*n* = value after reset

Table 10-35. Device IDL Register (DEV_IDL) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DEV_ID	Device ID low byte. Provides unique vendor identification through I2C.

10.3.2.4 Device IDH Register (DEV_IDH)

The device IDH register is shown in Figure 10-26 and described in Table 10-36.

Figure 10-26. Device IDH Register (DEV_IDH)

31	8	7	0
Reserved		DEV_IDH	
R-0h		R-97h	

LEGEND: R = Read only; -*n* = value after reset

Table 10-36. Device IDH Register (DEV_IDH) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DEV_ID	Device ID high byte. Provides unique vendor identification through I2C.

10.3.2.5 Device Revision Register (DEV_REV)

The device revision register is shown in Figure 10-27 and desribed in Table 10-37.

Figure 10-27. Device Revision Register (DEV_REV)

31	8	7	0
Reserved		DEV_REV	
R-0h		R-0h	

LEGEND: R = Read only; -*n* = value after reset

Table 10-37. Device Revision Register (DEV_REV) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DEV_REV	Allows distinction between revisions of same device.

10.3.2.6 Software Reset Register (SRST)

The software reset register (SRST) is shown in Figure 10-28 and described in Table 10-38.

Figure 10-28. Software Reset Register (SRST)

31	16
Reserved	
R-0h	

15	2	1	0
Reserved		FIFORST	SWRST
R-0h		R/W-0h	R/W-0h

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-38. Software Reset Register (SRST) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	FIFORST		Audio FIFO reset
		0	Normal operation
		1	Reset (flush) audio FIFO
0	SWRST		Software reset
		0	Normal operation
		1	Reset all sections, including audio FIFO but not writable registers or HDCP

10.3.2.7 System Control Register 1 (SYS_CTRL1)

The system control register 1 is shown in Figure 10-29 and described in Table 10-39.

Figure 10-29. System Control Register 1 (SYS_CTRL1)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R-0h	R-x	R/W-1h	R/W-1h	R-0h	R/W-1h	R/W-0h	R/W-0h

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; x = value is indeterminate

Table 10-39. System Control Register 1 (SYS_CTRL1) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	VSYNC	x	The current status of the VSYNC input pin. Refer to the INTR2 register for an interrupt tied to VSYNC active edge.
5	VEN		VSYNC enable
		0	Fixed LOW
		1	Follow VSYNC input
4	HEN		HSYNC enable
		0	Fixed LOW
		1	Follow HSYNC input
3	Reserved	0	Reserved
2	BSEL		Input bus select
		0	12-bit Data Bus
		1	24-bit Data Bus
1	EDGE		Edge select
		0	Latch Input on Falling Edge
		1	Latch Input on Rising Edge
0	PD		Power down mode. Most other register values are not affected by assertion of the PD bit.
		0	Interrupts are in power-down mode
		1	Normal operation

10.3.2.8 System Status Register (SYS_STAT)

The system status register is shown in Figure 10-30 and described in Table 10-40.

Figure 10-30. System Status Register (SYS_STAT)

31	16
Reserved	
R-0h	

15	8

R-0h	

7	6	3	2	1	0
VLOW	Reserved		RSEN	HPD	P_STABLE
R-1h	R-0h		R-x	R-X	R-x

LEGEND: R = Read only; -*n* = value after reset; x = value is indeterminate

Table 10-40. System Status Register (SYS_STAT) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	VLOW	1	VREF mode. Always HIGH.
6-4	Reserved	0	Reserved
2	RSEN		Receiver sense (works in DC-coupled systems only) RSEN is active when the TMDS link is terminated, usually into a powered-on TMDS receiver chip. An active RSEN implies an active Hot Plug Detect; as the link must also be physically connected.
		0	No receiver is connected
		1	Receiver is connected and powered on
1	HPD	x	Hot plug detect. The state of the hot plug detect pin can be read here.
0	P_STABLE	x	IDCK (io_pclkpin) to TMDS clock (v_ck2x) is stable and the Transmitter can send reliable data on the TMDS link. A change to the IDCK sets this bit LOW. After a subsequent LOW to HIGH transition, indicating a stable input clock, a software reset is recommended.

10.3.2.9 System Control Register 3 (SYS_CTRL3)

The system control register 3 is shown in Figure 10-31 and shown in Table 10-41.

Figure 10-31. System Control Register 3 (SYS_CTRL3)

31	16
Reserved	
R-0h	

15	3	2	1	0

Table 10-41. System Control Register 3 (SYS_CTRL3) Field Descriptions

Bit	Field	Description
31-3	Reserved	Reserved
2-1	CTL	The states of these control bits are transmitted across the TMDS link during blanking times for DVI 1.0 mode only.
0	Reserved	Reserved

10.3.2.10 Data Control Register (DCTL)

The data control register is shown in Figure 10-32 and described in Table 10-42.

Figure 10-32. Data Control Register (DCTL)

31	16
Reserved	
R-0h	

15	3	2	1	0
Reserved		VID_BLANK	AUD_MUTE	HDCP_SEL
R-0h		R/W-0h	R/W-0h	R-0h

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 10-42. Data Control Register (DCTL) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2	VID_BLANK	0	Normal operation (video output is not blanked)
		1	Video output is blanked and the colors sent are those specified in registers VID_BLANK1, VID_BLANK2, and VID_BLANK3.
1	AUD_MUTE	0	Do not send zeroes in audio pocket
		1	Send zeroes in audio pocket
0	HDCP_SEL	0	This register gets the value of the pin io_hdcp_sel. When connected to 1 b0; enables firmware to take the decision whether to send unencrypted data or not. By connecting to 1 b1; HDMI Tx will be able to send ONLY encrypted data.

10.3.2.11 HDCP Control Register (HDCP_CTRL)

The HDCP control register is shown in Figure 10-33 and described in Table 10-43.

Figure 10-33. HDCP Control Register (HDCP_CTRL)

R-0h	R-0h	R-0h	R/W-0h	R/W-0h	R/W-0h	R-0h	R/W-0h

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-43. HDCP Control Register (HDCP_CTRL) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	ENC_ON		Encryption status
		0	Encryption disabled or not in progress
		1	Encryption enabled and in progress
5	BKSV_ERR		BKSV error. To clear BKSV_ERR; the firmware must first set the TX_ANSTOP bit; then perform an authentication twice with a valid BKSV value.
		0	No error in BKSV format
		1	Error in BKSV format
4	RX_RPTR		Repeater. If the HDMI Receiver is in a Repeater, write bit 4 (RX_RPTR) to 1 before beginning the authentication process. Note: This bit is written when the Source device detects an attached HDCP Repeater device. This is a necessary step in the computation of shared values in the HDCP protocol. For more information, sefer section 2.2 in the HDCP 1.0 Specification.
		0	Single HDMI Receiver
		1	HDMI Receiver is a Repeater
3	TX_ANSTOP	0	AN control. When cleared; the cipher engine is allowed to free run and the AN registers cycle through pseudo-random values. When set; the cipher engines stops and the AN register may be read and initialized in the HDCP-capable Receiver. To clear this bit; toggle the RX_RPTR bit. This bit is also cleared when the hardware is reset or BKSV_ERR is set.
2	CP_RESTN		Content protection reset
		0	Reset
		1	Normal operation
1	RI_RDY		Ri Ready
		0	Ri first value is not ready
		1	Ri first value is ready in the HDMI Transmitter. Cleared by a hardware reset. This bit is also cleared when the first byte of BKSV is written into the HDMI Transmitter (performed at the beginning of the next authentication process).
0	ENC_EN		Encryption enable
		0	Encryption is disabled
		1	Encryption is enabled. See description of HDCP_SEL bit in register DCTL (see Section 10.3.2.10).

10.3.2.12 HDCP BKSV Register (BKSV__0-BKSV__4)

The HDCP BKSV register is shown in Figure 10-34 and described in Table 10-44.

Figure 10-34. HDCP BKSV Register (BKSV__0-BKSV__4)

31	8	7	0
Reserved		BKSV	
R-0h		R/W-0h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-44. HDCP BKSV Register (BKSV__0-BKSV__4) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	BKSV	Write : Written with the HDCP receiver key selection vector register value. Writing 5th BKSV byte triggers the authentication logic in the HDMI Transmitter. Write this byte last.

10.3.2.13 HDCP AN Register (AN__0-AN__7)

The HDCP AN register is shown in Figure 10-35 and described in Table 10-45.

Figure 10-35. HDCP AN Register (AN__0-AN__7)

31	8	7	0
Reserved		AN	
R-0h		R/W-0h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-45. HDCP AN Register (AN__0-AN__7) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	AN	AN value is an HDCP 64-Bit pseudo-random value.

10.3.2.14 HDCP AKSV Register (AKSV__0-AKSV__4)

The HDCP AKSV registe is shown in Figure 10-36 and described in Table 10-46.

Figure 10-36. HDCP AKSV Register (AKSV__0-AKSV__4)

31	8	7	0
Reserved		AKSV	
R-0h		R-x	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; x = value is indeterminate

Table 10-46. HDCP AKSV Register (AKSV__0-AKSV__4) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	AKSV	HDCP-capable transmitter s key selection vector. Fifth AKSV byte triggers the authentication logic in the receiver. Write this byte last.

10.3.2.15 HDCP Ri1 Register (RI1)

The HDCP Ri1 register is shown in Figure 10-37 and described in Table 10-47.

Figure 10-37. HDCP Ri1 Register (RI1)

31	8	7	0
Reserved		RI	
R-0h		R-0h	

LEGEND: R = Read only; -*n* = value after reset

Table 10-47. HDCP Ri Register (RI1) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	RI1	R1i register. The value of this register should be read and compared with the HDMI Receiver s Ri value.

10.3.2.16 HDCP Ri2 Register (RI2)

The HDCP Ri2 register is shown in Figure 10-38 and described in Table 10-48.

Figure 10-38. HDCP Ri2 Register (RI2)

31	8	7	0
Reserved		RI2	
R-0h		R-0h	

LEGEND: R = Read only; -*n* = value after reset

Table 10-48. HDCP Ri2 Register (RI2) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	RI2	Ri2 register. The value of this register should be read and compared with the HDMI Receiver s Ri value.

10.3.2.17 HDCP Ri 128 Compare Register (RI_128_COMP)

The HDCP Ri 128 compare register is shown in Figure 10-39 and described in Table 10-49.

Figure 10-39. HDCP Ri 128 Compare Register (RI_128_COMP)

31	7	6	0
Reserved		RI_128_COMP	
R-0h		R/W-0h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-49. HDCP Ri 128 Compare Register (RI_128_COMP) Field Descriptions

Bit	Field	Description
31-7	Reserved	Reserved
6-0	RI_128_COMP	Limit counter for Ri comparison. When the frame counter (I_CNT) reaches the index set in this register an RI_128 interrupt is generated.

10.3.2.18 HDCP I Counter Register (I_CNT)

The HDCP I counter register is shown in Figure 10-40 and described in Table 10-50.

Figure 10-40. HDCP I Counter Register (I_CNT)

31	7	6	0
Reserved		I_CNT	
R-0h		R-0h	

LEGEND: R = Read only; -*n* = value after reset

Table 10-50. HDCP I Counter Register (I_CNT) Field Descriptions

Bit	Field	Description
31-7	Reserved	Reserved
6-0	I_CNT	Current value of I counter. This register counts frames from 0 to 127, then rolls over to zero.

10.3.2.19 Ri Status Register (RI_STAT)

The Ri status register is shown in Figure 10-41 and described in Table 10-51.

Figure 10-41. Ri Status Register (RI_STAT)

31	1	0
Reserved		RI_STARTED
R-0h		R-0h

LEGEND: R = Read only; -*n* = value after reset

Table 10-51. Ri Status Register (RI_STAT) Field Descriptions

Bit	Field	Description
31-1	Reserved	Reserved
0	RI_STARTED	Ri check started status. This signal is used for handshaking between the firmware and the hardware. After the Ri check is enabled, the hardware waits for the DDC master to finish the current transaction before taking control. After this bit is set, the firmware loses the ability to use the DDC Master, unless it disables Ri Check and resets to 0.

10.3.2.20 Ri Command Register (RI_CMD)

The Ri command register is shown in Figure 10-42 and described in Table 10-52.

Figure 10-42. Ri Command Register (RI_CMD)

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	BCAP_EN		Enable polling of the BCAP_DONE bit (in the register INTR2). Note: To poll the BCAP_DONE bit; the ENC_EN (in HDPC_CTRL register) bit and the Ri_EN (in RI_CMD register) bit must be enabled on the HDMI Transmitter.
		0	Disable
		1	Enable
0	RI_EN		Enable Ri check. Check bit RI_STARTED of the Ri_STAT register for firmware and hardware DDC control handshaking.
		0	Disable
		1	Enable

10.3.2.21 Ri Line Start Register (RI_START)

The Ri line start register is shown in Figure 10-43 and described in Table 10-53.

