16	SBGR	0 1	<p>Stop at block gap request. This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCHS_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCHS_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (MMCHS_DATA).</p> <p>0 Transfer mode</p> <p>1 Stop at block gap</p>
15-12	Reserved	0	Reserved bit field. Do not write any value.
11-9	SDVS	5h 6h 7h	<p>SD bus voltage select (All cards). The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (MMCHS_CAPA[26] VS18 bit, MMCHS_CAPA[25] VS30 bit, MMCHS_CAPA[24] VS33 bit) before starting a transfer.</p> <p>MMCHS2. This field must be set to 5h.</p> <p>MMCHS3. This field must be set to 5h.</p> <p>5h 1.8 V (Typical)</p> <p>6h 3.0 V (Typical)</p> <p>7h 3.3 V (Typical)</p>
8	SDBP	0 1	<p>SD bus power. Before setting this bit, the host driver shall select the SD bus voltage (MMCHS_HCTL[11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically cleared to 0. If the module is power off, a write in the command register (MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (MMCHS_CAPA[VS*]).</p> <p>0 Power off</p> <p>1 Power on</p>
7	CDSS	0 1	<p>Card Detect Signal Selection. This bit selects source for the card detection. When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing.</p> <p>0 SDCD# is selected (for normal use).</p> <p>1 The Card Detect Test Level is selected (for test purposes).</p>
6	CDTL	0 1	<p>Card Detect Test Level. This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not.</p> <p>0 No card</p> <p>1 Card inserted.</p>
5	Reserved	0	Reserved bit field. Do not write any value.

Table 18-33. Control Register (MMCHS_HCTL) Field Descriptions (continued)

Bit	Field	Value	Description
4-3	DMAS	0-1h Reserved 2h 32-bit Address ADMA2 is selected. 3h Reserved	DMA Select. One of the supported DMA modes can be selected. The host driver shall check support of DMA modes by referencing the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MADMA_EN is set to 1. When MADMA_EN is cleared to 0 the bit field is read only and returned value is 0.
2	HSPE	0 Normal speed mode 1 High speed mode	High Speed Enable. Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is cleared to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock. This bit shall not be set when dual data rate mode is activated in MMCHS_CON[DDR].
1	DTW	0 1-bit Data width (mmc_dat0 used) 1 4-bit Data width (mmc_dat[3:0] used)	Data transfer width. This bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card.
0	Reserved	0	Reserved bit field. Do not write any value.

18.4.21 SD System Control Register (MMCHS_SYCTL)

This register defines the system controls to set software resets, clock frequency management and data timeout.

- MMCHS_SYCTL[31:24] = Software resets
- MMCHS_SYCTL[23:16] = Timeout control
- MMCHS_SYCTL[15:0] = Clock control

The SD system control register (MMCHS_SYCTL) is shown in [Figure 18-55](#) and described in [Table 18-34](#).

Figure 18-55. SD System Control Register (MMCHS_SYCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-34. SD System Control Register (MMCHS_SYCTL) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reserved bit field. Do not write any value.
26	SRD	0 1	Software reset for mmc_dat line. This bit is set to 1 for reset and released to 0 when completed. mmc_dat finite state machine in both clock domain are also reset. These registers are cleared by the MMCHS_SYCTL[26] SRD bit: <ul style="list-style-type: none"> • MMCHS_DATA • MMCHS_PSTATEBRE, BWE, RTA, WTA, DLA and DATI • MMCHS_HCTLSBGR and CR • MMCHS_STATBRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized. Notel f a soft reset is issued when an interrupt is asserted, data may be lost.
25	SRC	0 1	Software reset for mmchs_cmd line. This bit is set to 1 for reset and released to 0 when completed. mmchs_cmd finite state machine in both clock domain are also reset. These registers are cleared by the MMCHS_SYCTL[25] SRC bit: <ul style="list-style-type: none"> • MMCHS_PSTATECMDI • MMCHS_STATCC Interconnect and MMC command status management is reinitialized. Notel f a soft reset is issued when an interrupt is asserted, data may be lost.
24	SRA	0 1	Software reset for all. This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers.
23-20	Reserved	0	Reserved bit field. Do not write any value.

Table 18-34. SD System Control Register (MMCHS_SYCTL) Field Descriptions (continued)

Bit	Field	Value	Description
19-16	DTO	<p>0 TCF x 2¹³</p> <p>1h TCF x 2¹⁴</p> <p>Eh TCF x 2²⁷</p> <p>Fh Reserved</p>	<p>Data timeout counter value and busy timeout. This value determines the interval by which mmc_dat lines timeouts are detected.</p> <p>The host driver needs to set this bit field based on:</p> <ul style="list-style-type: none"> • The maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer) • The data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card • The timeout clock base frequency (MMCHS_CAPA[5:0] TCF bits) <p>If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCHS_STAT[20] DTO bit). The MMCHS_SYCTL[19,16] DTO bit field is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write.</p>
15-6	CLKD	<p>0 Clock Ref bypass</p> <p>1h Clock Ref bypass</p> <p>2h Clock Ref / 2</p> <p>3h Clock Ref / 3</p> <p>3FFh Clock Ref / 1023</p>	<p>Clock frequency select. These bits define the ratio between a reference clock frequency (system dependant) and the output clock frequency on the mmc_clk pin of either the memory card (MMC, SD, or SDIO).</p>
5-3	Reserved	0	Reserved bit field. Do not write any value.
2	CEN	<p>0 The clock is not provided to the card . Clock frequency can be changed .</p> <p>1 The clock is provided to the card and can be automatically gated when MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCHS_SYCTL[1] ICS bit).</p>	<p>Clock enable. This bit controls if the clock is provided to the card or not.</p>
1	ICS	<p>0 The internal clock is not stable.</p> <p>1 The internal clock is stable after enabling the clock (MMCHS_SYCTL[0] ICE bit) or after changing the clock ratio (MMCHS_SYCTL[15:6] CLKD bits).</p>	<p>Internal clock stable (status)This bit indicates either the internal clock is stable or not.</p>
0	ICE	<p>0 The internal clock is stopped (very low power state).</p> <p>1 The internal clock oscillates and can be automatically gated when MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value).</p>	<p>Internal clock enable. This register controls the internal clock activity. In very low power state, the internal clock is stopped. NoteThe activity of the debounce clock (used for wake-up events) and the interface clock (used for reads and writes to the module register map) are not affected by this register.</p>

18.4.22 Interrupt Status Register (MMCHS_STAT)

The interrupt status regroups all the status of the module internal events that can generate an interrupt.

- MMCHS_STAT[31:16] = Error Interrupt Status
- MMCHS_STAT[15:0] = Normal Interrupt Status

The error bits are located in the upper 16 bits of the MMCHS_STAT register. All bits are cleared by writing a 1 to them. Additionally, bits 15 and 8 serve as special error bits. These cannot be cleared by writing a 1 to them. Bit 15 (ERRI) is automatically cleared when the error causing to ERRI to be set is handled. (that is, when bits 31:16 are cleared, bit 15 will be automatically cleared). Bit 8 (CIRQ) is cleared by writing a 0 to MMCHS_IE[8] (masking the interrupt) and servicing the interrupt.

The interrupt status register (MMCHS_STAT) is shown in [Figure 18-56](#) and described in [Table 18-35](#).

Figure 18-56. Interrupt Status Register (MMCHS_STAT)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-35. Interrupt Status Register (MMCHS_STAT) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reserved bit field. Do not write any value
29	BADA	Read 0 Write 0 Read 1 Write 1	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: <ul style="list-style-type: none"> • During a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE bit =0) • During a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_PSTATE[10] BWE bit=0) No interrupt Status bit unchanged Bad access Status is cleared.
28	CERR	Read 0 Write 0 Read 1 Write 1	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E (error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCHS_CSRE is set. There is no card error detection for autoCMD12 command. The host driver shall read MMCHS_RSP76 register to detect error bits in the command response. No error Status bit unchanged Card error Status is cleared.
27-26	Reserved	0	Reserved bit field. Do not write any value

Table 18-35. Interrupt Status Register (MMCHS_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
25	ADMAE	Read 0 Write 0 Read 1 Write 1	ADMA Error. This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. No interrupt Status bit unchanged ADMA error Status is cleared.
24	ACE	Read 0 Write 0 Read 1 Write 1	Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1. No error Status bit unchanged AutoCMD12 error Status is cleared.
23	Reserved	0	Reserved bit field. Do not write any value
22	DEB	Read 0 Write 0 Read 1 Write 1	Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on mmc_dat line or at the end position of the CRC status in write mode. No error Status bit unchanged Data end bit error Status is cleared.
21	DCRC	Read 0 Write 0 Read 1 Write 1	Data CRC Error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command. No error Status bit unchanged Data CRC error Status is cleared.
20	DTO	Read 0 Write 0 Read 1 Write 1	Data timeout error. This bit is set automatically according to the following conditions: <ul style="list-style-type: none"> • Busy timeout for R1b, R5b response type • Busy timeout after write CRC status • Write CRC status timeout • Read data timeout No error Status bit unchanged Time out Status is cleared.
19	CIE	Read 0 Write 0 Read 1 Write 1	Command index error. This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable bit (MMCHS_CMD[20] CICE). No error Status bit unchanged Command index error Status is cleared.

Table 18-35. Interrupt Status Register (MMCHS_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
18	CEB	Read 0 Write 0 Read 1 Write 1	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response. No error Status bit unchanged Command end bit error Status is cleared.
17	CCRC	Read 0 Write 0 Read 1 Write 1	Command CRC error. This bit is set automatically when there is a CRC7 error in the command response depending on the enable bit (MMCHS_CMD[19] CCCE). No error Status bit unchanged Command CRC error Status is cleared.
16	CTO	Read 0 Write 0 Read 1 Write 1	Command timeout error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles. No error Status bit unchanged Time Out Status is cleared.
15	ERRI	Read 0 Read 1	Error interrupt. If any of the bits in the Error Interrupt Status register (MMCHS_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. No interrupt Error interrupt event(s) occurred
14-11	Reserved	0	Reserved bit field. Do not write any value
10	BSR	Read 0 Write 0 Read 1 Write 1	Boot Status Received Interrupt. This bit is set automatically when MMCHS_CON[BOOT] is set 1 or 2 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card. No interrupt Status bit unchanged Boot Status Received Interrupt occurred. Status is cleared.
9	OBI	Read 0 Write 0 Read 1 Write 1	Out-of-band interrupt (This interrupt is only useful for MMC card). This bit is set automatically when MMCHS_CON[14] OBIE bit is set and an out-of-band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCHS_CON[13] OBIP bit. The out-of-band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. No out-of-band interrupt Status bit unchanged Interrupt out-of-band occurs Status is cleared.

Table 18-35. Interrupt Status Register (MMCHS_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
8	CIRQ	Read 0 Read 1	<p>Card interrupt. This bit is only used for SD and SDIO cards.</p> <p>In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wake-up). In 4-bit mode, interrupt source is sampled during the interrupt cycle.</p> <p>In CE-ATA mode, interrupt source is detected when the card drives mmchs_cmd line to zero during one cycle after data transmission end.</p> <p>All modes above are fully exclusive.</p> <p>The controller interrupt must be clear by setting MMCHS_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCHS_IE[8] CIRQ_ENABLE is set to 1.</p> <p>Writes to this bit are ignored.</p> <p>No card interrupt</p> <p>Generate card interrupt</p>
7	CREM	Read 0 Write 0 Read 1 Write 1	<p>Card Removal. This bit is set automatically when MMCHS_PSTATE[CINS] changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]).</p> <p>Card State stable or debouncing</p> <p>Status bit unchanged</p> <p>Card Removed</p> <p>Status is cleared</p>
6	CINS	Read 0 Write 0 Read 1 Write 1	<p>Card Insertion. This bit is set automatically when MMCHS_PSTATE[CINS] changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]).</p> <p>Card State stable or debouncing</p> <p>Status bit unchanged</p> <p>Card inserted</p> <p>Status is cleared.</p>
5	BRR	Read 0 Write 0 Read 1 Write 1	<p>Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it.</p> <p>Not if the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.</p> <p>Not ready to read buffer</p> <p>Status bit unchanged</p> <p>Ready to read buffer</p> <p>Status is cleared.</p>
4	BWR	Read 0 Write 0 Read 1 Write 1	<p>Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCHS_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer.</p> <p>Not if the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.</p> <p>Not ready to write buffer</p> <p>Status bit unchanged</p> <p>Ready to write buffer</p> <p>Status is cleared.</p>
3	DMA	Read 0 Write 0 Read 1 Write 1	<p>DMA Interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion.</p> <p>DMA Interrupt detected</p> <p>Status bit unchanged</p> <p>No DMA Interrupt</p> <p>Status is cleared.</p>

Table 18-35. Interrupt Status Register (MMCHS_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
2	BGE	Read 0 Write 0 Read 1 Write 1	<p>Block gap event. When a stop at block gap is requested (MMCHS_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.</p> <p>This event does not occur when the stop at block gap is requested on the last block.</p> <p>In read mode, a 1-to-0 transition of the mmc_dat line active status (MMCHS_PSTATE[2] DLA bit) between data blocks generates a Block gap event interrupt.</p> <p>No block gap event</p> <p>Status bit unchanged</p> <p>Transaction stopped at block gap</p> <p>Status is cleared</p>
1	TC	Read 0 Write 0 Read 1 Write 1	<p>Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCHS_HCTL[16] SBGR bit).</p> <p>This bit is also set when exiting a command in a busy state (if the command has a busy notification capability).</p> <p>In Read mode This bit is automatically set on completion of a read transfer (MMCHS_PSTATE[9] RTA bit).</p> <p>In write mode This bit is set automatically on completion of the mmc_dat line use (MMCHS_PSTATE[2] DLA bit).</p> <p>No transfer complete</p> <p>Status bit unchanged</p> <p>Data transfer complete</p> <p>Status is cleared</p>
0	CC	Read 0 Write 0 Read 1 Write 1	<p>Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI bit)</p> <p>If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCHS_STAT[16] CTO bit) has higher priority than command complete (MMCHS_STAT[0] CC bit).</p> <p>If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.</p> <p>No command complete</p> <p>Status bit unchanged</p> <p>Command complete</p> <p>Status is cleared</p>

18.4.23 Interrupt SD Enable Register (MMCHS_IE)

This register allows to enable/disable the module to set status bits, on an event-by-event basis.

- MMCHS_IE[31:16] = Error Interrupt Status Enable
- MMCHS_IE[15:0] = Normal Interrupt Status Enable

The interrupt SD enable register (MMCHS_IE) is shown in [Figure 18-57](#) and described in [Table 18-36](#).

18.4.25 Auto CMD12 Error Status Register (MMCHS_AC12)

The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this MMCHS_AC12 register when an auto CMD12 error interrupt occurs.

This register is valid only when auto CMD12 is enabled (MMCHS_CMD[2] ACEN bit) and auto CMD12Error (MMCHS_STAT[24] ACE bit) is set to 1.

NOTE: These bits are automatically reset when starting a new adtc command with data.

The auto CMD12 error status register (MMCHS_AC12) is shown in [Figure 18-59](#) and described in [Table 18-38](#).

Figure 18-59. Auto CMD12 Error Status Register (MMCHS_AC12)

Table 18-38. Auto CMD12 Error Status Register (MMCHS_AC12) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved bit field. Do not write any value.
7	CNI	Read 0 Read 1	Command not issue by auto CMD12 error. If this bit is set to 1, it means that pending command is not executed due to auto CMD12 error ACEB, ACCE, ACTO, or ACNE. Not error Command not issued
6-5	Reserved	0	Reserved bit field. Do not write any value.
4	ACIE	Read 0 Read 1	Auto CMD12 index error. This bit is a set to 1 when response index differs from corresponding command auto CMD12 index previously emitted. This bit depends on the command index check enable (MMCHS_CMD[20] CICE bit). No error Auto CMD12 index error
3	ACEB	Read 0 Read 1	Auto CMD12 end bit error. This bit is set to 1 when detecting a 0 at the end bit position of auto CMD12 command response. No error AutoCMD12 end bit error
2	ACCE	Read 0 Read 1	Auto CMD12 CRC error. This bit is automatically set to 1 when a CRC7 error is detected in the auto CMD12 command response depending on the enable in the MMCHS_CMD[19] CCCE bit. No error Auto CMD12 CRC error
1	ACTO	Read 0 Read 1	Auto CMD12 timeout error. This bit is set to 1 if no response is received within 64 clock cycles from the end bit of the auto CMD12 command. No error Auto CMD12 time out
0	ACNE	Read 0 Read 1	Auto CMD12 not executed. This bit is set to 1 if multiple block data transfer command has started and if an error occurs in command before auto CMD12 starts. Auto CMD12 executed Auto CMD12 not executed

18.4.26 Capabilities Register (MMCHS_CAPA)

This register lists the capabilities of the MMC/SD/SDIO host controller. The capabilities register (MMCHS_CAPA) is shown in [Figure 18-60](#) and described in [Table 18-39](#).

Figure 18-60. Capabilities Register (MMCHS_CAPA)

24	VS33	Read 0 Write 0 Read 1 Write 1	Voltage support 3.3V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal) 3.3 V not supported 3.3 V not supported 3.3 V supported 3.3 V supported

Table 18-39. Capabilities Register (MMCHS_CAPA) Field Descriptions (continued)

Bit	Field	Value	Description
23	SRS	Read 0 Read 1	Suspend/resume support (SDIO cards only). This bit indicates whether the host controller supports Suspend/Resume functionality. The Host controller does not suspend/resume functionality. The Host controller supports suspend/resume functionality.
22	DS	Read 0 Read 1	DMA support. This bit indicates that the Host controller is able to use DMA to transfer data between system memory and the Host controller directly. DMA not supported DMA supported
21	HSS	Read 0 Read 1	High-speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card. High-speed not supported High-speed supported
20	Reserved	0	Reserved bit field. Do not write any value.
19	AD2S	Read 0 Read 1	This bit indicates whether the Host Controller is capable of using ADMA2. It depends on setting of generic parameter MADMA_EN. ADMA2 not supported ADMA2 supported
18	Reserved	0	Reserved bit field. Do not write any value.
17-16	MBL	Read 0 Read 1 Read 2	Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. The host controller supports 512 bytes and 1024 bytes block transfers. 512 bytes 1024 bytes 2048 bytes
15-14	Reserved	0	Reserved bit field. Do not write any value.
13-8	BCF	Read 0	Base clock frequency for clock provided to the card. The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. See the <i>Power, Reset, and Clock Management</i> chapter for more information on the value of FUNC_96M_CLK clock signal.
7	TCU	Read 0 Read 1	Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCHS_STAT[20] DTO bit). kHz MHz
6	Reserved	0	Reserved. This bit is initialized to zero, and writes to it are ignored.
5-0	TCF	Read 0	Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (MMCHS_STAT[20] DTO bit). The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.

18.4.27 Force Event Register for Error Interrupt Status (MMCHS_FE)

The Force Event register is not a physically implemented register. Rather, it is an address at which the Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register, if corresponding bit of the Error Interrupt Status Enable Register is set.

The force event register (MMCHS_FE) is shown in [Figure 18-61](#) and described in [Table 18-40](#).

Figure 18-61. Interrupt Signal Enable Register (MMCHS_FE)

15-8	Reserved	0	Reserved bit field. Any writes to these bits result in 0.
7	FE_CNI	Write 0 Write 1	Force Event Command not issue by Auto CMD12 error No effect; no interrupt Interrupt forced.
6-5	Reserved	0	Reserved bit field. Any writes to these bits result in 0.
4	FE_ACIE	Write 0 Write 1	Force Event Auto CMD12 index error No effect; no interrupt Interrupt forced.
3	FE_ACEB	Write 0 Write 1	Force Event Auto CMD12 end bit error No effect; no interrupt Interrupt forced.
2	FE_ACCE	Write 0 Write 1	Force Event Auto CMD12 CRC error No effect; no interrupt Interrupt forced.
1	FE_ACTO	Write 0 Write 1	Force Event Auto CMD12 timeout error No effect; no interrupt Interrupt forced.
0	FE_ACNE	Write 0 Write 1	Force Event Auto CMD12 not executed. No effect; no interrupt Interrupt forced.

18.4.28 ADMA Error Status Register (MMCHS_ADMAES)

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because do not generate ADMA error in this state.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In the case of a write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid = 0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

The ADMA error status register (MMCHS_BLK) is shown in [Figure 18-62](#) and described in [Table 18-41](#).

Figure 18-62. ADMA Error Status Register (MMCHS_ADMAES)

31	Reserved	3	2	1	0
R-0			LME	AES	
			R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-41. ADMA Error Status Register (MMCHS_ADMAES) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved bit field. Do not write any value.
2	LME	0 1	ADMA Length Mismatch Error: <ul style="list-style-type: none"> • While Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length. • Total data length cannot be divided by the block length. No error Error
1-0	AES	Read 0 Write 1h Read 2h Write 3h	ADMA Error State. This field indicates the state of ADMA when an error occurred during an ADMA data transfer. This field never indicates "10" because ADMA never stops in this state. ST_STOP (Stop DMA). Contents of the SYS_SDR register ST_STOP (Stop DMA). Points to the error descriptor. Never set this state. (Not used) ST_TFR (Transfer Data). Points to the 'next' of the error descriptor.

18.4.29 ADMA System Address Low Bits Register (MMCHS_ADMASAL)

This register holds the byte address of the executing command of the Descriptor table. The 32-bit Address Descriptor uses the lower 32 bits of this register. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table.

The ADMA System address low bits register (MMCHS_ADMASAL) is shown in [Figure 18-63](#) and described in [Table 18-42](#).

Figure 18-63. ADMA System Address Low Bits (MMCHS_ADMASAL)

LEGEND: R/W = Read/Write; -n = value after reset

Table 18-42. ADMA System Address Low Bits (MMCHS_ADMASAL) Field Descriptions

Bit	Field	Value	Description
31-0	ADMA_A32B	0-FFFF FFFFh	The ADMA increments this register address, which points to the next line, whenever fetching a Descriptor line. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The Host Driver shall program the Descriptor Table on a 32-bit boundary and set the 32-bit boundary address to this register. ADMA2 ignores the lower 2 bits of this register and assumes it to be 00b.

18.4.30 ADMA System Address High Bits Register (MMCHS_ADMASAH)

The ADMA System address high bits register (MMCHS_ADMASAH) is shown in [Figure 18-63](#) and described in [Table 18-42](#).

Figure 18-64. ADMA System Address High Bits Register (MMCHS_ADMASAH)

LEGEND: R/W = Read/Write; -n = value after reset

Table 18-43. ADMA System Address High Bits Register (MMCHS_ADMASAH) Field Descriptions

Bit	Field	Value	Description
31-0	ADMA_A32B	0	This register is only used on devices with greater than 32-b address space. This register is not used on this device.

18.4.31 Versions Register (MMCHS_REV)

This register contains the hard coded RTL vendor revision number, the version number of SD specification compliancy and a slot status bit.

- MMCHS_REV[31:16] = Host Controller Version
- MMCHS_REV[15:0] = Slot Interrupt Status

The versions register (MMCHS_REV) is shown in [Figure 18-65](#) and described in [Table 18-44](#).

Figure 18-65. Versions Register (MMCHS_REV)

31	24 23	16 15	1 0
VREV	SREV	Reserved	SIS
R-x	R-0	R-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-44. Versions Register (MMCHS_REV) Field Descriptions

Bit	Field	Value	Description
31-24	VREV	0	Vendor Version Number. Bits [7:4] is the major revision, bits [3:0] is the minor revision. Examples: 10h for 1.0 21h for 2.1
23-16	SREV	Read 0	Specification Version Number. This status indicates the Standard SD Host Controller Specification Version. The upper and lower 4-bits indicate the version. SD Host Specification Version 1.0
15-1	Reserved	0	Reserved bit field. Do not write any value.
0	SIS	0-1	Slot Interrupt Status. This status bit indicates the inverted state of interrupt signal for the module. By a power on reset or by setting a software reset for all (MMCHS_SYSCTL[24] SRA), the interrupt signal shall be deasserted and this status shall read 0.

Peripheral Component Interconnect Express (PCIe) Module

This chapter describes the Peripheral Component Interconnect Express (PCIe) module. The PCIe provides a high speed glueless serial interconnect to peripherals utilizing high bandwidth applications.

Topic	Page
19.1 Introduction / Feature Overview	2288
19.2 Peripheral Architecture	2292
19.3 Supported Use Case	2310
19.4 Encoding of LTSSM State in DEBUG registers	2314
19.5 PCISS Memory Map	2314

19.1 Introduction / Feature Overview

The Peripheral Component Interconnect Express (PCIe) module is a single-lane I/O interconnect that provides low pin-count, high reliability, and high-speed data transfer at line rates of up to 5.0 Gbps per lane per direction, for serial links on backplanes and printed wiring boards. It is a 3rd Generation I/O interconnect technology succeeding the PCI and ISA bus, that is designed to be used as a general-purpose serial I/O interconnect in multiple market segments, including desktop, mobile, server, storage and embedded communications. It is also used as a bridge to other interconnects like SATA, USB2/3.0, GbE MAC, and more.

The PCI ESS contains the Synopsys DesignWare Core (DWC) PCIe Dual Mode core and Texas Instruments SERDES PHY. The dual mode (DM) core operates as either endpoint (EP) mode or root complex (RC) port mode. The core supports a single in-port and a single out-port. The operating mode of the device; that is, the role that the PCIe core assumes, is set to either EP or RC based on the value sampled from the BOOTMODE[4:0] pins and can be changed by a secondary bootloader or by application software configuring PCIE_CFG[PCIE_DEVTYPE] register. The DM core can be switched between modes at runtime by applying a power-on reset.

19.1.1 Purpose of the Peripheral

The incumbent design, PCI, is a parallel bus architecture that is increasingly difficult to scale-up in bandwidth, which is usually performed by increasing the number of data signal lines. More signal lines result in difficult clock-to-data skew management, creating complex PCB layout rules that make cost-effective implementations in the FR4 technology difficult. Increasing the number of signal lines also increases the power dissipation. The PCIe architecture was developed to help minimize I/O bus bottlenecks within systems and to provide the necessary bandwidth for high-speed, chip-to-chip, and board-to-board communications within a system. It is designed to replace the PCI-based shared, parallel-bus-signaling technology that is approaching its practical performance limits while simplifying the interface design. It includes cost, performance, and scalability advantages, ensuring a long life span for applications, system designs, and investments.

PCIe is a serial-based technology which uses low-voltage differential data signaling/lines (LVDS) to reduce the number of data signal lines and high-frequency clock signals in a point-to-point interconnect arrangement between two devices. It also serves to eliminate multiple host presences on the same bus.

19.1.2 Terminology Used in This Document

Table 19-1. Terminology Used

Term	Definition
ADPLL	All digital phase locked loop
ASPM	Active state power management
AXI	AMBA AXI bus protocol
DBI	Direct bus interface
EP	Endpoint
LVDS	Low voltage differential signaling
MMR	Memory mapped register
OCP	Open core protocol
PCI	Peripheral component interconnect
PCIe	PCI Express
PCI ESS	PCI Express subsystem
PCISIG	PCI special interest group
PHY	Physical interface device
PIPE	Physical interface for PCI Express - Programmable Image Processing Element
PME	Power management event
RC	Root complex
TC	Traffic class

Table 19-1. Terminology Used (continued)

Term	Definition
TLP	Transaction layer packet
VC	Virtual channel
VCXO	Voltage controlled crystal oscillator
VPD	Vital Product data

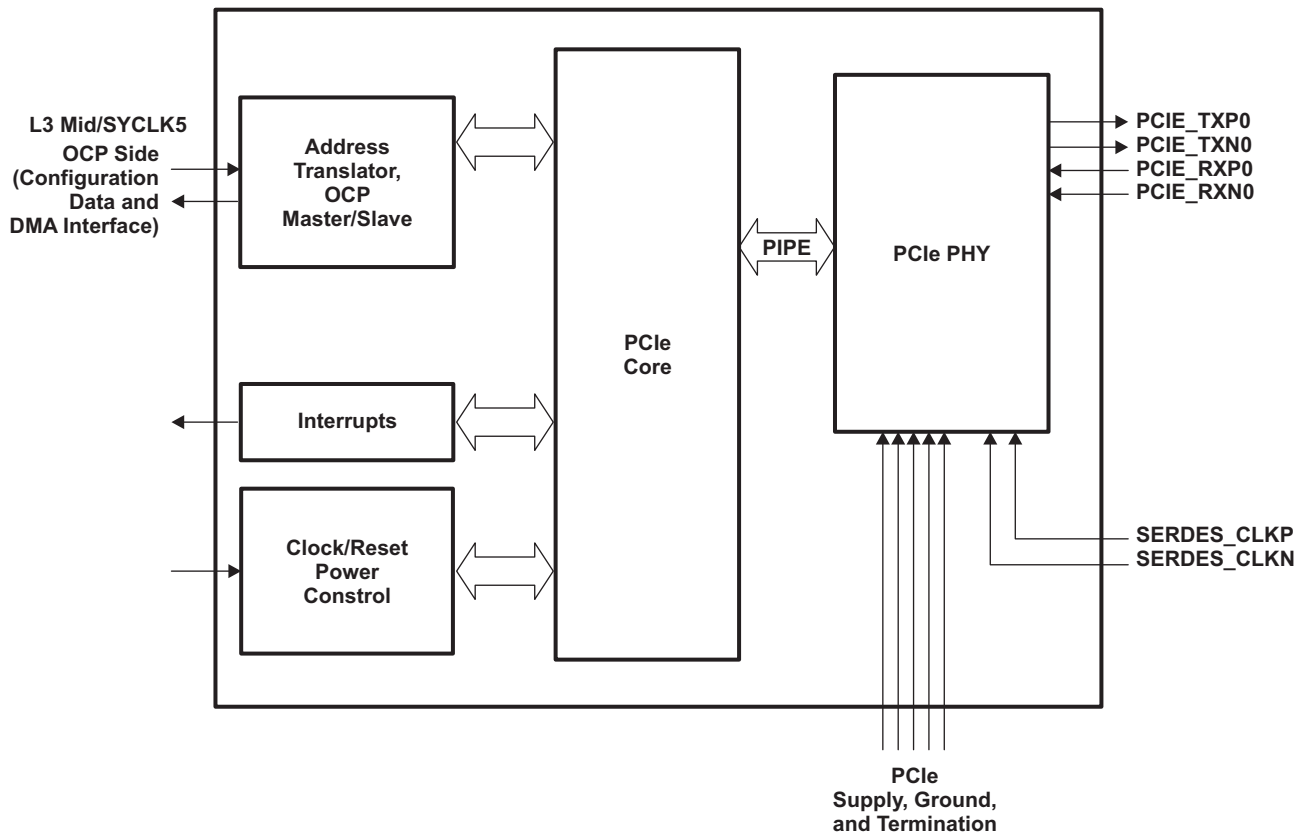

19.1.3 Features Supported

The PCI ESS on the device supports an interface width of x1 lane. The following features are included:

- 250 MHz functional clock frequency operation (PIPE clock frequency)
- Supports a single bi-directional link interface (for example, a single Ingress and a single Egress ports) single channel lane width (x1)
- Operates at a raw speed of 2.5Gbps and 5.0 Gbps per direction
- Maximum outbound payload size of 128 bytes
- Maximum inbound payload size of 256 bytes
- Maximum remote read request size of 256 bytes
- Ultra-low transmit and receive latency
- Supports dynamic-width conversion
- Automatic lane reversal
- Polarity inversion on receive
- Single virtual channel (VC)
- Single traffic class (TC)
- Automatic credit management
- Single function in endpoint (EP) mode
- ECRC generation and checking
- PCI device power management with the exception of D3 cold with Vaux
- PCI Express active state power management (ASPM) state L0s and L1
- PCI Express link power management states except L2 state
- PCI Express advanced error reporting
- PCI Express messages for both transmit and receive
- Filtering for posted, non-posted, and completion traffic
- Configurable BAR filtering, I/O filtering, configuration filtering and completion lookup/timeout
- Access to configuration space registers and external application memory mapped registers through BAR0 and through configuration access
- Legacy interrupts reception (Root Complex (RC)) and generation (EP)
- MSI generation and reception
- PHY loopback in RC mode

19.1.4 Functional Block Diagram

The PCI ESS is shown in [Figure 19-1](#).

Figure 19-1. PCIe Subsystem (PCIESS) Block Diagram

19.1.4.1 PCIe Core

The PCI Express core contains the transaction layer, data link layer, and MAC part of the PHY. The PCIe core is a dual mode core that can operate as either an RC or EP. As an EP, it can operate as a legacy endpoint or native PCIe endpoint. The role it assumes is based on the state of the PCIe configuration register (within the control module) bit field PCIE_DEVTYPE. PCIE_CFG.DEVTYPE = 00b/ 01b/ 10b = EP/ Legacy Endpoint/ RC, respectively. The user software or BOOTROM is required to initialize this field. When the PCIe is used as a boot device, the state of bootmode pins will determine the boot type used (in this case it will be PCIe) and the address size to be used which is either 32-bit or 64-bit addressing. The bootloader software configures the PCIe core to operate in EP mode. No RC bootmode is supported.

19.1.4.2 PCIe PHY

The PCI PHY (SERDES) contains the analog portion of the PHY which is the transmission line channel that is used to transmit and receive data. It contains a phase-locked loop, analog transceiver, phase interpolator-based clock/data recovery, parallel to serial converter, serial to parallel converter, scrambler, configuration, and test logic.

19.1.4.3 Configuration and DMA Access Interface

CPU side access, configuration registers, data access, and remote EP DMA access is performed through the configuration and DMA access interface. The maximum amount of data burst access made through this port is 128 bytes.

19.1.4.4 Clock, Reset, Power Control Logic

Several clock domains exist within PCI ESS; these are functional clocks used by the PCIe controller and interface bridges, as well as receive and transmit clocks used to clock data in and out. The clocks required for clocking data and PHY functional clocks are generated by the PHY through the supplied external input 100 MHz differential clock that complies to the requirements listed in the SERDES_CLKNP Input Clock section of the data manual. The PCIe controller functional clock frequency is generated from the internal PLL and should be programmed to generate a clock frequency of 250 MHz. The input clock source for the controller is derived from the main device input clock source and the frequency of this source should be a 20 MHz clock source.

The PCI ESS supports the conventional reset mechanism that is specified within the PCI Express Specification. The reset shown on the block diagram pertains to a hardware reset (cold or warm reset).

In addition to automatic power down mode exercised and entered by the hardware (active state power management) when no activity is present, PCI ESS supports higher level power down modes controlled (activated and deactivated) by application software.

Note that link state L2 is not supported.

19.1.4.5 Interrupts

The PCI ESS is capable of generating multiple interrupts events via the four interrupt lines (INTA/B/C/D – legacy interrupts combined, MSI, error, and PM/reset) connected to the interrupt controller. The user software is required to acknowledge the serviced interrupt by writing to the corresponding vector onto the EOI register.

19.1.4.6 PCIe Power/Ground/Termination

Several supplies, grounds, and termination exist to properly power up the PHY.

19.1.4.7 Differential Data Lines

A pair of differential data lines exists, for both transmit and receive paths, for each lane.

19.1.5 Supported Use Case Statement

The PCIe subsystem has only one interface link with a x1 lane arrangement that connects to a single device. It also means that it can not be used as a switch.

19.1.6 Industry Standard(s) Compliance Statement

The PCI ESS complies with the following standards.

- Revision 2.0 of the PCI Express base specification.
- Synopsys DWC PCIe Dual Core Version 3.60a
- TI SERDES PHY (Mercury)

19.1.7 Features Not Supported

The following features are not supported by the PCI ESS.

- Multiple VCs
- Multiple TCs
- Outbound transactions involving less than 4 bytes
- Function level reset
- PCI Express beacon for in-band wake
- Built-in hardware support for hot plug
- Vendor messaging
- IO access in inbound direction
- Addressing modes other than incremental for burst transactions

- Auxiliary power to maintain controller state to come out D3cold state
- Link state L2 support

19.2 Peripheral Architecture

This section discusses the architecture of the PCI ESS.

19.2.1 Clock Control

The PCI ESS uses multiple clock domains. At the top level, there are only two functional clocks of relevance – a reference clock to the PCIE PHY and a clock for OCP interfaces of the subsystem.

The OCP interface functional clock, SYSCLK4, is derived from the PLL_L3 which is generated from an off-chip/external 20 MHz VCXO.

The other clock input to the PCI ESS is the differential 100MHz clock with a maximum frequency of deviation value of 300ppm. This differential clock is used by the PHY PLL to generate the necessary PHY functional, PIPE clock and Tx and Rex bit clocks required by the PHY.

The PCI ESS operation is completely dependent upon availability of clock from the PLL that is inside the PHY. All registers in PCI ESS are located in the clock domain that is dependent upon PLL to be in lock and properly configured. This implies that transactions initiated before PLL lock will not be processed or could result with undefined condition. The PLL registers reside at the SoC level (for example, external to the PCIe register file space) and these registers are used to control and insure/verify lock status of the PLL.

19.2.2 Supported PCIe Transactions

All of the PCIe transactions defined, posted and non-posted, are supported except the locked memory read request transaction and its subsequent completion locked response transaction. In-bound I/O read/write transactions are also not supported.

Table 19-2. PCIe Transaction Layer Packets Supported

Transaction Packet Types	Posted/Non-posted
Memory Read	Non-posted
Memory Write	Posted
IO read	Non-posted
IO Write (Outbound only is supported)	Non-posted
Configuration Read (Type 0 and Type 1)	Non-posted
Configuration Write (Type 0 and Type 1)	Non-posted
Message Request without Data	Posted
Message Request with Data	Posted
Completion without Data	-
Completion with Data	-

19.2.3 Address Translations

PCI Express TLP transactions that use address routing, use PCIe addresses. A built-in hardware address translation mechanisms accommodates the mapping requirement that exists between a PCIe address and a local OCP/internal address. That is, if the “type” field of an outgoing or received TLP indicates the use of address routing, then an Outbound or Inbound address translation is required. This translation is performed accordingly, to map an OCP/internal address to a PCIe address or vice-versa, using hardware address translators. Address translations for Outbound and Inbound transactions are discussed below.

PCIe recognizes four address spaces: memory, I/O, configuration, and message. Messages do not consume any memory or I/O resource and no type of translation is required. I/O addressing is used by PCIe that supports legacy device operation capabilities; this is not a mandatory feature by PCIe and when supported, the I/O space is memory-mapped to system memory. This implies that there exists a need to map only two types of device address spaces: configuration and memory address spaces. The address translators apply to translating configuration and memory addresses between external, PCIe address and OCP/internal address.

The address space of the physical device is divided into two spaces (Range 0 and Range 1). Address space (Range 0) that is used for PCI configuration task, is referred to as configuration space and a second address space (Range 1) that is used for accessing memory (non-configuration related), is referred to as memory space.

Note: All I/O access use address routing. There is no-support for I/O access in Inbound direction. That is, when it comes to a transaction that performs I/O access, only TLPs with outbound transactions are supported.

19.2.3.1 Outbound Address Translations

Outgoing transaction layer packets (TLP) associated with address routing would require the use of the outbound address translator that creates a mapping between the device OCP/internal memory address and external PCIe address.

The PCIE Subsystem allows mapping of physical device address to PCIe address on outgoing TLPs. This is accomplished by using outbound address translation logic. For each outbound read/write request, the address translation module within PCIESS can convert an OCP address (OCP/internal address) to a PCIE address (PCIe address) of memory read/write type. The address translation logic uses information in address translation registers to perform the mapping. The registers, OB_SIZE, OB_OFFSET_INDEXn, OB_OFFSETn_HI are used in conjunction with outbound address translator.

The physical memory range that PCIESS occupies in the devices internal address range is divided into 32 equally sized translation regions (Regions 0 to 31). These equally divided regions can be programmed to have a size of 1, 2, 4, or 8 MB and this size value is communicated with the outbound address translator via the OB_SIZE register. Each such region (OCP/internal address) can be remapped to a PCIE address range the same size as the size of translation region itself. The address translation logic identifies and extracts the 5 bits (32 regions) from the OCP/internal address and uses this value as an index to one of the 32 regions. The bit address position for these 5 bits depends on the range size. Once the region is identified, the address translation logic then generates PCIe base address, from the values provided within the corresponding configuration registers for that region (the registers OB_OFFSET_INDEXn and OB_OFFSETn_HI [n=0-31]). If 32-bit addressing is used, OB_OFFSETn_HI will always be programmed with zero.

Once the PCIe base address has been identified, the offset that is to be added to this base address is derived from the lower bit fields of the OCP/internal address. The bit fields that make up this offset correspond to the size of the regions.

Application software is required to identify the desired physical memory that is to be accessible by the PCIe module and initialize the corresponding registers prior to enabling PCIe transactions. For outbound translation of the registers in use, initialization, and usage is discussed below.