Figure 10-43. Ri Line Start Register (RI_START)

31	8	7	0
Reserved		RI_LINE_START	
R-0h		R/W-4h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-53. Ri Line Start Register (RI_START) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	RI_LINE_START	Indicates at what line within frame 127 or 0 to start the Ri Check. Note that the value for this register bit represents the power of 2; the 2 LSBs are 0.

10.3.2.22 Ri From RX Registers (Low) (RI_RX_L)

The Ri from RX registers (low) are shown in Figure 10-44 and described in Table 10-54.

Figure 10-44. Ri From RX Registers (Low) (RI_RX_L)

31	8	7	0
Reserved		RI_RX	
R-0h		R-0h	

LEGEND: R = Read only; -*n* = value after reset

Table 10-56. Ri Debug Registers (RI_DEBUG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	RI_DBG_TRASH		Ri value trash
		0	Continue with regular updates to Ri
		1	Force a corruption of the Ri values
6	RI_DBG_HOLD		Ri value hold
		0	Continue with regular updates to Ri
		1	Hold the Ri value steady; stop updating
5-0	Reserved	0	Reserved

10.3.2.25 VIDEO DE Delay Register (DE_DLY)

The VIDEO DE delay register is shown in Figure 10-47 and described in Table 10-57.

Figure 10-47. VIDEO DE Delay Register (DE_DLY)

31	8	7	0
Reserved		DE_DLY[7:0]	
R-0h		R/W-0h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-57. VIDEO DE Delay Register (DE_DLY) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DE_DLY	Width of the area to the left of the active display. The unit of measure is pixels. This register should be set to the sum of (HSYNC width) + (horizontal back porch) + (horizontal left border), and is used only for DE generation. Note that this 12-bit value includes four bits from register DE_CTRL (see Section 10.3.2.26). The valid range is 1-4095. 0 is invalid.

10.3.2.26 VIDEO DE Control Register (DE_CTRL)

The VIDEO DE control register is shown in Figure 10-48 and described in Table 10-58.

Figure 10-48. VIDEO DE Control Register (DE_CTRL)

Table 10-58. VIDEO DE Control Register (DE_CTRL) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	DE_GEN		Generate DE signal
		0	Disabled
		1	Enabled
5	VS_POL		VSYNC polarity
		0	Positive polarity (leading edge rises)
		1	Negative polarity (leading edge falls)
			Set this bit to the input VSYNC polarity for the source that provides VSYNC. For embedded syncs, set this bit to the desired VSYNC polarity that is generated from the embedded sync codes.
4	HS_POL		HSYNC polarity
		0	Positive polarity (leading edge rises)
		1	Negative polarity (leading edge falls)
			Set this bit to the input HSYNC polarity for the source that provides HSYNC. For embedded syncs, set this bit to the desired HSYNC polarity that is generated from the embedded sync codes.
3-0	DE_DLY	0	Width of the area to the left of the active display. The unit of measure is pixels. This register should be set to the sum of (HSYNC width) + (horizontal back porch) + (horizontal left border), and is used only for DE generation.
			Note that this 12-bit value includes eight bits from register DE_DLY (see Section 10.3.2.25).

10.3.2.27 VIDEO DE Top Register (DE_TOP)

The VIDEO DE top register is shown in Figure 10-49 and described in Table 10-59.

Figure 10-49. VIDEO DE Top Register (DE_TOP)

31	8	7	0
Reserved		DE_TOP

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 10-68. Video Interlace Adjustment Register (IADJUST) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2	DE_ADJ		Setting this bit HIGH disables VSYNC adjustments and sets the DE generator to be more compatible with the existing transmitters. Clearing this bit enables detection circuits to locate the position of VSYNC relative to HSYNC and only include HSYNC edges that are greater than 3/4 lines from VSYNC in the line count for DE_TOP. Enable VSYNC detection when not using DE generator.
		0	Enable VSYNC
		1	Disable VSYNC.
1	F2VADJ		VBIT_TO_VSYNC value (in register VBIT_TO_VSYNC) adjust enable
		0	The VBIT_TO_VSYNC value is not adjusted.
		1	The VBIT_TO_VSYNC value is adjusted during field 2 of an interlace frame according to the setting of the F2VOFST bit.
0	F2VOFST		VBIT_TO_VSYNC value (in register VBIT_TO_VSYNC) offset
		0	If F2VADJ is set, VBIT_TO_VSYNC is decremented by one during field 2 of an interlace frame.
		1	If F2VADJ is set, VBIT_TO_VSYNC is incremented by one during field 2 of an interlace frame.

10.3.2.37 Video SYNC Polarity Detection Register (POL_DETECT)

The video SYNCH polarity detection register is shown in Figure 10-59 and described in Table 10-69.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-78. Video Control Register (VID_CTRL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	IFPOL		Invert field polarity. This bit is used when the 656 Flag bit is opposite the standard polarity for Field1 and Field2. Inverting the field polarity causes the sync extraction to format HSYNC and VSYNC properly based on the F bit. In embedded sync mode, the HDMI Transmitter does not detect even from odd field, except based on the setting of the F bit. With explicit syncs, the HDMI transmitter encodes HSYNC and VSYNC across the HDMI/TMDS link regardless of field sequence.
		0	Do not invert field bit
		1	Invert field bit
6	Reserved	0	Reserved
5	EXTN		Extended bit mode
		0	All 8-bit input modes
		1	All 12-bit 4:2:2 input modes. For 4:2:2 inputs wider than 8 bits but less than 12 bits; the unused bits should be cleared to 0.
4	CSCSEL		Color space conversion standard select
		0	BT.601 conversion
		1	BT.709 conversion
3-2	Reserved	0	Reserved
1-0	ICLK		Clock mode If the DEMUX bit in the VID_MODE register is cleared to 0, set the ICLK bit and the pixel replication field of the AVI v2 data byte 5 to the same value. If the DEMUX bit in the VID_MODE register is set to 1, set the pixel replication field of the AVI v2 data byte 5 to the next higher pixel replication rate. For example, if DEMUX = 1 and ICLK = 1, set the pixel replication field of AVI v2 data byte 5 to 3h.
		0	Pixel data is not replicated
		1h	Pixels are replicated once (each sent twice)
		2h	Reserved
		3h	Pixels are replicated 4 times (each sent four times)

10.3.2.47 Video Action Enable Register (VID_ACEN)

The video action enable register is shown in Figure 10-69 and described in Table 10-79.

Table 10-79. Video Action Enable Register (VID_ACEN) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-6	WIDE_BUS		Identifies the number of bits per input video channel
		0	8 bits per channel or 24-bit bus mode
		1h	10 bits per channel or 30-bit bus mode
		2h	12 bits per channel or 36-bit bus mode
		3h	Reserved
5	Reserved	0	Reserved
4	CLIP_CS_ID		Identifies the output color space on the link - used by the Clipper block to determine which way to clip
		0	Output color space is RGB 1
		1	Output color space is YCbCr
3	RANGE_CLIP		Enable range clip from 16 to 235 (RGB and Y)/ 240 (CbCr)
		0	Disable
		1	Enable
2	RGB_2_YCBCR		Enable RGB to YCbCr color-space converter
		0	Disable
		1	Enable
1	RANGE_CMPS		Enable range compress 0-255 to 16-234
		0	Disable
		1	Enable
0	DOWN_SMPL		Enable down sampler 4:4:4 to 4:2:2
		0	Disable
		1	Enable

10.3.2.48 Video Mode1 Register (VID_MODE)

The video mode1 register is shown in Figure 10-70 and described in Table 10-80.

Figure 10-70. Video Mode1 Register (VID_MODE)

Table 10-80. Video Mode1 Register (VID_MODE) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-6	DITHER_MODE		Identifies the number of bits per output video channel
		0	Dither to 8 bits
		1h	Dither to 10 bits
		2h	Dither to 12 bits
		3h	Reserved
5	DITHER		Dither enable
		0	Dither disabled; the video output is truncated to the output width specified in the DITHER_MODE bit.
		1	Dither enabled; the video output is dithered to the output width specified in the DITHER_MODE bit.
4	RANGE		Data range 16–235 to 0–255 expansion
			When this bit is set, the HDMI transmitter expands the range of pixel data values from 16-235 into the full 8-bit range of 0-255. This is suitable for translating input YCbCr data into output RGB data in PC modes that use the complete range. The HDMI Specification allows one non-CEA-861D mode in the first and only 18-byte descriptor of the Sink's EDID 1.3. This is the native resolution of the Sink, which may be RGB. It may be a standard PC resolution (XGA, SXGA, WXGA, and so on), or a specific native resolution. In these cases (or for a Sink with the Type B HDMI connector, which allows multiple PC modes), when the HDMI transmitter receives YCbCr data, the data must be expanded to full range for outputting RGB full-range modes.
		0	Disable
		1	Enable
3	CSC		YcbCr to RGB color space conversion
		0	Disable
		1	Enable
2	UPSMP		Upsampling 4:2:2 to 4:4:4

Reserved		INTR
R-0h		R-0h

LEGEND: R = Read only; -*n* = value after reset

Table 10-111. Interrupt State Register (INTR_STATE) Field Descriptions

Bit	Field	Description
31-1	Reserved	Reserved
0	INTR	Interrupt State. When an interrupt is asserted; this bit is set to 1. The polarity of the INT output signal is set using this bit and the POLARITY bit in the INT_CTRL register. Only INTR1, INTR2, INTR3, and INTR4 bits with matching set bits in INT_UNMASK can contribute to setting the INTR bit.

10.3.2.80 Interrupt Source Register (INTR1)

The interrupt source register is shown in Figure 10-102 and described in Table 10-112.

Figure 10-102. Interrupt Source Register (INTR1)

LEGEND: R = Read only; -*n* = value after reset

Table 10-112. Interrupt Source Register (INTR1) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7	SOFT	Software Induced Interrupt. Allows the firmware to generate an interrupt directly.
6	HPD	Monitor detect interrupt. Asserted if hot plug detect has changed state. The HDMI transmitter signals a change in the connectivity to a Sink, either unplug or plug. HDMI specifies that hot plug be active only when the Sink s EDID is ready to be read and that hot plug be toggled any time there is a change in connectivity downstream of an attached repeater.
5	RSEN	Receiver sense interrupt asserted if RSEN has changed. This interrupt is set whenever V_{CC} is applied to or removed from the attached HDMI receiver chip. A receiver with multiple input ports can also disconnect the TMDS termination to the unused port, which triggers this RSEN interrupt.
4	DROP_SAMPLE	New preamble forced to drop sample (S/PDIF input only). If the HDMI transmitter detects an 8-bit preamble in the S/PDIF input stream before the subframe has been captured, this interrupt is set. A S/PDIF input that stops signaling or a flat line condition can create such a premature preamble.
3	BIP_HASE_ERR	Input S/PDIF stream has bi-phase error. This can occur when there is noise or an Fs rate change on the S/PDIF input.
2	RI_128	Input counted past frame count threshold set in RI_128_COMP register. This interrupt occurs when the count written to register RI_128_COMP is matched by the VSYNC (frame) counter in the HDMI transmitter. It should trigger the firmware to perform a link integrity check. Such a match occurs every 128 frames.
1	OVER_RUN	Audio FIFO overflow. This interrupt occurs if the audio FIFO overflows when more samples are written into it than are drawn out across the HDMI link. Such a condition can occur from a transient change in the Fs or pixel clock rate.
0	UNDER_RUN	Audio FIFO underflow. Similar to OVER_RUN, this interrupt occurs when the audio FIFO empties.

10.3.2.81 Interrupt Source Register (INTR2)

The interrupt source register is shown in Figure 10-103 and described in Table 10-113.

Figure 10-103. Interrupt Source Register (INTR2)

LEGEND: R = Read only; -*n* = value after reset; x = value is indeterminate

Table 10-113. Interrupt Source Register (INTR2) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7	BCAP_DONE	If set, this interrupt detected that the FIFORDY bit is set to 1.
6	SPDIF_PAR	S/PDIF parity error. The S/PDIF stream includes a parity (P) bit at the end of each sub-frame. An interrupt occurs if the calculated parity does not match the state of this bit.
5	ENC_DIS	The ENC_EN bit (in register HDCP_CTRL) changed from 1 to 0. This interrupt occurs if encryption is turned off.
4	PREAM_ERR	This condition is the opposite of the condition that causes DROP_SAMPLE (in register INTR1). This interrupt occurs if a preamble is expected but not found when decoding the S/PDIF stream.
3	CTS_CHG	Change in ACR CTS value. This interrupt occurs when the change is of an unexpected magnitude. Such an interrupt should be expected when changing Fs or pixel clock frequency.
2	ACR_OVR	ACR packet overwrite. This interrupt occurs if the HDMI transmitter puts a NCTS packet into the queue before the previous NCTS packet has been sent. This can happen if very long active data times do not allow for sufficient NCTS packet bandwidth. For all CEA- 861D modes, no ACR_OVR interrupt should occur.
1	TCLK_STBL	Whenever IDCK changes, there is a temporary instability in the internal clocking. This interrupt is set when the internal clocking has stabilized.
0	VSYNC_REC	Asserted when VSYNC active edge is recognized. It is useful for triggering firmware actions that occur during vertical blanking.

10.3.2.82 Interrupt Source Register (INTR3)

The interrupt source register is shown in Figure 10-104 and described in Table 10-114.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-148. DDC I2C Command Register (DDC_CMD) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	DDC_FLT_EN		Enable the DCC delay. A DDC delay is inserted into the SDA line to create a 300 ns delay for the falling edge of the DDC SDA signal to avoid an erroneous I2C START condition. The real start condition must have a setup time of 600 ns so that this delay of 300 ns does not remove the real START condition. Filtering is done using a ring oscillator.
		0	Enable
		1	Disable
4	SDA_DEL_EN		Enable 3 ns glitch filtering on the DDC clock and data line. Filtering is done using a ring oscillator.
		0	Enable
		1	Disable
3-0	DDC_CMD		DDC command Writing to this register immediately initiates the I2C transaction on the DDC bus. Note: The clear FIFO command resets the FIFO read and write pointers to zero. Data formerly loaded into the FIFO cannot be re-read after a clear FIFO, as the FIFO will be empty. Other command codes are reserved and may cause the DDC bus to hang if used. The clock SCL command resets any I2C devices on the DDC lines. This should be initiated once before initiating the DDC commands.
		0	Current address read with no ACK on last byte
		2h	Sequential read with no ACK on last byte
		4h	Enhanced DDC read with no ACK on last byte
		6h	Sequential write ignoring ACK on last byte
		7h	Sequential write requiring ACK on last byte
		9h	Clear FIFO
		Ah	Clock SCL
		Fh	Abort transaction
			All other values are reserved.

10.3.2.117 DDC I2C Data Register (DDC_DATA)

The DDC I2C data register is shown in Figure 10-139 and described in Table 10-149.

Table 10-152. ROM Command Register (EPCM) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	LD_KSV		Load KSV enable
		0	Write 0 before enabling again
		1	Enable loading of KSV from OTP
4-0	EPCM		Command. Before writing a new value into this register, verify that the previous command is complete by checking the CMDD bit in the EPST register.
		3h	Run all BIST tests
		4h	Run only CRC test
		8h	Run only BIST self authentication test 1 (16-bit CRC to verify OTP contents)
		10h	Run only BIST self authentication test 2 (2 pass authentication to verify the HDCP cipher engine)
			All other values are reserved.

10.3.3 HDMI IP Core Gamut Registers

Table 10-153 lists the HDMI IP core gamut registers.

Table 10-153. HDMI IP Core Gamut Registers

Address Offset	Acronym	Register Name
00h	GAMUT_HEADER1	Gamut Metadata Register
04h	GAMUT_HEADER2	Gamut Metadata Register
08h	GAMUT_HEADER3	Gamut Metadata Register
0Ch-78h	GAMUT_DBYTE__0 - GAMUT_DBYTE__27	Gamut Metadata Registers

10.3.3.1 Gamut Metadata Register (GAMUT_HEADER1)

The gamut metadata register is shown in Figure 10-143 and described in Table 10-154.

Figure 10-143. Gamut Metadata Register (GAMUT_HEADER1)

31	8	7	0
Reserved		HEADER1

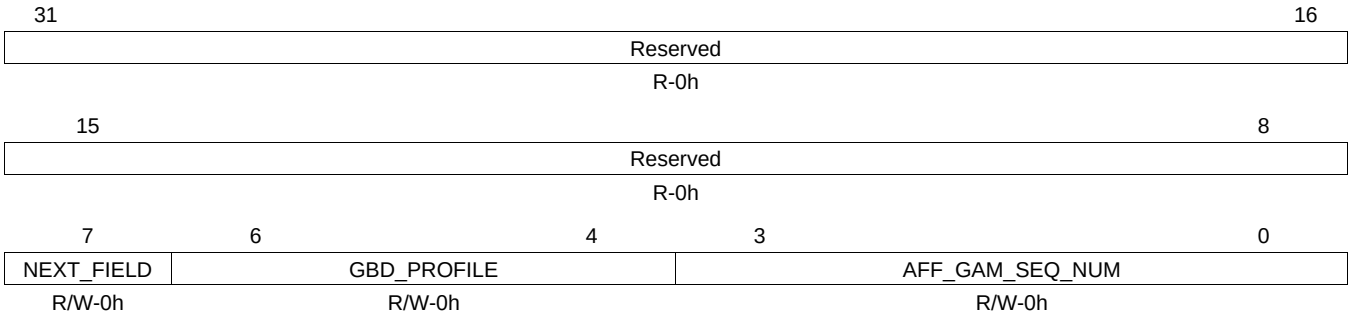
Bit	Field	Description
31-8	Reserved	Reserved
7-0	HEADER1	Gamut metadata header information

10.3.3.2 Gamut Metadata Register (GAMUT_HEADER2)

The gamut metadata register is shown in Figure 10-144 and described in Table 10-155.

Figure 10-144. Gamut Metadata Register (GAMUT_HEADER2)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

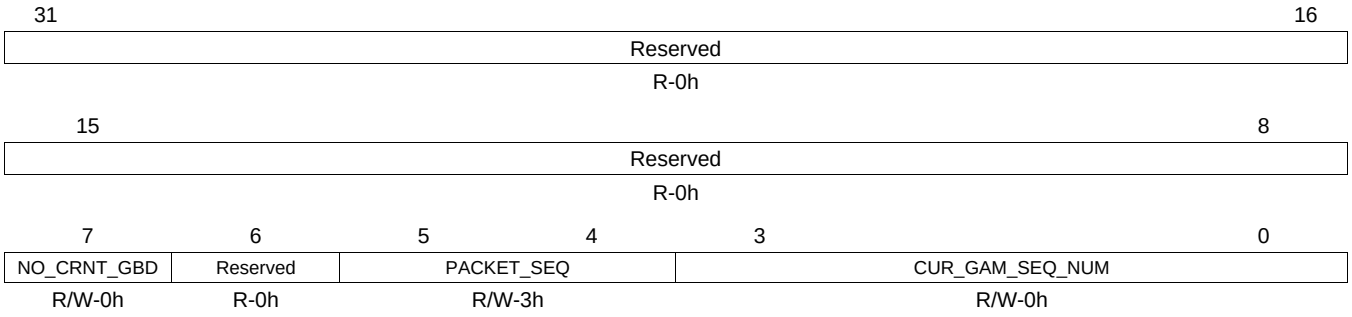
Table 10-155. Gamut Metadata Register (GAMUT_HEADER2) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	NEXT_FIELD	0	Indicates that the GBD will be effective on the next video field. NEXT_FIELD should be set even if the GBD is already effective (for example, Current = Affected)
6-4	GBD_PROFILE		Transmission profile number. Values from 4h-7h are reserved.
		0	P0
		1h	P1
		2h	P2
		3h	P3
3-0	AFF_GAM_SEQ_NUM	0	Indicates which video fields are relevant for this metadata.

10.3.3.3 Gamut Metadata Register (GAMUT_HEADER3)

The gamut metadata register is shown in Figure 10-145 and described in Table 10-156.

Figure 10-145. Gamut Metadata Register (GAMUT_HEADER3)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

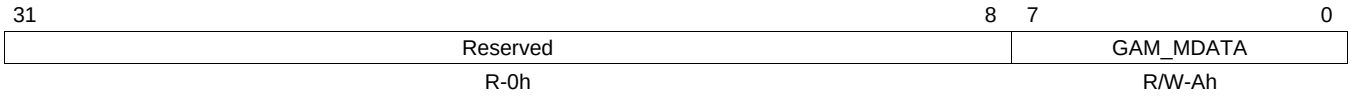
Table 10-156. Gamut Metadata Register (GAMUT_HEADER3) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	NO_CRNT_GBD	0	Indicates no gamut metadata available for currently transmitted video. When set to 1, CUR_GAM_SEQ_NUM shall be ignored by the sink.
6	Reserved	0	Reserved
5-4	PACKET_SEQ		Indicates the position of current packet.
		0	Intermediate packet
		1h	First packet
		2h	Last packet
		3h	Only packet in sequence
3-0	CUR_GAM_SEQ_NUM	0	Indicates the gamut number of the currently transmitted video stream.

10.3.3.4 Gamut Metadata Registers (GAMUT_DBYTE__0-GAMUT_DBYTE__27)

The gamut metadata registers are shown in Figure 10-146 and described in Table 10-157.

Figure 10-146. Gamut Metadata Registers (GAMUT_DBYTE__0-GAMUT_DBYTE__27)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-157. Gamut Metadata Registers (GAMUT_DBYTE__0-GAMUT_DBYTE__27) Field Descriptions

10.3.4.1 ACR Control Register (ACR_CTRL)

The ACR control register is shown in Figure 10-147 and described in Table 10-159.

Figure 10-147. ACR Control Register (ACR_CTRL)

31	16
Reserved	
R-0h	

15	2	1	0
Reserved		NCTSPKT_EN	CTS_SEL
R-0h		R/W-1h	R/W-0h

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-159. ACR Control Register (ACR_CTRL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	NCTSPKT_EN		CTS request enable
		0	N/CTS packet is disabled
		1	N/CTS packet is enabled
0	CTS_SEL		CTS source select
		0	Send hardware-updated CTS value in N/CTS packet (recommended)
		1	Send software-updated CTS value in N/CTS packet (for diagnostic use)

10.3.4.2 ACR Audio Frequency Register (FREQ_SVAL)

The ACR audio frequency register is shown in Figure 10-148 and described in Table 10-160.

Figure 10-148. ACR Audio Frequency Register (FREQ_SVAL)

31	16
Reserved	
R-0h	

15	3	2	0
Reserved		MCLK_CONF	
R-0h		R/W-1h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-160. ACR Audio Frequency Register (FREQ_SVAL) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	MCLK_CONF		MCLK input mode. The HDMI transmitter uses these bits to divide the MCLK input to produce CTS values according to the 128 × Fs formula. The MCLK to Fs ratio is for the input Fs, not the down-sampled output Fs (see Section 10.3.4.25).
		0	MCLK is 128 × Fs
		1h	MCLK is 256 × Fs
		2h	MCLK is 384 × Fs
		3h	MCLK is 512 × Fs
		4h	MCLK is 768 × Fs
		5h	MCLK is 1024 × Fs
		6h	MCLK is 1152 × Fs
		7h	MCLK is 192 × Fs

10.3.4.3 ACR N Software Value Register 1 (N_SVAL1)

The ACR N software value register is shown in Figure 10-149 and described in Table 10-161.

Figure 10-149. ACR N Software Value Register 1 (N_SVAL1)

31	8	7	0

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	HBRA_ON		High Bit Rate Audio On. All of the I2S control bits will apply to the control of the High Bit Rate Audio.
		0	Input stream is not high bit rate
		1	Input stream is high bit rate
6	SCK_EDGE		SCK sample edge
		0	Sample edge is falling; SD3-SD0 and WS source should change state on the rising edge of SCK
		1	Sample clock is rising; SD3-SD0 and WS source should change state on the falling edge of SCK
5	CBIT_ORDER	0	This bit should be set to 1 for High Bit Rate Audio.
4	VBIT		V bit value
		0	PCM
		1	Compressed
3	I2S_WS		WS polarity
		0	Left polarity when WS is LOW
		1	Left polarity when WS is HIGH
2	I2S_JUST		SD justify
		0	Data is left-justified
		1	Data is right-justified
1	I2S_DIR		SD direction
		0	MSB shifted first
		1	LSB shifted first
0	I2S_SHIFT		WS to SD first bit shift
		0	First bit shift (refer to the Philips Specification)
		1	No shift

R-0h	R/W-0h	R/W-0h		R/W-0h		R/W-0h

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-185. HDMI Control Register (HDMI_CTRL) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	DC_EN		Deep-color packet enable.
			The following data is sent in data byte 1 of the packet: 7 = Reserved, 6 = PP2, 5 = PP1, 4 = PP0, 3 = PP_valid, 2 = CD2, 1 = CD1, 0 = CD0, The CD bits indicate deep-color mode (defined in the same register bits 5:3). The PP bits indicate the fragment s phase related information that comes from the hardware state machine.
		0	Do not send deep-color related information in the packet to the HDMI Receiver.
		1	Send deep-color related information in the packet to the HDMI Receiver.
5-3	PACKET_MODE		Specifies the number of bits per pixel sent to the paketizer. The firmware must program 24 bits per pixel (8 bits per pixel; no packing) for initialization.
		0-3h	Reserved
		4h	24 bits per pixel (8 bits per pixel; no packing)
		5h	30 bits per pixel (10 bits per pixel pack to 8 bits)
		6h	36 bits per pixel (12 bits per pixel pack to 8 bits)
		7h	48 bits per pixel (16 bits per pixel; no packing)
2-1	LAYOUT		Audio packet header layout indicator.
		0	Layout 0 (2-channel)
		1h	Layout 1 (up to 8 channels)
		2h-3h	Reserved
0	HDMI_MODE		HDMI Mode
		0	Disable
		1	Enable

10.3.4.28 Audio Path Status Register (AUDO_TXSTAT)

NOTE: MUTE is not set immediately when the SETAVM bit in register CP_BYTE1 is written. After writing SETAVM to 1, MUTE is set after the Control Packet is transmitted in HDMI mode. In DVI mode, MUTE is set at the start of VSYNC. MUTE is cleared when a Control Packet with CLRAVM = 1 is sent, or (in DVI mode) at the start of VSYNC after CLRAVM has been written to 1. Note that the combinations {SETAVM, CLRAVM} = {0,0} and {1,1} are not supported by HDMI. Such a packet is not compliant.