- **Outbound Size Register (OB_SIZE)** — Application software initializes this register with the size value that applies to all 32 regions. OB_SIZE=0,1,2, and 3 correspond to region sizes of 1MB, 2MB, 4MB, and 8MB and the corresponding indexed regions for these sizes are identified from the OCP/internal address. Note that a single OB_SIZE register exist and the size of region entered/ programed pertains to all regions, for example, all regions are made of equal size. Bits[24:20], bits [25:21], bits[26:22], and bits[27:23] of the OCP/internal address holds the Index value used to identify one of the 32 regions for the 1MB, 2MB, 4MB and 8MB regions respectively. Size of regions also affect the meaningful bit fields within OB_OFFSET_INDEXn [n=0-31] register. The lower bit fields corresponding to the size of the region are masked and not used in the mapping.
- **Outbound Translation Region n Offset Low and Index Register (OB_OFFSET_INDEXn [n=0-31])** — Application software initializes this register with the 32-bit PCIe address. The useful address bits used by the outbound translator from this register depends upon the size of the region. If each region is 1MB, 2MB, 4MB, or 8MB, then the relevant address field bits used to create PCIe address are the

higher address bits, specifically bits[31:20], bits[31:21], bits[31:22], and bits[31:23] respectively.

- Outbound Address High Offset (OB_OFFSETn_HI [n=0-31]) – Application software initializes this register if using 64-bit addressing with the higher 32-bit address. This register is required to be programmed with a Zero value if using 32-bit addressing.

The following example demonstrates the mapping of a given OCP/internal address to a PCIe address.

Example 1:

For a given OCP/internal device address of 0x9D3A_1234; what would be the corresponding PCIe address that would be used on an outgoing TLP Header (assume a 2MB region partition)?

For this example, further assume the following: 64 bit addressing is to be used and for region 9, application software has initialized OB_OFFSET9_HI with 0x3344_5566 and OB_OFFSET9 with 0x56Ex_xxxx (where 'x' here is a don't care hexadecimal value). Note that bits[31:21] of OB_OFFSET9 register is the part of this register content that is meaningful for this example, since the size of the regions is assumed to be 2MB.

The procedure that is used to convert this OCP/internal address to a PCIe address is as follows:

- Extract the five bits index and offset from given input OCP/internal address of 0x9D31_1234: Since region size is given to be 2MB, bits [25:21] of address 0x9D3A_1234 is extracted to be used as an Index and this comes out to be 01001b, which is 9. Since size of all regions is 2MB, the offset address corresponds to bits[20:00] of the OCP/internal address. Note that the offset of the OCP/internal address, bits[20:00], is directly mapped to the PCIe address; that is, bits[20:00]. For this example that translates to 0xXX1A_1234. Since index value for this example corresponds to bits[25:21] of 0x9D3A_1234 which is 01001b or 9 decimal, translation registers contents for region 9 will be used.

Index is now matched to Region 9 and offset is 0x001A1234 which is bits [20:00] of 0x9D3A_1234.

- Generate PCIe base address: Using the Index value identified above, 9, generate base address from register OB_OFFSET9_HI (bits[63:32]) for 64-bit addressing and register OB_OFFSET9 (bits[31:21]). The PCIe base address for this example would result with: 0x3344_5566__0x56E0_0000.
- Compute translated address, PCIe address: Using the generated base address and offset, the PCIe address corresponding to an OCP/internal address of 0x9D3A_1234 is 0x3344_5566__0x56FA_1234.

Note: For this example, 2MB size region will allow unique address mapping for OCP/internal address values 0x0000_0000 to 0x03FF_FFFF. This allows a total of 2MB * 32 = 64MB unique OCP/internal address location to be mapped onto a corresponding unique PCIe address. Any OCP/internal address outside this 64MB space will not be uniquely mapped and the OCP/internal address will be truncated to fall in within the 64MB space, for this example. In other words, bits[31:26] of the given example input OCP/internal address is masked and does not contribute to the PCIe address generation.

For this example, OCP/internal addresses 0x9D3A_1234, 0x913A_1234, 0x953A_1234, 0x993A_1234, and more, are few of other physical values that will all map to the same PCIe address 0x3344_5566__0x56FA_1234.

19.2.3.2 Inbound Address Translations

Incoming error free accepted Transaction Layer Packets (TLP) associated with address routing would require the use of the inbound address translator to map received PCIe address to OCP/internal address.

The PCIe subsystem allows mapping of accepted PCI Express addresses to a physical device address internal to the device using the Inbound address translation logic. For each Inbound read/write request, that results with incoming TLP, the address translation module within PCI ESS can convert a PCIe address to OCP (internal/physical) address for memory or configuration read/write type transactions.

PCI ESS is aware of two OCP address spaces (internal/physical memory spaces). The first address space, Address Space Zero (also known as region 0), is fixed and is dedicated for local application registers, local configuration accesses, remote configuration accesses and remote IO accesses (RC only). In other words, Address Space Zero is mapped to a fixed unique dedicated location and can not be moved or re-mapped. The second, address space, Address Space One (also known as region 1), is dedicated for data transfer and there exists no fixed or unique mapping for this address space. Details on this are captured on later sections below.

Address Space Zero occupies a contiguous 16K Bytes of location where 4KB of 16KB is the configuration space. Address Space One is used for data buffering and is large in size and not necessarily contiguous. To perform a mapping of a PCIe addresses that would land within Address Space One, four dedicated Regions exist, (Regions [0-3]), for the use of the Inbound Address Translator. Note that Outbound translation has 32 regions while Inbound translation has four regions.

This means that any Accepted TLP that has found a match with one of the BARs, BAR[0-5] will be mapped to one of the two address spaces: Address Space Zero or Address Space One. BAR0 is dedicated to Address Space Zero and implicit mapping is done and no region association is required. However BARs[1-5] are dedicated to Address Space One and association with one of the four regions, Regions[0-3], is required. Note that this is valid in the context of an accepted TLP with 32-bit Addressing. If 64-bit Addressing is used, then the association of the six BARs with the address spaces change to a total of three since a pair of adjacent BARs concatenated is required to hold the 64-bit Address. This implies that BAR0 and BAR1 will hold 64-bit Address with BAR0 holding the low 32-bit PCIe address to match while BAR1 holds the high 32-bit PCIe address to match (associated with Address Space Zero). The same holds for Address Space One association. BARs[2-3] and BARs[4-5] will hold the accepted 64-bit address that will be associated to Address Space One where mapping takes place via the use of Regions[0-3].

Address Translation for address space zero does not exist since the internal location is unique and is contiguous. All is needed is the PCIe Address within the received TLP address matching BAR0, for 32-bit addressing, and BARs[0:1] for 64-bit addressing.

However, Address Translation for Address Space One requires the use of one of the four Regions (Regions[0-3]) to map accepted TLPs to internal/physical memory. Four region specific memory mapped registers exist and used by the Inbound Address Translator.

Association between regions (Regions[0-3]) and BARs is made via the corresponding IB_BARn [n=0-3] register. IB_STARTn_HI [n=0-3] and IB_STARTn_LO [n=0-3] are used to hold the start address of a 64-bit PCIe Address to match, and IB_OFFSETn [n=0-3] is used to hold the Offset for that particular Region (note that what is referred here as offset could be viewed as the physical Memory Base Address). Note that for 32-bit addressing, IB_STARTn_HI[0-3] should be programmed with ZERO.

The procedure used by the In-Bound Address Translator to perform the mapping between the PCIe Address and Address Space One is as follows:

1st. Extract the Offset: PCIe Address – (IB_STARTn_HI : IB_STARTn_LO)

2nd. Compute absolute OCP/internal address: Add Base Address IB_OFFSETn to the Offset extracted on step 1.

Note: When using TLPs with 64-bit addressing a pair of adjacent BARs are concatenated to hold the 64-bit Address. This implies that BAR0 and BAR1 will hold 64-bit Address with BAR0 holding the high 32-bit PCIe address to match and BAR1 holding the low 32-bit PCIe address to match. Same argument holds for BAR3, BAR4 and BAR5, BAR6 where BAR3 and BAR5 hold the high 32-bit of the 64-bit addresses.

Example 2:

For a given 64-bit PCIe Address of 0x1234_5678_ABC5_0000, that qualifies for acceptance; what would be the corresponding mapped internal (physical) device address? (Assume that Region 1 registers are programmed to match BAR2, BAR3 RC programmed addresses)?

Further assume that application software has programmed the set of registers corresponding to Region 1 with the values shown below.

IB_BAR1 = 2. This assignment associates Region 1 with BAR2, BAR3 for 64-bit Addressing. The value programmed 2 here associate the match between Region 1 (IB_BAR1) and Configuration Register BAR2.

IB_START1_HI = 0x1234_5678

IB_START1_LO = 0xABC0_0000

IB_OFFSET1 = 0x3340_0000

The OCP/internal address is computed by subtracting the PCIe Base Address and extracting the offset from the PCIe Address (Address within the TLP Header) and adding the difference to the start Address of the OCP/internal address.

Extract the Offset from the PCIe Address.

Extracted Offset = PCIe address – (IB_STARTn_HI : IB_STARTn_LO)

- - Extracted Offset = 0x1234_5678_ABC5_0000 – 0x1234_5678_0xABC0_0000
= 0x0005_0000

Compute the absolute OCP/internal address.

Add the extracted Offset to the internal Base Address

OCP/internal address = Extracted Offset + IB_OFFSET

- - internal/physical absolute address = 0x3340_0000 + 0x0005_0000
= 0x3345_0000

In example 2, PCIe Address of 0x1234_5678_ABC5_0000 is translated or mapped to OCP/internal address, 0x3345_0000.

19.2.3.2.1 BAR0 Exception for In-Bound Address Translation

The memory space covered by BAR0 in inbound direction is completely dedicated to accessing the application registers, address space zero. It implies that the BAR0 cannot be remapped to any other location but to application registers. Any remote inbound access matching the BAR0 region will automatically be routed to these registers. It allows RC devices to control EP devices in absence of dedicated software running on EP. For RC and EP, this mapping of BAR0 to registers allows the message signaled interrupts to work. There is no support to disable BAR0 accesses from reaching the application registers.

19.2.3.2.2 Mapping Multiple Non-contiguous Memory Ranges to One Region

A single inbound TLP address translation region (matching RC programmed PCIe BAR Address) can be used to map accesses to multiple non-contiguous internal address ranges, within Address Space One, by ensuring that the start addresses of these regions are programmed in ascending order in the inbound start address registers.

Example 3:

In this example, two BARs (BAR1 and BAR2) are remapped to four separate locations (4 regions) that are non-contiguous using 32-bit addressing. The first two regions (Region 0 and Region 1) remap accesses landing in BAR1 space (IB_BAR0 = 1 and IB_BAR1 = 1 associates two Regions 0 & 1 with the same BAR, BAR1), and the following two regions (Region 2 and Region 3) remap accesses landing in BAR2 space. Each BAR is treated as a 32-bit BAR.

Assumed RC programmed Value of Base Address Registers in Configuration Space:

BAR1: 0x11110000

BAR2: 0x22220000

Table 19-3.

Region (IB_BARn)	BAR	IB_STARTn_HI	IB_OFFSETn	TLPAddress	TranslatedAddress
0	1	0x11110000	0x33330000	0x11110080	[0x11110080 - 0x11110000] +0x33330000 = 0x33330080
1	1	0x11118000	0x44440000	0x11119000	[0x11119000 - 0x11118000] +0x44440000 = 0x44441000

Table 19-3. (continued)

2	2	0x22220000	0x55550000	0x22220400	[0x22220400 – 0x22220000] +0x55550000 = 0x55550400
3	2	0x22220800	0x66660000	0x22231000	[0x22231000 – 0x22220800] + 0x66660000 = 0x66670800

Note: In case there are more than one matching BAR, then the highest start address that is greater than the TLP address is the one that is considered for translation.

19.2.3.2.3 Using BAR1 Value as Start Address

The inbound address translation for BAR1 has additional capability of using the value of BAR1 register (from PCIe Configuration Space) as the start address for inbound address translation. This feature can be activated by leaving the start address of the corresponding inbound translation region (one of the four Regions associated to BAR1) programmed with zero. When an incoming read/write access matches BAR1 and the inbound region's BAR match (IB_BARn) is set to one with start address programmed to zero, the BAR1 value is used to compute the translated address. Note that if this feature is used, only one inbound translation window is available and it will be relative to BAR1 programmed value. No other BARs or inbound translation windows can be used if BAR1 is designated as the reference for inbound address translation.

19.2.3.2.4 BAR Mask Registers

The PCI Configuration register BARs in end point devices are programmed by RC during the PCI Configuration process; that is, RC performing PCIe enumeration or PCIe device discovery process.. Since the PCI ESS is a dual mode (DM) core, prior to the start of PCI configuration, the PCI ESS EP device has the opportunity to modify the behavior of BAR registers prior to RC starting the enumeration process and assignment of PCIe Base Address. Using the BAR Mask registers which are overlaid on the BAR registers, the software on the EP device can configure the size of address space that the EP will request from the RC during configuration for each of its BARs. The software can also modify the BAR types and can enable/disable the BARs. That is, the read-only bit fields (BAR bits[3:0]) of the Configuration Register BARs are user programmable and are required to be programmed prior to enumeration or device discovery process begins.

Note that the BAR Mask registers are accessible, for configuration purposes of the BARs, only when operating as EP and at the same time only when CMD_STATUS[DBI_CS2] is set/enabled state. Firmware needs to always read back the data written after modification to ensure that the write has completed since the confirmation read will not happen until the write completion insuring the register update is made prior to use. Firmware needs to clear CMD_STATUS[DBI_CS2] after initial configuration prior to RC starting enumeration.

It is important to not attempt modification of BAR Mask registers from serial link side as unpredictable behavior may occur and the system could become unstable and even worse unusable.

19.2.3.3 Address Alignment Requirements

As per PCIe standard, no transaction can cross a 4 KB aligned address boundary.

The limit on transaction size on the internal bus interface (OCP) is 128 bytes. So, the transactions must be 128 byte or smaller on the internal bus interface. If a transaction received in inbound direction crosses a 128 byte aligned address, then the PCI ESS master interface can split such transaction into multiple transactions at the 128 byte boundary.

19.2.3.4 Byte Strobe Usage Requirements

For any type of write transactions, the byte enables can only have a single unbroken string of 1s. In other words, in a transaction, if a byte's write strobe is set, then all following bytes must have write strobe set until the last byte with write enabled. "Holes" or "Zeros" in between the byte enables are not allowed.

Since the internal bus width is greater than 32-bit, the TLP size will not be 1 (PCIe counts in 32-bit units) and therefore, it is through the FBE/LBE (First/Last Byte Enable) that the actual data transfer size is controlled.

19.2.3.5 Zero-Length Read/Write Transactions

Read transactions that request zero bytes are not supported by PCI ESS. PCI ESS will issue a read transaction with FBE field of PCIe TLP set to 0xF. Writes of zero bytes are supported.

19.2.3.6 Transactions Crossing 4KB boundary

Any single transaction that reads/writes data on locations crossing a 4KB aligned address are invalid as per of PCI Express Base Specification Revision 2.0. If such a read is issued to PCI ESS Slave, it will lead to multiple transactions on the serial link so that PCIe protocol is not violated. But if the completions do not return in order from the remote PCIe link partner, then it may result in violation.

Outbound Transaction Involving Less Than 4 Bytes

The PCI ESS imposes a limitation on the minimum size of data to be accessed in Outbound transactions. The minimum data size is 4 bytes wide. It is not possible to access less than 4 bytes. This could potentially be a problem when accessing non-prefetchable memory resulting in accesses to undesired memory location.

19.2.3.7 Transaction Address Alignment

The PCI ESS imposes a limitation of a maximum of 128 byte outbound read/write command. However, if the starting address is not aligned to an 8 byte boundary, then the maximum transaction size is reduced to 120 bytes. Unspecified behavior will occur if misaligned transactions in outbound direction are not limited to a maximum of 120 bytes.

19.2.3.8 Read Interleaving

Read interleaving refers to the process of returning split read responses from multiple transactions. This implies that read data is not guaranteed to be sent in sequential order (data for one transaction to be sent completely before the next). PCIe core is guaranteed to not interleave read responses if the outbound read command/transaction size does not exceed the max transaction size configured in the PCIe core. Currently this is configured as 128 bytes.

19.2.3.9 Endian Mode

The PCI ESS is configured to operate in little endian mode. Most of the peripherals within the device are also configured in Little Endian mode. If user system is configured in big endian mode, then a conversion is required to transform data format.

19.2.4 Address Spaces

Internal device addressable resources, from PCI ESS perspective, are categorized in to two separate spaces. That is, PCI ESS has two OCP address spaces or regions. The first is dedicated for local application registers, local configuration accesses, remote configuration accesses and remote IO accesses (RC only). This space is referred as address space zero. The second is dedicated for data transfer and it is referred as Address Space One.

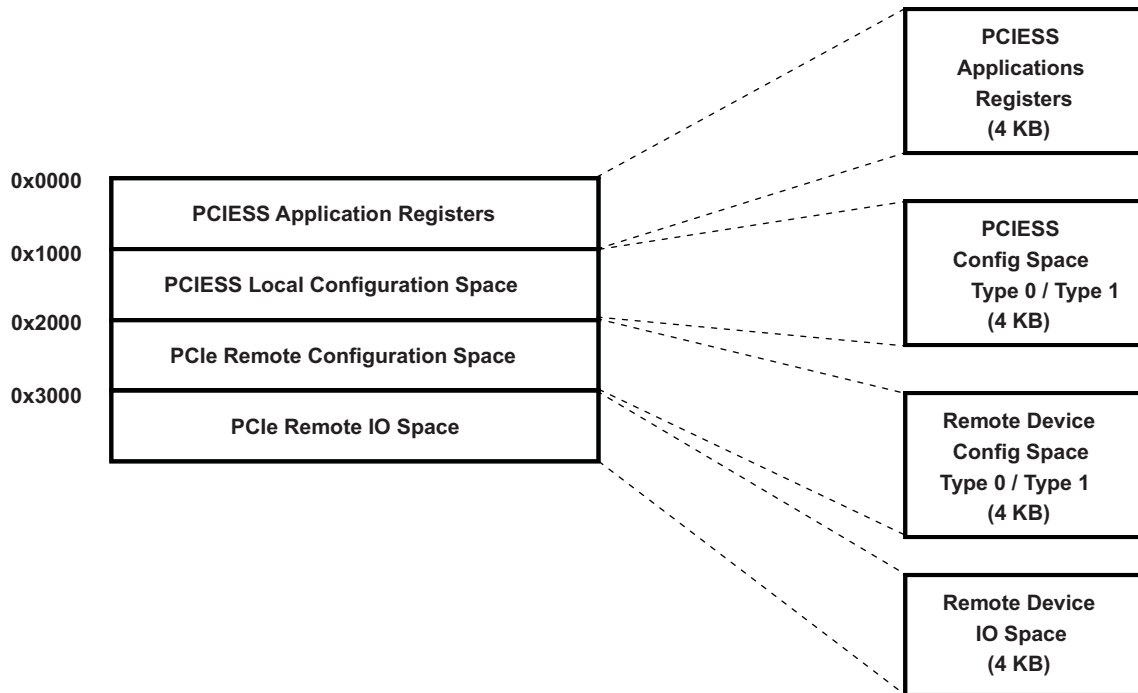

19.2.4.1 Address Space Zero

Address Space Zero is made of a contiguous 16 Kbytes of memory partitioned into four sections/regions with equal sizes (each 4 Kbytes long). These regions are:

- PCI ESS application registers
- PCIe local configuration registers
- PCIe remote configuration registers
- PCIe IO access window

Figure 19-2 illustrates the relationship of the various address regions within the address space zero.

Figure 19-2. Address Space Zero Regions

Each of the four address space zero regions is meant for accessing a set of registers.

- **PCI ESS Application Registers** – These registers are used to configure and monitor various settings within the PCI ESS. These registers are specific to the application needs and are not related to the PCIe Configuration registers. Note that all PCI ESS Application registers should be accessed in 32-bit mode.
- **PCIe Local Configuration Registers** – PCI ESS local configuration registers are used to read the settings of configuration registers of the local PCIe Device. Prior to PCI Express configuration is complete, these registers can also be written to. Depending upon whether PCI ESS is configured as RC or EP, the layout of these registers is either Config space Type 0 or Type 1. Note that all accesses on PCIe Local Configuration registers must be made in 32-bit mode.
- **PCIe Remote Configuration Registers** – Remote PCIe configuration registers are accessed by programming the bus number, device number and function number of the remote PCIe device in one of the application register and then accessing the PCI Remote configuration registers as if it were the PCIe Config space of a single PCIe function. The layout of the remote configuration registers varies based upon whether the device is an end point or a PCIe switch.
- **PCIe IO Access Window** – A 4KB region is dedicated for remote IO accesses when PCI ESS is in RC mode. Any access made on this space becomes an IO access. The actual address in the TLP gets its base address from the IO_BASE register value and an offset that is directly derived from the address of the OCP/VBUM access in this 4KB space.

None of the four address ranges described above support burst transactions. So, only single 32-bit transactions should be issued to these addresses. These addresses should also be configured as non-cacheable address space.

19.2.4.1.1 Remote Configuration and I/O Requests (Caution)

Since the remote configuration and IO transaction windows are directly mapped to internal bus space, the software must take caution not to access these spaces when there is no operational PCIe link. No response may be generated for such transactions. It is recommended that checks be built into software to avoid remote accesses in the absence of an operational link.

19.2.4.2 Address Space One

The second address space/region is used for data transfer. The BAR values setup within the PCIe local configuration registers define where within the memory map of the CPU on root complex side are the end points located. All locations other than what is setup in BAR registers of the end points are on the root complex side.

The Address Space One is mapped to multiple devices in RC mode. Each remote device could be allocated a portion of this memory space and any transaction that is targeted to this address space gets converted to a PCIe transaction targeted to the appropriate remote PCIe device.

19.2.4.2.1 Organization of Configuration Registers

As illustrated in [Table 19-4](#), the registers for various PCIe capabilities are linked to each other via address offsets specified in the registers.

Table 19-4. Register Blocks That Make up the PCIe Configuration Registers

Offset FROM START OF Configuration Space	REGISTER BLOCK
0x000	Configuration Registers Common to Type 0 and Type 1 Headers
0x040	Power Management Capabilities Registers
0x050	Message Signaled Capabilities Registers
0x070	PCI Express Capabilities Registers
0x100	PCI Express Extended Capabilities Registers
0x700	Port Logic Registers

19.2.5 Bus Mastering

An end point that is capable of becoming a bus master and initiate transactions in upstream direction must have its bus master enable bit set in configuration space registers (STATUS_COMMAND[BUS_MASTER]). If transactions are initiated (while assuming the role of a RC or EP) before enabling bus mastering capability, then transactions will not start until the bus master enable is set. There is no timeout or error response generated when transactions do not go out because of the bus master bit not being set.

19.2.6 PCIe Loopback

The PCIe specifications provides loopback support in two ways – through PIPE interface (link layer) and second through PHY loopback capability (PHY layer).

The PIPE interface loopback requires for two PCIe devices/components to attached to each other in a loopback master and a loopback slave configuration. A loopback master is the component requesting loopback. A loopback slave is the component looping back the data. Note that, regardless with the PCISS role it assumes (RC or EP), it can assume a role of a loopback master or a loopback slave.

The loopback, loopback at the PHY level, does not require another component.

19.2.6.1 PIPE Loopback

The procedure depends upon whether the device is operating in RC or EP mode. In either case, the PCISS can be loopback master or loopback slave as outlined in PCIe specifications. Note that this loopback mode cannot be used for looping back transactions. These modes are to be used with PCIe test equipment only for symbol level loopback.

The Loopback entry procedure when PCI ESS is a Loopback Master

RC Mode

- Set Loopback Enable in the Port Link Control Register in Port Logic Register space.
- The link retraining sequence must be initiated by writing to Link Retrain field in the Link Control Register in PCI Express Capabilities structure in the device's PCI configuration space.

EP Mode

- Set Loopback Enable in the Port Link Control register.
- Force the LTSSM to be in recovery state via the Port Force Link register of the Port Logic registers.
- Set Force Link bit to high in Port Force Link register in Port Logic registers.

Once this is done, devices at the end of a PCIe link enter PCIe LTSSM Loopback state. The initiator of the loopback state is the Loopback Master and the other device is Loopback Slave. Note that it is not possible to send TLPs in this mode and return them via the loopback state of the other device.

The Loopback entry procedure when PCI ESS is a Loopback Slave

If the PCI ESS is a Loopback slave, then the incoming serial data is routed back to the originating device from the PIPE interface as per PCIe loopback requirements. Typically, PCIe test equipment will be used as loopback master and it will transition PCI ESS into loopback slave state following which the inbound transactions will be Loopback to the test equipment. There is no programming required on PCI ESS to enter Loopback in slave mode. PHY support is not required to use this loopback mode.

19.2.6.2 PHY Loopback

The PHY loopback is accomplished by switching the PHY to loopback where the transmitted data is looped back to the receive path at the PHY level. This mode can be used to perform TLP loopback even if there is no link partner. It is, however, only possible to set up when PCI ESS is used in RC mode. This limitation is because link training cannot occur between two upstream ports; at least one port must be a downstream port.

The procedure is similar to the one for PIPE (link layer) interface but the PHY programming is used instead. This mode is entered by configuring the SERDES configuration registers. Both the transmit and receive paths must be set in loopback mode to enable PHY loopback mode.

Note that there are several other requirements for this to correctly work:

- The PHY should be configured to operate in loopback mode before any transaction is sent out. The recommended approach is to set loopback before link training. Otherwise, any transactions that were not looped back will cause sequence numbers to increment on transmitter but not on receiver and all following transactions will be dropped because of sequence number mismatch.
- The BAR0 and BAR1 values (if programmed) should not match the address for the transaction that is issued on slave interface. Otherwise, it will not get to the master port but to internal registers.
- The memory base/limit registers should not be configured such that the address of the transaction lies in the range specified by the memory base/limit registers. Otherwise, the transaction will be discarded as a misrouted packet.
- It is not possible to use configuration type transactions in this mode as RC cannot be a target of configuration transactions. Such transactions will be invalid and loopback will not work.

19.2.7 L3 Memory Map

The L3 address block for PCI ESS is 256MB wide with starting address of 0x2000_0000 and ending address of 0x2FFF_FFFF. This is also referred to as Address Space One.

NOTE: Some processors within the device may re-map the PCI ESS to a different address through use of a MMU. Also, not all masters have access to PCI ESS as defined in the L3 Master/Slave Connectivity table in the data manual.

19.2.8 Signal Descriptions

This section describes each of the signals on the external interface and their functions.

19.2.9 Reset Considerations

The PCISS supports the conventional reset mechanism that is specified within the PCI Express specification. Both hardware and software reset are supported. No support for the functional level reset is needed since the PCISS supports a single function.

19.2.9.1 Software Reset Considerations

Software reset is issued via the transmission of TS1 Ordered Sets.

19.2.9.2 Hardware Reset Considerations

Hardware reset is caused while power is being sourced to the device. The SoC level power-on-reset acts as the power on reset for PCISS.

19.2.9.3 PCIe Boot Capability

The device supports PCIe boot capability as an endpoint. No support for RC bootmode. See bootmode configuration details for the applicable settings of the bootmode pins.

19.2.9.4 PCIe System Module Registers

Several configuration registers are used for configuring PCIe PHY and PLL for operation as well as test mode generation. These registers exist within the configuration module space. Consult the system module for more information.

The base address for the control module is at 0x4814_0000 for Cortex-A8 and L3 Masters.

Table 19-5. PCIe System Module Registers

0x480	PCIE_CFG	PCIE Configuration Register
0x6D8	PCIE_PLLCFG0	PCIE SerDes PLL Configuration Register 0
0x6DC	PCIE_PLLCFG1	PCIE SerDes PLL Configuration Register 1
0x6E0	PCIE_PLLCFG2	PCIE SerDes PLL Configuration Register 2
0x6E4	PCIE_PLLCFG3	PCIE SerDes PLL Configuration Register 3
0x6E8	PCIE_PLLCFG4	PCIE SerDes PLL Configuration Register 4
0x6EC	PCIE_PLLSTATUS	PCIE SerDes PLL Status Register
0x6F0	PCIE_RXSTATUS	PCIE SerDes Receive Status Register
0x6F4	PCIE_TXSTATUS	PCIE SerDes Transmit Status Register
0xE24	SERDES_REFCLK_CTL	SerDes Refclk Powerdown Control

19.2.10 Interrupt Support

The PCISS provides a total of four interrupts to the device interrupt controller, for example, it generates four interrupt events aggregated. In other words, each of these interrupts has more than one underlying event that the interrupt represents. Once all pending interrupts have been cleared, the hardware EOI for the interrupt generic will be generated.

Both message signaled interrupt (MSI) and legacy interrupt are handled by the PCISS. When operating as an EP, the PCISS is capable of generating MSI or legacy interrupt, depending on the role it is assuming. Note that one PCIe component can not generate both type of interrupts. It is either one or the other. The interrupt type an EP generates is configured during configuration time. When operating as RC, the PCISS is capable of handling both MSI and legacy interrupts. This is because when operating as RC it should be able to service both PCIe endpoints as well as legacy endpoints.

19.2.10.1 Interrupt Events and Requests

A total of four interrupt events are supported by the PCISS. Some of the events are meaningful based on the role the PCISS assumes (RC or EP). [Table 19-6](#) captures the interrupt events supported for both RC and EP modes.

Table 19-6. PCISS Interrupt Events

Interrupt	Interrupt Description
0	PCIe Express Legacy Interrupt Mode (RC mode only)
	[0] INTA
	[1] INTB
	[2] INTC
	[3] INTD
1	MSI Interrupts 0 through 31 in PCI Express Mode (EP/RC Modes)
	[0] MSI Interrupt 0
	[1..30] MSI Interrupt 1 and so on
	[31] MSI Interrupt 31
2	Error Interrupts (EP, RC)
	[0] System Error (OR of Fatal, Nonfatal, Correctable errors)
	[1] PCIe Fatal Error
	[2] PCIe Non-fatal Error
	[3] PCIe Correctable Error
	[4] AXI Error due to fatal condition in AXI bridge
3	[5] PCIe Advanced Error
	Power Management and Reset Event Interrupts (EP, RC)
	[0] Power Management Turn-off Message Interrupt (EP only)
	[1] Power Management Ack Message Interrupt
	[2] Power Management Event Interrupt
	[3] Link Request Reset Interrupt (Hot reset or Link down)

19.2.10.2 Interrupt Generation

Since the PCISS is capable of assuming a role of RC or EP, interrupt generation capability is dependent upon the role it is assuming.

19.2.10.2.1 Interrupt Generation in RC Mode

As per PCI Express base specifications, root complex ports only receive interrupts. There is no mechanism to generate interrupts from RC port to EP mode as per PCIe specifications. However, PCISS does support generation of interrupts from RC to EP. The behavior is similar to generation and reception of MSI interrupts in RC mode except for the fact that this functionality is enabled in EP mode as well.

The RC device can perform a memory write into the MSI IRQ register over the PCIe link to generate one of 32 EP interrupts. Note that the PCISS will follow PCIe MSI rules and will not necessarily accumulate multiple writes to the same MSI vector. Only one of such writes is guaranteed to be processed and subsequent writes on the same vector arriving before the interrupt status is cleared may be lost.

19.2.10.2.2 Interrupt Generation in EP Mode

When PCI-ESS is operating as an EP, either the legacy interrupts or the MSI interrupts can be triggered to the upstream ports (eventually leading to an interrupt in RC device). As per PCIe specifications, each PCIe function may generate only one of the legacy or MSI interrupt types as decided during configuration period.

- Legacy interrupt generation in EP mode

The endpoint can trigger generation of a PCI legacy interrupt at the root complex via an in-band Assert_INTx / Deassert_INTx PCIe Message. The actual interrupt that is generated on RC port is based on the configuration of the EP that generates the interrupt and it could be one of INTA, INTB, INTC or INTD. See Interrupt related registers in configuration space registers.

To generate an interrupt, following steps are required:

- Write 0x1 to EP_IRQ_SET register to enable the legacy interrupt
- A ASSERT INTA/B/C/D message is automatically sent.
- Write 0x1 to EP_IRQ_CLR register to disable the legacy interrupt by sending a DEASSERT INT A/B/C/D message.

Once an assert message has been generated, it cannot be generated again until a de-assert message is generated. Thus, only one interrupt can be pending at a time. The pending status can be checked in the EP_IRQ_STATUS register.

Note that the interrupt messaging mechanism makes it unfeasible to guarantee a time of delivery of the interrupt unlike in conventional designs where the interrupt line is often electrically connected to the final destination.

There is no hardware input port provided that will allow generation of legacy interrupts on the EP port.

- MSI interrupt generation in EP mode

MSI Interrupts are generated by a PCIe write transaction that performs a 32-bit memory write to a pre-determined address with a pre-determined data. The PCIe system software configures the address and the data that is to be used in the memory write transaction at the time of initialization of the EP device. The MSI scheme supports multiple interrupts and each device can request up to 32 interrupt vectors even though the allotted interrupts may be less than the requested number.

To generate MSI interrupts, following steps need to be taken:

- Ensure that the MSI support has been enabled in the device
- Read the value of MSI Address register in the local PCIe configuration space
- Read the value of MSI Data register in the local PCIe configuration space
- Determine the number of MSI vectors allocated (and the number requested) to the device
- Depending upon the number of MSI interrupts allocated, issue a Memory Write transaction with the address same as MSI Address register and data same as MSI Data register. In the data, the LSBs can be modified to reflect appropriate MSI event that needs to be notified to Root Complex
- The Memory Write transaction can also be optionally routed through the outbound address translation interface if the destination PCIe address is not directly accessible.

For more details about how MSI interrupts are expected to behave, refer to PCIe Standard Specifications.

19.2.10.3 Interrupt Reception

Since the PCI-ESS is capable of assuming a role of RC or EP, interrupt reception capability is dependant upon the role it is assuming.

19.2.10.3.1 Interrupt Reception in EP Mode

The PCIe specification does not have provision for end points to receive legacy interrupts. As a result, only events other than PCIe related can cause interrupts. The MSI interrupts are not supported on EP devices as per PCIe Specification but PCI-ESS does support these interrupts. The MSI interrupt is generated as a result of one of the 32 events that are triggered by a write to MSI_IRQ register by the RC.

These interrupts, delivered via register writes over the serial link, could also be coming from another end point that performs a write to the appropriate interrupt registers in the EP's BAR0 space. It is up to software designers to implement a way to determine the actual source of the interrupt.

19.2.10.3.1.1 Host Reset Request Interrupt Reception in EP Mode

When the link is down, the upstream port may request reset of the end point. This request is terminated as an interrupt to the end point host software. The PCISS automatically disables LTTSSM by de-asserting `app_ltssm_enable` bit in `CMD_STATUS` register and suspends LTSSM in DETECT QUIET state. All outstanding transactions are errored out on slave port and further transactions are no generated on master port. Once the transactions are completely stopped through OCP disconnect protocol, the software should issue a local reset to PCISS. The re-initialization process may then be started.

19.2.10.3.2 Interrupt Reception in RC Mode

When PCISS operates in RC mode, the endpoints on the PCI fabric can be a Switch, PCIe EP or legacy EP. For this reason, it should be able to handle both MSI and legacy interrupt.

19.2.10.3.3 MSI Interrupt Reception in RC Mode

A total of 32 MSI interrupts can be generated from one or more downstream devices. These MSI interrupts represent the MSI interrupts that have been allocated to various downstream devices during PCIe configuration/enumeration procedure. Before the end point devices can issue MSI interrupts, the MSI address and data registers must be configured. Each end point can either use MSI interrupts or legacy interrupts and not both at the same time. MSI interrupt have the same race condition hazard as the legacy interrupts. Hence, software drivers should take precaution.

19.2.10.3.4 Legacy Interrupt Reception in RC Mode

Any of the four legacy interrupts may be generated by the PCISS. Each interrupt can originate from multiple end point devices. The software should service these by probing the interrupt registers in each downstream device's configuration space. When all devices have been serviced, the last device serviced will send a interrupt deassert message which will clear the interrupt.

The interrupt request signal at the PCISS boundary is a pulse signal that is triggered each time a assert interrupt message is received. The interrupt pending signal is a level signal that is high as long as the interrupt has not be serviced and the interrupt status not cleared through a register write.

Note that the traditional EOI procedure, although implemented, may not operate as expected if the deassert message arrives after the EOI has been issued. This can not be corrected but only worked around by doing a read on the interrupt register downstream before issuing EOI. If the EOI register is written to before the deassert message has reached the interrupt logic, the interrupt pending status will not have cleared and the interrupt will retrigger.

In addition, the software drivers for downstream devices must ensure that the data transaction that is expected to complete before interrupt is triggered in RC device's CPU has completed. Since PCIe write transactions are posted, it is not necessary that a write from EP to system memory in RC has completed before a write to MSI interrupt generation register has completed. This could create a potential race condition.

It is optional to support Legacy Interrupts in PCI Express (non-legacy) devices.

19.2.11 DMA Support

The PCISS has no built-in DMA and makes use of the EDMA to move data in and out of the PCISS without the need of the CPU intervention. EDMA is only used when PCISS is the initiator of a transaction and is accessing other PCIe components. When another PCIe component is accessing a resource within the device, the PCISS in this case acts as a master and makes use of the master port to directly access the necessary resource requiring no need for the EDMA usage. The EDMA chapter provides more details.

See the L3 Master/Slave Connectivity table in the datasheet to determine the master/slave connectivity for PCISS.

NOTE: Master/Slave reference here does not mean RC/EP mode. As an RC or EP, the PCI ESS can act as both Master and Slave on the L3 interconnect. Instead, Master/Slave refers to who is generating the request on the L3 interconnect. If the PCI ESS is generating a request on the L3 interconnect, it means that an external PCIe component is the actual entity generating the request and the PCI ESS is now regarded as a Master. If the PCI ESS is accessing external PCIe component, the PCI ESS is regarded as a slave on the L3 interconnect.

19.2.11.1 DMA Support in RC Mode

When operating in Root Complex mode, the EDMA controller can perform DMA transfer between device internal resource and any remote device located on the PCI Express fabric. The memory address of such devices is available to the software via the PCI Express bus enumeration procedure. In addition, the PCIe subsystem has a provision to perform memory address translation on outbound requests. Thus, the software is able to map different memory regions in its memory map to correspond to different addresses (and different access types) on the PCI Express side.

There are bandwidth implications of using an external DMA. If the PCIe core has been programmed to establish a link in PCIe 2.5 Gbps rate, then the DMA controller that drives PCI ESS slave port must be able to write/read data at about 85% of 2 Gbps bandwidth per PCIe link. For a PCIe link speed of 5.0 Gbps, the DMA controller must be able to provide bandwidth of about 85% of 4 Gbps per PCIe link.

In addition, the master port on PCIe port can issue read/write accesses that have been initiated by remote PCI Express device. The interconnect fabric should provide sufficient capacity to serve 85% of 2 Gbps (4 Gbps if operating in Gen2) per PCIe link in each direction.

19.2.11.2 DMA Support in EP Mode

When operating as a PCIe end point, the device will be located in PCIe memory map at location programmed in the Base Address registers by the PCIe root device. In end point mode, the PCI ESS provides address translation functionality. It is possible to map IO, config and memory accesses originating on PCI Express side to memory accesses with different address on the OCP side. These address ranges are configurable through application registers.

The approximate data rate for each of these transactions will be about 85% of 2 Gbps (4Gbps in Gen2 mode) in each direction on each PCIe lane.

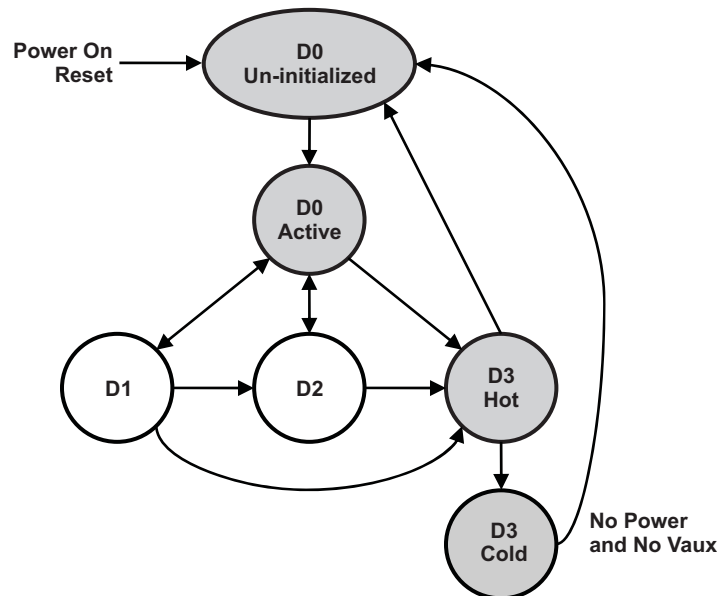

19.2.12 Power Management

PCI Express has multiple power management protocols. Some of these are invoked by the hardware solely, Advanced State Power Management (ASPM) feature, while others are activated at higher levels via software.

19.2.12.1 Device Power Management

The PCI Express protocol is compatible with all PCI power management functionality. As shown in [Figure 19-3](#), the power states specified are D0, D1, D2, D3Hot and D3cold. All functions must support D0 and D3 states.

Figure 19-3. PCI Express Power Management State Transitions

19.2.12.1.1 D0 State

Upon completion of a reset such a power-on or hot reset, the function is considered to be in D0 uninitialized state. Once the function is enumerated, configured and one or more of the memory space enable, IO space enable or bus master enable bits are set, it is considered to be in D0 active state. The D0 active state is the full-operation state of a PCI Express function.