Bit	Field	Description
31-5	Reserved	Reserved
4	CLRAVM	Clear AV Mute flag
3-1	Reserved	Reserved
0	SETAVM	Set AV Mute flag. When the AVMUTE flag is set, the HDMI Transmitter sends a General Control Packet on the TMDS link to inform the Sink that the data may be incorrect. The HDMI Transmitter sends blanklevel data for all video packets and 00 for all audio packet data. When the AVMUTE flag is set, the Sink assumes that no valid data is being received. Optionally, the Sink can apply a mute function to the audio data and/or a blank function to the video data.

Inter-Integrated Circuit (I2C) Controller Module

This chapter describes the multi-master inter-integrated circuit (I2C) controller module which provides an interface between a CPU and any I2C-bus-compatible device that connects via the I2C serial bus. External components attached to the I2C bus can serially transmit/receive up to 8-bit data to/from the CPU device through the two-wire I2C interface.

Topic **Page**

11.1 Introduction

11.1.1 Overview

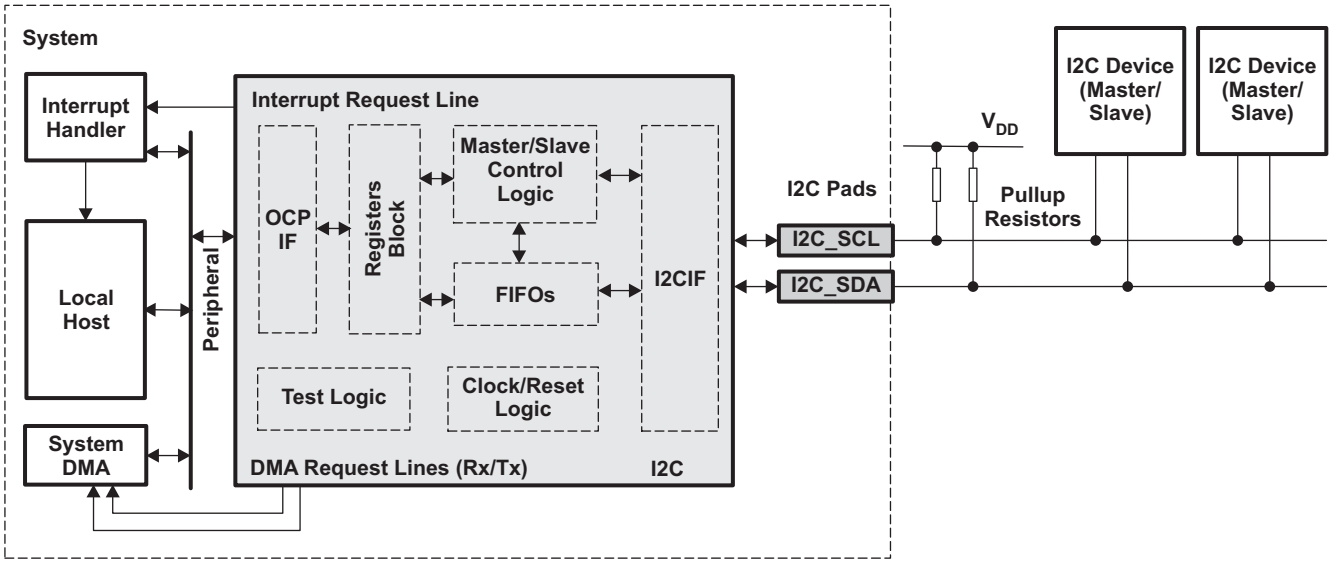
The multi-master I2C peripheral provides an interface between a CPU and any I2C-bus-compatible device that connects via the I2C serial bus. External components attached to the I2C bus can serially transmit/receive up to 8-bit data to/from the CPU device through the two-wire I2C interface.

The I2C bus is a multi-master bus. The I2C controller does support the multi-master mode that allows more than one device capable of controlling the bus to be connected to it. Each I2C device is recognized by a unique address and can operate as either transmitter or receiver, according to the function of the device. In addition to being a transmitter or receiver, a device connected to the I2C bus can also be considered as master or slave when performing data transfers. Note that a master device is the device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave.

11.1.2 Functional Block Diagram

Figure 11-1 shows an example of a system with multiple I2C compatible devices in which the I2C serial ports are all connected together for a two-way transfer from one device to other devices.

Figure 11-1. I2C Functional Block Diagram



11.1.3 Features

The multimaster I2C controller has the following features:

- Compliance with Philips I2C specification version 2.1
- Support for standard mode (up to 100K bits/s) and fast mode (up to 400K bits/s)
- 7-bit and 10-bit device addressing modes
- General call
- Start/restart/stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFO size of 32 bytes for buffered read or write
- Module enable/disable capability

- Programmable clock generation
- 8-bit-wide data access
- Designed for low-power consumption design
- Two DMA channels
- Wide interrupt capability

11.2 Architecture

The I2C peripheral consists of the following primary blocks:

- A serial interface: one data pin (I2C_SDA) and one clock pin (I2C_SCL).
- Data registers to temporarily hold receive data and transmit data traveling between the I2C_SDA pin and the CPU or the DMA controller.
- Control and status registers
- A peripheral data bus interface to enable the CPU and the DMA controller to access the I2C peripheral registers.
- A clock synchronizer to synchronize the I2C input clock (from the processor clock generator) and the clock on the I2C_SCL pin, and to synchronize data transfers with masters of different clock speeds.
- A prescaler to divide down the input clock that is driven to the I2C peripheral
- A noise filter on each of the two pins, I2C_SDA and I2C_SCL
- An arbitrator to handle arbitration between the I2C peripheral (when it is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- DMA event generation logic to send an interrupt to the CPU upon reception or transmission of data.

11.2.1 I2C Master/Slave Contoller Signals

Data is communicated to devices interfacing with the I2C via the serial data line (SDA) and the serial clock line (SCL). These two wires can carry information between a device and others connected to the I2C bus. Both SDA and SCL are bi-directional pins. They must be connected to a positive supply voltage via a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open drain to perform the required wired-AND function.

An example of multiple I2C modules that are connected for a two-way transfer from one device to other devices is shown in Figure 11-2.

Figure 11-2. Multiple I2C Modules Connected

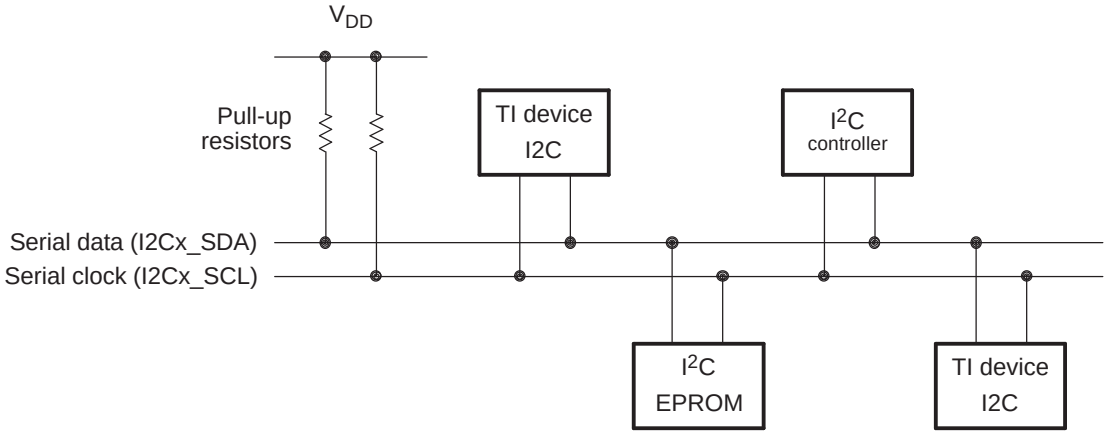


Table 11-1. Signal Pads

Name	I2C Mode	
	Default Operating Mode	Description
I2C_SCL	In/ Out	I2C serial CLK line Open-drain output buffer. Requires external pull-up resistor (Rp).
I2C_SDA	In/ Out	I2C serial data line Open-drain output buffer. Requires external pull-up resistor (Rp).

11.2.2 I2C Reset

The I2C module can be reset in the following three ways:

- A device reset causes all registers to be reset to their default values.
- A software reset by setting the SRST bit in the I2C_SYSC register. This bit has exactly the same action on the module logic as the device reset. All registers are reset to power up reset values.
- The I2C_EN bit in the I2C_CON register can be used to hold the I2C module in reset. When the device reset is removed, I2C_EN = 0 keeps the functional part of I2C module in reset state and all configuration registers can be accessed. I2C_EN = 0 does not reset the registers to power up reset values.

Table 11-2. Reset State of I2C Signals

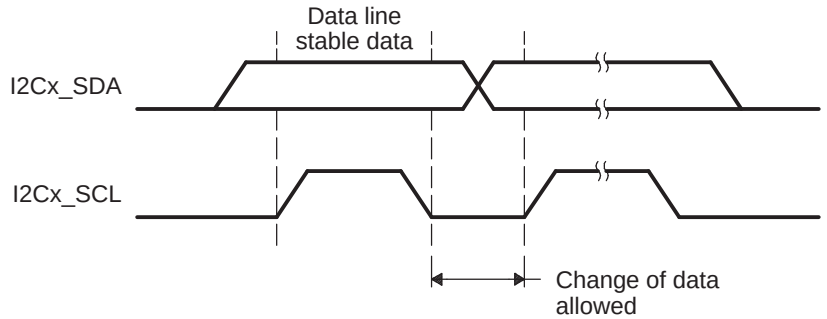
Pin	I/O/Z [1]	System Reset	I2C Reset (I2C_EN = 0)
SDA	I/O/Z	High impedance	High impedance
SCL	I/O/Z	High impedance	High impedance

(1) I = Input, O = Outpu, Z = High impedance

11.2.3 Data Validity

The data on the SDA line must be stable during the high period of the clock. The high and low states of the data line can only change when the clock signal on the SCL line is LOW.

Figure 11-3. Bit Transfer on the I2C Bus

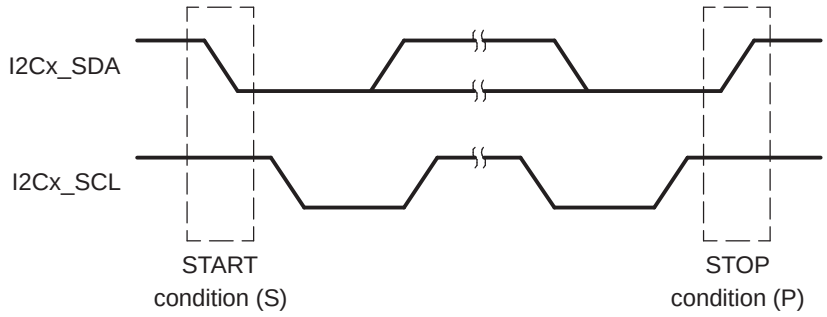


11.2.4 START & STOP Conditions

The I2C module generates START and STOP conditions when it is configured as a master.

- START condition is a high-to-low transition on the SDA line while SCL is high.
- STOP condition is a low-to-high transition on the SDA line while SCL is high.
- The bus is considered to be busy after the START condition (BB = 1) and free after the STOP condition (BB = 0).

Figure 11-4. Start and Stop Condition Events

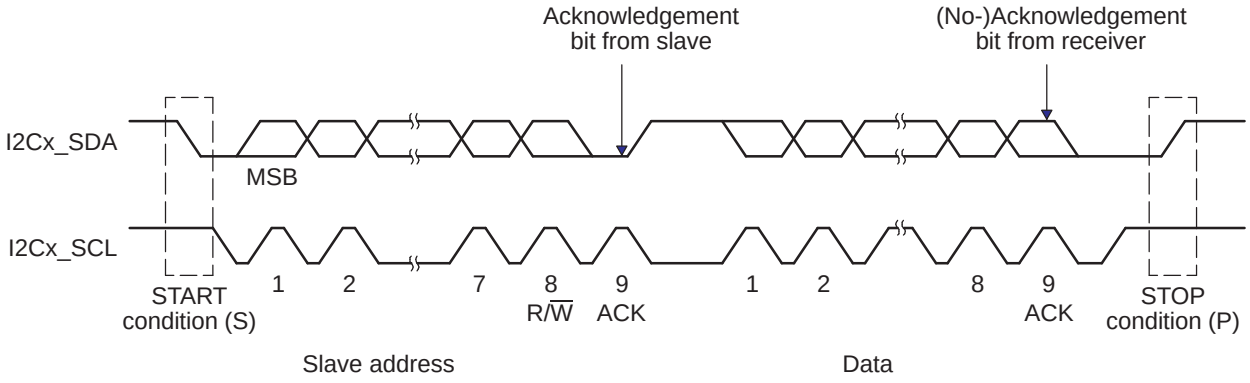


11.2.5 I2C Operation

11.2.5.1 Serial Data Formats

The I2C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte put on the SDA line is 8 bits long. The number of bytes that can be transmitted or received is restricted by the value programmed in the DCOUNT register. The data is transferred with the most significant bit (MSB) first. Each byte is followed by an acknowledge bit from the I2C module if it is in receiver mode.

Figure 11-5. I2C Data Transfer



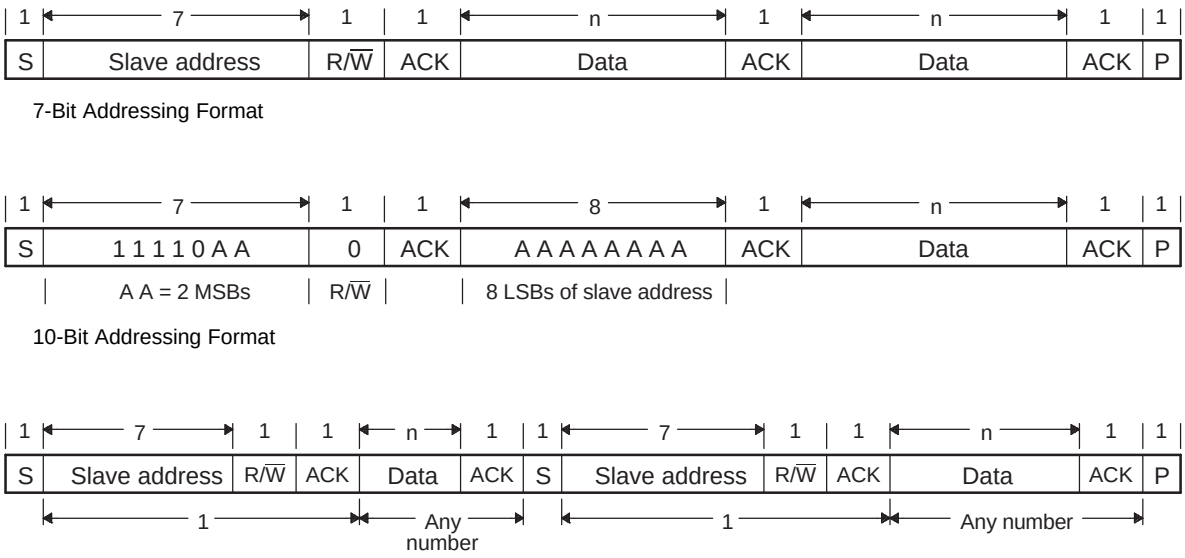
The I2C module supports two data formats, as shown in Figure 11-6:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start condition

The first byte after a start condition (S) always consists of 8 bits. In the acknowledge mode, an extra bit dedicated for acknowledgment is inserted after each byte. In the addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 LSB R/$\overline{W}$ bit. In the addressing formats with 10-bit addresses, the first byte is composed of 7 MSB slave address bits, such as 11110XX, where XX is the two MSB of the 10-bit addresses, and 1 LSB R/$\overline{W}$ bit, which is 0 in this case.

The least significant R/$\overline{W}$ of the address byte indicates the direction of transmission of the following data bytes. If R/$\overline{W}$ is 0, the master writes data into the selected slave; if it is 1, the master reads data out of the slave.

Figure 11-6. I2C Data Transfer Formats



11.2.5.2 Master Transmitter

In this mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in synch with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL held low when the intervention of the processor is required (XUDF) after a byte has been transmitted.

11.2.5.3 Master Receiver

This mode can only be entered from the master transmitter mode. With either of the address formats (Figure 6 (a), (b), and (c)), the master receiver is entered after the slave address byte and bit R/$\overline{W}$ has been transmitted, if R/$\overline{W}$ is high. Serial data bits received on bus line SDA are shifted in synch with the self-generated clock pulses on SCL. The clock pulses are inhibited and SCL held low when the intervention of the processor is required (ROVR) after a byte has been received. At the end of a transfer, it generates the stop condition.

11.2.5.4 Slave Transmitter

This mode can only be entered from the slave receiver mode. With either of the address formats (Figure 6 (a), (b), and (c)), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/$\overline{W}$ has been transmitted, if R/$\overline{W}$ is high. The slave transmitter shifts the serial data out on the data line SDA in synch with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the CPU is required (XUDF).

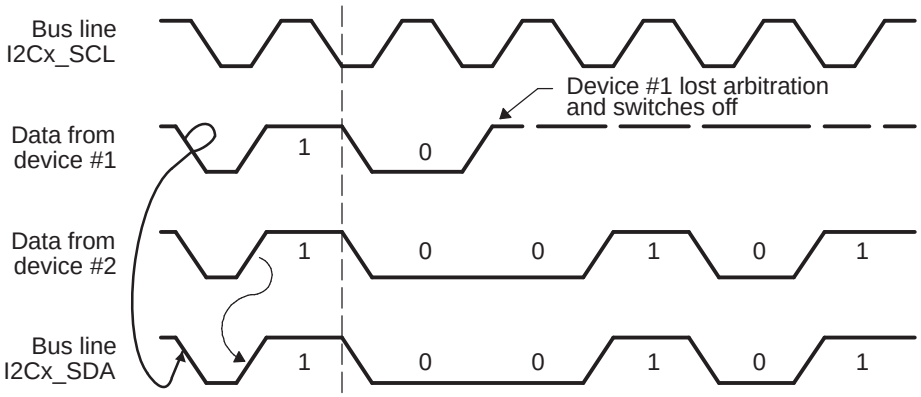
11.2.5.5 Slave Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in synch with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the CPU is required (ROVR) following the reception of a byte.

11.2.6 Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 11-7 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 11-7. Arbitration Procedure Between Two Master Transmitters

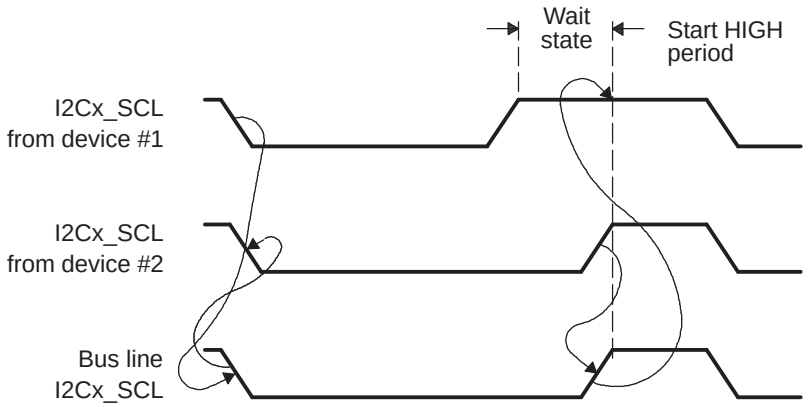


11.2.7 I2C Clock Generation and I2C Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or to prepare a byte to be transmitted. Figure 11-8 illustrates the clock synchronization.

Figure 11-8. Synchronization of Two I2C Clock Generators



11.2.8 Prescaler (SCLK/ICLK)

The I2C module is operated with a functional clock (SCLK) frequency that can be in a range of 12-100 MHz, according to I2C mode that must be used (an internal ~24 MHz clock (ICLK) is recommended in case of F/S operation mode). Note that the frequency of the functional clock influences directly the I2C bus performance and timings.

The internal clock used for I2C logic - ICLK - is generated via the I2C prescaler block. The prescaler consists of a 4-bit register - I2C _PSC, and is used to divide the system clock (SCLK) to obtain the internal required clock for the I2C module.

11.2.9 Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less, in the case of F/S mode of operation. It is designed to suppress noise with one ICLK. The noise filter is always one ICLK cycle, regardless of the bus speed. For FS mode (prescaler = 4, ICLK = 24 MHz), the maximum width of the suppressed spikes is 41.6 ns. To ensure a correct filtering, the prescaler must be programmed accordingly.

11.2.10 I2C Interrupts

The I2C module generates 12 types of interrupt: addressed as slave, bus free (stop condition detected), access error, start condition, arbitration-lost, no acknowledge, general call, registers-ready-for-access, receive and transmit data, receive and transmit draining. These 12 interrupts are accompanied with 12 interrupt masks and flags defined in the I2C_IRQENABLE_SET and respectively I2C_IRQSTATUS_RAW registers. Note that all these 12 interrupt events are sharing the same hardware interrupt line.

- Addressed As Slave interrupt (AAS) is generated to inform the Local Host that an external master addressed the module as a slave. When this interrupt occurs, the CPU can check the I2C_ACTOA status register to check which of the 4 own addresses was used by the external master to access the module.
- Bus Free interrupt (BF) is generated to inform the Local Host that the I2C bus became free (when a Stop Condition is detected on the bus) and the module can initiate his own I2C transaction.
- Start Condition interrupt (STC) is generated after the module being in idle mode have detected (synchronously or asynchronously) a possible Start Condition on the bus (signalized with WakeUp).
- Access Error interrupt (AERR) is generated if a Data read access is performed while RX FIFO is empty or a Data write access is performed while TX FIFO is full.
- Arbitration lost interrupt (AL) is generated when the I2C arbitration procedure is lost.
- No-acknowledge interrupt (NACK) is generated when the master I2C does not receive acknowledge from the receiver.
- General call interrupt (GC) is generated when the device detects the address of all zeros (8 bits).
- Registers-ready-for-access interrupt (ARDY) is generated by the I2C when the previously programmed address, data, and command have been performed and the status bits have been updated. This interrupt is used to let the CPU know that the I2C registers are ready for access.
- Receive interrupt/status (RRDY) is generated when there is received data ready to be read by the CPU from the I2C_DATA register (see the FIFO Management subsection (Section 11.2.13) for a complete description of required conditions for interrupt generation). The CPU can alternatively poll this bit to read the received data from the I2C_DATA register.
- Transmit interrupt/status (XRDY) is generated when the CPU needs to put more data in the I2C_DATA register after the transmitted data has been shifted out on the SDA pin (see the FIFO Management subsection (Section 11.2.13)for a complete description of required conditions for interrupt generation). The CPU can alternatively poll this bit to write the next transmitted data into the I2C_DATA register.
- Receive draining interrupt (RDR) is generated when the transfer length is not a multiple of threshold value, to inform the CPU that it can read the amount of data left to be transferred and to enable the draining mechanism. (see the Draining Feature subsection (Section 11.2.13.4) for additional details).
- Transmit draining interrupt (XDR) is generated when the transfer length is not a multiple of threshold value, to inform the CPU that it can write the amount of data left to be written and to enable the draining mechanism. (see the Draining Feature subsection (Section 11.2.13.4) for additional details).

When the interrupt signal is activated, the Local Host must read the I2C_IRQSTATUS_RAW register to define the type of the interrupt, process the request, and then write into these registers the correct value to clear the interrupt flag.

11.2.11 DMA Events

The I2C module can generate two DMA requests events, read (I2C_DMA_RX) and write (I2C_DMA_TX) that can be used by the DMA controller to synchronously read received data from the I2C_DATA or write transmitted data to the I2C_DATA register. The DMA read and write requests are generated in a similar manner as RRDY and XRDY, respectively.

The I2C DMA request signals (I2C_DMA_TX and I2C_DMA_RX) are activated according to the FIFO Management subsection (Section 11.2.13).

11.2.12 Interrupt and DMA Events

I2C has two DMA channels (Tx and Rx). For event numbers, see the *Device Interrupts and EDMA Events* chapter.

I2C has one interrupt line for all the interrupt requests. For the interrupt number, see the *Device Interrupts and EDMA Events* chapter.