19.2.12.1.2 D1 State

Support for D1 state is optional and is primarily driven by software. It is considered to be a light sleep state that provides some power savings compared to D0 state while still allowing transition to D0 state. While in the D1 state, function must not initiate any Request TLPs on the Link except for a PME Message. Configuration and message requests are the only TLPs accepted by a Function in the D1 state. All other received Requests must be handled as unsupported requests, and all received Completions may optionally be handled as unexpected completions. A function's software driver participates in the process of transitioning the Function from D0 to D1. It contributes to the process by saving any functional state (if necessary), and otherwise preparing the function for the transition to D1. As part of this quiescence process the function's software driver must ensure that any mid-transaction TLPs (for example, requests with outstanding completions), are terminated prior to handing control to the system configuration software that would then complete the transition to D1.

19.2.12.1.3 D2 State

Support for D2 state is optional in PCI Express and is primarily driven by software. It provides significant power savings while still retaining capability to transition back to previous condition. In this state, the PCI function can only initiate power management events and it can only respond to configuration accesses.

19.2.12.1.4 D3Hot and D3cold State

All PCI Express functions are required to support D3 state. In D3hot state, power is still present while in D3cold there is no power. Devices in D3Hot state may be transitioned back to D0 state while the devices in D3Hot state need re-initialization to be brought back to D0 state.

Functions in D3hot respond to configuration space accesses as long as power and clock are supplied so that they can be returned to D0 by software. When programmed to D0, the function may return to the D0 Initialized or D0 Un-initialized state without PCIe reset being asserted. There is an option of either performing an internal reset or not performing an internal reset. If not performing an internal reset, upon completion of the D3hot to D0 Initialized state, no additional operating system intervention is required beyond writing the Power State bits. If the internal reset is performed, devices return to D0 Un-initialized and a full re-initialization is performed on the device. The full re-initialization sequence returns the device to D0 Initialized when normal operation may resume.

19.2.12.2 Link State Power Management

There are multiple states for the physical layer – L0, L0s, L1, L2 and L3 states that provide incrementally higher power savings as the states transition from L0 towards L3. PCIeSS supports L0, L0s and L1 states. L3 state is power-off state and is supported by default. PCIeSS does not support L2 power down states.

Some of the link power states are autonomously managed by hardware. This scheme is referred to as Active State Power Management (ASPM). The following diagram illustrates the transitions between states L0, L0s and L1 that are managed by ASPM. The transitions between gray states are allowed in ASPM. These transitions can be enabled through registers in the PCI Express Configuration Space to allow either just L0s transition or both L0s and L1 transitions.

Figure 8:

Figure 19-4. ASPM Link State Transitions Diagram

The L1 power state can also be entered via software control. When the device power state is D1, D2 or D3hot, then the link state must transition to L1 state. The following diagram shows such state transition.

Figure 19-5. Software driven Link Power State Transition

19.2.12.2.1 L0s State

L0s is a lower power state enabled by Active State Power Management. Each device can control its L0s transition on its transmitter. Receiver side is controlled by the remote device.

19.2.12.2.2 L1 State

The L1 state is reached either through ASPM timer mechanism or via the software initiated transition to a D state other than the D0 state. In L1 state, the link is in idle state and both receiver and transmitter in devices on both ends of a link are able to conserve energy.

19.2.12.2.3 L2/L3 Ready State

This state is a transitional state reached from L1 where from the link must either transition to L2 or to L3 state. The L3 state is a full power off state. The L2 state is also a power off state except that the WAKE signal can be used by end point devices to request power and clock from the system.

19.2.12.2.4 L2 State

The L2 state is appropriate when a device needs to monitor an external event while in deep power down mode. In L2 state, auxiliary power is supplied and a minimal amount of current is drawn from the power source. Almost all of the logic is devoid of power. To recover, the wake signal is used.

19.2.12.2.5 L3 State

In this state, device is supplied no power from the PCIe fabric. There is no mechanism to communicate in L3 state. To recover, the system must re-establish power and reference clock followed by a fundamental reset.

19.2.12.3 Relationship Between Device and Link Power States

The device D-states are correlated to the link power states. For each D state, there are specific states that the PCIe link or interconnect can transition to. The table below shows the permissible state combinations.

Table 19-7.

Downstream Device State	Permissible Upstream Device State	Permissible Link State
D0	D0	L0 (required), L0s (required), L1 ASPM (optional)
D1	D0 – D1	L1
D2	D0 – D2	L1
D3hot	D0 – D3hot	L1, L2/L3 Ready
D3cold	D0 – D3cold	L2aux, L3

19.2.13 OCP Power Management

The OCP bus power management is accomplished via the use of Idle and Standby Mode. The list of Idle/Standby states support by PCISS are:

Table 19-8. Supported Idle/Standby States

IDLE/STANDBY Mode	Remarks
NO IDLE	Supported.
SMART IDLE	Default State
SMART IDLE w/ WAKEUP	Supported
FORCE IDLE	Supported
NO STANDBY	Supported
SMART STANDBY	Default State
SMART STANDBY w/ WAKE	Not supported
FORCE STANDBY	Supported

Note that if idle mode is reached in default state, the hardware will not request wakeup once in Idle mode. Software must ensure that it wakes up the hardware by exiting IDLE state in such situations.

The compatibilities of various states are tabulated below.

Table 19-9. Compatibilities of Various States

STANDBY Mode	IDLE Mode(s)	Link States and Transitions
NO STANDBY	NO IDLE	States: L0 and L1 Transitions: L0→L1, L1→L0
SMART STANDBY	SMART IDLE WITH WAKE	States: L0, L1 The valid transitions among these states are tested Transitions: L0→L1, L1→L0, L0→L2/L3 Ready The states L2 and L3 need fundamental reset to recover from.
SMART STANDBY	SMART IDLE	States: L0, L1, L2/L3 Ready Transitions: L0→L1, L0→L2/L3 Ready Valid transitions among these states are tested. Note that the Remote partner cannot wake up PCI ESS if OCP Wakeup is not enabled. A fundamental reset is always required to wake from L2 or L3 states.
SMART STANDBY	NO IDLE	States: L0, L1 Transitions: L0→L1 Only master port will enter standby. No clock gating is achievable in this configuration.
SMART STANDBY w/ WAKE	NA	Not supported
FORCE STANDBY	FORCE IDLE	States: Uninitialized Link, L0 Transitions: None It is not recommended to keep OCP in standby/idle and link in initialized state. This should be done only when the remote side is aware that the device interconnect is not operational and therefore, no transactions should be initiated.

19.3 Supported Use Case

19.3.1 Software Configuration

19.3.1.1 PCIe Root Complex

When the PCI ESS is desired to operate as a Root Complex (RC), the below initialization sequence are recommended to be followed.

19.3.1.1.1 Initialization Sequence of PCIe Root Complex

The initialization sequence is as follows:

- Configure PCIe mode of operation to RC mode by programming PCIE_CFG.PCIE_DEVTYPE with a value of 2.
- Bring PCI ESS out of reset through the device level reset controller.
- Configure the PCIe PHY PLL registers in Control Module to enable the PHY bit clock . (These registers have to be configured in sequence)
 - SERDES_REFCLK_CTL=0x2; //PowerDown
 - PCIE_PLLCFG0 = 0; //SERDES CFG0
 - PCIE_PLLCFG1 = 0x00640000; //SERDES CFG1
 - PCIE_PLLCFG2 = 0x00000000; //cfgpll2 //SERDES CFG2
 - PCIE_PLLCFG3 = 0x004008E0; //cfgpll3 //SERDES CFG3
 - PCIE_PLLCFG4 = 0x0000609C; //cfgpll4 //SERDES CFG4
 - wait a bit (about 50 μs)
 - PCIE_PLLCFG0 = 0x00000004; //Config PLL CFG0 bit [2] - ENBGSC_REF
 - wait a bit (about 50 μs)
 - PCIE_PLLCFG0 = 0x00000014; //Config PLL CFG0 bit [4] - DIGLDO
 - wait a bit (about 50 μs)

- PCIE_PLLCFG0 = 0x00000016; //Config PLL CFG0 bit [1] - ENPLLLDO
wait a bit (about 50 μ s)
- PCIE_PLLCFG0 = 0x30000016; // Configure proxy TXLDO and RXLDO enables
wait a bit (about 50 μ s)
- PCIE_PLLCFG0 = 0x70007016; // Configure multiplier
wait a bit (about 200 μ s)
- PCIE_PLLCFG0 = 0x70007017; // Enable PLL
- Ensure that the link is idle. Disable link training by de-asserting the *LTSSM Enable* bit in PCIESS Control Register. Upon reset, the LTSSM Enable is de-asserted automatically by hardware, CMD_STATUS.LTSSM_EN is zero.
- Configure core registers through OCP slave interface address space 0.
- Initiate link training can be initiated by asserting *LTSSM Enable* bit in PCIESS Control register, for example, by programming CMD_STATUS.LTSSM_EN with a 1.
- Insure link training completion and success by observing DEBUG0.LTSSM_STATE field change to 0x11.
- In conjunction with the system software, start bus enumeration and setup configuration space on downstream ports.
- Continue software handshake and initialization on the remote devices. This includes setting up DMA protocols, interrupt procedures and more.
- With the completion of software initialization, DMA accesses can be started on various end points.

19.3.1.1.2 Configuration Accesses

Configuration accesses are made by RC port to individual function in each downstream EP device to program the PCIe specific operating parameters. In particular, the configuration accesses are used to allocate memory ranges for each downstream device, configure those memory ranges as IO or Memory type, enable bus master capability on the device if necessary and also build a software database of PCIe attributes and capabilities of each downstream device. Each downstream device can be configured through the configuration access region of PCIESS. The PCIESS convert memory reads and writes on the configuration region of OCP interface into configuration access on the serial link.

19.3.1.1.3 Memory Accesses

There are two types of memory accesses – the outbound memory accesses that are initiated by the DMA on the PCIESS Slave port and the inbound memory accesses that are initiated by the PCIESS Master port targeted to internal memory regions within the OCP interconnect.

The outbound PCIe memory read and write accesses are made through the PCIESS slave port through the device memory range that is dedicated to data transfers. The read and write transactions on this region are directly mapped to PCI Express space by the PCIESS in conjunction with the outbound address translation mechanism. The completions to the bus transactions are generated by PCIESS when it receives completions from remote devices. In case of errors or timeouts, an error response is provided. For reads, the error responses span as many phases as there would be data phases if the error had not occurred.

The inbound memory accesses received by PCIESS on the serial link are initiated by remote PCIe end points that are capable of bus mastership. Such accesses are converted to bus transactions on PCIESS master port and once a Response/Completion is received, the PCIESS sends data/response back to the PCIe bus master over the serial links. Typically, the inbound accesses will be targeted to memory space resident on the bus side of the RC port. The locations to which inbound memory accesses map are determined by software. The software must inform the remote devices about what protocol is to be followed so that the remote device will access the relevant memory regions to read or write data/control information. Not all end points have the capability to initiate inbound accesses.

An inbound access cannot cross a 4 KB boundary as per PCIe specifications. In addition, any access that spans a 128 byte boundary in the device memory map can get split into two transactions at the 128 byte boundary.

19.3.1.1.4 I/O Accesses

I/O accesses are optional in PCI Express. In PCI ESS, these accesses can be made through a 4KB memory space and a programmable register. All accesses made to the 4KB space become IO accesses and the IO Base register determines the target address for such accesses. The IO accesses cannot be for more than 32-bits of data aligned at 4 byte boundary.

19.3.1.2 PCIe End Point

When the PCI ESS is desired to operate as an endpoint (EP), the below initialization sequence are recommended to be followed.

19.3.1.2.1 Initialization Sequence of PCIe Endpoint

Upon de-assertion of reset, the PCI ESS is configured as end point by chip level setting of PCI ESS inputs. Before a Root Complex is allowed to access the configuration space of the end point, the following initialization sequence should be followed:

- Configure PCIe Mode of operation for EP Mode by programming PCIE_CFG.PCIE_DEVTYPE with a value of 0.
- Bring PCI ESS out of reset through the device level reset controller.
- Configure the PCIe PHY PLL registers in the Control Module to enable the PHY bit clock . (These registers have to be configured in sequence)
 - SERDES_REFCLK_CTL=0x2; //PowerDown
 - PCIE_PLLCFG0 = 0; //SERDES CFG0
 - PCIE_PLLCFG1 = 0x00640000; //SERDES CFG1
 - PCIE_PLLCFG2 = 0x00000000; //cfgpll2 //SERDES CFG2
 - PCIE_PLLCFG3 = 0x004008E0; //cfgpll3 //SERDES CFG3
 - PCIE_PLLCFG4 = 0x0000609C; //cfgpll4 //SERDES CFG4
 - wait a bit (about 50 μ s)
 - PCIE_PLLCFG0 = 0x00000004; //Config PLL CFG0 bit [2] - ENBGSC_REF
 - wait a bit (about 50 μ s)
 - PCIE_PLLCFG0 = 0x00000014; //Config PLL CFG0 bit [4] - DIGLDO
 - wait a bit (about 50 μ s)
 - PCIE_PLLCFG0 = 0x00000016; //Config PLL CFG0 bit [1] - ENPLLLDO
 - wait a bit (about 50 μ s)
 - PCIE_PLLCFG0 = 0x30000016; // Configure proxy TXLDO and RXLDO enables
 - wait a bit (about 50 μ s)
 - PCIE_PLLCFG0 = 0x70007016; // Configure multiplier
 - wait a bit (about 200 μ s)
 - PCIE_PLLCFG0 = 0x70007017; // Enable PLL
- Ensure that the link is idle. Disable link training by de-asserting the *LTSSM Enable* bit in PCI ESS Control Register. Upon reset, the LTSSM Enable is de-asserted automatically by hardware, CMD_STATUS.LTSSM_EN is zero.
- Program the configuration registers in the PCI ESS to desired values.
- Initiate link training can be initiated by asserting *LTSSM Enable* bit in PCI ESS Control Register, for example, by programming CMD_STATUS.LTSSM_EN with a 1.
- Insure link training completion and success by observing DEBUG0.LTSSM_STATE field change to 0x11.
- If further configuration register initialization is required, the *Application Request Retry* bit should be set. This will lead to incoming accesses to be responded with the retry response. This feature allows slow devices extra time before the Root Port assumes the devices to be inactive. Once programming is complete, de-assert *Application Request Retry* field to allow transactions from the Root Complex

- Once configuration setup is complete, DMA transactions can begin.
- Inbound PCIe transactions will arrive at the master port of the PCI ESS end point. These will be responded to by the target slave devices and the PCI ESS will relay the response back to the PCIe device that initiated the transaction.
- Outbound PCIe transactions will be targeted to the slave port of the PCI ESS end point. These transactions will be serviced only if the PCI ESS end point has been given Bus Master Capability by the Root Complex.

19.3.1.2.2 Configuration Accesses

As an endpoint, the PCI ESS can only be a target of configuration accesses from upstream. Until the link is established and APP_RETRY_EN is disabled, the PCI ESS will not respond to configuration accesses. When enabled, the PCI ESS will respond to configuration accesses automatically and these accesses do not get relayed to the master interface on the device interconnect side.

End point is not capable to accessing configuration space of devices other than its own. The system software can initialize the read only fields in PCI ESS Configuration Space via the slave port before the link training has been initiated. Once the configuration is complete by the PCI Express Root Complex, the system software should not modify the PCI ESS configuration parameters. There is no explicit prevention mechanism in hardware to disallow such accesses though.

19.3.1.2.3 Memory Accesses

There are two types of Memory Accesses – inbound and outbound memory accesses.

An inbound access is typically initiated by a Root Complex port or by another end point that is reaching the PCI ESS via a PCI Express switch that supports peer-to-peer access. In either case, the incoming PCIe transaction results in an access on the PCI ESS master port. The response to the such accesses is relayed back to the originating PCIe device.

In an outbound access, a DMA module or a host CPU initiates a read/write access on the PCI ESS Slave port. This request is converted into a PCIe memory read/write transaction over the PCIe link. Once the PCI ESS receives completion from the remote device, it generates a completion on the OCP slave port. The software/hardware that initiates the request on the slave port must perform it in a memory region that has been determined previously through software protocols. For example, the software may get information about applicable memory regions from the software that is running on the Root Complex device.

19.3.1.2.4 I/O Accesses

IO accesses are not supported in PCI ESS operating as a PCIe end point.

19.3.2 Accessing Read-only Registers in Configuration Space

Some of the register fields provided in the configuration space can be written to prior to bus enumeration via the slave interface of PCI ESS. Note that the hardware does not prevent modification of read only field after bus enumeration but it is strongly advised that read only fields not be written once the bus enumeration is complete.

In addition, the BAR Mask registers can also be programmed by first enabling the DBI_CS2 bit and then performing writes on the BAR registers. The BAR mask registers are overlaid on BAR registers. For the BAR mask registers to be writable, the respective BAR must first be enabled.

19.3.3 Accessing EP Application Registers from PCIe RC

The application registers are also mapped at 2K and above address, in the configuration space. The RC software can access these registers over PCIe link provided the registers are programmed to some default values by the BOOT code in the PCI ESS host device that enables link training and TLP exchange.

19.4 Encoding of LTSSM State in DEBUG registers

The LTSSM state value that is read from DEBUG0 Register bits[4:0] is an encoded value. The literal names of the LTSSM states corresponding to the encoded values are tabulated below.

Table 19-10. LTSSM States

CODE	LTSSM STATE
0x00	DETECT_QUIET
0x01	DETECT_ACT
0x02	POLL_ACTIVE
0x03	POLL_COMPLIANCE
0x04	POLL_CONFIG
0x05	PRE_DETECT_QUIET
0x06	DETECT_WAIT
0x07	CFG_LINKWD_START
0x08	CFG_LINKWD_ACEPT
0x09	CFG_LANENUM_WAIT
0x0A	CFG_LANENUM_ACEPT
0x0B	CFG_COMPLETE
0x0C	CFG_IDLE
0x0D	RCVRY_LOCK
0x0E	RCVRY_SPEED
0x0F	RCVRY_RCVRCFG
0x10	RCVRY_IDLE
0x11	L0
0x12	L0S
0x13	L123_SEND_IDLE
0x14	L1_IDLE
0x15	L2_IDLE
0x16	L2_WAKE
0x17	DISABLED_ENTRY
0x18	DISABLED_IDLE
0x19	DISABLED
0x1A	LPBK_ENTRY
0x1B	LPBK_ACTIVE
0x1C	LPBK_EXIT
0x1D	LPBK_EXIT_TIMEOUT
0x1E	HOT_RESET_ENTRY
0x1F	HOT_RESET

19.5 PCI ESS Memory Map

19.5.1 Application Registers

The Application registers are accessible in multiple ways depending on the point of origin of such accesses. When accessed from the OCP side (on board CPU or EDMA performing the access), these registers are accessed via the 4KB space in Address Space or Address Region Zero. When accessed from the PCIe serial link side, the application registers are mapped to BAR0 of an EP as well as RC. In other words, if a PCIe component desires access to the application registers, based on the address type used (memory or configuration) the right block of memory is accessed automatically. In addition, an RC can access these registers in a PCI ESS EP via the upper 1 KB space of the PCIe configuration space. The offsets of the registers remain the same regardless with the access method used.

The starting base address of the application registers (also referred as PCIe Configuration registers) is 0x5100_0000.

19.5.1.1 Application Registers Summary

The applications registers summary is shown below.

Table 19-11. Applications Registers Summary

Name	Reset	Offset
PID	NA	0x000

19.5.1.2 PID Register

The peripheral version and ID register (PID) is described in the figure and table below.

Figure 19-6. PID Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

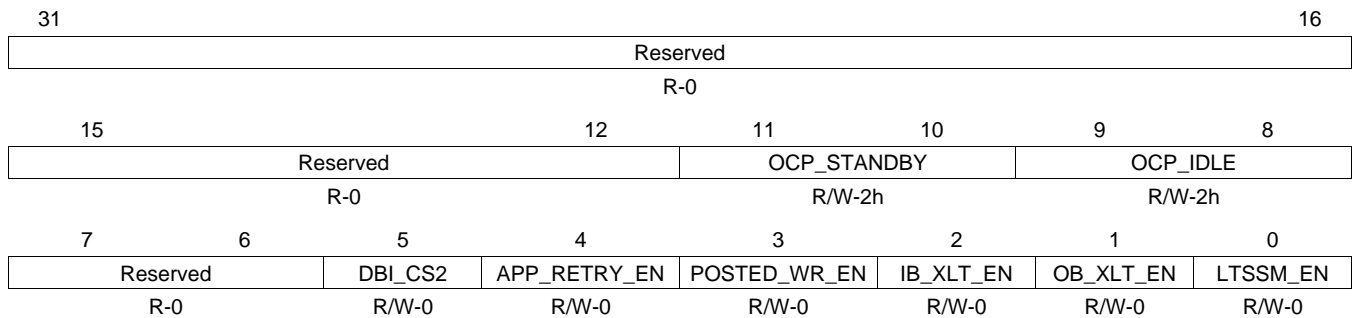

Table 19-12. PID Register Field Descriptions

Bit	Field	Value	Description
31-30	SCHEME	0-3h	PID Register Format Scheme
29-28	Reserved	0	Reserved
27-16	FUNC	0-FFFh	Function code of the peripheral
15-11	RTL	0-1Fh	RTL version number (R)
10-8	MAJOR	0-7h	Major revision code (X)
7-6	CUSTOM	0-3h	Custom code
5-0	MINOR	0-3Fh	Minor revision code (Y)

19.5.1.3 CMD_STATUS Register

The command status register (CMD_STATUS) is described in the figure and table below.

Figure 19-7. CMD_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-13. CMD_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reserved
11-10	OCP_STANDBY	0-3h	The OCP standby mode bitfield defines the local clock-management behavior of the PCIe module based on Standby (master) protocol with the device PRCM. For more information on Standby states relations to the PCIe protocol link power states, refer to Section 19.2.13, OCP Power Management.
			0h : Force standby / The module unconditionally asserts the standby request to the PRCM module, regardless of its internal operations. The PRCM module may gate the functional and interface clocks to the module. This mode must be used carefully (should NOT be used in normal usage but for debug purposes only) because it does not prevent loss of data at the time the clocks are gated. /
			1h : No standby / The module never asserts the standby request to the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active; however, it is not efficient from a power-saving perspective because it never allows the PRCM module output clocks to be gated. /
			2h : Smart standby / The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idled. The PRCM module can then gate the clocks to the module. Note that, this mode is NOT wake-up capable, i.e. the module can NOT generate (IRQ- or DMA request-related) wake-up events when in IDLE state. /
			3h : Reserved
9-8	OCP_IDLE	0-3h	The OCP idle mode bitfield defines the local clock-management behavior of the PCIe module based on Idle (Slave) protocol with the device PRCM. For more information on Idle states relations to the PCIe protocol link power states, refer to Section 19.2.13, OCP Power Management.
			0h : Force Idle / The module unconditionally acknowledges an IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully (should NOT be used in normal usage but for debug purposes only), because it does not prevent loss of data at the time the clock is switched off. /
			1h : No Idle / The module never acknowledges any IDLE request from the PRCM module. This mode is safe from a module point of view because it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM module output clock to be shut off, and thus the power domain to be set to a lower power state. /
			2h : Smart Idle / The module acknowledges an IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management. Note that, this mode is NOT wake-up capable, i.e. the module can NOT generate (IRQ- or DMA request-related) wake-up events when in IDLE state. /
			3h : Smart Idle (wake-up capable) / The module acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management. The module may generate (IRQ- or DMA request-related) wake-up events when in IDLE state. /
7-6	Reserved	0	Reserved
5	DBI_CS2	0	Set to enable writing to BAR mask registers that are overlaid on BAR registers.
4	APP_RETRY_EN	0	Application Request Retry Enable—Setting this bit will enable all incoming PCIe transactions to be returned with a retry response. This feature can be used if initialization can take longer than PCIe stipulated time frame.
3	POSTED_WR_EN	0	Posted Write Enable—Setting this bit will cause the OCP master to use posted write commands. Default is zero with all OCP Master writes defaulting to non-posted.
2	IB_XLT_EN	0	Inbound Address Translation Enable—Setting this bit will enable translation of inbound memory/io read/write requests into memory read/write requests.
1	OB_XLT_EN	0	Outbound Address Translation Enable—Setting this bit will enable translation of outbound memory read/write requests into memory/io/cfg read/write requests.
0	LTSSM_EN	0	Link Transitioning Enable—Setting this bit will enable LTSSM in PCI Express Core and link negotiation with link partner will begin.

19.5.1.4 CFG_SETUP Register

The config transaction setup register (CFG_SETUP) is described in the figure and table below.

Figure 19-8. CFG_SETUP Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-14. CFG_SETUP Register Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved
24	CFG_TYPE	0	Configuration Type for outbound configuration accesses. Set for Type 1 access and clear for Type 0 access.
23-16	CFG_BUS	0-FFh	PCIe Bus number for outbound configuration accesses
15-13	Reserved	0	Reserved
12-8	CFG_DEVICE	0-1Fh	PCIe Device number for outbound configuration accesses
7-3	Reserved	0	Reserved
2-0	CFG_FUNC	0-7h	PCIe Function number for outbound configuration accesses

19.5.1.5 IOBASE Register

The IO TLP base register (IOBASE) is described in the figure and table below.

Figure 19-9. IOBASE Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-15. IOBASE Register Field Descriptions

Bit	Field	Value	Description
31-12	IOBASE	0-F FFFFh	Bits 31-12 of outgoing IO TLP. RC mode only.
11-0	Reserved	0	Reserved

19.5.1.6 TLPCFG Register

The TLP attribute configuration register (TLPCFG) is described in the figure and table below.

Figure 19-10. TLPCFG Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-16. TLPCFG Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	RELAXED	0	Enable Relaxed Ordering for all outgoing TLPs.
0	NO_SNOOP	0	Enable No Snoop attribute on all outgoing TLPs.

19.5.1.7 RSTCMD Register

The reset command and status register (RSTCMD) is described in the table and figure below.

Figure 19-11. RSTCMD Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-17. RSTCMD Register Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	FLUSH_N	1	Bridge Flush Status—Reads a zero when no transaction is pending. Used to ensure no pending transactions before issuing warm reset. Only applicable in PCIExpress versions that use Designware core version 3.57 and newer.
15-1	Reserved	0	Reserved
0	INIT_RST	0	Write one to initiate a downstream hot reset sequence on downstream.

19.5.1.8 PMCMD Register

The power management command register (PMCD) is described in the figure and table below.

Figure 19-12. PMCMD Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-18. PMCMD Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	PM_XMT_TURNOFF	0	Write one to transmit a PM_TURNOFF message. Reads zero. Applicable in RC mode only.
0	PM_XMT_PME	0	Write one to transmit a PM_PME message. Reads zero. Applicable to EP mode only.

19.5.1.9 PMCFG Register

The power management configuration register (PMCFG) is described in the figure and table below.

Figure 19-13. PMCFG Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-19. PMCFG Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2	RDY_ENTR_L23	0	Read L2/L3 entry readiness. Applicable to RC and EP.
1	Reserved	0	Reserved
0	ENTR_L23	0	Write one to enable entry to L2/L3 ready state. Applicable to RC and EP.

19.5.1.10 ACT_STATUS Register

The activity status register (ACT_STATUS) is described in the figure and table below.

Figure 19-14. ACT_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-20. ACT_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	OB_NOT_EMPTY	0	Outbound buffers are empty if this bit is read as 0.
0	IB_NOT_EMPTY	0	Inbound buffers are empty if this bit is read as 1.

19.5.1.11 OB_SIZE Register

The outbound size register (OB_SIZE) is described in the figure and table below.

Figure 19-15. OB_SIZE Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-21. OB_SIZE Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	OB_SIZE	0-7h	Write 0, 1, 2, or 3 and so on to set each outbound translation window size to 1, 2, 4, or 8 MB region size. Applicable to RC and EP.

19.5.1.12 DIAG_CTRL Register

The diagnostic control register (DIAG_CTRL) is described in the figure and table below.

Figure 19-16. DIAG_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-22. DIAG_CTRL Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	INV_ECRC	0	Write 1 to force inversion of LSB of ECRC for next one packet. It is self-cleared when the ECRC error has been injected on one TLP.
0	INV_LCRC	0	Write 1 to force inversion of LSB of LCRC for next one packet. It is self-cleared when the ECRC error has been injected on one TLP.

19.5.1.13 ENDIAN Register

The endian mode register (ENDIAN) is described in the figure and table below.

Figure 19-17. ENDIAN Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-23. ENDIAN Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	ENDIAN	0-3h	Applicable in CBA version of PCIess only. Not applicable to OCP bus.

19.5.1.14 PRIORITY Register

The CBA transaction priority register (PRIORITY) is described in the figure and table below.

Figure 19-18. PRIORITY Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-24. PRIORITY Register Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	MST_PRIV	0	Value on master transactions
15-12	Reserved	0	Reserved
11-8	MST_PRIVID	0-Fh	Value on master transactions
7-2	Reserved	0	Reserved
1-0	MST_PRIORITY	0-3h	Priority level for each inbound transaction on the CBA master port. This field is not used for OCP interface.

19.5.1.15 IRQ_EOI Register

The end of interrupt register (IRQ_EOI) is described in the figure and table below.

Figure 19-19. IRQ_EOI Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-25. EOI Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	EOI	0-3h	EOI for each interrupt. Write to indicate end-of-interrupt for the interrupt events. Write 0 to mark EOI for INTA/INTB/INTC/INTD, 1 to mark EOI for MSI interrupts and so on.

19.5.1.16 MSI_IRQ Register

The MSI interrupt IRQ register (MSI_IRQ) is described in the figure and table below.

Figure 19-20. MSI_IRQ Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-26. MSI_IRQ Register Field Descriptions

Bit	Field	Value	Description
31-0	MSI_IRQ	0-FFFF FFFFh	This register is written to by the remote device. Writes initiated by an EP over PCIe link that target BAR0 of the RC land to this register if the offset matches. To generate MSI Interrupt 0, the EP should write 0000_0000h to this register. It will result in a pulse on bit 0 triggering the MSI interrupt from PCIExpress to the external processor.

19.5.1.17 EP_IRQ_SET Register

The endpoint interrupt request set register (EP_IRQ_SET) is described in the figure and table below.

Figure 19-21. EP_IRQ_SET Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-27. EP_IRQ_SET Register Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	EP_IRQ_SET	0	Write 1 to generate assert interrupt message. If MSI is disabled, legacy interrupt assert message will be generated. On read, a 1 indicates currently asserted interrupt.

19.5.1.18 EP_IRQ_CLR Register

The endpoint interrupt request clear register (EP_IRQ_CLR) is described in the figure and table below.

Figure 19-22. EP_IRQ_CLR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-28. EP_IRQ_CLR Register Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	EP_IRQ_CLR	0	Write 1 to generate deassert interrupt message. If MSI is disabled, legacy interrupt deassert message will be generated. On read, a 1 indicates currently asserted.

19.5.1.19 EP_IRQ_STATUS Register

The endpoint interrupt status register (EP_IRQ_STATUS) is described in the figure and table below.

Figure 19-23. EP_IRQ_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-29. EP_IRQ_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	EP_IRQ_STATUS	0	Indicates whether interrupt for function 0 is asserted or not.

19.5.1.20 GPR0 Register

The general purpose 0 register (GPR0) is described in the figure and table below.

Figure 19-24. GPR0 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-30. GPR0 Register Field Descriptions

Bit	Field	Value	Description
31-0	GENERIC0	0-FFFF FFFFh	Generic Info field 0

19.5.1.21 GPR1 Register

The general purpose 1 register (GPR1) is described in the figure and table below.

Figure 19-25. GPR1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-31. GPR1 Register Field Descriptions

Bit	Field	Value	Description
31-0	GENERIC1	0-FFFF FFFFh	Generic Info field 1

19.5.1.22 GPR2 Register

The general purpose 2 register (GPR2) is described in the figure and table below.

Figure 19-26. GPR2 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-32. GPR2 Register Field Descriptions

Bit	Field	Value	Description
31-0	GENERIC2	0-FFFF FFFFh	Generic Info field 2

19.5.1.23 GPR3 Register

The general purpose 3 register (GPR3) is described in the figure and table below.

Figure 19-27. GPR3 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-33. GPR3 Register Field Descriptions

Bit	Field	Value	Description
31-0	GENERIC3	0-FFFF FFFFh	Generic Info field 3

19.5.1.24 MSI0_IRQ_STATUS_RAW Register

The MSI 0 interrupt raw status register (MSI0_IRQ_STATUS_RAW) is described in the figure and table below.

Figure 19-28. MSI0_STATUS_RAW Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-34. MSI0_STATUS_RAW Register Field Descriptions

Bit	Field	Value	Description
31-0	MSI0_RAW_STATUS	0-FFFF FFFFh	Each bit indicates raw status of MSI vector associated with the bit. Typically, writes to this register are only done for debug purposes.

19.5.1.25 MSI0_IRQ_STATUS Register

The MSI 0 interrupt enabled status register (MSI0_IRQ_STATUS) is described in the figure and table below.

Figure 19-29. MSI0_IRQ_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-35. MSI0_IRQ_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-0	MSI0_IRQ_STATUS	0-FFFF FFFFh	Each bit indicates raw status of MSI vector associated with the bit. Each of the bits can be written with a one to clear the respective interrupt status bit.

19.5.1.26 MSI0_IRQ_ENABLE_SET Register

The MSI 0 interrupt enable set register (MSI0_IRQ_ENABLE_SET) is described in the figure and table below.

Figure 19-30. MSI0_IRQ_ENABLE_SET Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-36. MSI0_IRQ_ENABLE_SET Register Field Descriptions

Bit	Field	Value	Description
31-0	MSI0_IRQ_ENABLE_SET	0-FFFF FFFFh	Each bit, when written to, enables the MSI interrupt associated with the bit.

19.5.1.27 MSI0_IRQ_ENABLE_CLR Register

The MSI0 interrupt enable clear register (MSI0_IRQ_ENABLE_CLR) is described in the figure and table below.

Figure 19-31. MSI0_IRQ_ENABLE_CLR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-37. MSI0_IRQ_ENABLE_CLR Register Field Descriptions

Bit	Field	Value	Description
31-0	MSI0_IRQ_ENABLE_CLR	0-FFFF FFFFh	Each bit, when written to, disables the MSI interrupt associated with the bit.

19.5.1.28 IRQ_STATUS_RAW Register

The raw interrupt status register (IRQ_STATUS_RAW) is described in the figure and table below.

Figure 19-32. IRQ_STATUS_RAW Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-38. IRQ_STATUS_RAW Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	INTD	0	Legacy Interrupt D raw status. RC mode only.
2	INTC	0	Legacy Interrupt C raw status. RC mode only.
1	INTB	0	Legacy Interrupt B raw status. RC mode only.
0	INTA	0	Legacy Interrupt A raw status. RC mode only.

19.5.1.29 IRQ_STATUS Register

The interrupt enabled status register (IRQ_STATUS) is described in the figure and table below.

Figure 19-33. IRQ_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-39. IRQ_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	INTD	0	Legacy Interrupt D status. Set when interrupt is active. Write one, '1', to clear the interrupt event. RC mode only.
2	INTC	0	Legacy Interrupt C status. Set when interrupt is active. Write one, '1', to clear the interrupt event. RC mode only.
1	INTB	0	Legacy Interrupt B status. Set when interrupt is active. Write one, '1', to clear the interrupt event. RC mode only.
0	INTA	0	Legacy Interrupt A status. Set when interrupt is active. Write one, '1' to clear the interrupt event. RC mode only.

19.5.1.30 IRQ_ENABLE_SET Register

The interrupt enable set register (IRQ_ENABLE_SET) is described in the figure and table below.

Figure 19-34. IRQ_ENABLE_SET Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-40. IRQ_ENABLE_SET Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	INTD	0	Legacy Interrupt D status. Set to enable the interrupt. On read, one/zero means interrupt is enabled/disabled.
2	INTC	0	Legacy Interrupt C status. Set to enable the interrupt. On read, one/zero means interrupt is enabled/disabled.
1	INTB	0	Legacy Interrupt B status. Set to enable the interrupt. On read, one/zero means interrupt is enabled/disabled.
0	INTA	0	Legacy Interrupt A status. Set to enable the interrupt. On read, one/zero means interrupt is enabled/disabled.

19.5.1.31 IRQ_ENABLE_CLR Register

The interrupt enable clear register (IRQ_ENABLE_CLR) is described in the figure and table below.

Figure 19-35. IRQ_ENABLE_CLR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-41. IRQ_ENABLE_CLR Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	INTD	0	Legacy Interrupt D disable. Set to enable the interrupt. On read, one/zero means interrupt is enabled/disabled.
2	INTC	0	Legacy Interrupt C disable. Set to enable the interrupt. On read, one/zero means interrupt is enabled/disabled.
1	INTB	0	Legacy Interrupt B disable. Set to enable the interrupt. On read, one/zero means interrupt is enabled/disabled.
0	INTA	0	Legacy Interrupt A disable. Set to enable the interrupt. On read, one/zero means interrupt is enabled/disabled.

19.5.1.32 ERR_IRQ_STATUS_RAW Register

The raw ERR interrupt status register (ERR_IRQ_STATUS_RAW) is described in the figure and table below.

Figure 19-36. ERR_IRQ_STATUS_RAW Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-42. ERR_IRQ_STATUS_RAW Register Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	ERR_AER	0	ECRC error raw status.
4	ERR_AXI	0	AXI tag lookup fatal error raw status.
3	ERR_CORR	0	Correctable error raw status.
2	ERR_NONFATAL	0	Nonfatal error raw status.
1	ERR_FATAL	0	Fatal error raw status.
0	ERR_SYS	0	System Error (FATAL, NONFATAL, or CORRECTABLE error) raw status.

19.5.1.33 ERR_IRQ_STATUS Register

The ERR interrupt enabled status register (ERR_IRQ_STATUS) is described in the figure and table below.

Figure 19-37. ERR_IRQ_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-43. ERR_IRQ_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	ERR_AER	0	ECRC error raw status.
4	ERR_AXI	0	AXI tag lookup fatal error raw status.
3	ERR_CORR	0	Correctable error raw status.
2	ERR_NONFATAL	0	Nonfatal error raw status.
1	ERR_FATAL	0	Fatal error raw status.
0	ERR_SYS	0	System Error (FATAL, NONFATAL, or CORRECTABLE error) raw status.

19.5.1.34 ERR_IRQ_ENABLE_SET Register

The ERR interrupt enable set register (ERR_IRQ_ENABLE_SET) is described in the figure and table below.

Figure 19-38. ERR_IRQ_ENABLE_SET Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-44. ERR_IRQ_ENABLE_SET Register Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	ERR_AER	0	ECRC error interrupt enable. Set to enable. On read, one/zero means enabled/disabled respectively.
4	ERR_AXI	0	AXI tag lookup fatal error interrupt enable. Set to enable. On read, one/zero means enabled/disabled respectively.
3	ERR_CORR	0	Correctable error interrupt enable. Set to enable. On read, one/zero means enabled/disabled respectively.
2	ERR_NONFATAL	0	Nonfatal error interrupt enable. Set to enable. On read, one/zero means enabled/disabled respectively.
1	ERR_FATAL	0	Fatal error interrupt enable. Set to enable. On read, one/zero means enabled/disabled respectively.
0	ERR_SYS	0	System Error (FATAL, NONFATAL, or CORRECTABLE error) interrupt enable. Set to enable. On read, one/zero means enabled/disabled respectively.

19.5.1.35 ERR_IRQ_ENABLE_CLR Register

The ERR interrupt enable clear register (ERR_IRQ_ENABLE_CLR) is described in the figure and table below.

Figure 19-39. ERR_IRQ_ENABLE_CLR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-45. ERR_IRQ_ENABLE_CLR Register Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	ERR_AER	0	ECRC error interrupt disable. Set to disable. On read, one/zero means enabled/disabled respectively.
4	ERR_AXI	0	AXI tag lookup fatal error interrupt disable. Set to disable. On read, one/zero means enabled/disabled respectively.
3	ERR_CORR	0	Correctable error interrupt disable. Set to disable. On read, one/zero means enabled/disabled respectively.
2	ERR_NONFATAL	0	Nonfatal error interrupt disable. Set to disable. On read, one/zero means enabled/disabled respectively.
1	ERR_FATAL	0	Fatal error interrupt disable. Set to disable. On read, one/zero means enabled/disabled respectively.
0	ERR_SYS	0	System Error (FATAL, NONFATAL, or CORRECTABLE error) interrupt disable. Set to disable. On read, one/zero means enabled/disabled respectively.

19.5.1.36 PMRST_IRQ_STATUS_RAW Register

The power management and reset interrupt status register (PMRST_IRQ_STATUS_RAW) is described in the figure and table below.

Figure 19-40. PMRST_IRQ_STATUS_RAW Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-46. PMRST_IRQ_STATUS_RAW Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	LINK_RST_REQ	0	Link Request Reset interrupt raw status
2	PM_PME	0	Power Management PME message received interrupt raw status
1	PM_TO_ACK	0	Power Management ACK received interrupt raw status
0	PM_TURNOFF	0	Power Management Turnoff message received raw status

19.5.1.37 PMRST_IRQ_STATUS Register

The power management and reset interrupt enabled status register (PMRST_IRQ_STATUS) is described in the figure and table below.

Figure 19-41. PMRST_IRQ_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-47. PMRST_IRQ_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	LINK_RST_REQ	0	Link Request Reset interrupt raw status
2	PM_PME	0	Power Management PME message received interrupt raw status
1	PM_TO_ACK	0	Power Management ACK received interrupt raw status
0	PM_TURNOFF	0	Power Management Turnoff message received raw status

19.5.1.38 PMRST_ENABLE_SET Register

The power management and reset interrupt enabled set register (PMRST_ENABLE_SET) is described in the figure and table below.