11.2.13 FIFO Management

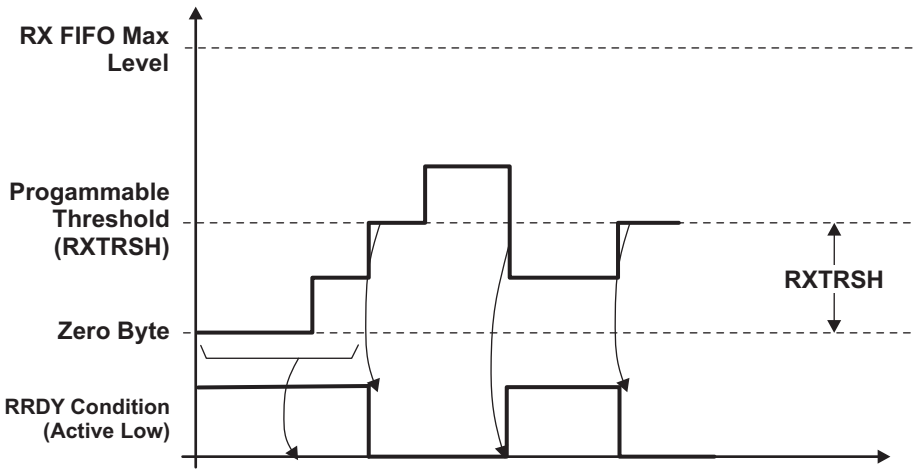
The I2C module implements two internal 32-bytes FIFOs with dual clock for RX and TX modes. The depth of the FIFOs is reflected in I2C_BUFSTAT.FIFODEPTH register.

11.2.13.1 FIFO Interrupt Mode Operation

In FIFO interrupt mode (relevant interrupts enabled via I2C_IRQENABLE_SET register), the processor is informed of the status of the receiver and transmitter by an interrupt signal. These interrupts are raised when receive/transmit FIFO threshold (defined by I2C_BUF.TXTRSH or I2C_BUF.RXTRSH) is reached; the interrupt signals instruct the Local Host to transfer data to the destination (from the I2C module in receive mode and/or from any source to the I2C FIFO in transmit mode).

Figure 11-9 and Figure 11-10, respectively, illustrate receive and transmit operations from FIFO management point of view.

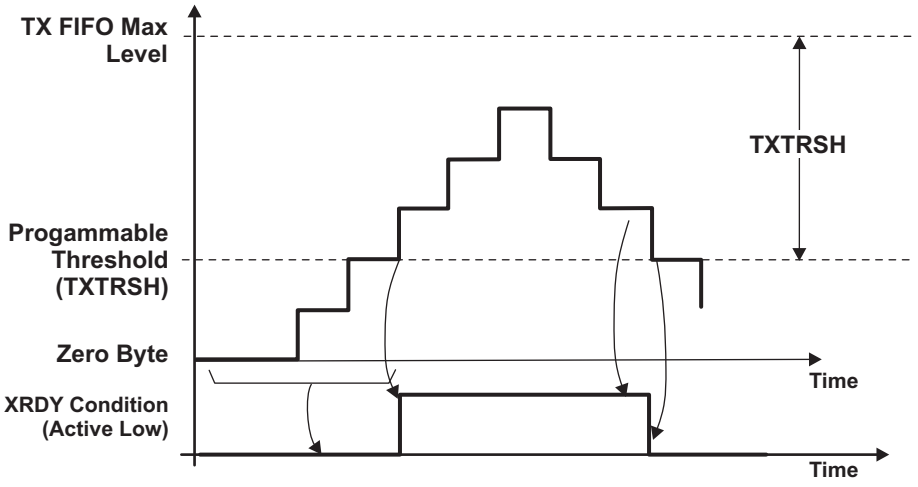
Figure 11-9. Receive FIFO Interrupt Request Generation



Note that in Figure 11-9, the RRDY Condition illustrates that the condition for generating a RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the CPU by writing a 1 in the corresponding interrupt flag. If the condition is still present after clearing the previous interrupt, another interrupt request will be generated.

In receive mode, RRDY interrupt is not generated until the FIFO reaches its receive threshold. Once low, the interrupt can only be de-asserted when the Local Host has handled enough bytes to make the FIFO level below threshold. For each interrupt, the Local Host can be configured to read an amount of bytes equal with the value of the RX FIFO threshold + 1.

Figure 11-10. Transmit FIFO Interrupt Request Generation



Note that in the figure above, the XRDY Condition illustrates that the condition for generating a XRDY interrupt is achieved. The interrupt request is generated when this condition is achieved (when TX FIFO is empty, or the TX FIFO threshold is not reached and there are still data bytes to be transferred in the TX FIFO), and it can be cleared only by the CPU by writing a 1 in the corresponding interrupt flag after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request will be generated.

Note that in interrupt mode, the module offers two options for the CPU application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the CPU can write/read one data byte to/from the FIFO and then clear the interrupt. The module will not reassert the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the CPU can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF.TXTRSH + 1 or I2C_BUF.RXTRSH + 1). In this case, the interrupt condition will be cleared and the next interrupt will be asserted again when the XRDY or RRDY condition is met again.

If the second interrupt serving approach is used, an additional mechanism (draining feature) is implemented for the case when the transfer length is not a multiple of FIFO threshold (see the Draining Feature subsection (Section 11.2.13.4)).

In slave TX mode, the draining feature cannot be used, since the transfer length is not known at the configuration time, and the external master can end the transfer at any point by not acknowledging one data byte.

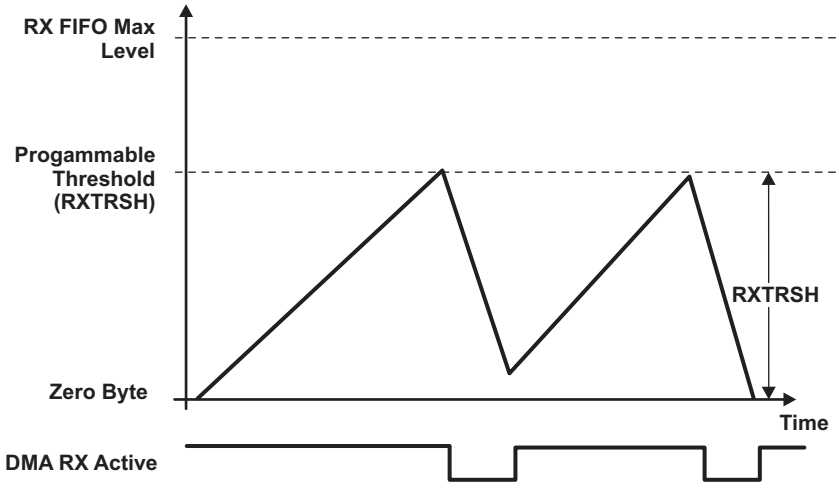
11.2.13.2 FIFO Polling Mode Operation

In FIFO polled mode (I2C_IRQENABLE_SET.XRDY_IE and I2C_IRQENABLE_SET.RRDY_IE disabled and DMA disabled), the status of the module (receiver or transmitter) can be checked by polling the XRDY and RRDY status registers (I2C_IRQSTATUS_RAW) (RDR and XDR can also be polled if draining feature is used). The XRDY and RRDY flags are accurately reflecting the interrupt conditions mentioned in Interrupt Mode. This mode is an alternative to the FIFO interrupt mode of operation, where the status of the receiver and transmitter is automatically known by means of interrupts sent to the CPU.

11.2.13.3 FIFO DMA Mode Operation

In receive mode, a DMA request is generated as soon as the receive FIFO exceeds its threshold level defined in the threshold level register (I2C_BUF.RXTRSH +1). This request should be de-asserted when the number of bytes defined by the threshold level has been read by the DMA, by setting the I2C_DMARXENABLE_CLR.DMARX_ENABLE_CLEAR field.

Figure 11-11. Receive FIFO DMA Request Generation



In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request should be de-asserted when the number of bytes defined by the number in the threshold register (I2C_BUF.TXTHRS+1) has been written in the FIFO by the DMA, by setting the I2C_DMATXENABLE_CLR. DMATX_ENABLE_CLEAR field. If an insufficient number of characters are written, then the DMA request will remain active. Figure 11-12 and Figure 11-13 illustrate DMA TX transfers with different values for TXTRSH.

Figure 11-12. Transmit FIFO DMA Request Generation (High Threshold)

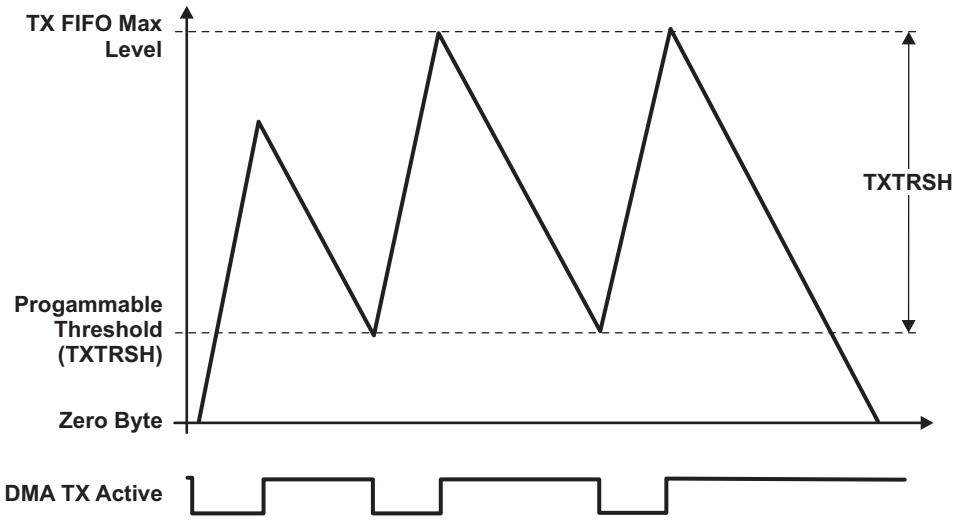


Figure 11-13. Transmit FIFO DMA Request Generation (Low Threshold)

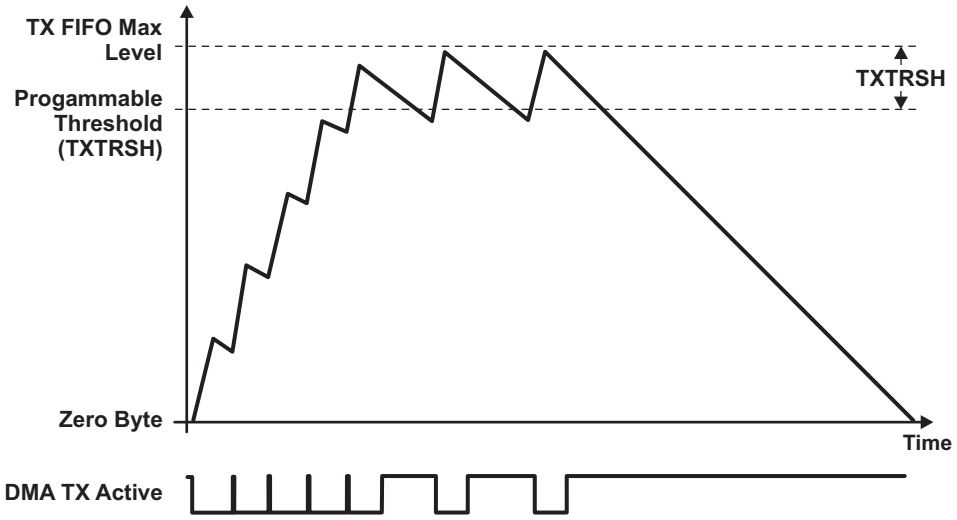

Note that also in DMA mode it is possible to have a transfer whose length is not multiple of the configured FIFO threshold. In this case, the DMA draining feature is also used for transferring the additional bytes of the transfer (see the Draining Feature subsection (Section 11.2.13.4) for additional details).

In I2C Slave RX Mode, the Local Host can program the RX threshold with the desired value, and use the FIFO draining feature at the end of the I2C transfer to extract from the FIFO the remaining bytes if the threshold is not reached (see the Draining Feature subsection (Section 11.2.13.4) for additional details).

Note that in I2C Slave TX Mode, the TX FIFO threshold should be set to 1 (I2C_BUF.TXTRSH=0, default value), since the length of the transfer may not be known at configuration time. In this way, the interrupt (or accordingly, DMA) requests will be generated for each byte requested by the remote I2C master to be transferred over the I2C bus. This configuration will prevent the I2C core to request additional data from the CPU or from the DMA controller (using IRQ or DMA), data that will eventually not be extracted from the FIFO by the external master (which can use not acknowledge at any time to end the transfer). If the TX threshold is not set to 1, the module will generate an interrupt or assert a DMA only when the external master requests a byte and the FIFO is empty. However, in this case the TX FIFO will require to be cleared at the end of the transfer.

The I2C module offers the possibility to the user to clear the RX or TX FIFO. This is achieved through I2C_BUF.RXFIFO_CLR and I2C_BUF.TXFIFO_CLR registers, which act like software reset for the FIFOs. In DMA mode, these bits will also reset the DMA state machines.