Figure 19-42. PMRST_ENABLE_SET Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-48. PMRST_ENABLE_SET Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	LINK_RST_REQ	0	Link Request Reset interrupt enable. Set to enable the interrupt. Read 1 means interrupt is enabled.
2	PM_PME	0	Power Management PME message received interrupt enable. Set to enable the interrupt. Read 1 means interrupt is enabled.
1	PM_TO_ACK	0	Power Management ACK received interrupt enable. Set to enable the interrupt. Read 1 means interrupt is enabled.
0	PM_TURNOFF	0	Power Management Turnoff message received enable. Set to enable the interrupt. Read 1 means interrupt is enabled.

19.5.1.39 PMRST_ENABLE_CLR Register

The power management and reset interrupt enabled clear register (PMRST_ENABLE_CLR) is described in the figure and table below.

Figure 19-43. PMRST_ENABLE_CLR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-49. PMRST_ENABLE_CLR Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	LINK_RST_REQ	0	Link Request Reset interrupt disable. Set to disable the interrupt. Read 1 means interrupt is enabled.
2	PM_PME	0	Power Management PME message received interrupt disable. Set to disable the interrupt. Read 1 means interrupt is enabled.
1	PM_TO_ACK	0	Power Management ACK received interrupt disable. Set to disable the interrupt. Read 1 means interrupt is enabled.
0	PM_TURNOFF	0	Power Management Turnoff message received disable. Set to disable the interrupt. Read 1 means interrupt is enabled.

19.5.1.40 OB_OFFSET_INDEXn (0x200 + N*8) Register

The outbound translation region N offset low and index register (OB_OFFSET_INDEXn) is described in the figure and table below.

Figure 19-44. OB_OFFSET_INDEXn Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-50. OB_OFFSET_INDEXn Register Field Descriptions

Bit	Field	Value	Description
31-20	OB_OFFSETn_LO	0-FFFh	Offset bits 31-20 for translation region N (N=0-31)
19-1	Reserved	0	Reserved
0	OB_ENABLEn	0	Enable translation region N (N=0-31)

19.5.1.41 OB_OFFSETn_HI Register (0x200 + N*8 + 0x4)

The outbound translation region N offset high register (OB_OFFSETn_HI) is described in the figure and table below.

Figure 19-45. OB_OFFSETn_HI Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-51. OB_OFFSETn_HI Register Field Descriptions

Bit	Field	Value	Description
31-0	OB_OFFSETn_HI	0-FFFF FFFFh	Offset bits 31-0 for translation region N (N=0-31)

19.5.1.42 IB_BAR0 Register

The inbound translation bar match 0 register (IB_BAR0) is described in the figure and table below.

Figure 19-46. IB_BAR0 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-52. IB_BAR0 Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	IB_BAR0	0-7h	BAR number to match for inbound translation region 0

19.5.1.43 IB_START0_LO Register

The inbound translation 0 start address low register (IB_START0_LO) is described in the figure and table below.

Figure 19-47. IB_START0_LO Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-53. IB_START0_LO Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_START0_LO	0-FF FFFFh	Start address bits 31-8 for inbound translation region 0.
7-0	Reserved	0	Reserved

19.5.1.44 IB_START0_HI Register

The inbound translation 0 start address high register (IB_START0_HI) is described in the figure and table below.

Figure 19-48. IB_START0_HI Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-54. IB_START0_HI Register Field Descriptions

Bit	Field	Value	Description
31-0	IB_START0_HI	0-FFFF FFFFh	Start address bits 63-0 for inbound translation region 0.

19.5.1.45 IB_OFFSET0 Register

The inbound translation 0 address offset register (IB_OFFSET0) is described in the figure and table below.

Figure 19-49. IB_OFFSET0 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-55. IB_OFFSET0 Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_OFFSET0	0-FF FFFFh	Offset address bits 31-8 for inbound translation region 0.
7-0	Reserved	0	Reserved

19.5.1.46 IB_BAR1 Register

The inbound translation bar match 1 register (IB_BAR1) is described in the figure and table below.

Figure 19-50. IB_BAR1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-56. IB_BAR1 Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	IB_BAR1	0-7h	BAR number to match for inbound translation region 1

19.5.1.47 IB_START1_LO Register

The inbound translation 1 start address low register (IB_START1_LO) is described in the figure and table below.

Figure 19-51. IB_START1_LO Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-57. IB_START1_LO Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_START1_LO	0-FF FFFFh	Start address bits 31-8 for inbound translation region 1
7-0	Reserved	0	Reserved

19.5.1.48 IB_START1_HI Register

The inbound translation 1 start address high register (IB_START1_HI) is described in the figure and table below.

Figure 19-52. IB_START1_HI Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-58. IB_START1_HI Register Field Descriptions

Bit	Field	Value	Description
31-0	IB_START1_HI	0-FFFF FFFFh	Start address bits 63-0 for inbound translation region 1

19.5.1.49 IB_OFFSET1 Register

The inbound translation 1 address offset register (IB_OFFSET1) is described in the figure and table below.

Figure 19-53. IB_OFFSET1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-59. IB_OFFSET1 Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_OFFSET1	0-FF FFFFh	Offset address bits 31-8 for inbound translation region 1
7-0	Reserved	0	Reserved

19.5.1.50 IB_BAR2 Register

The inbound translation bar match 2 register (IB_BAR2) is described in the figure and table below.

Figure 19-54. IB_BAR2 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-60. IB_BAR2 Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	IB_BAR2	0-7h	BAR number to match for inbound translation region 2

19.5.1.51 IB_START2_LO Register

The inbound translation 2 start address low register (B_START2_LO) is described in the figure and table below.

Figure 19-55. IB_START2_LO Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-61. IB_START2_LO Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_START2_LO	0-FF FFFFh	Start address bits 31-8 for inbound translation region 2
7-0	Reserved	0	Reserved

19.5.1.52 IB_START2_HI Register

The inbound translation 2 start address high register (B_START2_HI) is described in the figure and table below.

Figure 19-56. IB_START2_HI Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-62. IB_START2_HI Register Field Descriptions

Bit	Field	Value	Description
31-0	IB_START2_HI	0-FFFF FFFFh	Start address bits 63-0 for inbound translation region 2

19.5.1.53 IB_OFFSET2 Register

The inbound translation 2 address offset register (IB_OFFSET2) is described in the figure and table below.

Figure 19-57. IB_OFFSET2 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-63. IB_OFFSET2 Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_OFFSET2	0-FF FFFFh	Offset address bits 31-8 for inbound translation region 2
7-0	Reserved	0	Reserved

19.5.1.54 IB_BAR3 Register

The inbound translation bar match 3 register (B_BAR3) is described in the figure and table below.

Figure 19-58. IB_BAR3 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-64. IB_BAR3 Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	IB_BAR3	0-7h	BAR number to match for inbound translation region 3

19.5.1.55 IB_START3_LO Register

The inbound translation 3 start address low register (IB_START3_LO) is described in the figure and table below.

Figure 19-59. IB_START3_LO Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-65. IB_START3_LO Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_START3_LO	0-FF FFFFh	Start address bits 31-8 for inbound translation region 3
7-0	Reserved	0	Reserved

19.5.1.56 IB_START3_HI Register

The inbound translation 3 start address high register (IB_START3_HI) is described in the figure and table below.

Figure 19-60. IB_START3_HI Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-66. IB_START3_HI Register Field Descriptions

Bit	Field	Value	Description
31-0	IB_START3_HI	0-FFFF FFFFh	Start address bits 63-0 for inbound translation region 3

19.5.1.57 IB_OFFSET3 Register

The inbound translation 3 address offset register (IB_OFFSET3) is described in the figure and table below.

Figure 19-61. IB_OFFSET3 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-67. IB_OFFSET3 Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_OFFSET3	0-FF FFFFh	Offset address bits 31-8 for inbound translation region 3
7-0	Reserved	0	Reserved

19.5.1.58 PCS_CFG0

The PCS configuration 0 (PCS_CFG0) is described in the figure and table below.

Figure 19-62. PCS_CFG0 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-68. PCS_CFG0 Register Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reserved
28-24	PCS_SYNC	0-1Fh	Receiver Lock/Sync Control
23-16	PCS_HOLDOFF	0-FFh	Receiver Initialization Hold Off Control
15-14	Reserved	0	Reserved
13-12	PCS_RC_DELAY	0-3h	Rate Change Delay
11-8	PCS_DET_DELAY	0-Fh	Detection Delay
7	PCS_SHRT_TM	0	Enable short times for debug purposes.
6	PCS_STAT186	0	Enable PIPE Spec 1.86 for PHY status behavior
5	PCS_FIX_TERM	0	Fed term output to 3'b100 during reset.
4	PCS_FIX_STD	0	Fix std output to 2'b10
3	PCS_L2_ENIDL_OFF	0	Deassert ENIDL during L2 state.
2	PCS_L0S_RX_OFF	0	Deassert Rx Enable in L0s state.
1	PCS_RXTX_ON	0	RX and TX on during reset. TX also on in P1 state.
0	PCS_RXTX_RST	0	RX and TX on during reset

19.5.1.59 PCS_CFG1

The PCS configuration 1 (PCS_CFG1) is described in the figure and table below.

Figure 19-63. PCS_CFG1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-69. PCS_CFG1 Register Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reserved
25-16	PCS_ERR_BIT	0-3FFh	Error Bit enable
15-10	Reserved	0	Reserved
9-8	PCS_ERR_LN	0-3h	Error Lane enable
7-2	Reserved	0	Reserved
1-0	PCS_ERR_MODE	0-3h	Error Injection Mode

19.5.1.60 PCS_STATUS

The PCS status register is described in the figure and table below.

Figure 19-64. PCS_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-70. PCS_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved
14-12	PCS_REV	0-7h	PCS RTL Revision
11-10	Reserved	0	Reserved
9-8	PCS_LN_EN	0-3h	PCS Lanes enabled status
7-6	Reserved	0	Reserved
5-4	PCS_TX_EN	0-3h	PCS Transmitters enabled status
3-2	Reserved	0	Reserved
1-0	PCS_RX_EN	0-3h	PCS Receivers enabled status

19.5.1.61 SERDES_STATUS

The SerDes status register (SERDES_STATUS) is described in the figure and table below.

Figure 19-65. SERDES_STATUS Register

31	16	15	0
STSTX		SRSRX	
R-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

19.5.1.62 SERDES_RXCFG0

The SerDes RX Config 0 status register (SERDES_RXCFG0) is described in the figure and table below.

Figure 19-66. SERDES_RXCFG0 Register

31	30	29	28	27	26	25	24
LOOPBACK		RX_TRIM_BYP ASS	CDR_ELV_IDL E_FIX	CDRAUX		CAL_FILTER_DEPTH

R/W-0		R/W-0x0		R/W-0x0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-71. SERDES_RXCFG0 Register Field Descriptions

Bit	Field	Value	Description
31-30	LOOPBACK	10/11	Internal Loopback with following options CFGRX_1[14] Loop back from TX (pre-driver digital output) to RX (input of RXDIG20). Digital loop back. CFGRX_1[14] Loop back from TX (pre-driver digital output) to RX (input of equalizer). Analog loop back.
		0	Loopback disabled
		1	Not supported

Table 19-71. SERDES_RXCFG0 Register Field Descriptions (continued)

Bit	Field	Value	Description
29	RX_TRIM_BYPASS	0	For calibration --> Bypasses the trim bits generated from the calibration algorithm Use the trim code generated by trx_dig
		1	Bypass the trim code generated by trx_dig
28	CDR_ELV_IDLE_FIX	0	CDR ELV Idle fix is enabled
		1	CDR ELV Idle fix is disabled
27-26	CDRAUX		CDRAUX[1:0]: Clock/data recovery auxilliary. Along with the CDR field, configures the clock/data recovery algorithm.
25-24	CAL_FILTER_DEPTH	00	For calibration --> Average engine can be programmed to have depth of 7,15, 31 Depth of 7 samples
		01	Depth of 15 samples
		10	Depth of 31 samples
		11	Depth of 7 samples
23	ENOC	0	ENOC: Enable offset compensation. Enables samplers offset compensation. Can be written DYNAMIC
		1	
22-19	EQ	0	Equalizer. Enables and configures the adaptive equalizer to compensate for loss in the transmission media Equalizer enabled
		1	Equalizer disabled
18-16	CDR	0	Clock/data recovery. Along with the CDRAUX field, configures the clock/data recovery algorithm.
		1	
15-13	LOS	0000	Enables loss of signal detection LOS disabled
		100	LOS enabled, without CDR override control [CDR enable]
		110	LOS enabled, with CDR override control [CDR disable]
		001	LOS disabled
		01x	LOS disabled
		101	LOS disabled
		11x	-LOS disabled
12-11	ALIGN	00	Symbol alignment. Enables internal or external symbol alignment Alignment disabled
		01	Comma alignment enabled
		10	Alignment Jog
		11	Reserved
10-8	TERM	000	Selects input termination options. External AC and DC coupled modes supported. Reserved
		001	Common point set to 0.8 VDDA. This configuration is for AC coupled systems
		010	Reserved
		011	Common point floating. This configuration is for DC coupled systems which require the common mode voltage to be determined by the transmitter only.
		100	Common point set to VSSA. This configuration is for PCI- Express and USB3.0
		101	Common point set to 0.2 VDDA. (For SATA system).
		110	Reserved
111	Common point floating, wide common mode range.		

Table 19-71. SERDES_RXCFG0 Register Field Descriptions (continued)

Bit	Field	Value	Description
7	INVPAIR	0 1	Inverts polarity of RXPi and RXNi. Normal Polarity. RXP considered to be positive Inverted Polarity. RXN considered to be positive
6-5	RATE	00 01 1x	Operating rate. Selects full, full, half, quarter or twentieth rate operation Full rate Half rate Reserved Bit 5 ONLY can be written DYNAMIC.
4-2	BUSWIDTH	000 001 01x 1xx	Selects the parallel interface width (8 or 10 bit). Only 10-bit mode will be used. 8-bit mode not officially supported. 10-bit operation Reserved Reserved Reserved
1	ENRXLDO	0 1	Enables RXLDO when high. When ENRXLDO='0', RX Analog circuits will be powered down. RXLDO has to be enabled and allowed to settle prior to enabling the receiver with ENRX.
0	ENRX	0 1	Enables receiver when high. When ENRX='0', all digital circuitry will be disabled and clocks are gated. All current sources in analog will be powered down with the exception of those associated with LOS detector and IEEE 1149.6 boundary scan comparators

19.5.1.63 SERDES_RXCFG1

The SerDes RX Config 1 status register (SERDES_RXCFG1) is described in the figure and table below.

Figure 19-67. SERDES_RXCFG1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-72. SERDES_RXCFG1 Register Field Descriptions

Bit	Field	Value	Description
31-30	EQ_ICM_S2	0 1	Trims common mode pullup current in second equalizer stage
29-28	EQ_ICM_S1	0 1	Trims common mode pullup current in first equalizer stage
27-24	RESERVED_RX1_27_24	0 1	Reserved for future use
23-21	EQ_I_STAGE2	0 1	Trims the current in the second stage of the equalizer
20-18	EQ_I_STAGEFB	0 1	Trims the current in the feedback stage of the equalizer
17-15	EQ_I_STAGE1	0 1	Trims the current in the first stage of the equalizer
14	ANALOG_LOOPBACK	0 1	Enables analog loop back
13	RXTRIM_CALIB	0 1	RX trimming control to the calibration block In function mode eFuse training mode
12	RXTRIM_BYPASS_CTRL	0 1	res_nwell settings are controlled by fuse/calib settingsRXTRIM[4:0] res_nwell settings are controlled by cfg_ctrl[11:7](CFGRX_1[11:7])
11-7	RXTRIM_BYPASS_BITS	0 1	Bypass bits for RXTRIM[4:0] when CFGRX_1[12]=1
6	BYPASS_CALOUT_AVG	0 1	For calibration --> Bypasses the averaging filter for the calout signal inside digital Use the output of the digital filter for CALOUT Ignore the output of the digital filter and use the output from the bubble removal circuit for CALOUT
5	CTG_DIG_RSVD1	0 1	Clock inversion for rpclk. In X2256, this was mapped to ctl_dig_rsvd[1]. This is a temporary mapping.
4	CTG_DIG_RSVD0	0 1	Clock inversion for fclk. In X2256, this was mapped to ctl_dig_rsvd[0]. This is a temporary mapping.
3	ENTEST	0 1	Enable test. Enables test modes specified via LOOPBACK (CFGRX_0[31:30]).

Table 19-72. SERDES_RXCFG1 Register Field Descriptions (continued)

Bit	Field	Value	Description
2-0	TESTPATT		Enables and selects test patterns.
		000	Reserved
		100	Uses a 31-bit LFSR with feedback polynomial $x^{31}+x^{28}+1$.
		001	An alternating 0/1 pattern with a period of 2 UI.
		010	Uses a 7-bit LFSR with feedback polynomial x^7+x^6+1 .
		011	Uses a 23-bit LFSR with feedback polynomial $x^{23}+x^{18}+1$
		101	Reserved
		110	Reserved
		111	Reserved

19.5.1.64 SERDES_RXCFG2

The SerDes RX Config 2 status register (SERDES_RXCFG2) is described in the figure and table below.

Figure 19-68. SERDES_RXCFG2 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-73. SERDES_RXCFG2 Register Field Descriptions

Bit	Field	Value	Description
31-27	SAMP_BYPASS_SAD1	0	Bypass bits for SAD1[4:0] when CFG_CTRL[94](CFGRX_3[30]) = 1
		1	
26-22	SAMP_BYPASS_SAT0	0	Bypass bits for SAT0[4:0] when CFG_CTRL[94](CFGRX_3[30]) = 1
		1	
21-17	SAMP_BYPASS_SAD0	0	Bypass bits for SAD0[4:0] when CFG_CTRL[94](CFGRX_3[30]) = 1
		1	
16-12	SAMP_BYPASS_SAT1	0	Bypass bits for SAT1[4:0] when CFG_CTRL[94](CFGRX_3[30]) = 1
		1	
11-0	RESERVED_RX2_11_0	0	Reserved for future use
		1	

19.5.1.65 SERDES_RXCFG3

The SerDes RX Config 3 status register (SERDES_RXCFG3) is described in the figure and table below.

Figure 19-69. SERDES_RXCFG3 Register

	31	30	29	28	27	26	25	24
	AMUX_EYESCAN_REF	SAMP_OC_SEL	SAMP_ES_VREF_BYPASS_BITS					
	R/W-0	R/W-0	R/W-0x00					
	23	22	21	20	19	18	17	16
	SAMP_ESCM_RES				SAMP_ESCM_I			SAMP_3_VREF_2_ES

	R/W-0	R/W-0x0			R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-74. SERDES_RXCFG3 Register Field Descriptions

Bit	Field	Value	Description
31	AMUX_EYESCAN_REF	0 1	=1 Connect the eyescan reference voltages to the test mux inputs (used with amuxsel_rx[3:0])
30	SAMP_OC_SEL	0 1	=0 Sampler offset correction is controlled via the TRXDIG SAT1, SAD0, SAT0, SAD1 =1 Sampler offset correction is controlled via the configuration register (CFG_CTRL[63:44])(CFGRX_2[31:12])
29-24	SAMP_ES_VREF_BYPASS_BITS	0 1	Adjusts the eyescan reference voltage level, which introduces linearly decreasing offset with code
23-20	SAMP_ESCM_RES	0 1	Trims the pullup resistors in the eyescan common mode loop; roughly should track CFGRX_1[10:7]
19-17	SAMP_ESCM_I	0 1	Trims the current in the eyescan common mode loop; roughly should track CFG_CTRL[23:21](CFGRX_1[23:21])
16	SAMP_3_VREF_2_ES	0 1	=0 reference voltages are EQCM =1 Connect reference voltage of sampler 3 to eyescan
15	SAMP_2_VREF_2_ES	0 1	=0 reference voltages are EQCM =1 Connect reference voltage of sampler 2 to eyescan
14	SAMP_1_VREF_2_ES	0 1	=0 reference voltages are EQCM =1 Connect reference voltage of sampler 1 to eyescan
13	SAMP_0_VREF_2_ES	0 1	=0 reference voltages are EQCM =1 Connect reference voltage of sampler 0 to eyescan
12-8	SAMP_IBIAS_Z	0 1	Adjusts the current mirror ratio in the sampler bias current block. Lower numbers correspond to higher bias current.

Table 19-74. SERDES_RXCFG3 Register Field Descriptions (continued)

Bit	Field	Value	Description
7	SAMP_ES_VREF_BYPASS_CTRL	0 1	=0 Eyescan reference offset voltage controled through IEEE1500 =1 Eyescan reference offset voltage controled through CFGRX_3[29:24]
6-4	RESERVED_RX3_6_4	0 1	UNUSED
3	SAMP_EN_3_ODD	0 1	=1 Enable sampler 3 (odd data)
2	SAMP_EN_2_EODD	0 1	=1 Enable sampler 2 (even to odd transition)
1	SAMP_EN_1_EVEN	0 1	=1 Enable sampler 1 (even data)
0	SAMP_EN_0_EODD	0 1	=1 Enable sampler 0 (odd to even transition)

19.5.1.66 SERDES_RXCFG4

The SerDes RX Config 4 status register (SERDES_RXCFG4) is described in the figure and table below.

Figure 19-70. SERDES_RXCFG4 Register

Table 19-77. SERDES_TXCFG1 Register Field Descriptions

Bit	Field	Value	Description
31-28	TRIM_HIGH_THRESHOLD		For calibration --> 4-b programmable threshold Unless the difference between the previous and new trim code required exceeds 4-b threshold, trim bit will be updated in one shot. Otherwise the trim bits will be updated in steps determined by TRIM_STEP_CHANGE.
27	TX_DISABLE_ON_THE_FLY	0 1	For calibration --> Disables the pattern match. Updates can only be made through electrical idle or TX_FORCE_UPDATE bit. 0 Enables pattern match 1 Disables pattern match
26	TX_FORCE_UPDATE	0 1	For calibration --> Forces the update to be made to the Analog trim bits without looking for any specific data pattern or electrical idle. 0 Disables forced update. 1 Enables forced update Can be written DYNAMIC.
25	TX_TRIM_BYPASS	0 1	For calibration --> Bypasses the trim bits generated from the calibration algorithm 0 Use the trim code generated by trx_dig 1 Bypass the trim code generated by trx_dig
24	TRIM_2B_MODE	0 1	For calibration --> Enables 2-b data pattern detection mode for trim updates. 0 2-b detection mode, e.g. "00" or "11" 1 3-b detection mode, e.g. "00" or "111"
23	RESERVED		Reserved
22-21	TRIM_STEP_CHANGE	00 01 10 11	For calibration --> Step change value for staircase logic 00 make updates in steps of 1 01 make updates in steps of 2 10 make updates in steps of 4 11 make updates in steps of 8

Table 19-77. SERDES_TXCFG1 Register Field Descriptions (continued)

Bit	Field	Value	Description
20-19	TRIM_LOW_THR ESHOLD	00	For calibration --> 2-b programmable threshold. make updates only when diff is >= 1
		01	make updates only when diff is >= 2
		10	make updates only when diff is >= 3
		11	make updates only when diff is >= 4
			Unless the difference between the previous and current trim code exceeds or equals above mentioned threshold, no updates trim bit updates are made in Analog.
18-17	CALIB_WAIT_CY CLES	0	For calibration --> 2-b programmable number of wait cycles before polling the callout signal Additional clock cycle delay of 1 MHz clock
		1	Additional clock cycle delay of 1 MHz clock
		2	Additional clock cycle delay of 1 MHz clock
		3	Additional clock cycle delay of 1 MHz clock
16	ENABLE_LOOP_ DELAY	0	For calibration --> Enables the additional loop delay of 40 clock cycles before sweeping the trim code during the calibration Disables the loop delay
		1	Enables the loop delay, ensures at least 32-clock cycles between two full cycles of trim code sweep
15	BYPASS_CALOU T_AVG	0	For calibration --> Bypasses the averaging filter for the callout signal inside digital Use the output of the digital filter for CALOUT
		1	Ignore the output of the digital filter and use the output from the bubble removal circuit for CALOUT.
14	NOLCKRST		Reset override bit during PLL unlock. Only for internal use. Not for SOC.
13	ENBSPLS		Receiver pulse boundary scan. Configures IEEE 1149.6 boundary scan comparators connected to RXP and RXN for EXTEST_PULSE and EXTEST_TRAIN when high and EXTEST when low
12	ENBSRX		Enables IEEE 1149.6 boundary scan control of RXP and RXN from the BSRX bit
11	ENBSTX		Enables IEEE 1149.6 boundary scan control of TXP and TXN from the BSTX bit
10	BSINITCLK		BS initialization clock
9	BSINRXN		Boundary scan initialization for RXN. The IEEE1149.6 boundary scan comparator attached to RXN is initialized to the value of this bit on the rising edge of BSINITCLK
8	BSINRXP		Boundary scan initialization for RXP. The IEEE1149.6 boundary scan comparator attached to RXP is initialized to the value of this bit on the rising edge of BSINITCLK
7	TSYNC_ENABLE		In x2256: was mapped to CFGTX_0 [21] In x2282: DO NOT USE
6	ENTEST		Enable test. Enables test modes specified via LOOPBACK (CFGTX_0[31:30]).
5	BSTX		Boundary scan data. Determines the logic level output on TXP and TXN when boundary scan outputs are enabled.
4-2	TESTPATT		Not Used. The RX has similar settings, hence this field is not used.
1	USE_STAIRCAS E	0	For calibration Disables staircase logic for trim code change
		1	Enables staircase logic for trim code change
0	ENLFPS		DO NOT USE: Drive Low

19.5.1.69 SERDES_TXCFG2

The SerDes TX Config 2 register (SERDES_TXCFG2) is described in the figure and table below.

Figure 19-73. SERDES_TXCFG2 Register

31	30	29	28	27	26	25	24
Reserved	TM_DUMMY2IDLE	TM_DUMMY1IDLE	TM_TEXTRALOAD	DISABLE_FB2_UNUSED			
R/W-0	R/W-0x0	R/W-0x0	R/W-0x0	R/W-0x0			R/W-0
23	22	21	20	19	18	17	16

		TMTRIM	TRIMBYPASS	RDTCT_VTMODE	RESERVED		
		R/W-0x00	R/W-0x0	R/W-0x0	R/W-0		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-78. SERDES_TXCFG2 Register Field Descriptions

Bit	Field	Value	Description
31	Reserved		Reserved
30-29	TM_DUMMY2IDLE	00 01 10 11	TestMode.Default is 00. If tm_dummy2_enz=1, then this controls Ido dummy digital load. no resistive dummy load 1.5 mA dummy load 1.5 mA dummy load 3mA dummy load Other settings: Extra load turned on
28-27	TM_DUMMY1IDLE	00 01 10 11	TestMode.Default is 00. If tm_dummy1_enz=1, then this controls Ido dummy resistor load. no resistive dummy load 6 mA resistive dummy load 9.6 mA resistive dummy load 15mA resistive dummy load Other settings: Extra load turned on
26-25	TM_TEXTRALOAD	00 01 10 11	TestMode: default is 00. If txa_tmel_enz=1, the driver dummy current controlled by tx_extraload. Extra load current turned off 1mA dummy load 2 mA dummy load 3 mA dummy load
24	DISABLE_FB2_UNUSED		Reserved
23	DISABLE_FB1_TM_SRCONTROL		TM_SRCONTROL
22-21	SC_SATA		TestMode: Control for SATA slew-control. Default value is 00.
20-19	SC_PCIE		TestMode: Control for PCIe slew-control. Default value is 00
18	DISABLE_PCIE_SC	0 1	TestMode: Default value for PCIe/SATA mode=0. 0 Enable output divider slew-rate control for PCIe mode (default) 1 Disable slew-rate control from digital and instead force from SC_PCIE

Table 19-78. SERDES_TXCFG2 Register Field Descriptions (continued)

Bit	Field	Value	Description
17	DISABLE_SATA_SC	0 1	TestMode. Automatically disabled in pcie mode. Default value for PCIE/SATA mode=0. Enable output driver slew-rate control for SATA mode (default). Slew rate automatically adjusted based on RATE in SATA mode. Disable slew-rate control from digital and instead force from SC_SATA
16	RESERVED		Boundary scan initialization for RXN. The IEEE1149.6 boundary scan comparator attached to RXN is initialized to the value of this bit on the rising edge of BSINITCLK
15	RESERVED		Boundary scan initialization for RXP. The IEEE1149.6 boundary scan comparator attached to RXP is initialized to the value of this bit on the rising edge of BSINITCLK
14	TXDCC_PWRDN	0 1	TestMode. Default is 0. TX clock will be duty-cycle corrected (default) TX clock will bypass duty-cycle correction logic
13-9	RESERVED1		Reserved. Default is 00000
8-4	TMTRIM		TestMode: Termination resistor calibration code for grounded resistor. Default is 00000
3	TRIMBYPASS	0 1	TestMode: Default is 0. TX Termination resistor calibrated through continuous digital loop (default) Over-ride digital control of termination resistor with TMTRIM
2-1	RDTCT_VTMODE	00 01 10 11	Receive detect test mode to program threshold. Default is 00. .285V threshold 0.3V threshold .27V threshold 0.35V (V _{BG_REF})
0	RESERVED		Reserved

19.5.1.70 SERDES_TXCFG3

The SerDes TX Config 3 register (SERDES_TXCFG3) is described in the figure and table below.

Figure 19-74. SERDES_TXCFG3 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-79. SERDES_TXCFG3 Register Field Descriptions

Bit	Field	Value	Description
31-28	RESERVED		Reserved
27-12	RXLDO_CTRL		TestMode: RX LDO control bits [27:24] = 0111 (LDO loop compensation control) [23] = 0 (When '1', overrides LDO UP signal to be always high) [22] = 0 (Low dropout mode) [21] = 1 (Vref magnitude selection) [20] = 1 (Iref magnitude selection) [19:18]= 11 (Quiescent current programmability) [17] = 0 (disable overshoot control block) [16:12]=01110 (default trim setting to get 1.2V)

Table 19-79. SERDES_TXCFG3 Register Field Descriptions (continued)

Bit	Field	Value	Description
11	RXLDO_HITRAN_UNUSED		TestMode: RX LDO transient improvement bit
10-1	TXLDO_CTRL		TestMode:TX LDO control bits [10:7] = 0111 (LDO loop compensation control) [6] = 0 (When '1', overrides LDO UP signal to be always high) [5] = 0 (Low dropout mode) [4] = 1 (Vref magnitude selection) [3] = 1 (Iref magnitude selection) [2:1]= 11 (Quiescent current programmability)
0	TXLDO_DISABLE_OVERSHOOT		TestMode: TX LDO disable overshoot control if 1. Default is 0.

19.5.1.71 SERDES_TXCFG4

The SerDes TX Config 4 register (SERDES_TXCFG4) is described in the figure and table below.

Figure 19-75. SERDES_TXCFG4 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-80. SERDES_TXCFG4 Register Field Descriptions

Bit	Field	Value	Description
31-5	Reserved		Reserved
4	TM_BIASCTR		TM_BIASCTR used in DCC
3-1	TRIM_MODE		TRIM_MODE[2:0]
0	HYST_DISABLE		HYST_DISABLE_Z and CALOUT_TX

19.5.2 Configuration Registers Common to Type 0 and Type 1 Headers

Table 19-81. Configuration Registers Common to Type 0 and Type 1 Headers

Offset	Acronym
0h	VENDOR_DEVICE_ID
4h	STATUS_COMMAND
8h	CLASSCODE_REVID

19.5.2.1 VENDOR_DEVICE_ID

The vendor and device identification register (VENDOR_DEVICE_ID) is described in the figure and table below.

Figure 19-76. VENDOR_DEVICE_ID Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-82. VENDOR_DEVICE_ID Register Field Descriptions

Bit	Field	Value	Description
31-16	DEVICE_ID	0-FFFFh	PCIe Vendor ID. Writable from internal bus interface.
15-0	VENDOR_ID	0-FFFFh	PCIe Device ID. Writable from internal bus interface.

19.5.2.2 STATUS_COMMAND Register

The status and command register (STATUS_COMMAND) is described in the figure and table below.

Figure 19-77. STATUS_COMMAND Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-83. STATUS_COMMAND Register Field Descriptions

Bit	Field	Value	Description
31	Parity Error	0	Set if function receives poisoned TLP.
30	Signaled System Error	0	Set if function sends a ERR_FATAL or ERR_NONFATAL message and SERR enable bit is set to one.
29	Received Master Abort	0	Set when a Requester receives a Completion with Unsupported Request Completion Status.
28	Received Target Abort	0	Set when a Requester receives a Completion with Completer Abort Status.
27	Signaled Target Abort	0	Set when a function acting as a Completer terminates a request by issuing Completer Abort Completion Status to the Requester.
26-25	Reserved	0	Reserved
24	Data Parity Error	0	This bit is set by a Requester if the Parity Error Enable bit is set in its Command register and either the condition that the requester receives a poisoned Completion or the condition that the requester poisons a write request are true.
23-21	Reserved	0	Reserved
20	Capabilities List	0	For PCIe, this field must be set to 1.

Table 19-83. STATUS_COMMAND Register Field Descriptions (continued)

Bit	Field	Value	Description
19	Interrupt Status	0	Indicates that the function has received an interrupt.
18-11	Reserved	0	Reserved
10	INTx Disable	0	Setting this bit disables generation of INTx messages.
9	Reserved	0	Reserved
8	SERR Enable	0	When set, it enables System Error reporting to the Root Complex.
7	Reserved	0	Reserved
6	Parity Error	0	This bit controls whether or not the device responds to detected parity errors. If this bit is set, the PCIExpress will respond normally to parity errors. If this bit is cleared, the PCIExpress will ignore detected parity errors.
5-3	Reserved	0	Reserved
2	Bus Master	0	Enables mastership of the bus.
1	Memory Space	0	This bit is set to enable the device to respond to memory accesses.
0	IO Space	0	This bit is set to enable the device to respond to I/O accesses. This functionality is not supported in PCIExpress and there this bit is set to zero.

19.5.2.3 CLASSCODE_REVID

The class code and revision ID register (CLASSCODE_REVID) is described in the figure and table below.

Figure 19-78. CLASSCODE_REVID Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-84. CLASSCODE_REVID Register Field Descriptions

Bit	Field	Value	Description
31-8	Class Code	0-FF FFFFh	PCIe Class Code per PCIe Base Specifications Revision 2.0. Writable from internal bus interface.
7-0	Revision ID	0-FFh	Updated with each revision of hardware. Writable from internal bus interface.

19.5.3 Configuration Type 0 Registers

19.5.3.1 BIST_HEADER

The BIST, Header Type, Latency Time and Cache Line Size register (BIST_HEADER) is described in the figure and table below.

Figure 19-79. BIST_HEADER Register

31	30	29	28	27	24	23	22	16
BIST Capable	Start BIST	Reserved	Completion Code		Multi-function Device	Header Type		
R-0	R-0	R-0	R-0		R-0	R-0		
15	8				7	0		
Latency Timer					Cache Line Size			
R-0					R/W-0			

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-86. BIST_HEADER Register Field Descriptions

Bit	Field	Value	Description
31	BIST Capable	0	Returns a 1 for BIST capability and 0 otherwise. Not supported by PCIeSS.
30	Start BIST	0	Write a 1 to start BIST. Not supported by PCIeSS.
29-28	Reserved	0	Reserved
27-24	Completion Mode	0-Fh	Completion Code. Not supported by PCIeSS.
23	Multi-function Device	0	Returns 1 if it is a multi function device. Writable from internal bus interface.
22-16	Header Type	0-7Fh	Configuration Header Format. It is set to 1 for RC and cleared to 0 for EP.
15-8	Latency Timer	0-FFh	Not applicable in PCIe
7-0	Cache Line Size	0-FFh	Not applicable in PCIe

19.5.3.2 BAR0 Register

The base address register 0 (BAR0) is described in the figure and table below.

Figure 19-80. BAR0 Register

31						8
Base Address						
R-0						
7	6	4	3	2	1	0
Base Address	Reserved		Prefetchable	Type	Memory Space	
R-0	R-0		R-0	R-0	R-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-87. BAR0 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h 0h 1h 2h 3h	Decode type. Writable from internal bus interface. 32 bit decode Reserved 64 bit decode Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

19.5.3.3 BAR1

The base address register 1 (BAR1) is described in the figure and table below.

Figure 19-81. BAR1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-88. BAR1 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h 0h 1h 2h 3h	Decode type. Writable from internal bus interface. 32 bit decode Reserved 64 bit decode Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

19.5.3.3.1 BAR1 (64bit BAR0) Register

The base address register 1 (BAR1) (64bit BAR0) is described in the figure and table below.

Figure 19-82. BAR1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-89. BAR1 Register Field Descriptions

Bit	Field	Value	Description
31-0	Base Address	0-FFFF FFFFh	Upper 32 bits of BAR0 address

19.5.3.4 BAR2

The base address register 2 (BAR2) is described in the figure and table below.

Figure 19-83. BAR2 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-90. BAR2 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface. 0h 32 bit decode 1h Reserved 2h 64 bit decode 3h Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

19.5.3.5 BAR3 Register

The base address register 3 (BAR3) is described in the figure and table below.

Figure 19-84. BAR3 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-91. BAR3 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface.
		0h	32 bit decode
		1h	Reserved
		2h	64 bit decode
		3h	Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

19.5.3.5.1 BAR3 (64 bit BAR2) Register

The base address register 3 (BAR2) (64 bit BAR2) is described in the figure and table below.

Figure 19-85. BAR3 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-92. BAR3 Register Field Descriptions

Bit	Field	Value	Description
31-0	Base Address	0-FFFF FFFFh	Upper 32 bits of BAR2 address

19.5.3.6 BAR4

The base address register 4 (BAR4) is described in the figure and table below.

Figure 19-86. BAR4 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-93. BAR4 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h 0h 1h 2h 3h	Decode type. Writable from internal bus interface. 32 bit decode Reserved 64 bit decode Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

19.5.3.7 BAR5 Register

The base address register 5 (BAR5) is described in the figure and table below.

Figure 19-87. BAR5 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-94. BAR5 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h 0h 1h 2h 3h	Decode type. Writable from internal bus interface. 32 bit decode Reserved 64 bit decode Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

19.5.3.7.1 BAR5 (64 bit BAR4) Register

The base address register 5 (BAR5) (64 bit BAR4) is described in the figure and table below.

Figure 19-88. BAR5 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-95. BAR5 Register Field Descriptions

Bit	Field	Value	Description
31-0	Base Address	0-FFFF FFFFh	Upper 32 bits of BAR4 address

19.5.3.8 CARDBUS

The CardBus CIS pointer (CARDBUS) register is described in the figure and table below.

Figure 19-89. CARDBUS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-96. CARDBUS Register Field Descriptions

Bit	Field	Value	Description
31-0	Reserved	0	Reserved

19.5.3.9 SUBSYS_VNDR_ID

The subsystem and subsystem vendor ID register (SUBSYS_VNDR_ID) is described in the figure and table below.

Figure 19-90. SUBSYS_VNDR_ID Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-97. SUBSYS_VNDR_ID Register Field Descriptions

Bit	Field	Value	Description
31-16	subsystem_id	0-FFFFh	PCIe Subsystem ID (TBD). Writable from internal bus interface.
15-0	subsystem_vendor_id	0-FFFFh	PCIe Subsystem Vendor ID (TBD). Writable from internal bus interface.

19.5.3.10 EXPNSN_ROM

The expansion ROM base address (EXPNSN_ROM) is described in the figure and table below.

Figure 19-91. EXPNSN_ROM Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-98. EXPNSN_ROM Register Field Descriptions

Bit	Field	Value	Description
31-11	Expansion ROM Base Address	0-1F FFFFh	Address of Expansion ROM
10-1	Reserved	0	Reserved
0	Expansion ROM Enable	0	Expansion ROM Enable

19.5.3.11 CAP_PTR

The capabilities pointer register (CAP_PTR) is described in the figure and table below.

Figure 19-92. CAP_PTR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-99. CAP_PTR Register Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	cap_ptr	0-FFh	First Capability Pointer. By default, it points to Power Management Capability structure. Writable from internal bus interface.

19.5.3.12 Reserved Register

This register is reserved.

Figure 19-93. Reserved Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-100. Reserved Register Field Descriptions

Bit	Field	Value	Description
31-0	Reserved	0	Reserved

19.5.3.13 INT_PIN

The interrupt pin register (INT_PIN) is described in the figure and table below.

Figure 19-94. INT_PIN Register

31	24	23	16
max_latency		min_grant	
R-0		R-0	
15	8	7	0
int_pin		int_line	
R-1		R/W-FFh	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-101. INT_PIN Register Field Descriptions

Bit	Field	Value	Description
31-24	max_latency	0-FFh	Not applicable to PCI Express
23-16	min_grant	0-FFh	Not applicable to PCI Express
15-8	int_pin	0-FFh	Interrupt Pin. Valid values at 00h, 01h, 02h, 03h and 04h for unused legacy interrupt, INTA, INTB, INTC or INTD respectively. For single function configuration, the core only uses INTA. Writable from internal bus interface.
7-0	int_line	0-FFh	Interrupt Line

19.5.4 Configuration Type 1 Registers

Table 19-102. Configuration Type 1 Registers

Offset	Acronym	Section

19.5.4.1 BIST_HEADER

The BIST, Header Type, Latency Time and Cache Line Size register (BIST_HEADER) is described in the figure and table below.

Figure 19-95. BIST_HEADER Register

31	30	29	28	27	24	23	22	16			
BIST Capable		Start BIST		Reserved		Completion Code		Multi-function Device		Header Type	
R-0		R-0		R-0		R-0		R-0		R-1	
15							8	7	0		
Latency Timer								Cache Line Size			
R-0								R/W-0			

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-103. BIST_HEADER Register Field Descriptions

Bit	Field	Value	Description
31	BIST Capable	0	Returns a 1 for BIST capability and 0 otherwise. Not supported by PCIeSS.
30	Start BIST	0	Write a 1 to start BIST. Not supported by PCIeSS.
29-28	Reserved	0	Reserved
27-24	Completion Code	0-Fh	Completion Code. Not supported by PCIeSS.
23	Multi-function Device	0	Returns 1 if it is a multi function device. Writable from internal bus interface.
22-16	Header Type	0-7Fh	Configuration Header Format. It is set to 1 for RC and cleared to 0 for EP.
15-8	Latency Timer	0-FFh	Not applicable in PCIe.
7-0	Cache Line Size	0-FFh	Not applicable in PCIe.

19.5.4.2 BAR0 (64/32 Bit Mode)

The base address register 0 (64/32 bit mode) is described in the figure and table below.

Figure 19-96. BAR0 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-104. BAR0 Register Field Descriptions

Bit	Field	Value	Description
31-4	Base Address	0-FFF FFFFh	Base Address. Actual writable bits are determined by BAR0 Mask Register.
3	Prefetchable	0	Set to indicate prefetchable space. This field is writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface. 0h 32 bit decode 1h Reserved 2h 64 bit decode 3h Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

19.5.4.3 BAR1 (32-Bit Mode)

The base address register 1 (BAR1) (32-bit mode) is described in the figure and table below.

Figure 19-97. BAR1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-105. BAR1 Register Field Descriptions

Bit	Field	Value	Description
31-4	Base Address	0-FFF FFFFh	Base Address. Actual writable bits are determined by BAR0 Mask Register.
3	Prefetchable	0	Set to indicate prefetchable space. This field is writable from internal bus interface.
2-1	Type	0-3h 0h 1h 2h 3h	Decode type. Writable from internal bus interface. 32 bit decode Reserved 64 bit decode Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

19.5.4.3.1 BAR1(64 Bit Mode)

The base address register 1 (BAR1) (64 bit mode) is described in the figure and table below.

Figure 19-98. BAR1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-106. BAR1 Register Field Descriptions

Bit	Field	Value	Description
31-0	Base Address	0-FFFF FFFFh	Base Address high 32 bits for BAR0. Actual writable bits are determined by BAR0 Mask Register.

19.5.4.4 BUSNUM

The latency timer and bus number register (BUSNUM) is described in the figure and table below.

Figure 19-99. BUSNUM Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-107. BUSNUM Register Field Descriptions

Bit	Field	Value	Description
31-24	Secondary Latency Timer	0-FFh	Not applicable in PCI Express.
23-16	Subordinate Bus Number	0-FFh	Subordinate Bus Number. This is highest bus number on downstream interface.
15-8	Secondary Bus Number	0-FFh	Secondary Bus Number. It is typically 1h for RC.
7-0	Primary Bus Number	0-FFh	Primary Bus Number. It is zero for RC and nonzero for switch devices only.

19.5.4.5 SECSTAT

The secondary status and IO base/limit register (SECSTAT) is described in the figure and table below.

Figure 19-100. SECSTAT Register

31	30	29	28	27	26	25	24
DTCT_PERROR	RX_SYS_ERROR	RX_MST_ABORT	RX_TGT_ABORT	TX_TGT_ABORT	Reserved		MST_DPERR
R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R-0		R/W1C-0
23							16
Reserved							
R-0							
15			12	11	8		
IO Limit				Reserved		IO Addressing	
R/W-0				R-0		R-0	
7			4	3	0		
IO Base				Reserved		IO Addressing	
R/W-0				R-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-108. SECSTAT Register Field Descriptions

Bit	Field	Value	Description
31	DTCT_PERROR	0	Detected Parity Error
30	RX_SYS_ERROR	0	Received System Error
29	RX_MST_ABORT	0	Received Master Abort
28	RX_TGT_ABORT	0	Received Target Abort
27	TX_TGT_ABORT	0	Signaled Target Abort
26-25	Reserved	0	Reserved
24	MST_DPERR	0	Master Data Parity Error
23-16	Reserved	0	Reserved
15-12	IO Limit	0-Fh	I/O Space Limit
11-9	Reserved	0	Reserved
8	IO Addressing	0	32 bit IO Space indication for IO Limit Register. Indicates 16 bit and 32 bit addressing for 0 and 1 respectively.
7-4	IO Base	0-Fh	IO Space Base
3-1	Reserved	0	Reserved
0	IO Addressing	0	Indicates 0 for 16 bit and 1 for 32 bit addressing for the IO Base Register. Writable from internal bus interface.

19.5.4.6 MEMSPACE

The memory limit and base register (MEMSPACE) is described in the figure and table below.

Figure 19-101. MEMSPACE Register

31	20	19	16
Memory Limit			Reserved
R/W-0			R-0
15		4	3
Memory Base			Reserved
R/W-0			R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-109. MEMSPACE Register Field Descriptions

Bit	Field	Value	Description
31-20	Memory Limit	0-FFFh	Memory Limit Address
19-16	Reserved	0	Reserved
15-4	Memory Base	0-FFFh	Memory Base Address
3-0	Reserved	0	Reserved

19.5.4.7 PREFETCH_MEM

The prefetchable memory limit and base register (PREFETCH_MEM) is described in the figure and table below.

Figure 19-102. PREFETCH_MEM Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-110. PREFETCH_MEM Register Field Descriptions

Bit	Field	Value	Description
31-20	End Address	0-FFFh	Upper 12 bits of 32 bit Prefetchable Memory End Address
19-17	Reserved	0	Reserved
16	Memory Addressing	0 1	Memory addressing. Writable from internal bus interface. 32 bit memory addressing 64 bit memory addressing
15-4	Start Address	0-FFFh	Upper 12 bits of 32 bit Prefetchable Memory Start Address
3-1	Reserved	0	Reserved
0	Memory Addressing	0 1	Memory addressing. Writable from internal bus interface. 32 bit memory addressing 64 bit memory addressing

19.5.4.8 PREFETCH_BASE

The prefetchable memory base upper 32 bits register (PREFETCH_BASE) is described in the figure and table below.

Figure 19-103. PREFETCH_BASE Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-111. PREFETCH_BASE Field Descriptions

Bit	Field	Value	Description
31-0	Base Address	0-FFFF FFFFh	Upper 32 bits of base address of prefetchable memory space. Used when 64 bit addressing is enabled.

19.5.4.9 PREFETCH_LIMIT

The prefetchable limit upper 32 bits register (PREFETCH_LIMIT) is described in the figure and table below.

Figure 19-104. PREFETCH_LIMIT Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-112. PREFETCH_LIMIT Register Field Descriptions

Bit	Field	Value	Description
31-0	Limit Address	0-FFFF FFFFh	Upper 32 bits of Limit Address of Prefetchable Memory Space. Used with 64 bit prefetchable memory addressing only.

19.5.4.10 IOSPACE

The IO base and limit upper 16 bits register (IOSPACE) is described in the figure and table below.

Figure 19-105. IOSPACE Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-113. IOSPACE Register Field Descriptions

Bit	Field	Value	Description
31-16	IOBASE	0-FFFFh	Upper 16 bits of IO Base
15-0	IOLIMIT	0-FFFFh	Upper 16 bits of IO Limit

19.5.4.11 CAP_PTR

The capabilities pointer register (CAP_PTR) is described in the figure and table below.

Figure 19-106. CAP_PTR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-114. CAP_PTR Register Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	CAP_PTR	0-FFh	First Capability Pointer. By default, it points to Power Management Capability structure. Writable from internal bus interface.

19.5.4.12 EXPNSN_ROM

The expansion ROM base address register (EXPNSN_ROM) is described in the figure and table below.

Figure 19-107. EXPNSN_ROM Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

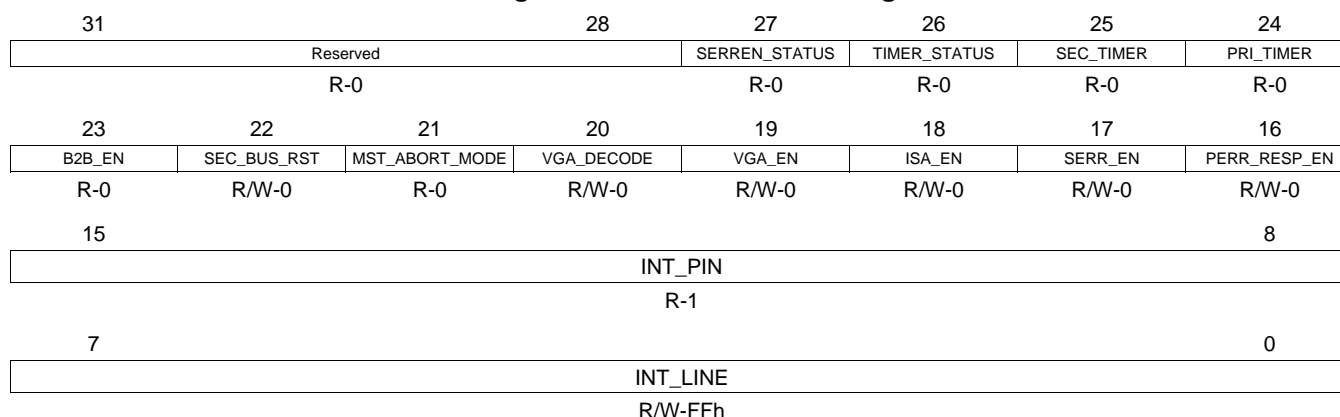

Table 19-115. EXPNSN_ROM Register Field Descriptions

Bit	Field	Value	Description
31-11	Expansion ROM Base Address	0-1F FFFFh	Address of Expansion ROM
10-1	Reserved	0	Reserved
0	Expansion ROM Enable	0	Expansion ROM Enable

19.5.4.13 BRIDGE_INT

The bridge control register (BRIDGE_INT) is described in the figure and table below.

Figure 19-108. BRIDGE_INT Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-116. BRIDGE_INT Register Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Reserved
27	SERREN_STATUS	0	Discard Timer SERR Enable Status. Not Applicable to PCI Express.
26	TIMER_STATUS	0	Discard Timer Status. Not applicable to PCI Express.
25	SEC_TIMER	0	Secondary Discard Timer. Not applicable to PCI Express
24	PRI_TIMER	0	Primary Discard Timer. Not applicable to PCI Express.
23	B2B_EN	0	Fast Back to Back Transactions Enable. Not applicable to PCI Express.
22	SEC_BUS_RST	0	Secondary Bus Reset
21	MST_ABORT_MODE	0	Master Abort Mode. Not applicable to PCI Express. Always zero.
20	VGA_DECODE	0	VGA 16 bit Decode
19	VGA_EN	0	VGA Enable

Table 19-116. BRIDGE_INT Register Field Descriptions (continued)

Bit	Field	Value	Description
18	ISA_EN	0	ISA Enable
17	SERR_EN	0	SERR Enable
16	PERR_RESP_EN	0	Parity Error Response Enable
15-8	INT_PIN	0-FFh	Interrupt Pin. It identifies the legacy interrupt message that the device uses. Valid values are 00h for legacy interrupt not used and 01h, 02h, 03h and 04h for INTA, INTB, INTC or INTD respectively. For single function configuration, the core only uses INTA. This register is writable through internal bus interface.
7-0	INT_LINE	0-FFh	Interrupt Line. Value is system software specified.

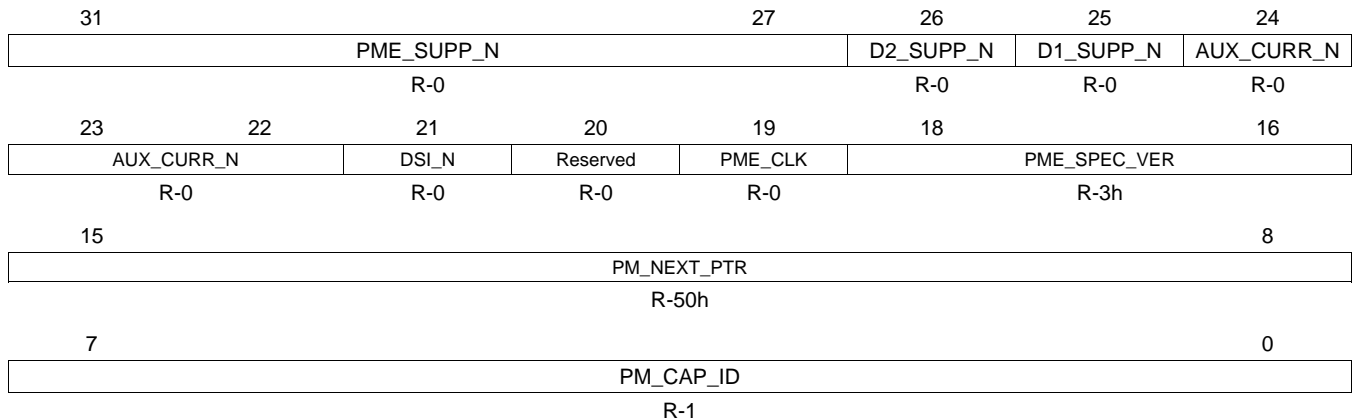

19.5.5 Power Management Capabilities Registers

Table 19-117. Power Management Capability Registers

Offset	Acronym	Section
0h	PMCAP	Section 19.5.5.1
4h	PM_CTL_STAT	Section 19.5.5.2

19.5.5.1 PMCAP Register

The power management capability register (PMCAP) is described in the figure and table below.

Figure 19-109. PMCAP Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

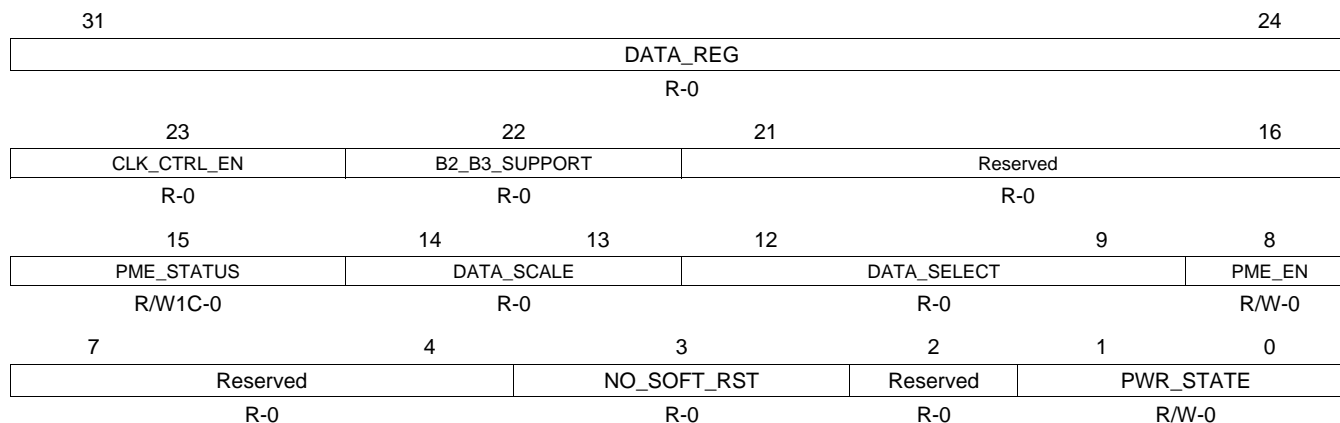

Table 19-118. PMCAP Register Field Descriptions

Bit	Field	Value	Description
31-27	PME_SUPP_N	0-1Fh	PME Support. Writable from internal bus interface.
26	D2_SUPP_N	0	D2 Support. Writable from internal bus interface.
25	D1_SUPP_N	0	D1 Support. Writable from internal bus interface.
24-22	AUX_CURR_N	0-7h	Auxiliary Current. Writable from internal bus interface.
21	DSI_N	0	Device Specific Initialization. Writable from internal bus interface.
20	Reserved	0	Reserved
19	PME_CLK	0	PME Clock. Hardwired to Zero.
18-16	PME_SPEC_VER	0-7h	Power Management Specification Version. Writable from internal bus interface.
15-8	PM_NEXT_PTR	0-FFh	Next Capability Pointer. Writable from internal bus interface.
7-0	PM_CAP_ID	0-FFh	Power Management Capability ID.

19.5.5.2 PM_CTL_STAT Register

The power management control and status register (PM_CTL_STAT) is described in the figure and table below.

Figure 19-110. PM_CTL_STAT Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-119. PM_CTL-STAT Register Field Descriptions

Bit	Field	Value	Description
31-24	DATA_REG	0-FFh	Data register for additional information. Not supported.
23	CLK_CTRL_EN	0	Bus Power/Clock Control Enable. Hardwired to zero.
22	B2_B3_SUPPORT	0	B2 and B3 support. Hardwired to zero.
21-16	Reserved	0	Reserved
15	PME_STATUS	0	PME Status. Indicates if a previously enabled PME event occurred or not.
14-13	DATA_SCALE	0-3h	Data Scale. Not supported.
12-9	DATA_SELECT	0-Fh	Data select. Not supported.
8	PME_EN	0	PME Enable. Value of 1 indicates device is enabled to generate PME. Writable from internal bus interface.
7-4	Reserved	0	Reserved
3	NO_SOFT_RST	0	No soft reset. It is set to disable reset during a transition from D3 to D0. Writable from internal bus interface.
2	Reserved	0	Reserved
1-0	PWR_STATE	0-3h	Power State. Controls the device power state. Writes are ignored if the state is not supported. Writable from internal bus interface.
		0	D0 power state
		1h	D1 power state
		2h	D2 power state
		3h	D3 power state

19.5.6 Message Signaled Interrupts Registers

Table 19-120. Message Signaled Interrupts Registers

Offset	Acronym	Section
0h	MSI_CAP	Section 19.5.6.1
4h	MSI_LOW32	Section 19.5.6.2
8h	MSI_UP32	Section 19.5.6.3
Ch	MSI_DATA	Section 19.5.6.4

19.5.6.1 MSI_CAP Register

The MSI capabilities register is described in the figure and table below.

Figure 19-111. MSI_CAP Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-121. MSI_CAP Register Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reserved
23	64BIT_EN	0	64-Bit address enabled. Writable from internal bus interface.
22-20	MULT_MSG_EN	0-7h	Multiple Message Enabled. Indicates that multiple message mode is enabled by software. Number of messages enabled must not be greater than Multiple Message Capable value.
19-17	MULT_MSG_CAP	0-7h	Multiple Message Capable. Writable from internal bus interface.
16	MSI_EN	0	MSI Enabled. When set, INTx must be disabled.
15-8	NEXT_CAP	0-FFh	Next Capability Pointer containing the offset to next capability structure. Writable from internal bus interface.
7-0	CAP_ID	0-FFh	MSI Capability ID

19.5.6.2 MSI_LOW32 Register

The MSI lower 32 bits register (MSI_LOW32) is described in the figure and table below.

Figure 19-112. MSI_LOW32 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-122. MSI_LOW32 Register Field Descriptions

Bit	Field	Value	Description
31-0	LOW32_ADDR	0-FFFF FFFFh	Lower 32 bit address

19.5.6.3 MSI_UP32 Register

The MSI upper 32 bits register (MSI_UP32) is described in the figure and table below.

Figure 19-113. MSI_UP32 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-123. MSI_UP32 Register Field Descriptions

Bit	Field	Value	Description
31-2	UP32_ADDR	0-3FFF FFFFh	Upper 32 bit address
1-0	Reserved	0	Reserved

19.5.6.4 MSI_DATA Register

The MSI data register (offset is 0x08 is 64 bit not enabled) (MSI_DATA) is described in the figure and table below.

Figure 19-114. MSI_DATA Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-124. MSI_DATA Register Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	MSI_DATA	0-FFFFh	MSI Data

19.5.7 PCI Express Capabilities Registers

Table 19-125. PCIExpress Capabilities Registers

Offset	Acronym	Section

30h	LINK_CTRL2	Section 19.5.7.12

19.5.7.1 PCIES_CAP

The PCI Express capabilities register (PCIES_CAP) is described in the figure and table below.

Figure 19-115. PCIES_CAP Register

31	30	29	25	24	23	20	19	16
Reserved			INT_MSG		SLT_IMPL_N	DPORT_TYPE		PCIE_CAP
R-0			R-0		R-0	R-x		R-2h
15	NEXT_CAP				8	7	CAP_ID	
R-0				R-10h				

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-126. PCIES_CAP Register Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reserved
29-25	INT_MSG	0-1Fh	Interrupt Message Number. Updated by hardware and writable through internal bus Interface.
24	SLT_IMPL_N	0	Slot Implemented. Writable from internal bus interface.
23-20	DPORT_TYPE	0-Fh	Device Port Type (4h for RC, 0 for EP)
19-16	PCIE_CAP	0-Fh	PCI Express Capability Version
15-8	NEXT_CAP	0-FFh	PCIe Next Capability Pointer containing the offset to next capability structure. Writable from internal bus interface.
7-0	CAP_ID	0-FFh	PCIe Capability ID

19.5.7.2 DEVICE_CAP

The device capabilities register (DEVICE_CAP) is described in the figure and table below.

Figure 19-116. DEVICE_CAP Register

31	28	27	26	25	18	17	16				
Reserved			PWR_LIMIT_SCALE		PWR_LIMIT_VALUE		Reserved				
R-0			R-0		R-0		R-0				
15	14	12	11	9	8	6	5	4	3	2	0
ERR_RPT	Reserved		L1_LATENCY	L0_LATENCY	EXT_TAG_FLD	PHANTOM_FLD		MAX_PAYLD_SZ			
R-1	R-0		R-3h	R-4h	R-0	R-0		R-1			

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-127. DEVICE_CAP Register Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Reserved
27-26	PWR_LIMIT_SCALE	0-3h	Captured Slot Power Limit Scale
25-18	PWR_LIMIT_VALUE	0-FFh	Captured Slow Power Limit Value
17-16	Reserved	0	Reserved
15	ERR_RPT	0	Role based Error Reporting. Writable from internal bus interface.
14-12	Reserved	0	Reserved
11-9	L1_LATENCY	0-7h	Endpoint L1 Acceptable Latency. Must be 0h in RC mode. It is 3h for Endpoint.
8-6	L0_LATENCY	0-7h	Endpoint L1 Acceptable Latency. Must be 0h in RC mode.
5	EXT_TAG_FLD	0	Extended Tag Field Supported. Writable from internal interface but should not be as the hardware is not capable.
4-3	PHANTOM_FLD	0-3h	Phantom Field Supported. Writable from internal bus interface.
2-0	MAX_PAYLD_SZ	0-7h	Maximum Payload size supported. Writable from internal bus interface.

19.5.7.3 DEV_STAT_CTRL

The device status and control register (DEV_STAT_CTRL) is described in the figure and table below.

Figure 19-117. DEV_STAT_CTRL Register

7	4			3	0				
MAX_LINK_WIDTH					MAX_LINK_SPEED				
R-2h					R-2h				

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-129. LINK_CAP Register Field Descriptions

Bit	Field	Value	Description
31-24	PORT_NUM	0-FFh	Port Number. Writable from internal bus interface.
23-22	Reserved	0	Reserved
21	BW_NOTIFY_CAP	0	Link Bandwidth Notification Capable. Always 1 for downstream and 0 for upstream.
20	DLL_REP_CAP	0	Data Link Layer Active Reporting Capable. Always 1 for downstream and 0 for upstream.
19	DOWN_ERR_REP_CAP	0	Surprise Down Error Reporting Capable. Not supported. Always zero.
18	CLK_PWR_MGMT	0	Clock Power Management. Zero for downstream ports. Writable from internal bus interface.
17-15	L1_EXIT_LAT	0-7h	L1 Exit Latency when common clock is used. Writable from internal bus interface.
14-12	LOS_EXIT_LAT	0-7h	L0s Exit Latency. Writable from internal bus interface.
11-10	AS_LINK_PM	0-3h	Active State Link PM Support. Writable from internal bus interface. By default, L0s is enabled and L1 is disabled.
9-4	MAX_LINK_WIDTH	0-3Fh	Maximum Link Width. Writable from internal bus interface.
3-0	MAX_LINK_SPEED	0-Fh	Maximum Link Speed. Writable from internal bus interface.

19.5.7.5 LINK_STAT_CTRL

The link status and control register (LINK_STAT_CTRL) is described in the figure and table below.

Figure 19-119. LINK_STAT_CTRL Register

31	30	29	28	27	26	25	24
LINK_BW_STATUS	LINK_BW_MGMT_STATUS	DLL_ACTIVE	SLOT_CLK_CFG	LINK_TRAINING	UNDEF	NEGOTIATED_LINK_WD	
R/W1C-0	R/W1C-0	R-0	R-1	R-0	R-0	R-0	
23	NEGOTIATED_LINK_WD		20	19	LINK_SPEED		
R-1		R-1					
15	Reserved		12	11	10	9	8
R-0			LINK_BW_INIT_EN	LINK_BW_MGMT_INT_EN	HW_AUTO_WIDTH_DIS	CLK_PWR_MGMT_EN	
R-0			R-0	R-0	R-0	R/W-0	
7	6	5	4	3	2	1	0
EXT_SYNC	COMMON_CLK_CFG	RETRAIN_LINK	LINK_DISABLE	RCB	Reserved	ACTIVE_LINK_PM	
R/W-0	R/W-0	R/W-0	R/W-0	R-1	R-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-130. LINK_STAT_CTRL Register Field Descriptions

Bit	Field	Value	Description
31	LINK_BW_STATUS	0	Link Autonomous Bandwidth Status. NA and Reserved for End Point.
30	LINK_BW_MGMT_STATUS	0	Link Bandwidth Management Status. NA and Reserved for End Point.
29	DLL_ACTIVE	0	Data Link Layer Active
28	SLOT_CLK_CFG	0	Slot Clock Configuration. Writable from internal bus interface.
27	LINK_TRAINING	0	Link Training. Not applicable to Root Complex.
26	UNDEF	0	Undefined for PCI Express
25-20	NEGOTIATED_LINK_WD	0-3Fh	Negotiated Link Width. Set automatically by hardware after link initialization.
19-16	LINK_SPEED	0-Fh	Link Speed. Set automatically by hardware after link initialization.
15-12	Reserved	0	Reserved
11	LINK_BW_INT_EN	0	Link Autonomous Bandwidth Interrupt Enable. Not applicable and is Reserved for End Point.
10	LINK_BW_MGMT_INT_EN	0	Link Bandwidth Management Interrupt Enable. Not applicable and is Reserved for End Point.
9	HW_AUTO_WIDTH_DIS	0	Hardware Autonomous Width Disable. Not supported and hardwired to zero.
8	CLK_PWR_MGMT_EN	0	Enable Clock Power Management
7	EXT_SYNC	0	Extended Synch
6	COMMON_CLK_CFG	0	Common Clock Configuration
5	RETRAIN_LINK	0	Retrain Link. Not applicable and Reserved for EP.
4	LINK_DISABLE	0	Link disable.
3	RCB	0	Read Completion Boundary. Writable via internal bus interface for Root Complex.
2	Reserve	0	Reserved
1-0	ACTIVE_LINK_PM	0-3h	Active State Link PM Control

19.5.7.6 SLOT_CAP

The slot capabilities register (RC Mode only) (SLOT_CAP) is described in the figure and table below.

Figure 19-120. SLOT_CAP Register

31								24							
SLOT_NUM															
R-0															
23				19				18		17		16			
SLOT_NUM								CMD_COMP_SUPP		EML_PRESENT		PWR_LMT_SCALE			
R-0								R-0		R-0		R-0			
15				14								8			
PWR_LMT_SCALE		PWR_LMT_VALUE													
R-0		R-0													
7		6		5		4		3		2		1		0	
PWR_LMT_VALUE		HP_CAP		HP_SURPRISE		PWR_IND		ATTN_IND		MRL_SENSOR		PWR_CTL		ATTN_BUTTON	
R-0		R-1		R-0		R-0		R-0		R-0		R-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-131. SLOT_CAP Register Field Descriptions

Bit	Field	Value	Description
31-19	SLOT_NUM	0-1FFF	Physical Slot Number. Writable from internal bus interface.
18	CMD_COMP_SUPP	0	No Command Complete Support. Writable from internal bus interface.
17	EML_PRESENT	0	Electromechanical Interlock Present. Writable from internal bus interface.
16-15	PWR_LMT_SCALE	0-3h	Slow Power Limit Scale. Writable from internal bus interface.
14-7	PWR_LMT_VALUE	0-FFh	Slow Power Limit Value. Writable from internal bus interface.
6	HP_CAP	0	Hot Plug Capable. Writable from internal bus interface.
5	HP_SURPRISE	0	Hot Plug Surprise. Writable from internal bus interface.
4	PWR_IND	0	Power Indicator Present. Writable from internal bus interface.
3	ATTN_IND	0	Attention Indicator Present. Writable from internal bus interface.
2	MRL_SENSOR	0	MRL Sensor Present. Writable from internal bus interface.
1	PWR_CTL	0	Power Controller Present. Writable from internal bus interface. If there is no power controller, software must ensure that system power is up before reading Presence Detect state.
0	ATTN_BUTTON	0	Attention Indicator Present. Writable from internal bus interface.

19.5.7.7 SLOT_STAT_CTRL

The slot status and control register (RC mode only register (SLOT_STAT_CTRL) is described in the figure and table below.

Figure 19-121. SLOT_STAT_CTRL Register

31								25				24					
Reserved												DLL_STATE					
R-0												RW1C-0					
23		22		21		20		19		18		17		16			
EM_LOCK		PRESENCE_DET		MRL_STATE		CMD_COMLETE		PRESENCE_CHG		MRL_CHANGE		PWR_FAULT		ATTN_PRESSED			
R-0		R-1		R-0		RW1C-0		RW1C-0		RW1C-0		RW1C-0		RW1C-0			
15				13				12		11		10		9		8	
Reserved				DLL_CHG_EN		EM_LOCK_CTL		PM_CTL		PM_IND_CTL							
R-0				R/W-0		R/W-0		R/W-0		R/W-3h							
7		6		5		4		3		2		1		0			
ATTN_IND_CTL		HP_INT_EN		CMD_CMP_INT_EN		PRS_DET_CHG_EN		MRL_CHG_EN		PWR_FLT_DET_EN		ATTN_BUTT_EN					
R/W-3h		R/W-3		R/W-0		R/W-0		R/W-0		R/W-0		R/W-0					

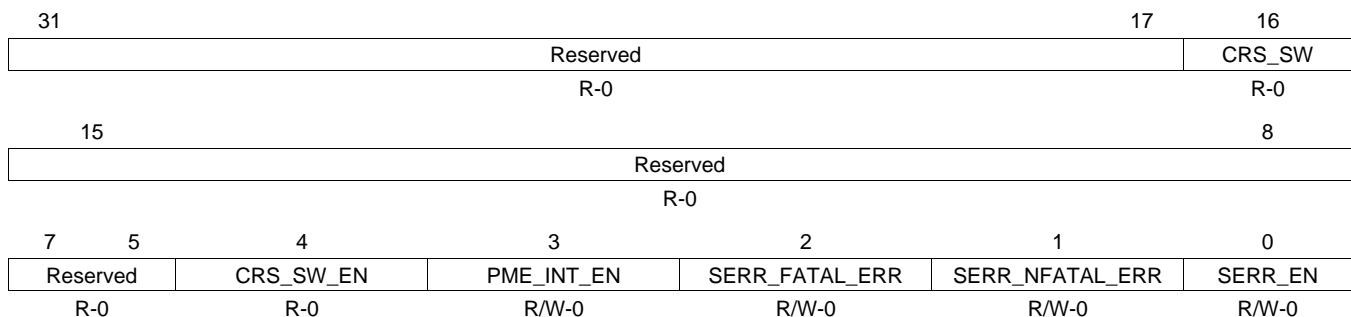

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-132. SLOT_STAT_CTRL Register Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved
24	DLL_STATE	0	Data Link Layer State Changed
23	EM_LOCK	0	Electromechanical Lock Status
22	PRESENCE_DET	0	Presence Detect State
21	MRL_STATE	0	MRL Sensor State
20	CMD_COMPLETE	0	Command Completed
19	PRESENCE_CHG	0	Presence Detect Changed
18	MRL_CHANGE	0	MRL Sensor Changed
17	PWR_FAULT	0	Power Fault Detected
16	ATTN_PRESSED	0	Attention Button Pressed
15-13	Reserved	0	Reserved
12	DLL_CHG_EN	0	Data Link Layer State Changed Enable
11	EM_LOCK_CTL	0	Electromechanical Interlock Control
10	PM_CTL	0	Power Controller Control
9-8	PM_IND_CTL	0-3h	Power Indicator Control
7-6	ATTN_IND_CTL	0-3h	Attention Indicator Control
5	HP_INT_EN	0	Hot Plug Interrupt Enable
4	CMD_CMP_INT_EN	0	Command Completed Interrupt Enable
3	PRS_DET_CHG_EN	0	Presence Detect Changed Enable
2	MRL_CHG_EN	0	MRL Sensor Changed Enable
1	PWR_FLT_DET_EN	0	Power Fault Detected Enable
0	ATTN_BUTT_EN	0	Attention Button Pressed Enable

19.5.7.8 ROOT_CTRL_CAP

The root control and capabilities Register (RC Mode only) (ROOT_CTRL_CAP) is described in the figure and table below.

Figure 19-122. ROOT_CTRL_CAP Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-133. ROOT_CTRL_CAP Register Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	CRS_SW	0	CRS Software Visibility. Not Supported. Hardwired to Zero.
15-5	Reserved	0	Reserved
4	CRS_SW_EN	0	CRS Software Visibility Enable. Not Supported and set to 0h.
3	PME_INT_EN	0	PME Interrupt Enable
2	SERR_FATAL_ERR	0	System Error on Fatal Error Enable

Table 19-133. ROOT_CTRL_CAP Register Field Descriptions (continued)

Bit	Field	Value	Description
1	SERR_NFATAL_ERR	0	System Error on Non-fatal Error Enable
0	SERR_EN	0	System Error on Correctable Error Enable

19.5.7.9 ROOT_STATUS

The root status and control register (RC mode only) (ROOT_STATUS) is described in the figure and table below.

Figure 19-123. ROOT_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-134. ROOT_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reserved
17	PME_PEND	0	PME is pending.
16	PME_STATUS	0	Indicates that PME was asserted by the PME Requester.
15-0	PME_REQ_ID	0	ID of the last PME Requester.

19.5.7.10 DEV_CAP2

The device capabilities 2 register (DEV_CAP2) is described in the figure and table below.

Figure 19-124. DEV_CAP2 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-135. DEV_CAP2 Register Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4	CMPL_TO_DIS_SUPP	0	Completion timeout disable supported
3-0	CMPL_TO_EN	0-Fh	Completion timeout ranges supported. Applicable to RC/EP.

19.5.7.11 DEV_STAT_CTRL2

The device status and control register 2 (DEV_STAT_CTRL2) is described in the figure and table below.

Figure 19-125. DEV_STAT_CTRL2 Register

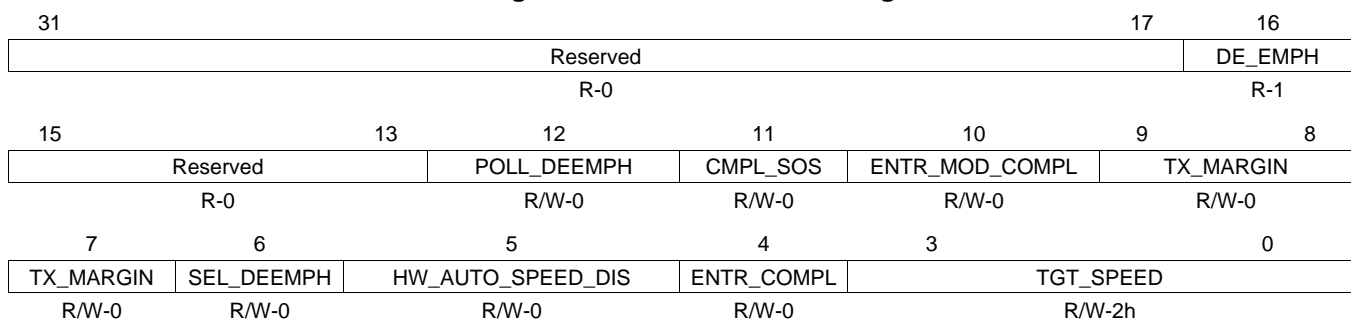

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-136. DEV_STAT_CTRL2 Register Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4	CMPL_TO_DIS	0	Completion timeout disabled
3-0	CMPL_TO	0-Fh	Completion timeout value

19.5.7.12 LINK_CTRL2

The link control register 2 (LINK_CTRL2) is described in the figure and table below.

Figure 19-126. LINK_CTRL2 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-137. LINK_CTRL2 Register Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	DE_EMPH	0	Current De-emphasis level
15-13	Reserved	0	Reserved
12	POLL_DEEMPH	0	DE-emphasis level in polling-compliance state
11	CMPL_SOS	0	Compliance SOS
10	ENTR_MOD_COMPL	0	Enter modified compliance
9-7	TX_MARGIN	0-7h	Value of non-de-emphasized voltage level at transmitter pins
6	SEL_DEEMPH	0	Selectable De-emphasis (0 for 6 dB and 1 for 3.5 dB)
5	HW_AUTO_SPEED_DIS	0	Hardware autonomous speed disable
4	ENTR_COMPL	0	Enter compliance
3-0	TGT_SPEED	0-Fh	Gen-1 is 1h and Gen-2 is 2h.

19.5.8 PCI Express Extended Capabilities Registers

Table 19-138. PCI Express Extended Capabilities Registers

Offset	Acronym	Section
100h	PCIE_EXTCAP	Section 19.5.8.1
104h	PCIE_UNCERR	Section 19.5.8.2
108h	PCIE_UNCERR_MASK	Section 19.5.8.3
10Ch	PCIE_UNCERR_SVRTY	Section 19.5.8.4
110h	PCIE_CERR	Section 19.5.8.5
114h	PCIE_CERR_MASK	Section 19.5.8.6
118h	PCIE_ACCR	Section 19.5.8.7
11Ch	HDR_LOG0	Section 19.5.8.8
120h	HDR_LOG1	Section 19.5.8.9
124h	HDR_LOG2	Section 19.5.8.10
128h	HDR_LOG3	Section 19.5.8.11
12Ch	RC_ERR_CMD	Section 19.5.8.12
130h	RC_ERR_ST	Section 19.5.8.13
134h	ERR_SRC_ID	Section 19.5.8.14

19.5.8.1 PCIE_EXTCAP

The PCI express extended capabilities header (PCIE_EXTCAP) is described in the figure and table below.

Figure 19-127. PCIE_EXTCAP Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

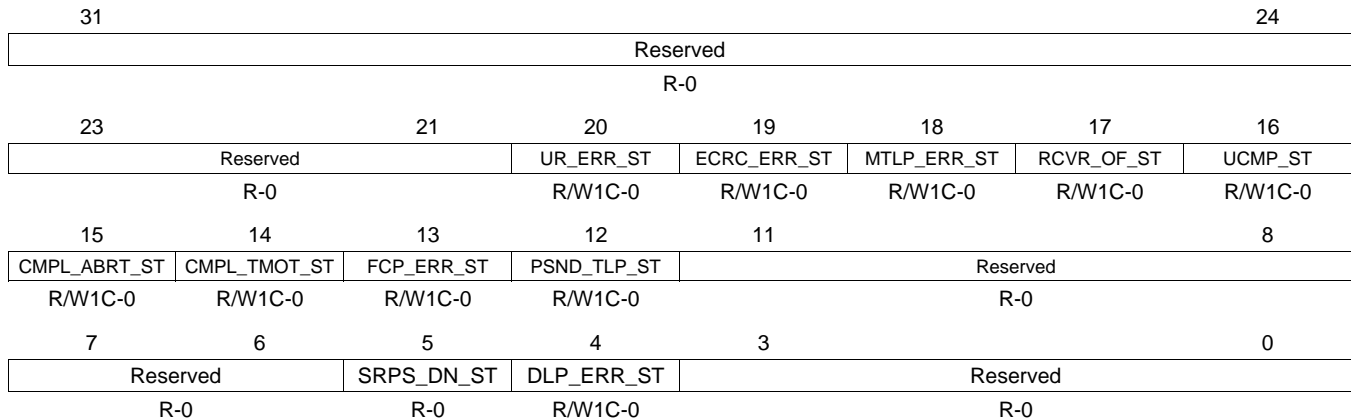

Table 19-139. PCIE_EXTCAP Register Field Descriptions

Bit	Field	Value	Description
31-20	NEXT_CAP	0	Next Capability Offset
19-16	EXT_CAP_VER	0-Fh	Extended Capability Version
15-0	EXT_CAP_ID	0-FFFFh	PCIe Extended Capability ID

19.5.8.2 PCIE_UNCERR

The PCI express uncorrectable error status register (PCIE_UNCERR) is described in the figure and table below.