The FIFO clearing feature can be used when the module is configured as a transmitter, the external receiver responds with a NACK in the middle of the transfer, and there is still data in TX FIFO waiting to be transferred.

On the Functional (I2C) domain, the thresholds can always be considered equal to 1. This means that the I2C Core can start transferring data on the I2C bus whenever it has data in the FIFOs (FIFO is not empty).

11.2.13.4 Draining Feature

The Draining Feature is implemented by the I2C core for handling the end of the transfers whose length is not a multiple of FIFO threshold value, and offers the possibility to transfer the remaining amount of bytes (since the threshold is not reached).

Note that this feature prevents the CPU or the DMA controller to attempt more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having in the FIFO less bytes than the configured DMA transfer length). Otherwise, an Access Error interrupt will be generated (see I2C_IRQSTATUS_RAW.AERR interrupt).

The Draining mechanism will generate an interrupt (I2C_IRQSTATUS_RAW.RDR or I2C_IRQSTATUS_RAW.XDR) at the end of the transfer informing the CPU that it needs to check the amount of data left to be transferred (I2C_BUFSTAT.TXSTAT or RXSTAT) and to enable the Draining Feature of the DMA controller if DMA mode is enabled (by re-configuring the DMA transfer length according to this value), or perform only the required number of data accesses, if DMA mode is disabled.

In receiving mode (master or slave), if the RX FIFO threshold is not reached but the transfer was ended on the I2C bus and there is still data left in the FIFO (less than the threshold), the receive draining interrupt (I2C_IRQSTATUS_RAW.RDR) will be asserted to inform the local host that it can read the amount of data in the FIFO (I2C_BUFSTAT.RXSTAT). The CPU will perform a number of data read accesses equal with RXSTAT value (if interrupt or polling mode) or re-configure the DMA controller with the required value in order to drain the FIFO.

In master transmit mode, if the TX FIFO threshold is not reached but the amount of data remained to be written in the FIFO is less than TXTRSH, the transmit draining interrupt (I2C_IRQSTATUS_RAW.XDR) will be asserted to inform the local host that it can write the amount of data remained to be written in the TX FIFO (I2C_BUFSTAT.TXSTAT). The CPU will need to write the required number of data bytes (specified by TXSTAT value) or re-configure the DMA controller with the required value in order to transfer the last bytes to the FIFO.

Note that in master mode, the CPU can alternatively skip the checking of TXSTAT and RXSTAT values since it can obtain internally this information (by computing DCOUNT modulo TX/RXTRSH).

The draining feature is default disabled, and it can be enabled using I2C_IRQENABLE_SET.XDR_IE or I2C_IRQENABLE_SET.RDR_IE registers (default disabled) only for the transfers with length not equal with the threshold value.

11.2.14 How to Program I2C

11.2.14.1 Module Configuration Before Enabling the Module

1. Program the prescaler to obtain an approximately 12-MHz I2C module clock (I2C_PSC = x; this value is to be calculated and is dependent on the System clock frequency).
2. Program the I2C clock to obtain 100 Kbps or 400 Kbps (SCLL = x and SCLH = x; these values are to be calculated and are dependent on the System clock frequency).
3. Configure its own address (I2C_OA = x) - only in case of I2C operating mode (F/S mode).
4. Take the I2C module out of reset (I2C_CON:I2C_EN = 1).

11.2.14.2 Initialization Procedure

1. Configure the I2C mode register (I2C_CON) bits.
2. Enable interrupt masks (I2C_IRQENABLE_SET), if using interrupt for transmit/receive data.
3. Enable the DMA (I2C_BUF and I2C_DMA/RX/TX/ENABLE_SET) and program the DMA controller - only in case of I2C operating mode (F/S mode), if using DMA for transmit/receive data.

11.2.14.3 Configure Slave Address and DATA Counter Registers

In master mode, configure the slave address (I2C_SA = x) and the number of bytes associated with the transfer (I2C_CNT = x).

11.2.14.4 Initiate a Transfer

Poll the bus busy (BB) bit in the I2C status register (I2C_IRQSTATUS_RAW). If it is cleared to 0 (bus not busy), configure START/STOP (I2C_CON: STT / I2C_CON: STP condition to initiate a transfer) - only in case of I2C operating mode (F/S mode).

11.2.14.5 Receive Data

Poll the receive data ready interrupt flag bit (RRDY) in the I2C status register (I2C_IRQSTATUS_RAW), use the RRDY interrupt (I2C_IRQENABLE_SET.RRDY_IE set) or use the DMA RX (I2C_BUF.RDMA_EN set together with I2C_DMARXENABLE_SET) to read the receive data in the data receive register (I2C_DATA). Use draining feature (I2C_IRQSTATUS_RAW.RDR enabled by I2C_IRQENABLE_SET.RDR_IE)) if the transfer length is not equal with FIFO threshold.

11.2.14.6 Transmit Data

Poll the transmit data ready interrupt flag bit (XRDY) in the I2C status register (I2C_IRQSTATUS_RAW), use the XRDY interrupt (I2C_IRQENABLE_SET.XRDY_IE set) or use the DMA TX (I2C_BUF.XDMA_EN set together with I2C_DMATXENABLE_SET) to write data into the data transmit register (I2C_DATA). Use draining feature (I2C_IRQSTATUS_RAW.XDR enabled by I2C_IRQENABLE_SET.XDR_IE)) if the transfer length is not equal with FIFO threshold.

11.3 I2C Registers

Table 11-3 lists the registers for the I2C module. For the base address of these registers, see Table 1-12.

NOTE: All bits defined as reserved must be written by software with 0s, for preserving future compatibility. When read, any reserved bit returns 0. Also, note that it is good software practice to use complete mask patterns for setting or testing individually bit fields within a register.

Table 11-3. I2C Registers

Address Offset	Acronym	Register Name	Section
00h	I2C_REVNB_LO	Module Revision Register (low bytes)	Section 11.3.1

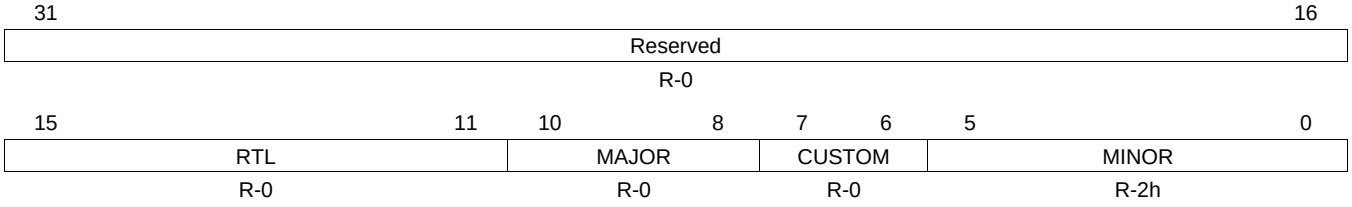
11.3.1 I2C_REVNB_LO Register (Module Revision LOW BYTES)

This read-only register contains the hard-coded revision number of the module. A write to this register has no effect.

NOTE:

- I2C controller with interrupt using interrupt vector register (I2C_IV) is revision 1.x.
- I2C controller with interrupt using status register bits (I2C_IRQSTATUS_RAW) is revision 2.x.

Figure 11-14. I2C_REVNB_LO Register (Module Revision) (LOW BYTES)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 11-4. I2C_REVNB_LO Register (Module Revision) (LOW BYTES) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-11	RTL	0-1Fh	RTL version.
10-8	MAJOR	0-7h	Major Revision. This field changes when there is a major feature change. This field does not change due to bug fix, or minor feature change.
7-6	CUSTOM	0-3h	Indicates a special version for a particular device. Consequence of use may avoid use of standard Chip Support Library (CSL) / Drivers. 0 if non-custom.
5-0	MINOR	0-3Fh	Minor Revision This field changes when features are scaled up or down. This field does not change due to bug fix, or major feature change.

11.3.2 I2C_REVNB_HI Register (HIGH BYTES) (Module Revision)

A reset has no effect on the value returned.

Figure 11-15. I2C_REVNB_HI Register (HIGH BYTES) (Module Revision)

31	16

R-0	R/W-0	R-0	R/W-0	R/W-0	R/W-0	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 11-6. I2C_SYSC Register (System Configuration) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-8	CLKACTIVITY		Clock Activity selection bits. Those bits (one bit for each clock signal present on the boundary of the module) are set to 1 to disable external clock gating mechanism in Idle Mode.
		0h	Both clocks can be cut off
		1h	Only Interface/OCP clock must be kept active; system clock can be cut off
		2h	Only system clock must be kept active; Interface/OCP clock can be cut off
		3h	Both clocks must be kept active
			Values after reset are low (for both 2 bits).
			Note: If the System (functional) Clock is cut-off, the module will assert a WakeUp event when it will asynchronously detect a Start Condition on the I2C Bus. Note that in this case the first transfer will not be taken into account by the module (NACK will be detected by the external master).
7-5	Reserved	0	Reads return 0h.
4-3	IDLEMODE		Idle Mode selection bits. These two bits are used to select one of the idle mode operation mechanisms.
		0h	Force Idle mode
		1h	No Idle mode
		2h	Smart Idle mode
		3h	smartidle_wakeup
			Value after reset is 00 (Force Idle).
2	ENAWAKEUP		Enable Wakeup control bit. When this bit is set to 1, the module enables its own wakeup mechanism.
		0	Wakeup mechanism is disabled
		1	Wakeup mechanism is enabled
			Value after reset is low.
1	SRST		SoftReset bit. When this bit is set to 1, entire module is reset as for the hardware reset. This bit is automatically cleared to 0 by the core and it is only reset by the hardware reset. During reads, it always returns 0.
		0	Normal mode
		1	The module is reset
			Value after reset is low.
0	AUTOIDLE		Autoidle bit. When this bit is set to 1, the module activates its own idle mode mechanism. By evaluating its internal state, the module can decide to gate part of his internal clock tree in order to improve the overall power consumption.
		0	Auto Idle mechanism is disabled
		1	Auto Idle mechanism is enabled
			Value after reset is high.

11.3.4 I2C_EOI Register (I2C End of Interrupt)

Software End-Of-Interrupt: Allows the generation of further pulses on the interrupt line, if an new interrupt event is pending, when using the pulsed output. Unused when using the level interrupt line (depending on module integration).

Figure 11-17. I2C_EOI Register (I2C End of Interrupt)

Bit	Field	Description
31-1	Reserved	Reserved
0	LINE_NUMBER	Software End Of Interrupt (EOI) control. Write number of interrupt output.

11.3.5 I2C_IRQSTATUS_RAW Register (I2C Status Raw)

This register provides core status information for interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit will set it to 1, that is, trigger the IRQ (mostly for debug). Writing a 0 will have no effect, that is, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 11-8. I2C_IRQSTATUS_RAW Register (I2C Status Raw) Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Write 0s for future compatibility. Read returns 0.
14	XDR		Transmit draining IRQ status. I2C Master Transmit mode only. This read/clear only bit is set to 1 when the module is configured as a master transmitter, the TX FIFO level is below the configured threshold (TXTRSH) and the amount of data still to be transferred is less than TXTRSH. When this bit is set to 1 by the core, CPU must read the I2C_BUFSTAT.TXSTAT register in order to check the amount of data that need to be written in the TX FIFO. Then, according to the mode set (DMA or interrupt), the CPU can enable the DMA draining feature of the DMA controller with the number of data bytes to be transferred (I2C_BUFSTAT.TXSTAT), or generate write data accesses according to this value (IRQ mode). The interrupt needs to be cleared after the DMA controller was reconfigured (if DMA mode enabled), or before generating data accesses to the FIFO (if IRQ mode enabled). If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU can also poll this bit. For more details about TDR generation, refer to the FIFO Management subsection. The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect.
		0	Transmit draining inactive
		1	Transmit draining enabled
			Value after reset is low.
13	RDR		Receive draining IRQ status. I2C Receive mode only. This read/clear only bit is set to 1 when the module is configured as a receiver, a stop condition was received on the bus and the RX FIFO level is below the configured threshold (RXTRSH). When this bit is set to 1 by the core, CPU must read the I2C_BUFSTAT.RXSTAT register in order to check the amount of data left to be transferred from the FIFO. Then, according to the mode set (DMA or interrupt), the CPU needs to enable the draining feature of the DMA controller with the number of data bytes to be transferred (I2C_BUFSTAT.RXSTAT), or generate read data accesses according to this value (IRQ mode). The interrupt needs to be cleared after the DMA controller was reconfigured (if DMA mode enabled), or before generating data accesses to the FIFO (if IRQ mode enabled). If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU can also poll this bit. For more details about RDR generation, refer to the FIFO Management subsection. The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect.
		0	Receive draining inactive
		1	Receive draining enabled
			Value after reset is low.