Figure 19-128. PCIE_UNCERR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

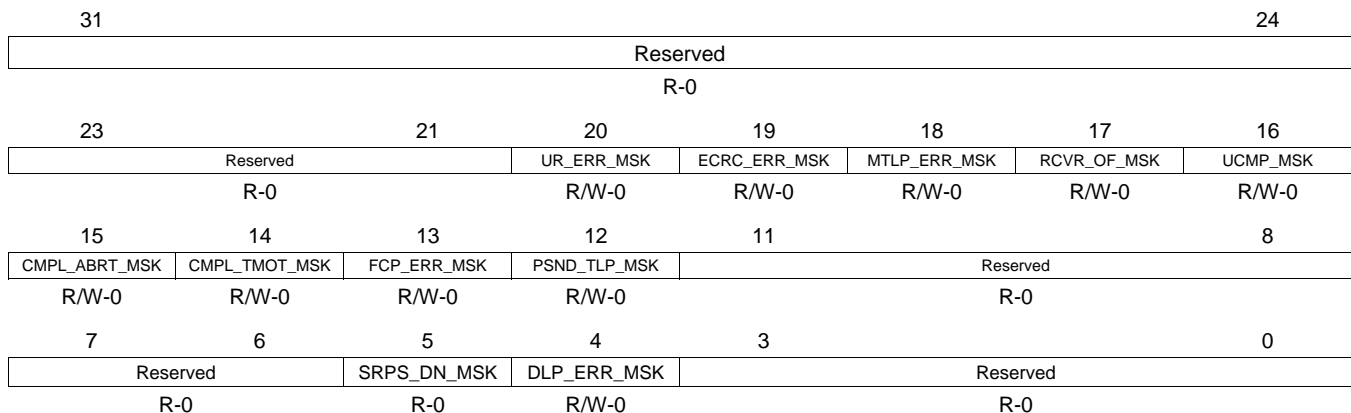

Table 19-140. PCIE_UNCERR Register Field Descriptions

Bit	Field	Value	Description
31-21	Reserved	0	Reserved
20	UR_ERR_ST	0	Unsupported Request Error Status
19	ECRC_ERR_ST	0	ECRC Error Status
18	MTPP_ERR_ST	0	Malformed TLP Status
17	RCVR_OF_ST	0	Receiver Overflow Status
16	UCMP_ST	0	Unexpected Completion Status
15	CMPL_ABRT_ST	0	Completer Abort Status
14	CMPL_TMOT_ST	0	Completion Timeout Status
13	FCP_ERR_ST	0	Flow Control Protocol Error Status
12	PSND_TLP_ST	0	Poisoned TLP Status
11-6	Reserved	0	Reserved
5	SRPS_DN_ST	0	Surprise Down Error Status (not supported)
4	DLP_ERR_ST	0	Data Link Protocol Error Status
3-0	Reserved	0	Reserved

19.5.8.3 PCIE_UNCERR_MASK

The PCI express uncorrectable error mask register (PCIE_UNCERR_MASK) is described in the figure and table below.

Figure 19-129. PCIE_UNCERR_MASK Register

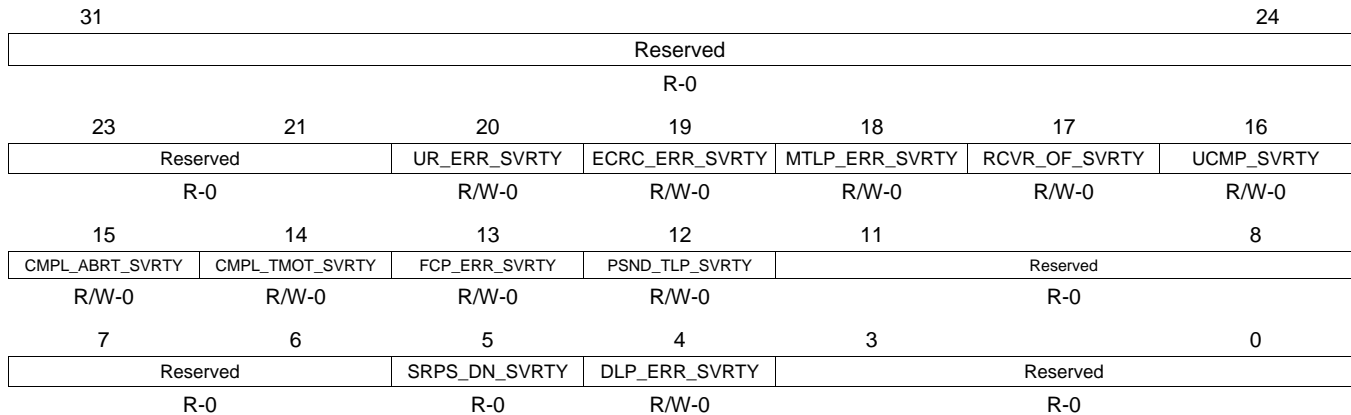

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-141. PCIE_UNCERR_MASK Register Field Descriptions

Bit	Field	Value	Description
31-21	Reserved	0	Reserved
20	UR_ERR_MSK	0	Unsupported Request Error Mask
19	ECRC_ERR_MSK	0	ECRC Error Mask
18	MTLP_ERR_MSK	0	Malformed TLP Mask
17	RCVR_OF_MSK	0	Receiver Overflow Mask
16	UCMP_MSK	0	Unexpected Completion Mask
15	CMPL_ABRT_MSK	0	Completer Abort Mask
14	CMPL_TMOT_MSK	0	Completion Timeout Mask
13	FCP_ERR_MSK	0	Flow Control Protocol Error Mask
12	PSND_TLP_MSK	0	Poisoned TLP Mask
11-6	Reserved	0	Reserved
5	SRPS_DN_MSK	0	Surprise Down Error Mask (not supported)
4	DLP_ERR_MSK	0	Data Link Protocol Error Mask
3-0	Reserved	0	Reserved

19.5.8.4 PCIE_UNCERR_SVRTY

The PCI express uncorrectable error severity register (PCIE_UNCERR_SVRTY) is described in the figure and table below.

Figure 19-130. PCIE_UNCERR_SVRTY Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-142. PCIE_UNCERR_SVRTY Register Field Descriptions

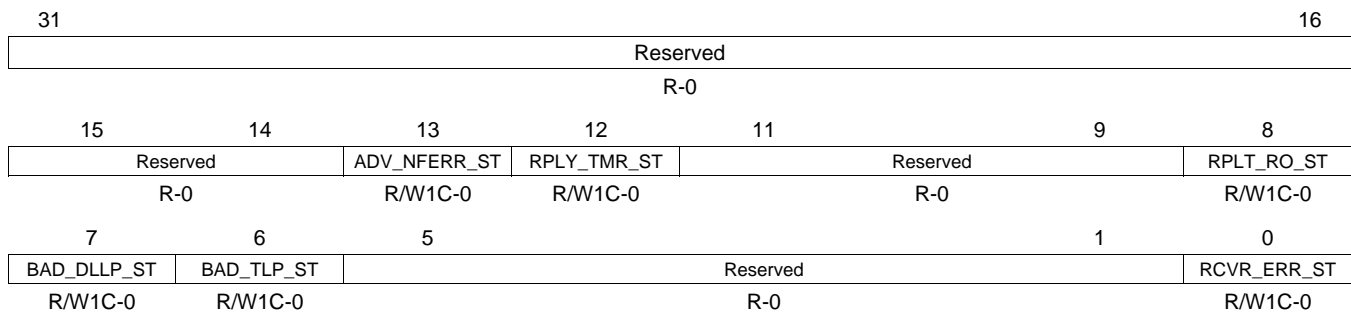

Bit	Field	Value	Description
31-21	Reserved	0	Reserved
20	UR_ERR_SVRTY	0	Unsupported Request Error Severity
19	ECRC_ERR_SVRTY	0	ECRC Error Severity
18	MTLP_ERR_SVRTY	0	Malformed TLP Severity
17	RCVR_OF_SVRTY	0	Receiver Overflow Severity
16	UCMP_SVRTY	0	Unexpected Completion Severity
15	CMPL_ABRT_SVRTY	0	Completer Abort Severity
14	CMPL_TMOT_SVRTY	0	Completion Timeout Severity
13	FCP_ERR_SVRTY	0	Flow Control Protocol Error Severity
12	PSND_TLP_SVRTY	0	Poisoned TLP Severity
11-6	Reserved	0	Reserved

Table 19-142. PCIE_UNCERR_SVRTY Register Field Descriptions (continued)

Bit	Field	Value	Description
5	SRPS_DN_SVRTY	0	Surprise Down Error Severity (not supported)
4	DLP_ERR_SVRTY	0	Data Link Protocol Error Severity
3-0	Reserved	0	Reserved

19.5.8.5 PCIE_CERR

The PCI express correctable error status register (PCIE_CERR) is described in the figure and table below.

Figure 19-131. PCIE_CERR Register

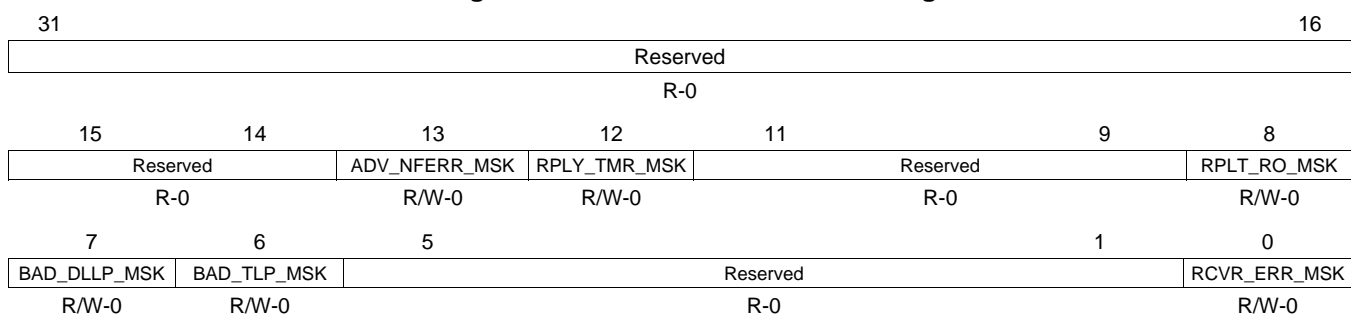

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-143. PCIE_CERR Register Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved
13	ADV_NFERR_ST	0	Advisory Non-fatal Error Mask
12	RPLY_TMR_ST	0	Reply Timer Timeout Mask
11-9	Reserved	0	Reserved
8	RPLT_RO_ST	0	REPLAY_NUM Rollover Mask
7	BAD_DLLP_ST	0	Bad DLLP Mask
6	BAD_TLP_ST	0	Bad TLP Mask
5-1	Reserved	0	Reserved
0	RCVR_ERR_ST	0	Receiver Error Mask

19.5.8.6 PCIE_CERR_MASK

PCI express correctable error mask register (PCIE_CERR_MASK) is described in the figure and table below.

Figure 19-132. PCIE_CERR_MASK Register

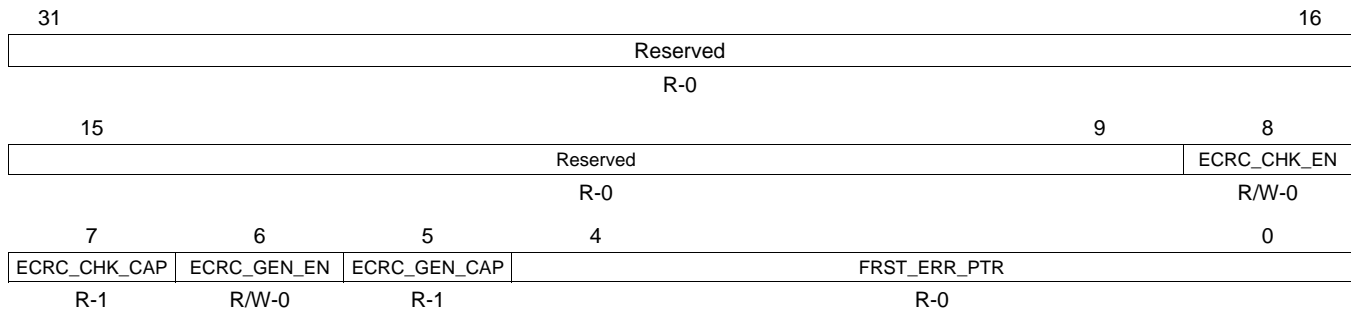

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-144. PCIE_CERR_MASK Register Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved
13	ADV_NFERR_MSK	0	Advisory Non-fatal Error Mask
12	RPLY_TMR_MSK	0	Reply Timer Timeout Mask
11-9	Reserved	0	Reserved
8	RPLT_RO_MSK	0	REPLAY_NUM Rollover Mask
7	BAD_DLLP_MSK	0	Bad DLLP Mask
6	BAD_TLP_MSK	0	Bad TLP Mask
5-1	Reserved	0	Reserved
0	RCVR_ERR_MSK	0	Receiver Error Mask

19.5.8.7 PCIE_ACCR

The PCI express advanced capabilities and control register (PCIE_ACCR) is described in the figure and table below.

Figure 19-133. PCIE_ACCR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-145. PCIE_ACCR Register Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved
8	ECRC_CHK_EN	0	ECRC Check Enable
7	ECRC_CHK_CAP	0	ECRC Check Capable
6	ECRC_GEN_EN	0	ECRC Generation Enable
5	ECRC_GEN_CAP	0	ECRC Generation Capable
4-0	FRST_ERR_PTR	0	First Error Pointer

19.5.8.8 HDR_LOG0

The header log0 register (HDR_LOG0) is described in the figure and table below.

Figure 19-134. HDR_LOG0 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-146. HDR_LOG0 Register Field Descriptions

Bit	Field	Value	Description
31-0	HDR_DW0	0-FFFF FFFFh	First DWORD of Header for a detected error

19.5.8.9 HDR_LOG1

The header log 1 register (HDR_LOG1) is described in the figure and table below.

Figure 19-135. HDR_LOG1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-147. HDR_LOG1 Register Field Descriptions

Bit	Field	Value	Description
31-0	HDR_DW1	0-FFFF FFFFh	Second DWORD of Header for a detected error

19.5.8.10 HDR_LOG2

The header log2 register (HDR_LOG2) is described in the figure and table below.

Figure 19-136. HDR_LOG2 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-148. HDR_LOG2 Register Field Descriptions

Bit	Field	Value	Description
31-0	HDR_DW2	0-FFFF FFFFh	Third DWORD of Header for a detected error

19.5.8.11 HDR_LOG3

The header log 3 register (HDR_LOG3) is described in the figure and table below.

Figure 19-137. HDR_LOG3 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-149. HDR_LOG3 Register Field Descriptions

Bit	Field	Value	Description
31-0	HDR_DW3	0-FFFF FFFFh	Fourth DWORD of Header for a detected error

19.5.8.12 RC_ERR_CMD

The root error command register (RC_ERR_CMD) is described in the figure and table below.

Figure 19-138. RC_ERR_CMD Register

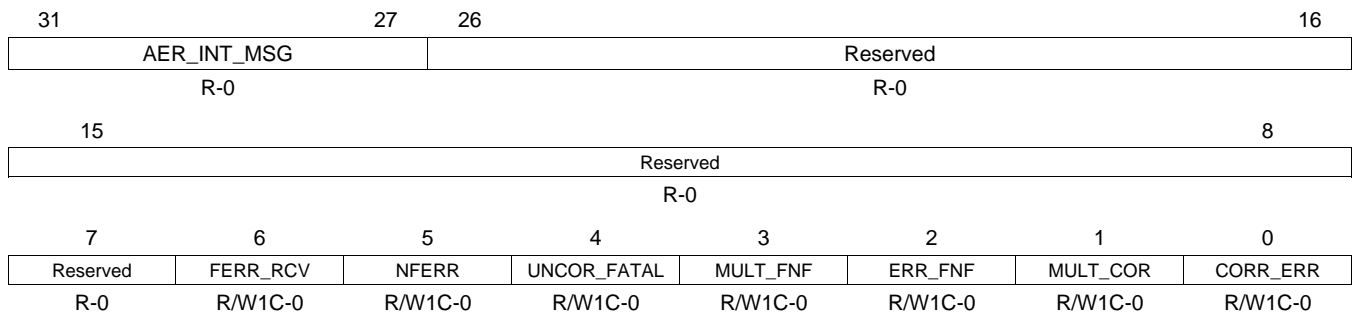

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-150. RC_ERR_CMD Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2	FERR_RPT_EN	0	Fatal Error Reporting Enable
1	NFERR_RPT_EN	0	Nonfatal Error Reporting Enable
0	CERR_RPT_EN	0	Correctable Error Reporting Enable

19.5.8.13 RC_ERR_ST

The root error status Register (RC_ERR_ST) is described in the figure and table below.

Figure 19-139. RC_ERR_ST Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-151. RC_ERR_ST Register Field Descriptions

Bit	Field	Value	Description
31-27	AER_INT_MSG	0-1Fh	AER Interrupt Message Number. Writable through internal bus interface
26-7	Reserved	0	Reserved
6	FERR_RCV	0	Fatal Error Messages Received
5	NFERR	0	0h Non-Fatal Error Messages Received
4	UNCOR_FATAL	0	First Uncorrectable Fatal
3	MULT_FNF	0	Multiple ERR_FATAL/NONFATAL Received
2	ERR_FNF	0	ERR_FATAL/NONFATAL Received
1	MULT_COR	0	Multiple ERR_COR Received
0	CORR_ERR	0	ERR_COR Received

19.5.8.14 ERR_SRC_ID

The error source identification register (ERR_SRC_ID) is described in the figure and table below.

Figure 19-140. ERR_SRC_ID Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-152. ERR_SRC_ID Register Field Descriptions

Bit	Field	Value	Description
31-16	FNF_SRC_ID	0-FFFFh	Error Fatal or Non-Fatal source identification
15-0	CORR_SRC_ID	0-FFFFh	Error Correctable source identification

19.5.9 Port Logic Registers

Table 19-153. Port Logic Registers

Offset	Acronym	Section
700h	PL_ACKTIMER	Section 19.5.9.1
704h	PL_OMSG	Section 19.5.9.2
708h	PL_FORCE_LINK	Section 19.5.9.3
70Ch	ACK_FREQ	Section 19.5.9.4
710h	PL_LINK_CTRL	Section 19.5.9.5
714h	LANE_SKEW	Section 19.5.9.6
718h	SYM_NUM	Section 19.5.9.7
71Ch	SYMTIMER_FLTMASK	Section 19.5.9.8
720h	FLT_MASK2	Section 19.5.9.9
728h	DEBUG0	Section 19.5.9.10
72Ch	DEBUG1	Section 19.5.9.11
80Ch	PL_GEN2	Section 19.5.9.12

19.5.9.1 PL_ACKTIMER Register

The Ack latency time and replay timer register (PL_ACKTIMER) is described in the figure and table below.

Figure 19-141. PL_ACKTIMER Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-154. PL_ACKTIMER Register Field Descriptions

Bit	Field	Value	Description
31-16	RPLY_LIMT	0-FFFFh	Replay Time Limit
15-0	RND_TRP_LMT	0-FFFFh	Round Trip Latency Time Limit

19.5.9.2 PL_OMSG Register

The other message register (PL_OMSG) is described in the figure and table below.

Figure 19-142. PL_OMSG Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-155. PL_OMSG Register Field Descriptions

Bit	Field	Value	Description
31-0	OMSG	0-FFFF FFFFh	Other Message Register. It can be used to send a specific PCI Express message in which case this register is programmed with the payload and bit 0 of Port Link Control Register is set to transmit the message.

19.5.9.3 PL_FORCE_LINK Register

The port force link register (PL_FORCE_LINK) is described in the figure and table below.

Figure 19-143. PL_FORCE_LINK Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-156. PL_FORCE_LINK Register Field Descriptions

Bit	Field	Value	Description
31-24	LPE_CNT	0-FFh	Low Power Entrance Count
23-22	Reserved	0	Reserved
21-16	LNK_STATE	0-3Fh	Link State
15	FORCE_LINK	0	Force Link
14-8	Reserved	0	Reserved
7-0	LINK_NUM	0-FFh	Link Number

19.5.9.4 ACK_FREQ Register

The ack frequency register (ACK_FREQ) is described in the figure and table below.

Figure 19-144. ACK_FREQ Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-157. ACK_FREQ Register Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved
30	ASPM_L1	0	Set to allow entering ASPM L1 even when link partner did not to L0s. When cleared, the ASPM L1 state is entered only after idle period during which both RX and TX are in L0s.
29-27	L1_ENTRY_LATENCY	0-7h	L1 Entrance Latency. The latency is set to 2 ^{L1_ENTRY_LATENCY} microseconds with the max being 64 microseconds.
26-24	L0S_ENTRY_LATENCY	0-7h	L0s Entrance Latency. The latency is set to L0S_ENTRY_LATENCY+1 microseconds. Maximum is 7 microseconds.
23-16	COMM_NFTS	0-FFh	Number of Fast Training Sequences when common clock is used and when transitioning from L0s to L0.
15-8	NFTS	0-FFh	Number of Fast Training Sequences to be transmitted when transitioning from L0s to L0. Value of zero is not supported.
7-0	ACK_FREQ	0-FFh	Ack Frequency. Default is to wait until 255 Ack DLLPs are pending before it is sent.

19.5.9.5 PL_LINK_CTRL Register

The port link control register (PL_LINK_CTRL) is described in the figure and table below.

Figure 19-145. PL_LINK_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-158. PL_LINK_CTRL Register Field Descriptions

Bit	Field	Value	Description
31-22	Reserved	0	Reserved
21-16	LNK_MODE	0-3Fh	Link Mode Enable.
		0	Reserved
		1h	x1
		2h	Reserved
		3h	x2
		4h-6h	Reserved
		7h	x4
		8h-Eh	Reserved
		Fh	x8
		10h-1Eh	Reserved
1Fh	x16		
20h-3Eh	Reserved		
3Fh	x32		
15-12	Reserved	0	Reserved
11-8	LNK_RATE	0-Fh	Default Link Rate. For 2.5, it is 1h. This register does not affect any functionality.
7	FLNK_MODE	0	Fast Link Mode
6	Reserved	0	Reserved
5	DLL_EN	0	DLL Link Enable

Table 19-158. PL_LINK_CTRL Register Field Descriptions (continued)

Bit	Field	Value	Description
4	Reserved	0	Reserved
3	RST_ASRT	0	Reset Assert
2	LPBK_EN	0	Loopback Enable
1	SCRM_DIS	0	Scramble Disable
0	OMSG_REQ	0	Other Message Request

19.5.9.6 LANE_SKEW Register

The lane skew register (LANE_SKEW) is described in the figure and table below.

Figure 19-146. LANE_SKEW Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-159. LANE_SKEW Register Field Descriptions

Bit	Field	Value	Description
31	L2L_DESKEW	0	Disable Lane to Lane deskew
30-26	Reserved	0	Reserved
25	ACK_DISABLE	0	Disable Ack and Nak DLLP transmission.
24	FC_DISABLE	0	Flow control disable. Set to disable transmission of Flow Control DLLPs.
23-0	LANE_SKEW	0-FF FFFFh	Insert Lane Skew for Transmit. The value is in units of one symbol time. Thus a value 02h will force a skew of two symbol times for that lane. Max allowed is five symbol times. This 24 bit field is used for programming skew for eight lanes with three bits per lane.

19.5.9.7 SYM_NUM Register

The symbol number register (SYM_NUM) is described in the figure and table below.

Figure 19-147. SYM_NUM Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-160. SYM_NUM Register Field Descriptions

Bit	Field	Value	Description
31-29	MAX_FUNC	0-7h	Configuration requests at function numbers above this value will result in UR response.
28-24	FCWATCH_TIMER	0-1Fh	Timer Modifier for Flow Control Watchdog Timer. Increases the timer value for Flow control watchdog timer in increments of 16 clock cycles.
23-19	ACK_LATENCY_TIMER	0-1Fh	Timer Modifier for Ack/Nak latency timer in increments of 64 clock periods.
18-14	REPLAY_TIMER	0-1Fh	Timer for replaying TLPs in increments of 64 clock cycles.

Table 19-160. SYM_NUM Register Field Descriptions (continued)

Bit	Field	Value	Description
13-11	Reserved	0	Reserved
10-8	SKP_COUNT	0-7h	Number of SKP symbols
7-4	NUM_TS2_SYMBOLS	0-Fh	Number of TS2 symbols. This field does not affect any functionality.
3-0	TS_COUNT	0-Fh	Number of TS symbols. Set the number of TS identifier symbols that are sent in TS1 and TS2 ordered sets.

19.5.9.8 SYMTIMER_FLTMASK Register

The symbol timer and filter mask register (SYMTIMER_FLTMASK) is described in the figure and table below.

Figure 19-148. SYMTIMER_FLTMASK Register

31	30	29	28	27	26	25	24

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0
15	14	11	10	0			
FC_WDOG_DISABLE	Reserved			SKP_VALUE			
R/W-0	R-0			R/W-500h			

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-161. SYMTIMER_FLTMASK Register Field Descriptions

Bit	Field	Value	Description
31	F1_CFG_DROP	0	Set to allow CFG TLPs on RC
30	F1_IO_DROP	0	Set to allow IO TLPs on RC
29	F1_MSG_DROP	0	Set to allow MSG TLPs on RC
28	F1_CPL_ECRC_DROP	0	Set to allow Completion TLPs with ECRC to pass up
27	F1_ECRC_DROP	0	Set to allow TLPs with ECRC to pass up
26	F1_CPL_LEN_TEST	0	Set to mask length match for received completion TLPs
25	F1_CPL_ATTR_TEST	0	Set to mask attribute match on received completion TLPs
24	F1_CPL_TC_TEST	0	Set to mask traffic class match on received completion TLPs
23	F1_CPL_FUNC_TEST	0	Set to mask function match for received completion TLPs
22	F1_CPL_REQID_TEST	0	Set to mask request ID match for received completion TLPs
21	F1_CPL_TAGERR_TEST	0	Set to mask tag error rules for received completion TLPs
20	F1_LOCKED_RD_AS_UR	0	Set to treat locked read TLPs as supported for EP, UR for RC.
19	F1_CFG1_RE_AS_US	0	Set to treat type 1 CFG TLPs as supported for EP and UR for RC
18	F1_UR_OUT_OF_BAR	0	Set to treat out-of-BAR TLPs as supported requests
17	F1_UR_POISON	0	Set to treat poisoned TLPs as supported requests
16	F1_UR_FUN_MISMATCH	0	Set to treat mismatched TLPs as supported
15	FC_WDOG_DISABLE	0	Disable FC Watchdog Timer
14-11	Reserved	0	Reserved
10-0	SKP_VALUE	0-7FFh	Number of symbol times to wait between transmitting SKP ordered sets. For example, for a setting of 1536 decimal, the wait will be for 1537 symbol times.

19.5.9.9 FLT_MASK2 Register

The filter mask two register (FLT_MASK2) is described in the figure and table below.

Figure 19-149. FLT_MASK2 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

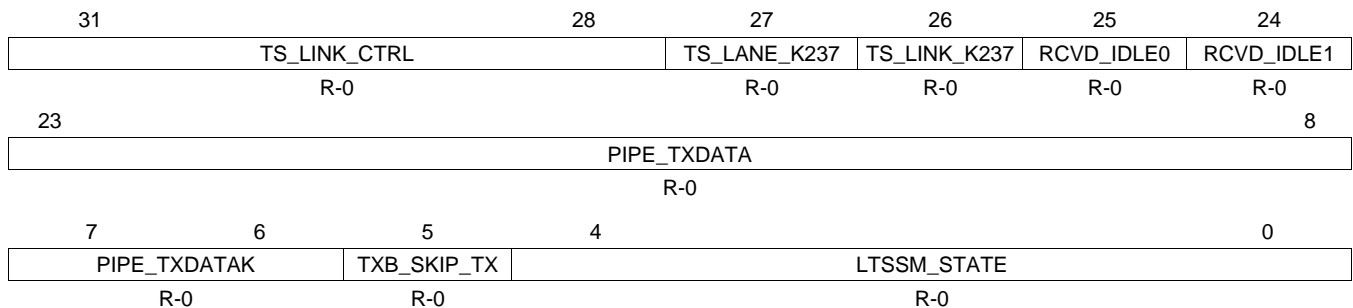

Table 19-162. FLT_MASK2 Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	FLUSH_REQ	0	Set to enable the filter to handle flush request
2	DLLP_ABORT	0	Set to disable DLLP Abort for unexpected CPL
1	VMSG1_DROP	0	Set to disable dropping of Vendor MSG Type 1. When cleared, Vendor MSG Type 1 will be passed to internal bus interface
0	VMSG0_DROP	0	Set to disable dropping of Vendor MSG Type 0 with UR reporting. When cleared, Vendor MSG Type 0 will be passed to internal bus interface

19.5.9.10 DEBUG0 Register

The debug 0 register (DEBUG0) is described in the figure and table below.

Figure 19-150. DEBUG0 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-163. DEBUG0 Register Field Descriptions

Bit	Field	Value	Description
31-28	TS_LINK_CTRL	0-Fh	Link control bits advertised by link partner
27	TX_LANE_K237	0	Currently receiving k237 (PAD) in place of lane number
26	TS_LINK_K237	0	Currently receiving k237 (PAD) in place of link number
25	RCVD_IDLE0	0	Receiver is receiving logical idle
24	RCVD_IDLE1	0	2nd symbol is also idle (16bit PHY interface only)
23-8	PIPE_TXDATA	0-FFFFh	PIPE Transmit data. Reset value is zero but changes at every clock after that.
7-6	PIPE_TXDATAK	0-3h	PIPE transmit K indication
5	TXB_SKIP_TX	0	A skip ordered set has been transmitted
4-0	LTSSM_STATE	0-1Fh	LTSSM current state. A read value of 11h indicates the up status of the Link.

19.5.9.11 DEBUG1 Register

The debug 1 register (DEBUG1) is described in the figure and table below.

Figure 19-151. DEBUG1 Register

31	30	29	28	27	26	24
SCRAMBLER_DISABLE	LINK_DISABLE	LINK_IN_TRAINING	RCVR_REVRS_POL_EN	TRAINING_RST_N	Reserved

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-164. DEBUG1 Register Field Descriptions

Bit	Field	Value	Description
31	SCRAMBLER_DISABLE	0	Scrambling disabled for the link
30	LINK_DISABLE	0	LTSSM in DISABLE state. Link inoperable
29	LINK_IN_TRAINING	0	LTSSM performing link training
28	RCVR_REVRS_POL_EN	0	LTSSM testing for polarity reversal
27	TRAINING_RST_N	0	LTSSM-negotiated link reset
26-23	Reserved	0	Reserved
22	PIPE_TXDETECTRX_LB	0	PIPE receiver detect/loopback request
21	PIPE_TXELECIDLE	0	PIPE transmit electrical idle request
20	PIPE_TXCOMPLIANCE	0	PIPE transmit compliance request
19	APP_INIT_RST	0	Application request to initiate training reset
18-16	Reserved	0	Reserved
15-8	RMLH_TS_LINK_NUM	0-FFh	Link number advertised/confirmed by link partner
7-5	Reserved	0	Reserved
4	XMLH_LINK_UP	0	LTSSM reports PHY link up
3	RMLH_INSKIP_RCV	0	Receiver reports skip reception
2	RMLH_TS1_RCVD	0	TS1 training sequence received (pulse)
1	RMLH_TS2_RCVD	0	TS2 training sequence received (pulse)
0	RMLH_RCVD_LANE_REV	0	Receiver detected lane reversal

19.5.9.12 PL_GEN2 Register

The Gen2 register (PL_GEN2) is described in the figure and table below.

Figure 19-152. PL_GEN2 Register

31	21	20	19	18	17	16
Reserved	DEEMPH	CFG_TX_CMPL	CFG_TX_SWING	DIR_SPD	LN_EN	
R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0
15	8	7	0			
LN_EN			NUM_FTS			
R/W-2h			R/W-Fh			

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 19-165. PL_GEN2 Register Field Descriptions

Bit	Field	Value	Description
31-21	Reserved	0	Reserved
20	DEEMPH	0	Set De-emphasis level for upstream ports
19	CFG_TX_CMPL	0	Configure TX Compliance Receive Bit
18	CFG_TX_SWING	0	Configure PHY TX Swing
17	DIR_SPD	0	Directed Speed Change
16-8	LN_EN	0-1FFh	Lane Enable. It is 1 for x1, 2 for x2, and so on.
7-0	NUM_FTS	0-FFh	Number of fast training sequences.

Real-Time Clock (RTC)

This chapter provides a functional presentation of real-time clock (RTC).

Topic	Page
20.1 Introduction	2401
20.2 Architecture	2402
20.3 Registers	2409

20.1 Introduction

20.1.1 Overview

The real-time clock is a precise timer which can generate interrupts on intervals specified by the user. Interrupts can occur every second, minute, hour, or day. The clock itself can track the passage of real time for durations of several years, provided it has a sufficient power source the whole time.

The basic purpose for the RTC is to keep time of day. The other equally important purpose of RTC is for Digital Rights management. Some degree of tamper proofing is needed to ensure that simply stopping, resetting, or corrupting the RTC does not go unnoticed so that if this occurs, the application can re-acquire the time of day from a trusted source. The final purpose of RTC is to wake the rest of chip up from a power down state.

Alarms are available to interrupt the CPU at a particular time, or at periodic time intervals, such as once per minute or once per day. In addition, the RTC can interrupt the CPU every time the calendar and time registers are updated, or at programmable periodic intervals.

20.1.2 Features

The real-time clock (RTC) provides the following features:

- 100-year calendar (xx00 to xx99)
- Counts seconds, minutes, hours, day of the week, date, month, and year with leap year compensation
- Binary-coded-decimal (BCD) representation of time, calendar, and alarm
- 12-hour clock mode (with AM and PM) or 24-hour clock mode
- Alarm interrupt
- Periodic interrupt
- Single interrupt to the CPU
- Supports external 32.768-kHz crystal or external clock source of the same frequency

20.1.3 Functional Block Diagram

Figure 20-1 shows the RTC module block diagram. Figure 20-2 shows a functional block diagram of the RTC.

Figure 20-1. RTC Block Diagram

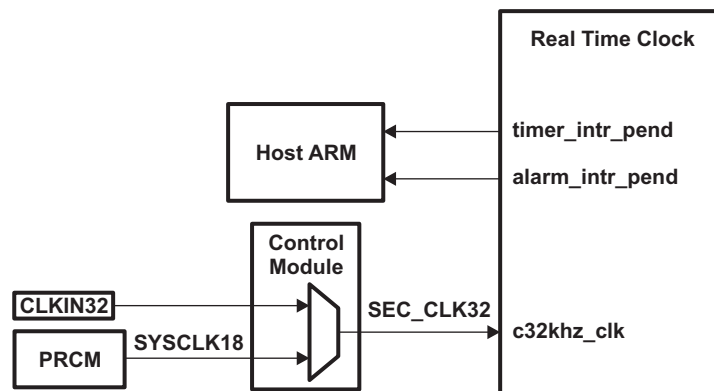

Figure 20-2. RTC Functional Block Diagram

20.2 Architecture

This section defines the module interrupt capabilities and requirements.

20.2.1 Clock Source

The clock reference for the RTC is an internal 32.768-kHz crystal or an external clock source of the same frequency. The source for the RTC reference clock may be provided by a crystal or by an external clock source. The RTC has an internal oscillator buffer to support direct operation with a crystal. The crystal is connected between pins RTC_XI and RTC_XO. RTC_XI is the input to the on-chip oscillator and RTC_XO is the output from the oscillator back to the crystal. For more information about the RTC crystal connection, see your device-specific data manual.

An external 32.768-kHz clock source may be used instead of a crystal. In such a case, the clock source is connected to RTC_XI, and RTC_XO is left unconnected.

If the RTC is not used, the RTC_XI pin should be held low and RTC_XO should be left unconnected. The RTC_disable bit in the control register (CTRL_REG) can be set to save power; however, the RTC_disable bit should not be cleared once it has been set. If the application requires the RTC module to stop and continue, the STOP_RTC bit in CTRL should be used instead.

20.2.2 Signal Descriptions

Table 20-1 lists the signals and their descriptions for the RTC.

Table 20-1. RTC Signals

Signal	I/O	Description
RTC_XI	I	RTC time base input signal. RTC_XI can either be driven with a 32.768-kHz reference clock, or RTC_XI and RTC_XO can be connected to an external crystal. This signal is the input to the RTC internal oscillator.
RTC_XO	O	RTC time base output signal. RTC_XO is the output from the RTC internal oscillator. If a crystal is not used as the time base for RTC_XI, RTC_XO should be left unconnected.

20.2.3 Interrupt Support

20.2.3.1 CPU Interrupts

The RTC generates two interrupt outputs:

- timer_intr is a timer interrupt.
- alarm_intr is an alarm interrupt.

NOTE: Both interrupt outputs support high-level and high-pulse.

20.2.3.2 Interrupt Description

20.2.3.2.1 Timer Interrupt (timer_intr)

The timer interrupt can be generated periodically: every second, every minute, every hour, or every day (see INTERRUPTS_REG[1:0] for a description of how to set this up). The IT_TIMER bit of the interrupt register enables this interrupt. The timer interrupt is active-low.

The RTC_STATUS_REG[5:2] are only updated at each new interrupt and occur according to [Table 20-2](#). For example, bit 2 (SEC) will always be set when one second has passed. It will also be set when one minute has passed since the completion of one minute also marks the completion of one second (from 59 seconds to 60 seconds). The same holds true for hours and days: each of them will also correspond to the passing of a second.

Conversely, bit 5 (DAY) will always be set when a day has passed. It might also be set when an hour, minute, or second has passed. However, this only occurs when the elapsed hour, minute, or second corresponds to the start of a new day.

Table 20-2. Interrupt Trigger Events

	One day has passed	One hour has passed	One minute has passed	One second has passed
STATUS_REG[5] (DAY)	1	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾
STATUS_REG[4] (HOUR)	1	1	0/1 ⁽¹⁾	0/1 ⁽¹⁾
STATUS_REG[3] (MIN)	1	1	1	0/1 ⁽¹⁾
STATUS_REG[2] (SEC)	1	1	1	1

⁽¹⁾ This event is only triggered when the elapsed time unit (for example, Day) corresponds to the passage of another unit (for example, Seconds). For example, when the clock ticks from 00:23:59:59 (days : hours : minutes : seconds) to 01:00:00:00.

20.2.3.2.2 Alarm Interrupt (alarm_intr)

The alarm interrupt can be generated when the time set into TC ALARM registers is exactly the same as in the TC registers. This interrupt is then generated if the IT_ALARM bit of the interrupts register is set. This interrupt is low-level sensitive. RTC_STATUS_REG[6] indicates that IRQ_ALARM_CHIP has occurred. This interrupt is disabled by writing '1' into the RTC_STATUS_REG[6].

To set up an alarm:

- Modify the ALARM_SECONDS, ALARM_MINUTES, ALARM_HOURS, ALARM_DAY, ALARM_WEEK, ALARM_MONTH, and ALARM_YEAR registers to the exact time you want an alarm to generate.
- Set the IT_ALARM bit in the RTC_INTERRUPTS register to enable the alarm interrupt.

20.2.4 Programming/Usage Guide

20.2.4.1 Time/Calendar Data Format

The time and calendar data in the RTC is stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. Although most of the time/calendar registers have 4 bits assigned to each BCD digit, some of the register fields are shorter since the range of valid numbers may be limited. For example, only 3 bits are required to represent the day of the week (WEEKS_REG) since only BCD numbers 1 through 7 are required. The following time and calendar registers are supported (BCD Format):

Note that the ALARM registers which share the names above also share the same BCD formatting.

- SECOND - Second Count (00-59)
- MINUTE - Minute Count (00-59)
- HOUR - Hour Count (12HR: 01-12; 24HR: 00-23)
- DAY - Day of the Month Count (01-31)
- WEEK - Day of the Week (0-6: SUN = 0)
- MONTH - Month Count (01-12; JAN = 1)
- YEAR - Year Count (00-99)

20.2.4.2 Register Access

The three register types are as follows and each has its own access constraints:

- TC and TC alarm registers
- General registers
- Compensation registers

20.2.4.3 OCP MMR Spurious WRT Protection

The module also contains a kicker mechanism (Figure 20-3) to prevent any spurious writes from changing the register values. This mechanism requires two MMR writes to the Kick0 and Kick1 registers with exact data values before the kicker lock mechanism is released. Once released, the MMRs are writeable. The Kick0 data is 83E7 0B13h; the Kick1 data is 95A4 F1E0h. Note that it remains in an unlocked state until an OCP reset or invalid data pattern is written to one of the Kick0 or Kick1 registers.

Figure 20-3. Kick Register State Machine Diagram

- S0 is the Reset/Idle state
- S1 is an OCP wrt cycle of 83E7 0B13h at Kick0 completed state
- S2 is the UNLOCK MMR WRT state
- S0 -> S1 when OCP wrt cycle of 83E7 0B13h at Kick0
- S1 -> S2 when OCP wrt cycle of 95A4 F1E0h at Kick1
- S1 -> S0 when OCP reset event
- S2 -> S0 when OCP reset event OR OCP wrt cycle of NOT 83E7 0B13h at Kick0 OR OCP wrt cycle at Kick1
- S2 ->S1 when OCP wrt cycle of 83E7 0B13h at Kick0

20.2.4.4 Reading the Timer/Calendar (TC) Registers

The TC registers have a read-show register. The reading of the Seconds register will update all of the TC registers. For example, the Year will only get updated on a reading of the Seconds register. The time/calendar registers are updated every second as the time changes. During a read of the SECONDS register, the RTC copies the current values of the time/date registers into shadow read registers. This isolation assures that the CPU can capture all the time/date values at the moment of the SECONDS read request and not be subject to changing register values from time updates.