Table 11-8. I2C_IRQSTATUS_RAW Register (I2C Status Raw) Field Descriptions (continued)

Bit	Field	Value	Description
12	BB		This read-only bit indicates the state of the serial bus. In slave mode, on reception of a start condition, the device sets BB to 1. BB is cleared to 0 after reception of a stop condition. In master mode, the software controls BB. To start a transmission with a start condition, MST, TRX, and STT must be set to 1 in the I2C_CON register. To end a transmission with a stop condition, STP must be set to 1 in the I2C_CON register. When BB = 1 and STT = 1, a restart condition is generated.
		0	Bus is free
		1	Bus is occupied
			Value after reset is low.
11	ROVR		Receive overrun status. Writing into this bit has no effect. I2C receive mode only. This read-only bit indicates whether the receiver has experienced overrun. Overrun occurs when the shift register is full and the receive FIFO is full. An overrun condition does not result in a data loss; the peripheral is just holding the bus (low on SCL) and prevents other bytes from being received. ROVR is set to 1 when the I2C has recognized an overrun. ROVR is clear when reading I2C_DATA register, or when resetting the I2C (I2C_CON:I2C_EN = 0).
		0	Normal operation
		1	Receiver overrun
			Value after reset is low.
10	XUDF		Transmit underflow status. Writing into this bit has no effect. I2C transmit mode only. This read-only bit indicates whether the transmitter has experienced underflow. In master transmit mode, underflow occurs when the shift register is empty, the transmit FIFO is empty, and there are still some bytes to transmit (DCOUNT M 0). In slave transmit mode, underflow occurs when the shift register is empty, the transmit FIFO is empty, and there are still some bytes to transmit (read request from external I2C master). XUDF is set to 1 when the I2C has recognized an underflow. The core holds the line till the underflow cause has disappeared. XUDF is clear when writing I2C_DATA register or resetting the I2C (I2C_CON:I2C_EN = 0).
		0	Normal operation
		1	Transmit underflow
			Value after reset is low.
9	AAS		Address recognized as slave IRQ status. I2C mode only. This read only bit is set to 1 by the device when it has recognized its own slave address (or one of the alternative own addresses), or an address of all zeros (8 bits). When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. This bit can be cleared in 2 ways: • If the interrupt was enabled, it will be cleared by writing 1 into this register (writing 0 has no effect) • If the interrupt was not enabled, the AAS bit is reset to 0 by restart or stop
		0	No action
		1	Address recognized
			Value after reset is low.
8	BF		I2C mode only. This read only bit is set to 1 by the device when the I2C bus became free (after a transfer is ended on the bus – stop condition detected). This interrupt informs the Local Host that it can initiate its own I2C transfer on the bus. When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.
		0	No action
		1	Bus Free
			Value after reset is low.

Table 11-8. I2C_IRQSTATUS_RAW Register (I2C Status Raw) Field Descriptions (continued)

Bit	Field	Value	Description
7	AERR		Access Error IRQ status. I2C mode only. This read/clear only bit is set to 1 by the device if an Interface/OCP write access is performed to I2C_DATA while the TX FIFO is full or if an Interface/OCP read access is performed to the I2C_DATA while the RX FIFO is empty. Note that, when the RX FIFO is empty, a read access will return to the previous read data value. When the TX FIFO is full, a write access is ignored. In both events, the FIFO pointers will not be updated. When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.
		0	No action
		1	Access Error
			Value after reset is low.
6	STC		Start Condition IRQ status. I2C mode only. This read/clear only bit is set to 1 by the device if previously the module was in idle mode and a start condition was asynchronously detected on the I2C Bus and signalized with an Wakeup (if the I2C_SYSC.ClockActivity allows the system clock to be cut-off). When the Active Mode will be restored and the interrupt generated, this bit will indicate the reason of the wakeup. **Note 1:** The corresponding interrupt for this bit should be enabled only if the module was configured to allow the possibility of cutting-off the system clock while in Idle State (I2C_SYSC.ClockActivity = 00 or 01). **Note 2:** The first transfer (corresponding to the detected start condition) will be lost (not taken into account by the module) and it will be used only for generating the WakeUp enable for restoring the Active Mode of the module. On the I2C line, the external master which generated the transfer will detect this behavior as a not acknowledge to the address phase and will possibly restart the transfer. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.
		0	No action
		1	Start Condition detected
			Value after reset is low.
5	GC		General call IRQ status. Set to '1' by core when General call address detected and interrupt signaled to MPUSS. Write '1' to clear. I2C mode only. This read/clear only bit is set to 1 by the device if it detects the address of all zeros (8 bits) (general call). When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect. **Note:** When this bit is set to 1, AAS also reads as 1.
		0	No general call detected
		1	General call address detected
			Value after reset is low.
4	XRDY		Transmit data ready IRQ status. Set to '1' by core when transmitter and when new data is requested. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear. Transmit mode only (I2C mode). This read/clear only bit (XRDY) is set to 1 when the I2C peripheral is a master or slave transmitter, the CPU needs to send data through the I2C bus, and the module (transmitter) requires new data to be served. Note that a master transmitter requests new data if the FIFO TX level is below the threshold (TXTRSH) and the required amount of data remained to be transmitted (I2C_BUFSTAT.TXSTAT) is greater than the threshold. A slave transmitter requests new data when the FIFO TX level is below the threshold (if TXTRSH > 1), or anytime there is a read request from external master (for each acknowledge received from the master), if TXTRSH = 1. When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can also poll this bit (refer to the FIFO Management subsection for details about XRDY generation). The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect. **Note:** If the DMA transmit mode is enabled (I2C_BUF.XDMA_EN is set, together with I2C_DMATXENABLE_SET), this bit is forced to 0 and no interrupt will be generated; instead, a DMA TX request to the main DMA controller of the system is generated.
		0	Transmission ongoing
		1	Transmit data ready
			Value after reset is low.

Table 11-8. I2C_IRQSTATUS_RAW Register (I2C Status Raw) Field Descriptions (continued)

Bit	Field	Value	Description
3	RRDY		Receive mode only (I2C mode). This read/clear only RRDY is set to 1 when the RX FIFO level is above the configured threshold (RXTRSH). When this bit is set to 1 by the core, CPU is able to read new data from the I2C_DATA register. If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU to read the received data in I2C_DATA register can also poll this bit (refer to the FIFO Management subsection for details about RRDY generation). The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect. If the DMA receive mode is enabled (I2C_BUF.RDMA_EN is set, together with I2C_DMARXENABLE_SET), this bit is forced to 0 and no interrupt will be generated; instead a DMA RX request to the main DMA controller of the system is generated.
		0	Receive FIFO threshold not reached
		1	Receive data ready for read (RX FIFO threshold reached)
			Value after reset is low.
2	ARDY		I2C mode only. This read/clear only bit, when set to 1, indicates that the previously programmed data and command (receive or transmit, master or slave) has been performed and status bit has been updated. The CPU uses this flag to let it know that the I2C registers are ready to be accessed again. The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect.
			Mode / **Others** / **ARDY Set Condition**: I2C Master transmit / STP = 1 / DCOUNT = 0 I2C Master receive / STP = 1 / DCOUNT = 0 and receiver FIFO empty I2C Master transmit / STP = 0 / DCOUNT passed 0 I2C Master receive / STP = 0 / DCOUNT passed 0 and receiver FIFO empty I2C Master transmit / - / Stop or restart condition received from master I2C Slave receive / - / Stop or restart condition and receiver FIFO empty
		0	No action
		1	Access ready
			Value after reset is low.
1	NACK		No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. Write '1' to clear this bit. I2C mode only. The read/clear only No Acknowledge flag bit is set when the hardware detects No Acknowledge has been received. When a NACK event occurs on the bus, this bit is set to 1, the core automatically ends the transfer and clears the MST/STP bits in the I2C_CON register and the I2C becomes a slave. Clearing the FIFOs from remaining data might be required. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.
		0	Normal operation
		1	Not Acknowledge detected
			Value after reset is low.
0	AL		Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. I2C mode only. The read/clear only Arbitration Lost flag bit is set to 1 when the device (configured in master mode) detects it has lost an arbitration (in Address Phase). This happens when two or more masters initiate a transfer on the I2C bus almost simultaneously or when the I2C attempts to start a transfer while BB (bus busy) is 1. When this is set to 1 due to arbitration lost, the core automatically clears the MST/STP bits in the I2C_CON register and the I2C becomes a slave receiver. The CPU can only clear this bit by writing a 1 to this register. Writing 0 has no effect.
		0	Normal operation
		1	Arbitration lost detected
			Value after reset is low.

11.3.6 I2C_IRQSTATUS Register (I2C Status)

This register provides core status information for interrupt handling, showing all active and enabled events and masking the others. The fields are read-write. Writing a 1 to a bit will clear it to 0, that is, clear the IRQ. Writing a 0 will have no effect, that is, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

For all the internal fields of the I2C_IRQSTATUS register, the descriptions given in the I2C_IRQSTATUS_RAW subsection are valid.

Bit	Field	Value	Description
5	GC		General call IRQ enabled status. Set to '1' by core when General call address detected and interrupt signaled to MPUSS. Write '1' to clear.
		0	No general call detected
		1	General call address detected
4	XRDY		Transmit data ready IRQ enabled status. Set to '1' by core when transmitter and when new data is requested. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear.
		0	Transmision ongoing
		1	Transmit data ready
3	RRDY		Receive data ready IRQ enabled status. Set to '1' by core when receiver mode, a new data is able to be read. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear.
		0	No data available
		1	Receive data available
2	ARDY		Register access ready IRQ enabled status. When set to '1' it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPUSS. Write '1' to clear.
		0	Module busy
		1	Access ready
1	NACK		No acknowledgement IRQ enabled status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. Write '1' to clear this bit.
		0	Normal operation
		1	Not Acknowledge detected
0	AL		Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0.
		0	Normal operation
		1	Arbitration lost detected

11.3.7 I2C_IRQENABLE_SET Register (I2C Interrupt Enable Set)

All 1-bit fields enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit will enable the field. Writing a 0 will have no effect, that is, the register value will not be modified.

For all the internal fields of the I2C_IRQENABLE_SET register, the descriptions given in the I2C_IRQSTATUS_RAW subsection are valid.

		0	Arbitration lost interrupt disabled
		1	Arbitration lost interrupt enabled

11.3.8 I2C_IRQENABLE_CLR Register (I2C Interrupt Enable Clear)

All 1-bit fields clear a specific interrupt event. Writing a 1 to a bit will disable the interrupt field. Writing a 0 will have no effect, that is, the register value will not be modified.

For all the internal fields of the I2C_IRQENABLE_CLR register, the descriptions given in the I2C_IRQSTATUS_RAW subsection are valid.

11.3.9 I2C_WE Register (I2C Wakeup Enable)

Every 1-bit field in the I2C_WE register enables a specific (synchronous) IRQ request source to generate an asynchronous wakeup (on the appropriate swakeup line). When a bit location is set to 1 by the local host, a wakeup is signaled to the local host if the corresponding event is captured by the core of the I2C controller. Value after reset is low (all bits).

NOTE:

- There is no need for an Access Error WakeUp event, since this event occurs only when the module is in Active Mode (for Interface/OCP accesses to FIFO) and is signaled by an interrupt.
- With the exception of Start Condition WakeUp, which is asynchronously detected when the Functional clock is turned-off, all the other WakeUp events require the Functional (System) clock to be enabled.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 11-12. I2C_WE Register (I2C Wakeup Enable) Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved
14	XDR_WE		Transmit draining wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode, the TX FIFO level is below the threshold and the amount of data left to be transferred is less than TXTRSH value. This allows for the module to inform the CPU that it can check the amount of data to be written to the FIFO.
		0	Transmit draining wakeup disabled
		1	Transmit draining wakeup enabled
13	RDR_WE		Receive draining wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C is in idle mode, configured as a receiver, and it has detected a stop condition on the bus but the RX FIFO threshold is not reached (but the FIFO is not empty). This allows for the module to inform the CPU that it can check the amount of data to be transferred from the FIFO.
		0	Receive draining wakeup disabled
		1	Receive draining wakeup enabled
12	Reserved	0	Reserved
11	ROVR_WE		Receive overrun wakeup enable
		0	Receive overrun wakeup disabled
		1	Receive overrun wakeup enabled
10	XUDF_WE		Transmit underflow wakeup enable
		0	Transmit underflow wakeup disabled
		1	Transmit underflow wakeup enabled

Table 11-12. I2C_WE Register (I2C Wakeup Enable) Field Descriptions (continued)

Bit	Field	Value	Description
9	AAS_WE		Address as slave IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode, and external master addresses the I2C module as a slave. This allows for the module to inform the CPU that it can check which of the own addresses was used by the external master to access the I2C core.
		0	Addressed as slave wakeup disabled
		1	Addressed as slave wakeup enabled
8	BF_WE		Bus free IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode and the I2C bus became free. This allows for the module to inform the CPU that it can initiate its own transfer on the I2C line.