If desired, the RTC also provides a one-time-triggered minute-rounding feature to round the MINUTE:SECOND registers to the nearest minute (with zero seconds). This feature is enabled by setting the ROUND_30S bit in the control register (CTRL); the RTC automatically rounds the time values to the nearest minute upon the next read of the SECONDS register.

NOTE: Software should always read the Seconds register first. However, the software does not have to poll any status bit to determine when to read the TC registers. [Table 20-3](#) defines the TC set that gets shadowed.

Table 20-3. RTC Register Names and Values

Time Unit	Range	Remarks
Year	00 to 99	
Month	01 to 12	
Day	01 to 31	Months 1, 3, 5, 7, 8, 10, 12
	01 to 30	Months 4, 6, 9, 11
	01 to 29	Month 2 (leap year)
	01 to 28	Month 2 (common year)
Week	00 to 06	Day of week
Hour	00 to 23	24 hour mode
	01 to 12	AM/PM mode
Minute	00 to 59	
Seconds	00 to 59	

20.2.4.4.1 Rounding Seconds

Time can be rounded to the closest minute, by setting the ROUND_30S bit of the control register. When this bit is set, TC values are set to the closest minute value at the next second. The ROUND_30S bit will be automatically cleared when rounding time is performed.

Example:

- If current time is 10H59M45S, round operation will change time to 11H00M00S.
- If current time is 10H59M29S, round operation will change time to 10H59M00S.

20.2.4.5 Modifying the TC Registers

To write correct data from/to the TC and TC alarm registers and read the TC alarm registers, the ARM must first read the BUSY bit of the STATUS register until BUSY is equal to zero. Once the BUSY flag is zero, there is a 15 μ s access period in which the ARM can program the TC and TC alarm registers. Once the 15 μ s access period passes, the BUSY flag has to be read again from the STATUS register as described previously. If the ARM accesses the TC registers outside of the access period, then the access is not guaranteed.

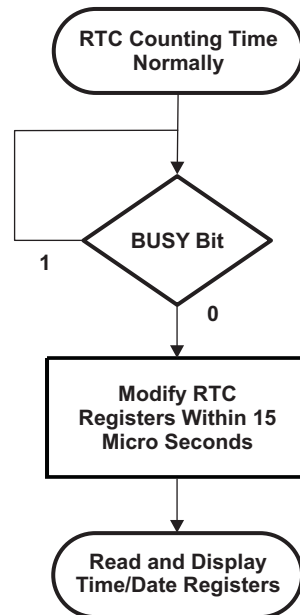

The ARM can access the STATUS_REG and CTRL_REG at any time, with the exception of CTRL_REG[5] which can only be changed when the RTC is stopped. The ARM can stop the RTC by clearing the STOP_RTC bit of the control register. After clearing this bit, the RUN bit in the STATUS_REG (bit 1) needs to be checked to verify the RTC has in fact stopped. Once this is confirmed, the TC values can be updated. After the values have been updated, the RTC can be re-started by resetting the STOP_RTC bit.

NOTE: After writing to a TC register, the user must wait 4 OCP clock cycles before reading the value from the register. If this wait time is not observed and the TC register is accessed, then old data will be read from the register.

CAUTION

In order to remove any possibility of interrupting the register's read process, thus introducing a potential risk of violating the authorized 15-microsecond access period, it is strongly recommended that you disable all incoming interrupts during the register read process.

Figure 20-4. Flow Control for Updating RTC Registers

20.2.4.5.1 General Registers

The ARM can access the STATUS_REG and the CTRL_REG at any time (except the CTRL_REG[5] bit which must be changed only when the RTC is stopped). For the INTERRUPTS_REG, the ARM should respect the available access period to prevent spurious interrupt.

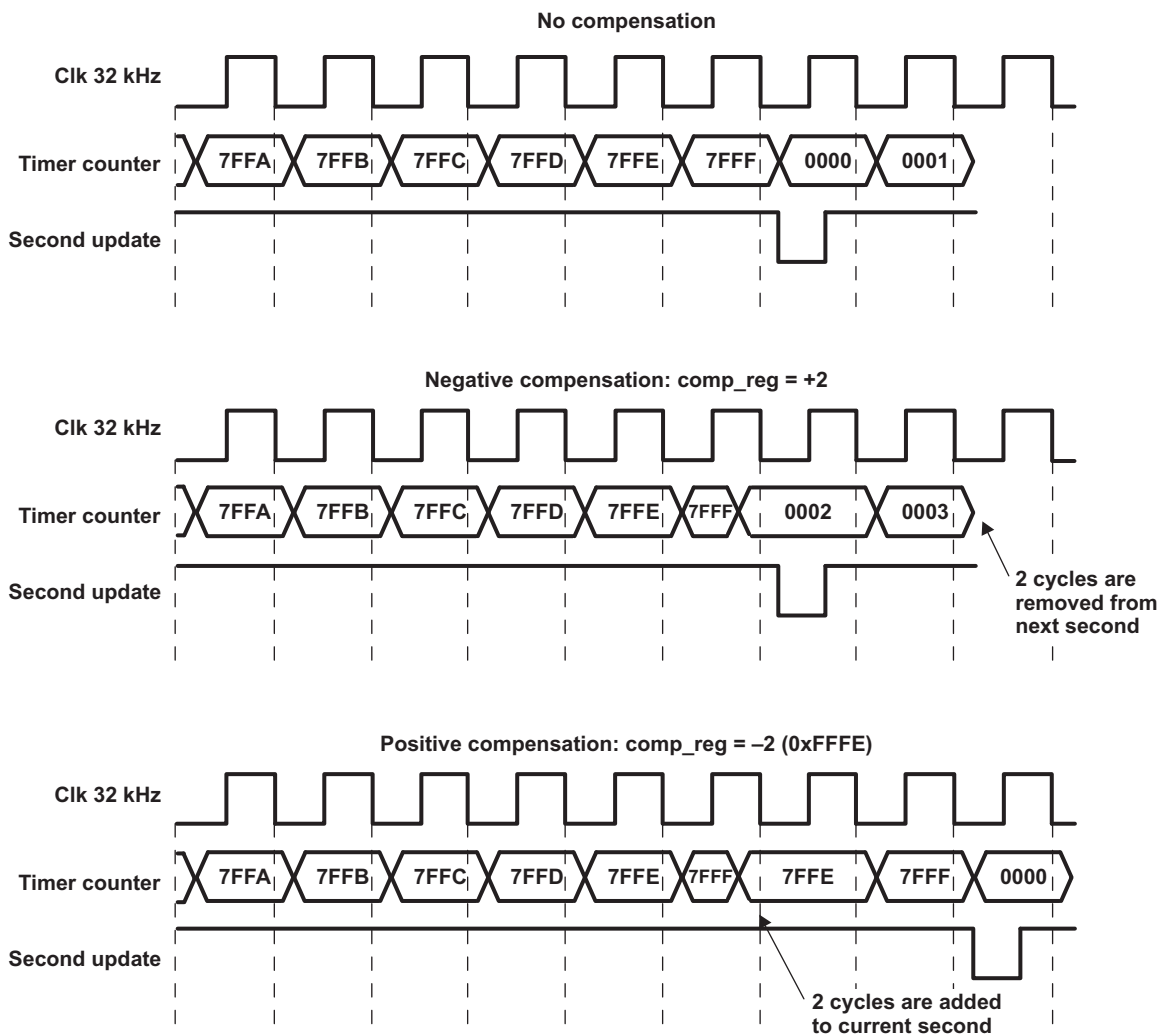

The RTC_DISABLE bit of the CTRL register must only be used to completely disable the RTC function. When this bit is set, the 32 kHz clock is gated, and the RTC is frozen. From this point, resetting this bit to zero can lead to unexpected behavior. In order to save power, this bit should only be used if the RTC function is unwanted in the application.

20.2.4.6 Crystal Compensation

To compensate for any inaccuracy of the 32 kHz oscillator, the ARM can perform a calibration of the oscillator frequency, calculate the drift compensation versus one-hour period, and load the compensation registers with the drift compensation value. Auto compensation is enabled by AUTO_COMP_EN bit in the RTC_CTRL register. If the COMP_REG value is positive, compensation occurs after the second change event. COMP_REG cycles are removed from the next second. If the COMP_REG value is negative, compensation occurs before the second change event. COMP_REG cycles are added to the current second. This enables compensation with a 1 32-kHz period accuracy each hour. The waveform below summarizes positive and negative compensation effect.

Access to the COMP_MSB_REG and COMP_LSB_REG registers must respect the available access period. These registers should not be updated during compensation (first second of each hour), but it is alright to update them during the second preceding a compensation event. For example, the ARM could load the compensation value into these registers after each hour event, during an available access period.

Figure 20-5. Compensation Illustration

20.2.5 Scratch Registers

The RTC provides three general-purpose registers (SCRATCHx_REG) that can be used to store 32-bit words -- these registers have no functional purpose for the RTC. Software using the RTC may find the SCRATCHx registers to be useful in indicating RTC states. For example, the SCRATCHx_REG registers may be used to indicate write-protection lock status or unintentional power downs. To indicate write-protection, the software should write a unique value to one of the SCRATCHx_REG registers when write-protection is disabled and another unique value when write-protection is enabled again. In this way, the lock-status of the registers can be determined quickly by reading the SCRATCH register. To indicate unintentional power downs, the software should write a unique value to one of the SCRATCHx_REG registers when RTC is configured and enabled. If the RTC is unintentionally powered down, the value written to the SCRATCH register is cleared. For more information, see the registers section.

20.2.6 Power Management

The RTC supports the power idle protocol. It has two SWakeup ports: one for the alarm event and one for a timer event.

When the RTC is in IDLE mode, the OCP clock is turned off and the 32 kHz clock remains on. The time and calendar continue to count in IDLE mode. When the RTC is placed back in FUNCTIONAL mode, the TC registers can be read.

The Alarm SWakeup event can be used to wakeup the RTC when it is in IDLE state. In order to do so, the alarm needs to be set and enabled before RTC enters the IDLE state. Once this is done, the SWakeup will occur when the alarm event triggers.

NOTE: Since SWakeup is not periodic, using it to wake up the RTC when in IDLE state is not recommended. Please use Alarm SWakeup instead.

20.2.7 Reset Considerations

When the device is initially powered on, the RTC may issue spurious interrupt signals to the CPU. To avoid issues, a software reset should be performed on the RTC module before the CPU interrupt controller is initialized. Also, see the register summary table in the registers section for reset states of each register.

20.3 Registers

Table 20-4 lists the memory-mapped registers for the RTC. See your device-specific data manual for the memory address of these registers.

Table 20-4. Real-Time Clock (RTC) Registers

Address Offset	Acronym	Register Description
0h	SECONDS_REG	Seconds Register
4h	MINUTES_REG	Minutes Register
8h	HOURS_REG	Hours Register
Ch	DAYS_REG	Day of the Month Register
10h	MONTHS_REG	Month Register
14h	YEARS_REG	Year Register
18h	WEEK_REG	Day of the Week Register
20h	ALARM_SECONDS_REG	Alarm Seconds Register
24h	ALARM_MINUTES_REG	Alarm Minutes Register
28h	ALARM_HOURS_REG	Alarm Hours Register
2Ch	ALARM_DAYS_REG	Alarm Days Register
30h	ALARM_MONTHS_REG	Alarm Months Register
34h	ALARM_YEARS_REG	Alarm Years Register
40h	RTC_CTRL_REG	Control Register
44h	RTC_STATUS_REG	Status Register
48h	RTC_INTERRUPTS_REG	Interrupt Enable Register
4Ch	RTC_COMP_LSB_REG	Compensation (LSB) Register
50h	RTC_COMP_MSB_REG	Compensation (MSB) Register
54h	RTC_OSC_REG	Oscillator Register
60h	RTC_SCRATCH0_REG	Scratch 0 Register (General-Purpose)
64h	RTC_SCRATCH1_REG	Scratch 1 Register (General-Purpose)
68h	RTC_SCRATCH2_REG	Scratch 2 Register (General-Purpose)
6Ch	KICK0R	Kick 0 Register (Write Protect)
70h	KICK1R	Kick 1 Register (Write Protect)
74h	RTC_REVISION	Revision Register
78h	RTC_SYSCONFIG	System Configuration Register
7Ah	RTC_IRQWAKEEN_0	Wakeup Enable Register

20.3.1 Seconds Register (SECONDS_REG)

The SECONDS_REG is used to program the required seconds value of the current time. Seconds are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the seconds value is 45, then the value of SEC0 is 5 and value of SEC1 is 4.

Figure 20-6. Seconds Register (SECONDS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-5. Seconds Register (SECONDS_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved.
6-4	SEC1	0-5h	2nd digit of seconds, Range is 0 to 5
3-0	SEC0	0-9h	1st digit of seconds, Range is 0 to 9

20.3.2 Minutes Register (MINUTES_REG)

The MINUTES_REG is used to program the minutes value of the current time. Minutes are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the minutes value is 32, then the value of MIN0 is 2 and value of MIN1 is 3.

Figure 20-7. Minutes Register (MINUTES_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-6. Minutes Register (MINUTES_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6-4	MIN1	0-5h	2nd digit of minutes, Range is 0 to 5
3-0	MIN0	0-9h	1st digit of minutes, Range is 0 to 9

20.3.3 Hours Register (HOURS_REG)

The HOURS_REG is used to program the hours value of the current time. Hours are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. In 24Hr time mode if you want to set the hour as 18, then HOUR0 is set as 8 and HOUR1 is set as 1.

Figure 20-8. Hours Register (HOURS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-7. Hours Register (HOURS_REG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	PM_nAM	0 1	Only used in PM_AM mode (otherwise 0) AM PM
6	Reserved	0	Reserved
5-4	HOUR1	0-2h	2nd digit of hours, Range is 0 to 2
3-0	HOUR0	0-9h	1st digit of hours, Range is 0 to 9

20.3.4 Days of the Month Register (DAYS_REG)

The DAYS_REG is used to program the day of the month value of the current date. Days are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the day value of the date is 28, DAY0 is set as 8 and DAY1 is set as 2.

Figure 20-9. Days of the Month Register (DAYS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-8. Day of the Month (DAYS_REG) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5-4	DAY1	0-3h	2nd digit of days, Range is 0 to 3
3-0	DAY0	0-9h	1st digit of days, Range is 0 to 9

20.3.5 Month Register (MONTHS_REG)

The MONTHS_REG is used to set the month in the year value of the current date. Months are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

NOTE: Usual notation is taken for month value:

- 01 => January
- 02 => February
- ...
- 12 => December

Figure 20-10. Month Register (MONTHS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-9. Month Register (MONTHS_REG) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4	MONTH1	0-1h	2nd digit of months, Range is 0 to 1
3-0	MONTH0	0-9h	1st digit of months, Range is 0 to 9

20.3.6 Year Register (YEARS_REG)

The YEARS_REG is used to program the year value of the current date. The year value is represented by only the last 2 digits and is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The year 1979 is programmed as 79 with YEAR0 set as 9 and YEAR1 set as 7.

Figure 20-11. Year Register (YEARS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-10. Year Register (YEARS_REG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-4	YEAR1	0-9h	2nd digit of years, Range is 0 to 9
3-0	YEAR0	0-9h	1st digit of years, Range is 0 to 9

20.3.7 Day of the Week Register (WEEKS_REG)

The WEEKS_REG is used to program the day of the week value of the current date. The day of the week is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

NOTE: Sunday is treated as 0, Monday 1, and ending at Saturday with 6.

Figure 20-12. Day of the Week Register (WEEKS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-11. Day of the Week (WEEKS_REG) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	WEEK	0-6h	1st digit of days in a week, Range from 0 (Sunday) to 6 (Saturday)

20.3.8 Alarm Second Register (ALARM_SECONDS_REG)

The ALARM_SECONDS_REG is used to program the second value for the alarm interrupt. Seconds are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-13. Alarm Second Register (ALARM_SECONDS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-12. Alarm Second Register (ALARM_SECONDS_REG) Field Descriptions

6-4	ALARMSEC1	0-5h	2nd digit of seconds, Range is 0 to 5
3-0	ALARMSEC0	0-9h	1st digit of seconds, Range is 0 to 9

20.3.9 Alarm Minute Register (ALARM_MINUTES_REG)

The ALARM_MINUTES_REG is used to program the minute value for the alarm interrupt. Minutes are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-14. Alarm Minute Register (ALARM_MINUTES_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-13. Alarm Minute Register (ALARM_MINUTES_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6-4	ALARM_MIN1	0-5h	2nd digit of minutes, Range is 0 to 5
3-0	ALARM_MIN0	0-9h	1st digit of minutes, Range is 0 to 9

20.3.10 Alarm Hour Register (ALARM_HOURS_REG)

The ALARM_HOURS_REG is used to program the hour value for the alarm interrupt. Hours are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-15. Alarm Hour Register (ALARM_HOURS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-14. Alarm Hour Register (ALARM_HOURS_REG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved.
7	ALARM_PM_nAM	0 1	Only used in PM_AM mode (otherwise 0) AM PM
6	Reserved	0	Reserved.
5-4	ALARM_HOUR1	0-2h	2nd digit of hours, Range is 0 to 2
3-0	ALARM_HOU0	0-9h	1st digit of hours, Range is 0 to 9

20.3.11 Alarm Day of the Month Register (ALARM_DAYS_REG)

The ALARM_DAYS_REG is used to program the day of the month value for the alarm interrupt. Days are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-16. Alarm Day of the Month (ALARM_DAYS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-15. Alarm Day of the Month Register (ALARM_DAYS_REG) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5-4	ALARM_DAY1	0-3h	2nd digit for days, Range from 0 to 3
3-0	ALARM_DAY0	0-9h	1st digit for days, Range from 0 to 9

20.3.12 Alarm Month Register (ALARM_MONTHS_REG)

The ALARM_MONTHS_REG is used to program the month in the year value for the alarm interrupt. The month is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-17. Alarm Month Register (ALARM_MONTHS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-16. Alarm Month Register (ALARM_MONTHS_REG) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4	ALARM_MONTH1	0-1h	2nd digit of months, Range from 0 to 1
3-0	ALARM_MONTH0	0-9h	1st digit of months, Range from 0 to 9

20.3.13 Alarm Year Register (ALARM_YEARS_REG)

The ALARM_YEARS_REG is used to program the year for the alarm interrupt. Only the last two digits are used to represent the year and is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-18. Alarm Year Register (ALARM_YEARS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-17. Alarm Year Register (ALARM_YEARS_REG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-4	ALARM_YEAR1	0-9h	2nd digit of years, Range from 0 to 9
3-0	ALARM_YEAR0	0-9h	1st digit of years, Range from 0 to 9

20.3.14 Control Register (CTRL_REG)

The CTRL_REG contains the controls to enable/disable RTC, set the 12/24 hour time mode, to enable the 30 second rounding feature, and to STOP/START RTC.

Figure 20-19. Control Register (CTRL_REG)

Reserved							
R-0							
31							8
7	6	5	4	3	2	1	0
Rsvd	RTC_disable	SET_32_COUNTER	TEST_MODE	MODE_12_24	AUTO_COMP	ROUND_30S	STOP_RTC
R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-18. Control Register (CTRL_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved.
6	RTC_disable	0 1	Disable RTC module and gate 32-kHz reference clock. RTC enable RTC disable (no 32 kHz clock)
5	SET_32_COUNTER	0 1	Set the 32-kHz counter with the value stored in the compensation registers when the SET_32_COUNTER bit is set. No action. Set the 32Khz counter with compensation registers value
4	TEST_MODE	0 1	Test mode. Functional mode Test mode (Auto compensation is enabled when the 32Khz counter reaches its end)
3	MODE_12_24	0 1	Enable 12-hour mode for HOURS and ALARMHOURS registers. 24-hr mode 12-hour mode
2	AUTO_COMP	0 1	Enable oscillator compensation mode. No auto compensation Auto compensation enabled
1	ROUND_30S	0 1	Enable one-time rounding to nearest minute on next time register read. No update Time is rounded to the nearest minute
0	STOP_RTC	0 1	Stop the RTC 32-kHz counter. RTC is frozen RTC is running

NOTE:

- The SET_32_counter must only be used when the RTC is frozen.
 - The RTC_DISABLE bit of the CTRL register must only be used to completely disable the RTC function. When this bit is set, the 32 kHz clock is gated, and the RTC is frozen. From this point, resetting this bit to zero can lead to unexpected behavior. This bit should only be used if the RTC function is unwanted in the application, in order to save power.
 - MODE_12_24: It is possible to switch between the two modes at any time without disturbing the RTC; read or write is always performed with the current mode.
 - Auto compensation is enabled by AUTO_COMP_EN bit in the RTC_CTRL register. If the COMP_REG value is positive, compensation occurs after the second change event. COMP_REG cycles are removed from the next second. If the COMP_REG value is negative, compensation occurs before the second change event. COMP_REG cycles are added to the current second. This enables it to compensate with one 32-kHz period accuracy each hour.
 - ROUND_30S is a toggle bit; ARM can only write 1 and RTC clears it. If the ARM sets the ROUND_30S bit and then reads it, the ARM read 1 until the round-to-the-closet-minute is performed at the next second.
 - ARM can stop the RTC by clearing STOP_RTC bit of the control register (owing to internal resynchronization, the RUN bit of the status must be checked to be ensure that the RTC is frozen), then update TC values, and re-start the RTC by resetting STOP_RTC bit.
-

20.3.15 Status Register (STATUS_REG)

The RTC STATUS_REG contains bits that signal the status of interrupts, events to the processor. Status for the alarm interrupt and timer events are notified by the register.

Figure 20-20. Status Register (STATUS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-19. Status Register (STATUS_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	ALARM	0-1	Indicates that an alarm interrupt has been generated
5	1D_EVENT	0-1	One day has occurred
4	1H_EVENT	0-1	One hour has occurred
3	1M_EVENT	0-1	One minute has occurred
2	1S_EVENT	0-1	One second has occurred
1	RUN	0 1	RTC is frozen or is running. RTC is frozen RTC is running
0	BUSY	0 1	Status of RTC module. Updating event in more than 15 μ s Updating event

NOTE:

- The alarm interrupt keeps its low level until the ARM writes 1 in the ALARM bit of the RTC_STATUS_REG register.
- ALARM: This bit will indicate the status of the alarm interrupt. Writing a 1 to the bit clears the interrupt.
- 1D_EVENT1: This bit will indicate if a day event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- 1H_EVENT1: This bit will indicate if an hour event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- 1M_EVENT1: This bit will indicate if a minute event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- 1S_EVENT1: This bit will indicate if a second event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- RUN: This bit will indicate if RTC is frozen or it is running. The RUN bit shows the real state of the RTC. Indeed, because the STOP_RTC signal is resynchronized on 32-kHz clock the action of this bit is delayed.
- BUSY: This bit will give the status of RTC module. The Time and alarm registers can be modified only when this bit is 0.
- The timer interrupt is a negative edge sensitive low-level pulse (1 OCP cycle duration).

20.3.16 Interrupt Register (INTERRUPTS_REG)

The INTERRUPTS_REG is used to enable or disable RTC from generating interrupts. The timer interrupt and alarm interrupt can be controlled using this register.

Figure 20-21. Interrupt Register (INTERRUPTS_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-20. Interrupt Register (INTERRUPTS_REG) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	IT_ALARM	0	Enable one interrupt when the alarm value is reached (TC ALARM registers) by the TC registers
2	IT_TIMER	0	Interrupt disabled
		1	Interrupt enabled
1-0	EVERY	0-3h	Interrupt period.
		0	Every second
		1h	Every minute
		2h	Every hour
		3h	Every day

NOTE:

- The ARM must respect the BUSY period to prevent spurious interrupt. To set a period timer interrupt, the respective period value must be set in the EVERY field. For example, to set a periodic timer interrupt for every hour, the EVERY field has to be set to 2. Along with this the IT_TIMER bit also has to be set for the periodic interrupt to be generated.
- IT_ALARM bit has to be set to generate an alarm interrupt.

20.3.17 Compensation (LSB) Register (COMP_LSB_REG)

The COMP_LSB_REG is used to program the LSB value of the 32 kHz periods to be added to the 32 kHz counter every hour. This is used to compensate the oscillator drift. The COMP_LSB_REG works together with the compensation (MSB) register (COMP_MSB_REG). The AUTOCOMP bit in the control register (CTRL_REG) must be enabled for compensation to take place.

Figure 20-22. Compensation (LSB) Register (COMP_LSB_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-21. Compensation (LSB) Register (COMP_LSB_REG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RTC_COMP_LSB	0-FFh	Indicates number of 32-kHz periods to be added into the 32-kHz counter every hour

NOTE: This register must be written in two's complement. That means that to add one 32-kHz oscillator period every hour, the ARM must write FFFFh into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. To remove one 32-kHz oscillator period every hour, the ARM must write 0001h into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. The 7FFFh value is forbidden.

20.3.18 Compensation (MSB) Register (COMP_MSB_REG)

The COMP_MSB_REG is used to program the MSB value of the 32 kHz periods to be added to the 32 kHz counter every hour. This is used to compensate the oscillator drift. The COMP_MSB_REG works together with the compensation (LSB) register (COMP_LSB_REG) to set the hourly oscillator compensation value. The AUTOCOMP bit in the control register (CTRL_REG) must be enabled for compensation to take place.

Figure 20-23. Compensation (MSB) Register (COMP_MSB_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-22. Compensation (MSB) Register (COMP_MSB_REG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RTC_COMP_MSB	0-FFh	Indicates number of 32-kHz periods to be added into the 32-kHz counter every hour

NOTE: This register must be written in two's complement. That means that to add one 32-kHz oscillator period every hour, the ARM must write FFFFh into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. To remove one 32-kHz oscillator period every hour, the ARM must write 0001h into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. The 7FFFh value is forbidden.

20.3.19 Oscillator Register (OSC_REG)

The OSC_REG is used to program the oscillator resistance value and the SW_RESET bit can be used to reset the RTC. This is the only way to reset the RTC.

Figure 20-24. Oscillator Register (OSC_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-23. Oscillator Register (OSC_REG) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	SWRESET	0-1	Software reset bit
4	OSC32KPWRDNR	0-1	Control of 32 kHz Oscillator powerdown
3-0	SWRESPROG	0-Fh	Value of the oscillator resistance

NOTE: SW_RESET bit is set to 1 to reset the RTC module. This bit is self-clearing, and is always read as 0. CPU must care of interrupt handling before RTC is reset. After setting the SW_RESET bit, you must not access any of the RTC registers for 3 32kHz clock cycles (roughly 2200 OCP cycles).

20.3.20 Scratch Registers (SCRATCHx_REG)

The SCRATCH_REG is used to hold some required values for the RTC register.

Figure 20-25. Scratch Registers (SCRATCHx_REG)

LEGEND: R/W = Read/Write; -n = value after reset

Table 20-24. Scratch Registers (SCRATCHx_REG) Field Descriptions

Bit	Field	Value	Description
31-0	RTCSCRATCHx	0-FFFF FFFFh	Scratch registers, available to program

20.3.21 Kick Registers (KICK0R, KICK1R)

The kick registers (KICKnR) are used to enable and disable write protection on the RTC registers. Out of reset, the RTC registers are write-protected. To disable write protection, correct keys must be written to the KICKnR registers.

Kick0 Register (KICK0R)

The Kick0 register allows writing to unlock the kick0 data. To disable RTC register write protection, the value of 83E7 0B13h must be written to KICK0R, followed by the value of 95A4 F1E0h written to KICK1R. RTC register write protection is enabled when any value is written to KICK0R.

Figure 20-26. Kick0 Register (KICK0R)

LEGEND: W = Write only; -n = value after reset

Table 20-25. Kick0 Register (KICK0R) Field Descriptions

Bit	Field	Value	Description
31-0	KICK0	0	Kick0 data

Kick1 Register (KICK1R)

The Kick1 register allows writing to unlock the kick1 data and the kicker mechanism to write to other MMRs. To disable RTC register write protection, the value of 83E7 0B13h must be written to KICK0R, followed by the value of 95A4 F1E0h written to KICK1R.

Figure 20-27. Kick1 Register (KICK1R)

LEGEND: W = Write only; -n = value after reset

Table 20-26. Kick1 Register (KICK1R) Field Descriptions

Bit	Field	Value	Description
31-0	KICK1	0	Kick1 data

20.3.22 RTC Revision Register (RTC_REVISION)

Figure 20-28. RTC Revision Register (RTC_REVISION)

31	30	29	28	27					16	
SCHEME		Reserved		FUNC

Table 20-27. RTC Revision Register (RTC_REVISION) Field Descriptions

Bit	Field	Value	Description
31-30	SCHEME	0-3h	Used to distinguish between old scheme and current
29-28	Reserved	0	Reserved
27-16	FUNC	0-FFFh	Function indicates a software compatible module family
15-11	R RTL	0-1Fh	RTL Version (R)
10-8	X MAJOR	0-7h	Major Revision
7-6	CUSTOM	0-3h	Indicates a special version for a particular device
5-0	Y MINOR	0-3Fh	Minor Revision (Y)

20.3.23 System Configuration Register (RTC_SYSCONFIG)

Figure 20-29. System Configuration Register (RTC_SYSCONFIG)

31					16	
Reserved						
R-0						
15				2	1	0
Reserved					IDLEMODE	
R-0					R/W-2h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-28. System Configuration Register (RTC_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	IDLEMODE	0-3h	Configuration of the local target state management mode. By definition target can handle read/write transaction as long as it is out of IDLE state.
		0	Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e., regardless of the IP module's internal requirements; Backup mode, for debug only.
		1h	No-idle mode: local target never enters idle state, Backup mode, for debug only.
		2h	Smart-idle mode: local target's state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements, IP module shall not generate (IRQ- or DMA-request-related) wakeup events.
		3h	Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements, IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state, Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.

20.3.24 Wakeup Enable Register (RTC_IRQWAKEEN)

Figure 20-30. Wakeup Enable Register (RTC_IRQWAKEEN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-29. Wakeup Enable Register (RTC_IRQWAKEEN) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	ALARM_WAKEEN	0	Wakeup generation for event Alarm.
		0	Wakeup disabled
		1	Wakeup enabled
0	TIMER_WAKEEN	0	Wakeup generation for event Timer.
		0	Wakeup disabled
		1	Wakeup enabled

Serial ATA (SATA) Controller

This chapter describes the Serial ATA Controller (SATA) in the device.

Topic	Page
21.1 Introduction	2428
21.2 Architecture	2432
21.3 Use Cases	2438
21.4 Registers (Controller and PHY)	2457
21.5 SATA PLL Registers	2508
21.6 SATA Subsystem Registers	2517

21.1 Introduction

The serial ATA is the successor of the parallel ATA/ATAPI controller that has served as the choice of the communication medium between a portable computer (PC) and a hard-disk drive for several decades. During these times, the PATA interface has gone through changes to sustain the demands of the newly emerging applications needs and eventually, it reached its technical limitation, creating a throughput bound. The PATA controller reached a point where it required major changes to satisfy the upcoming applications requirements and this led to its successor, the birth of the SATA controller. The SATA controller was designed to use the same logical command structures that PATA uses but with a whole new physical characteristic. The SATA controller makes use of two pairs of high-speed differential conductors as opposed to the parallel 16-bit, low-speed interface. This device has a built-in SATA controller with a single HBA port operating in AHCI mode, and is used to interface to data storage devices at both 1.5 Gbits/Sec and 3.0 Gbits/Sec line speeds per HBA port. AHCI describes a system memory structure which contains a generic area for control and status, and a table of entries describing a command list where each command list entry contains information necessary to program a SATA device, and a pointer to a descriptor table for transferring data between system memory and the device.

21.1.1 Purpose of the Peripheral

The SATA controller addresses the drawback of the PATA interface architecture, throughput, and protocol perspectives. PATA required 40/80 wire parallel cable with a length requirement not exceeding 18 inches. With the latest/final PATA H/W design, PATA's maximum transfer rate saturated to a 133 Mbytes/Sec of transfer. In addition to newly added features, like hot swapping and native command queuing, the SATA controller abandoned the parallel physical interface and transitioned to a high-speed serial format using two differential pairs supporting up to 3 Mbits/Sec transfer rate, translating to a 300 Mbytes/Sec raw throughput for the single HBA port.

With the intent on handling roles of the PATA controller and addressing the future needs, the SATA controller is architected with the option of operating in a Legacy mode (which behaves similar to the PATA controller from the protocol/driver perspective), and a new AHCI mode that is different from the Legacy mode. The AHCI mode has a new interface whose standard is not compatible with PATA and does not support the Legacy mode of operation. The communication between a device and software moves from the PATA task file registers access made via byte-wide accesses to a structure based, command Frame Information Structure (FIS), located in system memory that is fetched by the HBA. This reduces command setup time significantly, allowing for multiplexing more SATA devices to a single HBA port. A port multiplier (PM) is required for this task and allows as many as 15 devices to attach to a single HBA port. Software no longer communicates directly to a device via task file registers. In other words, all data transfers between the device and system memory occur through the HBA acting as a bus master to system memory and this transfer happens without intervention of user software. Whether the transaction is of a DMA type or a PIO type (the use of the PIO command type is strongly discouraged and all transfers should be performed using DMA unless a transaction is only performed via PIO command, which in this case is still done via the AHCI master port not the CPU), the HBA fetches and stores data to memory, offloading the CPU. No data port exists for moving data in and out of the system memory similar to the PATA offerings. Software written for AHCI is not allowed to utilize any of the legacy mechanisms to program devices.

The SATA controller uses a less massive thinner flexible cable that can be up to 3 feet (1 meter) in length allowing for easier routing and better air ventilation inside a case. Its power budget is significantly reduced to 250 mV compared to the required 5V and/or 3.3V power of PATA.

Like its predecessor, the SATA controller is most commonly used by PCs, portable devices, and embedded devices to interface a host processor with external data storage or CD/audio devices. It also has the support for hot swapping capability and the ability of interfacing to a port multiplier (PM) to increase the number of devices that can be attached to a single HBA port by as many as fifteen devices. Note that in the case where a PM is used, the bandwidth offered by a single HBA port will be shared amongst the total number of devices attached to the port multiplier.

21.1.2 Features Supported

The main features of the SATA controller are:

- Support for Synopsys DWH Serial ATA 1.5Gbps and 3Gbps speeds core

- Supports AHCI Controller (specification version 1.1)
- Supports one HBA port
- Integrated TI SERDES PHY (Mercury)
- Built in/integrated Rx and Tx data buffers
- Supports all SATA power management features
- Internal DMA engine per port
- Hardware-assisted native command queuing (NCQ) for up to 32 entries
- 32-bit addressing
- Supports port multiplier with command-based switching
- Activity LED support

21.1.3 Features Not Supported

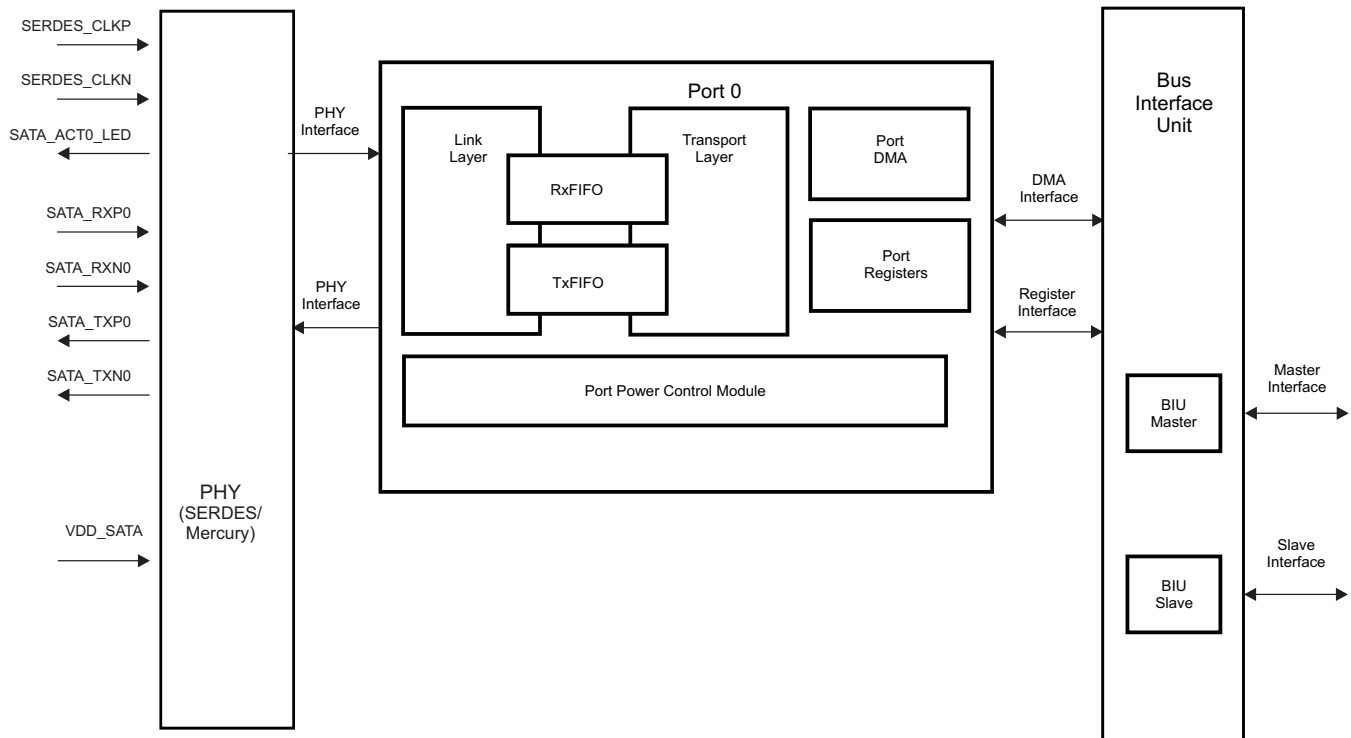

Features not supported in this SATA controller are:

- Legacy mode of operation
- Master/slave type of configuration
- Far-end analog loopback
- Message signaled interrupts
- 64-bit addressing
- Dedicated Mechanical Presence Switch Pin (GPIO usage is expected to supplement this task if necessary)
- Dedicated Cold Presence Detect Pin (GPIO usage is expected to supplement this task if necessary)

21.1.4 Functional Block Diagram

The SATASS is a fully contained Serial ATA host with built in DMA. It uses the AHCI standard for communication with a SATA device. It has no support for the Legacy mode of operation. [Figure 21-1](#) shows a high level block diagram of the SATA Subsystem (core and the integrated TI PHY (SERDES)).

Figure 21-1. SATA Core Block Diagram

21.1.5 Industry Standard(s) Compliance

The SATA Subsystem complies with the following industry standards:

- SATA revision 2.6 Gold standard
- AHCI revision 1.1 specification

21.1.6 Non-Industry Standard(s) Compliance

The SATA Subsystem complies with the following proprietary standards:

- Synopsys Design Ware Core DWC AHCI Controller Version 2.10
- TI SERDES PHY: Mercury GS70 Revision 1.2.

21.1.7 Terminology Used in this Document

The following is a brief explanation of some terms used in this document:

AHCI — Advanced Host Controller Interface (necessary for implementing newly supported features like native command queuing). The device supports only this mode of operation, i.e., has no support for Legacy mode. It also reduces CPU/Software overhead when moving data in and out of the system memory. Note that system software is responsible to ensure that queued and non-queued commands are not mixed in the command list.

ATA/ATAPI— Advanced Technology (AT) attachment/ATA packet interface

CF— Compact Flash

Device— External SATA or ATAPI device attached to the SATA controller

DMA— DMA within the ATA controller, not the processor EDMA system

DWORD— DWORD is 32 bits of data.

Command List— Command List is a memory buffer for as much as 32 commands. Each command is entered in a command slot. This is a required feature when supporting command queuing.

Command Slot— A command slot is a subset of the command list. It is the memory buffer for a single command. A total of 32 command slots exist.

D2H— D2H is an acronym for “device to HBA” and is mostly used to indicate the direction of the transmission of FIS which is from device to the HBA (host).

FIS— FIS is an acronym for “Frame Information Structure.” A frame is made of a data payload with computed CRC and a start and end primitives.

H2D— H2D is an acronym for “HBA to device” and is mostly used to indicate the direction of the transmission of FIS which is from HBA (host) to device.

HBA — HBA is an acronym for “host bus adapter.” It is the SATA controller that implements the AHCI specification to communicate between system memory and Serial ATA devices.

Legacy Mode— This mode of operation allows the user's application software or driver to view the SATA controller in a similar fashion as a PATA controller. However, the device does not support the Legacy mode of operation; it supports the AHCI mode of operation.

OOB — Out of Band. OOB signaling is used for during device detection and when recovering from power states.

PM — Port Multiplier. A port multiplier allows extending an HBA port connection capability to connect to multiple SATA Devices, a maximum of 15 Devices. Note that the operating bandwidth is shared amongst all the Devices when using this type of configuration.

PMP — Port Multiplier Port : A Port of a Port Multiplier (PM).

PORT— Refers to HBA Port, mainly within this document. However, the PORT is also be used to refer to a port of a PORT Multiplier.

PRD — PRD is an acronym for “physical region descriptor.” A PRD table is a data structure used by DMA engines that comply with the ATA/ATAPI Host Adapters standard. The PRD describes memory regions to be used as the source or destination of data during DMA transfers. A PRD table is often referred to as a scatter/gather list.

SATA Controller— Serial ATA controller, also HBA.

System Memory— Memory that is external from the SATA controller but is accessible by the built-in SATA controller DMA or the CPU.

21.2 Architecture

The Serial ATA Controller supports an advanced host controller interface (AHCI) which is a standard interface. The single host port SATA controller does not support the Legacy mode of operation. Since the controller complies with the AHCI standard (version 1.1) the details of its operation are captured within the AHCI version 1.1 specification. Please consult the specification for the general behavior of the AHCI SATA Core operation. The SATA controller supported within the device has one HBA port.

21.2.1 Clock Control

The SATA controller makes use of one internal 200 MHz clock (PRCM SYSCLK4 output clock) for both functional and keep alive functions. During a low powerdown event, the keep-alive clock is necessary to insure that portions of the controller interface remain up and running at all times to keep the controller context in tact, as well as to clock the hardware logic necessary used in detecting wakeup events from power-down modes. Access to the SATA controller and resources are implemented through SYSCLK4 derived from the output of the main input reference clock source. SYCLK4 to the SATA controller is gated by the PRCM (power, reset, and clock management) at the controller boundary and is required to be enabled prior to accessing the SATA controller. However, the keep-alive clock is always ON, i.e., it can not be gated at the controller boundary, and can not be turned off as long as the device is in normal operation state.

The SATA PHY requires multiple clock sources for operation. The main device reference 20 MHz clock is one of them and is required at all times. The other clock can be derived from the derivative of the 20MHz reference clock using the PHY PLL or it can be sourced from an external differential clock source. If sourced externally, it requires a high-quality, low-jitter external clock. A 100 MHz clock is preferred in such a case, since this external clock is shared with the PCIe SS that has this requirement..

The selection for the input clock source for the SERDES, i.e., the 20 MHz reference clock or the 100 MHz differential clock, is configured via one of the SATA PLL Configuration register fields (CFGPLL0. SEL_IN_FREQ bit field located @ 0x4814_0720) where 0/1 implies external SERDES differential input/reference 20 MHz clock input source. Note that the SATA PLL configuration registers are accessed from the device configuration register space and these registers lie within the control module space which is found in a different location from where the the SATA peripheral and PHY registers reside.

21.2.2 Signal Description

The device has bonded out the data lines (a set of differential data lines) and a device activity indicator. Signals needed to detect device detection and attached device power indicators need to be implemented via GPIO if desired and no dedicated signals for these tasks exist. The power pins and logic necessary to power-up a cold SATA device should be handled external to the device.

Table 21-1 summarizes the available SATA module signals.

Table 21-1. SATA Interface Signal Descriptions

Terminal Name	Direction from the HBA Perspective (In/Out)	Description
SATA_RXP0	Input	Receive Data Positive Differential Signal for Port 0
SATA_RXN0	Input	Receive Data Negative Differential Signal for Port 0
SATA_TXP0	Input	Transmit Data Positive Differential Signal for Port 0
SATA_TXN0	Input	Transmit Data Positive Differential Signal for Port 0
SERDES_CLKP	Input	PHY Reference Positive Differential Signal
SERDES_CLKN	Input	PHY Reference Negative Differential Signal
SATA_ACT0_LED	Output ⁽¹⁾	Device Activity Indicator for HBA Port 0
VDD_SATA (2)		

⁽¹⁾ Multiplexed with other peripherals.

21.2.3 DMA

The AHCI HBA port contain two DMA engines. One of the DMA engine is used to fetch command from the command list. The other DMA is used to move FISes in and out of system memory. These DMAs are part of the AHCI controller. All data movement in and out of the device is performed through the DMA and no CPU-driven data movement option is available.

The DMA used to move FISs in and out of system memory has a register, P0DMACR, to control the burst transfer. This DMA is used to transfer all information between system memory and the attached SATA device, as well as configuration and status FISs.

The user can program the maximum burst size that will be issued on the system bus independently for both reads and writes. The DMA will issue transactions equaling the programmed size or smaller (in DWORD increments). This can be used to optimize burst size for over-all system throughput efficiency. Refer to [Section 21.4.32](#) for details on legal values. Note that programming a burst size of greater than a transaction size (below), while is not invalid, is meaningless because the DMA maximizes out at the maximum transaction size.

The user can also program the transaction size for both receive and transmit (see [Section 21.4.32](#)). The transaction size is the minimum amount of data that the DMA will work on. For example, if there is an FIS coming from the device to the host, the DMA will not begin transferring data into system memory until there is at least RX_TRANSACTION_SIZE (RXTS) data in the receive FIFO. During transmit, the DMA will read data from system memory in TX_TRANSACTION_SIZE (TXTS) increments to put into the transmit FIFO. Note that transactions may be broken up into multiple bursts based on burst size, crossing of a 1k boundary, or end-of-frame.

21.2.4 Transport Layer

The transport layer handles all of the transport layer functions of the SATA protocol. During reception, it receives a FIS from the Link layer via the Rx FIFO, decodes the type, and routes it to the proper location via the port DMA. During transmission, it transfers a FIS constructed by the port DMA to the link layer via the Tx FIFO. It also passes link layer errors and checks for transport layer errors to pass up to the system.

21.2.5 FIFOs

The transport layer also contains the Tx and Rx FIFOs. These FIFOs are used as asynchronous data buffers between the serial domain and the bus clock domain. The size of these FIFOs affects the subsystems ability to buffer data before flow control must be asserted. It also affects the maximum programmable transaction and burst sizes that can be programmed into the port DMA. The Tx FIFO size is 64 DWORDS (256 bytes) deep while the Rx FIFO size is 128 DWORDS (512 bytes) deep.

21.2.6 Link Layer

The link layer maintains the link and supports all SATA link layer functionality including:

- Out-of-band (OOB) transmit signaling
- Frame negotiation and arbitration
- Envelope framing/de-framing
- CRC calculation (receive and transmit)
- 8b/10b encoding/decoding
- Flow control
- Frame acknowledgment and status
- Data width conversion
- Data scrambling/descrambling
- Primitive transmission
- Primitive detection and dropping
- Power management

21.2.7 PHY

The SATASS includes an integrated TI SERDES macro as a PHY. The PHY handles all of the serialization/de-serialization, symbol alignment, and Rx OOB signal detection.

21.2.8 Pin Multiplexing

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package; therefore, some of the SATA controller peripheral signals share pins with other peripherals; SERDES_CLKP/N is shared with PCI Express and SATA_AC0_LED is shared with multiple peripherals. When using the SATA_AC0_LED bit for SATA function, the corresponding PINMUX register is required to be configured for SATA usage. Since the same SERDES is used by SATA and PCI Express peripherals, it is recommended the use of a 100MHz differential input clock source that is ideal for both peripherals. Refer to the device-specific data manual to determine how pin multiplexing affects the SATA.

21.2.9 Power Management

The SATA controller can be placed in reduced power modes to conserve power during periods of no activity or no use. The main power management of the peripheral is controlled by the Power, Reset, and Clock Management (PRCM) unit. The PRCM acts as a master controller for power management of all of the peripherals on the processor. For detailed information on power management procedures using the PRCM, see the *System Reference Guide*.

During times that the SATA peripheral is in use, the SATASS supports the industry standard power down modes (both Partial and Slumber low power modes) as provided within the SATA specification. These modes allow for power savings by powering down part of the SERDES PHY and by providing the ability to gate off the clocks to the link layer. The Port Power Control Module is used to enter and exit this power down modes (that is power down mode is controlled at Port level) which may have the normal functional clocks gated off.

NOTE: When SATA communication is in the logical idle state, that is, when no disk activity takes place, the communication remains active with both the host and the device sending a logical sync primitive and scrambled data at the speed negotiated continuously. For power sensitive applications, the power consumed during the disk inactivity stage might be undesirable and it might be a desired task to place the communication interface into an electrical idle (Partial or Slumber) state until data transfer activity is needed in order to conserve power.

21.2.10 Reset

The SATA controller reset is handled via PRCM. Please consult the PRCM document for details on how to use the PRCM module. Other types of resets (HBA Reset, Port Reset, and Software Reset) supported by the SATA controller are part of the AHCI specification. See the AHCI Standard Specification 1.1 for details on HBA Reset, Port Rest, and Software Reset.

21.2.11 Interfacing to Single and Multiple Devices

The SATA controller supports one HBA port. This means that the HBA port can be used to interface directly to a single SATA device or to multiple SATA Devices via a port multiplier. Note that on a multiple target setup, the available bandwidth will be shared amongst all the attached devices.

Note that Port Multipliers and Power Supplies for external SATA devices, when needed, should be furnished external to the device. No dedicated signals for controlling power and device detection are not bonded out and usage of GPIO pins can be used to supplement this task. However, the controller supports the capability to spin-up-attached devices independently.

21.2.11.1 Interfacing to a Single Device

If need to interface directly to a single device, there is no need of populating a port multiplier. The software needs to ensure that the PMP field within the Command Header and the PM_PORT field of the FIS be cleared at all times.

If the external SATA device is not Self Powered, it is the responsibility of the System Designer to populate and furnish the right power supply needed. Consult the SATA Specification for details.

21.2.11.2 Interfacing to Multiple Devices

Interfacing to multiple devices is pretty much identical to interfacing with a single device except the addition of a hardware Port Multiplier and initialization on software side. User software is required to perform the additional task of detecting and configuring the PM prior to accessing the attached devices. The user software is required to populate the Port Multiplier Port (PMP) field of the FIS in order to select one of the fifteen devices that could be connected and accessed by the HBA. The details on this are fully captured within the AHCI specification Version 1.1.

21.2.12 Initialization

Proper initialization of the HBA is required after power up to ensure proper operation of the SATA controller peripheral. The initialization process starts by performing a write to one-time write only registers (this initialization step is documented as Firmware initialization within the AHCI specification) where the values programmed depend on the features that the applications support. Note that the features that are enabled by the Firmware initialization are subsets of the features supported by the SATA subsystem. This Firmware initialization is similar to what a PC BIOS does and allows the user to enable/disable some supported features by using software.

The software can then continue with the normal initialization that is required by the software. The details and sequence of initialization is documented within the AHCI specification. In general, everything that is achieved by the Software Initialization has to do with configuring and furnishing resources needed by the AHCI controller and these tasks include PHY Initialization, allocating structures and memories for Command Slots, FIS, and Data Memories and concludes by enabling the receive FIS DMA. The software will then spin-up the device and ensure that a proper Device Detection and Speed Negotiation has completed prior to enabling the Command DMA.

Note that DMA Configuration/Initialization should take place after Device Detection and Speed Negotiation. If done earlier, the default value is used (which is the recommended setting) since RESET removes the user programmed values. The only time it is advisable to change the DMA Configuration is when you need to prioritize System Resource access. This still has to be done after "PHY Ready" status is set (in other words, after the device detection and speed negotiation has completed). It also requires that the Command DMA is not running (POCMD.ST = 0) when modifying the value of the DMA Configuration fields.

21.2.12.1 Initialization (Firmware and Software)

Software reads the HBA capabilities register (CAP), ports implemented register (PI), AHCI version register (VS), global parameter 1 register (GPARAM1R), global parameter 2 register (GPARAM2R), and the port parameter register (PPARAMR) to obtain information about the subsystem's capabilities. The software should then take the following steps to configure each port for operation:

1. Do all firmware capability writes.
2. Setup all appropriate structures in memory as per the AHCI specification.
3. Set the port command list base address register (POCLB).
4. Set the port FIS base address register (POFB).
5. Set appropriate bits in the port command register (POCMD).
6. Program the port serial ATA control register (POSCTL).
7. Wait for Device Detection and Speed Negotiation to end.
8. Program the port DMA control register (PODMACR).
9. Enable the appropriate interrupts.
10. Enable FIS reception in POCMD.
11. Spin-up the device(s), if necessary.

21.2.12.2 Issuing a Command

Once the host and device are configured, perform the following steps to issue a command:

1. Create the appropriate FIS in system memory.
2. Create the PRD.
3. Queue the command to the command queue list (location specified by the port command list base address register (POCLB)).

For detailed information, see the AHCI Specification Version 1.1.

21.2.13 Interrupt Support

The AHCI controller supports both standard interrupt sourcing, where interrupts are generated when enabled events occur, or a different type of method of generating interrupts that minimize interrupt loading by either generating interrupts in a batch or periodically. The latter method is handled using Command Completion Coalescing method and the details is captured within the AHCI Specification Version 1.1.

21.2.13.1 Command Completion Coalescing

Command Completion Coalescing (CCC) is a feature designed to reduce the interrupt and command completion overhead in a heavily loaded system. The feature enables the number of interrupts taken per completion to be reduced significantly, while ensuring a minimum quality of service for command completions. When software specified number of commands have completed or a software specified timeout has expired, an interrupt is generated by hardware to allow software to process completed commands. The command completion coalescing ports register (CCC_PORTS) should be programmed by setting the corresponding bit of the Port that is to be included in command completion coalescing feature. Note that the device supports 1 HBA port.

For a detailed explanation of the CCC initialization and usage, see the AHCI Specification 1.1 Section 11.6.

21.2.13.1.1 CCC Interrupt Based on Timer Expiration

When CCC is enabled and the desired method to receive an interrupt is based on a timer elapse condition, then the user needs to communicate a resolution for a 1ms time by programming the TIMER1MS register with the OCP cycle count derived from the OCP clock frequency sourced to the SATA controller.

As an example, if a user desires for interrupt to be generated every 15ms, for OCP bus clock frequency of 200 MHz, the 1ms cycle count should be programmed with a value of 250,000, i.e., $250 \text{ MHz}/1000 = 200000$, and CCC_CTL.TV is programmed with a non-Zero millisecond value (15 in this case). When CCC_CTL.EN is set to 1 (CCC is enabled), the CCC will periodically generate an interrupt every 15 ms or every $15 * 200000 = 3,000,000$ OCP cycles.

NOTE: Make sure the EN bit in the command completion coalescing control register (CCC_CTL) is cleared to 0 (i.e., CCC is disabled, prior to programming this field).

21.2.13.1.2 CCC Interrupt Based on Completion Count

When CCC is enabled and the desired method to receive an interrupt is based on a completion count, that is, the CC bit in the command completion coalescing control register (CCC_CTL) is programmed with a non-zero value and the CCC interrupt is enabled (EN bit in CCC_CTL is set to 1), an interrupt is sourced from the SATA controller when the programmed desired number of interrupt is received.

NOTE: Make sure the EN bit in the command completion coalescing control register (CCC_CTL) is cleared to 0 (i.e., CCC is disabled, prior to programming this field).

21.2.13.2 Non CCC Interrupt Configuration

For a standard interrupt handling method where every event that is enabled generates an interrupt, is handled as follows. For more information, see the AHCI Specification.

After insuring that CCC is disabled, the EN bit in the command completion coalescing control register (CCC_CTL) is 0, in order for the SATA Core to source interrupts, the interrupt should be enabled at both global level (the IE bit in the global HBA control register (GHC) is set to 1) and port level by enabling the bit fields for the desired interrupt. An enable bit at a Port level controls corresponding interrupt dispatch to the processor interrupt handling resource. So long as the CPU interrupt handler is configured properly, the CPU receives the interrupt when the enabled event occurs.

21.2.14 EDMA Event Support

The SATA controller makes use of its own built-in DMA and has no need for the use of the processor EDMA.

21.3 Use Cases

The following sections include some sample program snippets that can be used as a guide for software development. The example demonstrates one of the ways of creating the necessary structures; properly aligned system memory resources, initialization, as well as performing basic DMA Read/Write transfer using a couple of the Command Slots.

[Section 21.3.2](#) contains examples in relations to System Memory resource allocations, Structures, and Subroutines used by the Initialization and Read/Write Transfer functions. The remaining sections include examples of basic Initialization, DMA Write transfer, and DMA Read transfer examples using Port 0.

21.3.1 Controller Clock, PLL and SERDES Initialization

The SATA PLL and SERDES configuration requires a predefined sequence of register access and initialization. The following initialization sequence is recommended to be followed prior to starting SATA controller initialization.

```
*SATA_PLLCFG0 = 0x00000004;
wait_for_cpu_cycles(2000);
*SATA_PLLCFG1 = 0xC12C003C;
wait_for_cpu_cycles(2000);
*SATA_PLLCFG3 = 0x004008E0;
wait_for_cpu_cycles(850);
*SATA_PLLCFG0 |= 0x00000010;
    wait_for_cpu_cycles(85);
*SATA_PLLCFG0 |= 0x00000002;
    wait_for_cpu_cycles(60);
wait_for_cpu_cycles(2000);

* CM_ALWON2_SATA_CLKCTRL |= 0x2;
while ((*CM_ALWON2_SATA_CLKCTRL & 0x0F) != 0x2);

* CM_DEFAULT_L3_MED_CLKSTCTRL |= 0x2; // Enable SATA Clock
while ((*CM_DEFAULT_L3_MED_CLKSTCTRL & 0x0F) != 0x102);

*CFGTX0_OFFSET = 0x01003622;
*CFGTX1_OFFSET = 0x40000002;
*CFGTX2_OFFSET = 0x00C201F8;
*CFGTX3_OFFSET = 0x073CE39E;
*CFGRX0_OFFSET = 0x008FCC22;
*CFGRX1_OFFSET = 0x008E0500;
*CFGRX2_OFFSET = 0x7BDEF000;
*CFGRX3_OFFSET = 0xC0007077;

*SATA_PLLCFG0 |= 0xC0007061;

while (*SATA_PLLSTATUS & 0x1) != 0x1); // wait until PLL lock
```

21.3.2 General Utilities: Structures and Subroutines Sample Program Uses

```

/* Allocating memory for Command List. The structure pointed to by this

```

21.4 Registers (Controller and PHY)

Due to the support of a standard controller, that is compliant with the AHCI 1.1 specifications, the memory-map of the controller and the register descriptions matches the memory-map documented within the standard. For features that are not part of the standard or are implementer specific, (for example, DMA burst control or built-in self test or PHY configuration registers) the reserved locations are used to document the necessary registers required by the non-standard features.

The sub-system core contains register space for global host programming and register space for port programming (the device supports two host ports and confirms to the AHCI specification calls for the support of multiple Host ports and the register space partitioning comes from this perspective). All registers that start below offset address 100h are global and meant to apply to the HBA, i.e., the registers settings entered at the global region applies to the single HBA port. Note that if the device happens to have multiple ports, then the registers within the global space would apply to all ports implemented. The Port 0 control registers reside at offset 100h and above. Dedicated registers that pertains to the specific port reside within this space. There are as many register banks as there are ports (for this device only one bank of registers is available for use).

The subsystem core contains register space for global host programming and space for port programming (the AHCI specification calls for the support of multiple host ports and the register space partitioning comes from this perspective). All registers that start below offset address 100h are global and meant to apply to the entire HBA. The Port 0 control registers reside at offset 100h to 17Fh. Dedicated registers that pertain to the specific port reside within this space. There are as many register banks as there are ports (for this device, one bank of registers is available).

[Table 21-2](#) lists the registers of the SATA subsystem. Note that a special class of registers whose reset state is listed as W/RO (write/read only) requires a one time initialization after power-up. These registers are written once after a hard reset by firmware, and then remain as read-only thereafter. These registers are not affected by software reset.

The base address for the SATA register file is located at: 0x4A14_0000.

Table 21-2. SATA Controller Registers

Address Offset	Acronym	Register Description	Section
0h	CAP	HBA Capabilities Register	Section 21.4.1
4h	GHC	Global HBA Control Register	Section 21.4.2
8h	IS	Interrupt Status Register	Section 21.4.3
Ch	PI	Ports Implemented Register	Section 21.4.4

21.4.1 HBA Capabilities Register (CAP)

The HBA capabilities register (CAP) indicates basic capabilities of the DWC SATA AHCI to the driver software.

The CAP register is shown in [Figure 21-2](#) and described in [Table 21-3](#).

Figure 21-2. HBA Capabilities Register (CAP)

31	30	29	28	27	26	25	24	23		20	19	18	17	16
S64A	SNCQ	SSNTF	SMPS	SSS	SALP	SAL	SCLO	ISS			SNZO	SAM	SPM	Rsvd
R-0	R-1	R-1	W/RO-0	W/RO-0	R-1	R-1	R-1	R-2h			R-0	R-1	R-1	R-0

PMD	SSC	PSC	NCS				CCCS	EMS	SXS	NP				
R-1	R-1	R-1	R-1Fh				R-1	R-0	R-0	R-1				

LEGEND: R/W = Read/Write; R = Read only; W/RO: written once after hard reset by firmware, then remain as read-only; -n = value after reset

Table 21-3. HBA Capabilities Register (CAP) Field Descriptions

Bit	Field	Value	Description
31	S64A	0	Indicates Support for 64-Bit Addressing. The SATASS only supports 32-bit addressing so this bit is always 0.
30	SNCQ	1	Supports Native Command Queuing. SATASS supports SATA native command queuing by handling DMA Setup FIS natively.
29	SSNTF	1	Supports SNotification Register. SATASS supports P0SNTF (SNotification) register and its associated functionality.
28	SMPS	0	Supports Mechanical Presence Switch. This bit is set by firmware when the platform supports a mechanical presence switch for hot plug operation. This should be written with Zero value. Can use GPIO to supplement this task.
27	SSS	0	Supports Staggered Spin-Up. Only writable once after power up. Set this bit during Firmware Initialization prior to attempting to spin up device (P0CMD[SUD]).
26	SALP	1	Supports Aggressive Link Power Management. SATASS supports auto-generating (Port-initiated) Link Layer requests to the PARTIAL or SLUMBER power management states when there are no commands to process.
25	SAL	1	Supports Activity LED.
24	SCLO	1	Supports Command List Override. Supports the P0CMD.CLO bit functionality for Port Multiplier devices enumeration.
23-20	ISS	2h	Interface Speed Support. SATASS Supports 1.5 and 3 Gbps.
19	SNZO	0	Supports Non-Zero DMA Offsets. Not supported.
18	SAM	1	Supports AHCI Mode Only. SATASS supports AHCI mode only and does not support legacy, task-file based register interface.
17	SPM	1	Supports Port Multiplier. SATASS supports command-based switching Port Multiplier on any of its Ports.
16	Reserved	0	Reserved.
15	PMD	1	PIO Multiple DRQ Block. SATASS supports multiple DRQ block data transfers for the PIO command protocol.
14	SSC	1	Slumber State Capable. SATASS supports transitions to the interface SLUMBER power management state.
13	PSC	1	Partial State Capable. SATASS supports transitions to the interface PARTIAL power management state.
12-8	NCS	1Fh	Number of Command Slots. SATASS supports 32 command slots per Port.
7	CCCS	1	Command Completion Coalescing Supported. SATASS supports command completion coalescing.
6	EMS	0	Enclosure Management Supported. Enclosure Management is not supported.
5	SXS	1	Supports External SATA.

Table 21-3. HBA Capabilities Register (CAP) Field Descriptions (continued)

Bit	Field	Value	Description
4-0	NP	0 1 2h - Fh	Number of Ports. 0's based value indicating the number of Ports supported by the SATSS. 1 Port 2 Ports Reserved

21.4.2 Global HBA Control Register (GHC)

The global HBA control register (GHC) provides various global functions for the SATASS.

The GHC register is shown in [Figure 21-3](#) and described in [Table 21-4](#).

Figure 21-3. Global HBA Control Register (GHC)

31	30				16
AE	Reserved				
R-1	R-0				
15	Reserved			2	1
			IE	HR	0
		R-0	R/W-0	W-0	

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

Table 21-4. Global HBA Control Register (GHC) Field Descriptions

Bit	Field	Value	Description
31	AE	1	AHCI Enable. This bit is always set since SATASS supports only AHCI mode as indicated by the SAM bit in the HBA capabilities register (CAP) = 1.
30-2	Reserved	0	Reserved.
1	IE	0 1	Interrupt Enable. This global bit enables interrupts from the SATASS. This field is reset on Global reset (GHC.HR = 1). All interrupt sources from all the Ports are disabled (masked). Interrupts are enabled and any SATASS interrupt event causes interrupt output assertion.
0	HR	0	HBA Reset. When set by the software, this bit causes an internal Global reset of the SATASS. All state machines that relate to data transfers and queuing return to an idle state, and all the Ports are reinitialized by sending COMRESET if staggered spin-up is not supported. If staggered spin-up is supported, then it is the responsibility of the software to spin-up each Port after this reset has completed. The SATASS clears this bit when the reset action is done. A software write of 0 has no effect.

21.4.3 Interrupt Status Register (IS)

The interrupt status register (IS) indicates which port inside of the subsystem has a pending interrupt.

The IS register is shown in [Figure 21-4](#) and described in [Table 21-5](#).

Figure 21-4. Interrupt Status Register (IS)

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -n = value after reset

Table 21-5. Interrupt Status Register (IS) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	IPS[n]	0-1	Interrupt Pending Status (IPS[0] is for Port 0 and IPS[1] is for Port[1]).. If a bit <i>n</i> is set to 1 If set, the corresponding Port has an interrupt pending. Software can use this information to determine which Ports require service after an interrupt. The bits of this field are set by the Ports that have interrupt events pending in the port interrupt status register (POIS) bits and enabled by the port interrupt enable register (POIE) bits. Set bits are cleared by the software writing 1 to all bits to clear.

21.4.4 Ports Implemented Register (PI)

The ports implemented register (PI) indicates which ports are exposed by the SATASS and are available for software to use. It is loaded by the BIOS. For example, the SATASS supports 2 Ports as indicated in the CAP.NP, only Port 1 could be available, while Port 0 is unavailable. During Firmware Initialization the software needs to indicate that Port 0 is not available by setting only PI[bit1] only. This means the Port Enabled is a subset of Port available. Note that a minimum of one port needs to be enabled.

The PI register is shown in [Figure 21-5](#) and described in [Table 21-6](#).

Figure 21-5. Ports Implemented Register (PI)

LEGEND: R/W = Read/Write; R = Read only; W/RO: written once after hard reset by firmware, then remain as read-only;
-*n* = value after reset

Table 21-6. Ports Implemented Register (PI) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	PI[<i>n</i>]	0-1	Ports Implemented. This register is bit significant. If a bit <i>n</i> is set to 1, the corresponding Port is available for software to use. If a bit <i>n</i> is cleared to 0, the Port is not available for software to use. The maximum number of bits that can be set is 2 for a module with two HBA ports. Note: The contents of this register are relevant to the command completion coalescing ports register (CCC_PORTS).

21.4.5 AHCI Version Register (VS)

The AHCI version register (VS) indicates the version of the Synopsis AHCI core embedded in the SATASS.

The VS register is shown in [Figure 21-6](#) and described in [Table 21-7](#).

Figure 21-6. AHCI Version Register (VS)

LEGEND: R = Read only; -*n* = value after reset

Table 21-7. AHCI Version Register (VS) Field Descriptions

Bit	Field	Value	Description
31-16	MJR	1	Major Revision Number.
15-0	MNR	100h	Minor Revision Number.

21.4.6 Command Completion Coalescing Control Register (CCC_CTL)

The command completion coalescing control register (CCC_CTL) is used to configure the command completion coalescing (CCC) feature for the SATASS core. It is reset on Global reset.

The CCC_CTL register is shown in [Figure 21-7](#) and described in [Table 21-8](#).

Figure 21-7. Command Completion Coalescing Control Register (CCC_CTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-8. Command Completion Coalescing Control Register (CCC_CTL) Field Descriptions

Bit	Field	Value	Description
31-16	TV	0-FFFFh	Time-out value. This bit field specifies the CCC time-out value in 1 ms intervals. Software loads this value prior to enabling CCC. This bit field is: <ul style="list-style-type: none"> Read/Write (R/W) when EN = 0 Read only (R) when EN = 1 A time-out value of 0 is reserved and should not be used.
15-8	CC	0-FFh	Command Completions. This bit field specifies the number of command completions that are necessary to cause a CCC interrupt. Software loads this value prior to enabling CCC. This bit field is: <ul style="list-style-type: none"> Read/Write (R/W) when EN = 0 Read only (R) when EN = 1 A value of 0 disables CCC interrupts being generated based on the number of commands completed, that is, CCC interrupts are only generated based on the timer in this case.
7-3	INT	0-1Fh	Interrupt. This bit field specifies the interrupt used by the CCC feature, using the number of ports configured for the core. For a single Port instantiation, INT should be programmed to 1. When a CCC interrupt occurs, the IS.IPS[INT] bit is set to 1.
2-1	Reserved	0	Reserved.
0	EN	0 1	CCC feature enable. When EN = 1, software can not change the bit fields: TV and CC. CCC feature is disabled and no CCC interrupts are generated. CCC feature is enabled and CCC interrupts may be generated based on the time-out or command completion conditions. Note: When EN = 1, software can not change the fields : CCC_CTL.TV and CCC_CTL.CC.

21.4.7 Command Completion Coalescing Ports Register (CCC_PORTS)

The command completion coalescing ports register (CCC_PORTS) specifies the Ports that are coalesced as part of the command completion coalescing (CCC) feature when CCC_CTL.EN = 1. It is reset on Global reset.

The CCC_PORTS register is shown in [Figure 21-8](#) and described in [Table 21-9](#).

Figure 21-8. Command Completion Coalescing Ports Register (CCC_PORTS)

31	Reserved	2	1	0
	R-0			PRT
				R/W-0

LEGEND: R/W = Read/Write; -n = value after reset

Table 21-9. Command Completion Coalescing Ports Register (CCC_PORTS) Field Description

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	PRT	0	This field is bit significant. Each bit corresponds to a particular Port, where bit 0 corresponds to Port 0 and bit 1 corresponds to Port 1. Bits set to 1 must also have the corresponding bit set to 1 in the ports implemented register (PI). The corresponding Port is not part of the CCC feature.
		1	The corresponding Port is part of the CCC feature.

21.4.8 BIST Active FIS Register (BISTAFR)

The BIST active FIS register (BISTAFR) is shown in [Figure 21-9](#) and described in [Table 21-10](#).

Figure 21-9. BIST Active FIS Register (BISTAFR)

31	Reserved			16
R-0				
15	8	7		
NCP			PD	
R-0			R-0	

LEGEND: R = Read only; -n = value after reset

Table 21-10. BIST Active FIS Register (BISTAFR) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-8	NCP	0-FFh	Non-Compliant Pattern. Least significant byte of the received BIST Activate FIS second DWORD (bits [7:0]). This value defines the required pattern for the far-end transmit only modes (PD=80h or A0h). If none of these values are decoded, the simultaneous switching pattern is transmitted by default.
		0-49h	Reserved
		4Ah	High frequency test pattern (HFTP)
		4Bh-77h	Reserved
		78h	Mid frequency test pattern (MFTP)
		79h-7Dh	Reserved
		7Eh	Low frequency test pattern (LFTP)
		7Fh	Simultaneous switching outputs pattern (SSOP)
		80h-8Ah	Reserved
		8Bh	Lone Bit pattern (LBP)
		8Ch-AAh	Reserved
		ABh	Low frequency spectral component pattern (LFSCP)
		ACh-B4h	Reserved
		B5h	High transition density pattern (HTDP)
		B6h-F0h	Reserved
		F1h	Low transition density pattern (LTDP)
F2h-FFh	Reserved		
7-0	PD	0-FFh	Pattern Definition. Indicates the pattern definition field of the received BIST Activate FIS (bits [23:16]) of the first DWORD. It is used to put the SATASS in one of the following BIST modes. All reserved values should not be used by the device; otherwise, the FIS is negatively acknowledged with R_ERRp. For far-end transmit only modes, the NCP bit field contains the required data pattern.
		0-7h	Reserved
		8h	Far-end analog (if PHY supports this mode)
		9h-Fh	Reserved
		10h	Far-end retimed
		11h-7Fh	Reserved
		80h	Far-end transmit only
		81h-9Fh	Reserved
		A0h	Far-end transmit only with scrambler bypassed
		A1h-FFh	Reserved

21.4.9 BIST Control Register (BISTCR)

The BIST control register (BISTCR) is shown in [Figure 21-10](#) and described in [Table 21-11](#).

Figure 21-10. BIST Control Register (BISTCR)

31	Reserved				24
R-0					
23	19	18	17	16	
Reserved		TXO	CNTCLR	NEALB	
R-0		W-0	W-0	R/W-0	
15	11	10	8		
Reserved			LLC		
R-0			R/W-7h		
7	6	5	4	3	0
Reserved	ERREN	FLIP	PV	PATTERN	
R-0	R/W-0	R/W-0	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

Table 21-11. BIST Control Register (BISTCR) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reserved.
18	TXO	0	Transmit Only. This bit is used to initiate transmission of one of the non-compliant patterns defined by the BISTCR.PATTERN value when the device is disconnected.
17	CNTCLR	0	Counter Clear. This bit clears BIST error count registers. Writing a 1 clears BISTFCTR, BISTSR, and BISTDECR registers.
16	NEALB	0 1	Near-end Analog Loopback. Places the Port PHY into near-end analog loopback mode. Near-end analog loopback is not requested. Initiates a near-end analog loopback request. BISTCR.CP field contains the appropriate pattern. This mode should be initiated either in the PARTIAL or SLUMBER power mode, or with the device disconnected from the Port PHY (Link NOCOMM state). BIST Activate FIS is not sent to the device in this mode.
15-11	Reserved	0	Reserved.
10-8	LLC	0-7h 0 1	Link Layer Control. This bit field controls the Port Link Layer functions: scrambler, descrambler, and repeat primitive drop (RPD). In normal mode, the functions scrambler, descrambler, or RPD are changed only during Port reset (POSCTL.DET = 1). Note the different meanings for normal and BIST modes of operation: Bit 10 (RPD): 0 Repeat primitive drop function is disabled in normal mode, enabled in BIST mode. 1 Repeat primitive drop function is enabled in normal mode, disabled in BIST mode. Bit 9 (DESCRAM): 0 Descrambler is disabled in normal mode, enabled in BIST mode. 1 Descrambler is enabled in normal mode, disabled in BIST mode. Bit 8 (SCRAM): 0 Scrambler is disabled in normal mode, enabled in BIST mode. 1 Scrambler is enabled in normal mode, disabled in BIST mode. The SCRAM bit is cleared (enabled) by the Port when the Port enters a responder far-end transmit BIST mode with scrambling enabled (BISTAFR.PD = 80h).
7	Reserved	0	Reserved.
6	ERREN	0 1	Error Enable. Used to allow or filter (disable) PHY internal errors outside the FIS boundary to set corresponding port serial ATA error register (POSERR) bits. 0 Filter errors outside the FIS, allow errors inside the FIS. 1 Allow errors outside or inside the FIS.
5	FLIP	0-1	Flip Disparity. Enables changing disparity of the current test pattern to the opposite every time its state is changed by software.

Table 21-11. BIST Control Register (BISTCR) Field Descriptions (continued)

Bit	Field	Value	Description
4	PV	0 1	<p>Pattern Version. Selects either short or long version of the SSOP, HTDP, LTDP, LFSCP, and COMP patterns.</p> <p>Short pattern version</p> <p>Long pattern version</p>
3-0	PATTERN	0-Fh 0 1h 2h 3h 4h 5h 6h 7h 8h 9h-Fh	<p>Defines one of the following SATA compliant patterns for far-end retimed/ far-end analog/near-end analog initiator modes, or non-compliant patterns for transmit-only responder mode when initiated by software writing to the BISTCR.TXO bit.</p> <p>Simultaneous switching outputs pattern (SSOP)</p> <p>High-transition density pattern</p> <p>Low-transition density pattern</p> <p>Low-frequency spectral component pattern (LFSCP)</p> <p>Composite pattern (COMP)</p> <p>Lone bit pattern (LBP)</p> <p>Mid-frequency test pattern (MFTP)</p> <p>High-frequency test pattern (HFTP)</p> <p>Low-frequency test pattern (LFTP)</p> <p>Reserved.</p>

21.4.10 BIST FIS Count Register (BISTFCTR)

The BIST FIS count register (BISTFCTR) contains the received BIST FIS count in the loopback initiator far-end retimed, far-end analog, and near-end analog modes. It is updated each time a new BIST FIS is received. It is reset by Global reset, Port reset (COMRESET) or by setting the BISTCR.CNTCLR bit. This register does not roll over and freezes when the FFFF FFFFh value is reached. It takes approximately 65 hours of continuous BIST operation to reach this value.

The BISTFCTR register is shown in [Figure 21-11](#) and described in [Table 21-12](#).

Figure 21-11. BIST FIS Count Register (BISTFCTR)

LEGEND: R/W = Read/Write; -n = value after reset

Table 21-12. BIST FIS Count Register (BISTFCTR) Field Description

Bit	Field	Value	Description
31-0	BISTFCTR	0-FFFF FFFFh	Received BIST FIS Count.

21.4.11 BIST Status Register (BISTSR)

The BIST status register (BISTSR) contains errors detected in the received BIST FIS in the loopback initiator far-end retimed, far-end analog, and near-end analog modes. It is not meaningful in responder mode. It is updated each time a new BIST FIS is received. It is reset by Global reset, Port reset (COMRESET) or by setting the BISTCR.CNTCLR bit.

The BISTSR register is shown in [Figure 21-12](#) and described in [Table 21-13](#).

Figure 21-12. BIST Status Register (BISTSR)

LEGEND: R = Read only; W = Write only; -n = value after reset

Table 21-13. BIST Status Register (BISTSR) Field Description

Bit	Field	Value	Description
31-24	Reserved	0	Reserved.
23-16	BRSTERR	0-FFh	Burst Error. This bit field contains the burst error count. It is accumulated each time a burst error condition is detected: DWORD error is detected in the received frame and 1.5 seconds (27,000 frames) passed since the previous burst error was detected. The BRSTERR value does not roll over and freezes at FFh. This bit field is updated if BIST_MODE = DWORD.
15-0	FRAMERR	0-FFFFh	Frame Error. This bit field contains the frame error count. It is accumulated (new value is added to the old value) each time a new BIST frame with a CRC error is received. The FRAMERR value does not roll over and freezes at FFFFh.

21.4.12 BIST DWORD Error Count Register (BISTDECR)

The BIST DWORD error count register (BISTDECR) contains the number of DWORD errors detected in the received BIST frame in the loopback initiator far-end retimed, far-end analog, and near-end analog modes. It is updated each time a new BIST frame is received. It is reset by Global reset, Port reset (COMRESET) or by setting the BISTCR.CNTCLR bit. This register is updated only when the parameter BIST_MODE=DWORD.

The BISTDECR register is shown in [Figure 21-13](#) and described in [Table 21-14](#).

Figure 21-13. BIST DWORD Error Count Register (BISTDECR)

LEGEND: R = Read only; -n = value after reset

Table 21-14. BIST DWORD Error Count Register (BISTDECR) Field Description

Bit	Field	Value	Description
31-0	DWERR	0-FFFF FFFFh	DWORD Error Count. This bit field contains the DWORD error count. It is accumulated (new value is added to the old value) each time a new BIST frame is received. The DWERR value does not roll over and freezes if it exceeds FFFF F000h.

21.4.13 BIST DWORD Error Count Register (TIMER1MS)

The BIST DWORD error count register (TIMER1MS) is used to generate 1ms tick for the command completion coalescing (CCC) logic based on the OCP clock frequency sourced to the SATA controller. Software must initialize this register with the required value after power up before using the CCC feature. This register is reset to 100,000d (corresponding to a VBUS Clock frequency of 100 MHz hclk) on power up and is not affected by Global reset.

The TIMER1MS register is shown in [Figure 21-14](#) and described in [Table 21-15](#).

Figure 21-14. BIST DWORD Error Count Register (TIMER1MS)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-15. BIST DWORD Error Count Register (TIMER1MS) Field Description

Bit	Field	Value	Description
31-20	Reserved	0	Reserved.
19-0	TIMV	0-F FFFFh	1ms Timer Value. This bit field contains the cycle count of the SATA VBUS Clock Cycle generating 1ms tick. This bit field is: <ul style="list-style-type: none"> • Read/Write (R/W) when CCC_CTL.EN = 0 • Read only (R) when CCC_CTL.EN = 1

21.4.14 Global Parameter 1 Register (GPARAM1R)

The global parameter 1 register (GPARAM1R) is a read-only register that contains encoded information about the configuration of the embedded Synopsis AHCI SATA Core.

The GPARAM1R register is shown in [Figure 21-15](#) and described in [Table 21-16](#).

Figure 21-15. Global Parameter 1 Register (GPARAM1R)

31	30	29	28	27	26	24

Table 21-16. Global Parameter 1 Register (GPARAM1R) Field Descriptions

Bit	Field	Value	Description
31	ALIGN_M	1	Rx Data Alignment. Data is always aligned.
30	RX_BUFFER	1	Rx Data Buffer. Core includes an Rx Data Buffer.
29-28	PHY_DATA	0	PHY Data Width. Indicates width = 0 (8-bits).
27	PHY_RST	0	PHY Reset Mode. Indicates that the PHY reset output is active-low.
26-21	PHY_CTRL	1Ah	PHY Control Width. Indicates that there are 32-bits of PHY control.
20-15	PHY_STAT	2h	PHY Status Width. Indicates that there are 32-bits of PHY status.
14	LATCH_M	0	Latch Mode. Indicates that the subsystem does not include latches.
13	BIST_M	0	BIST Loopback Checking Depth. Checks errors per FIS not DWORD.
12	PHY_TYPE	0	PHY Interface Type. Indicates a non-Synopsis PHY.
11	Reserved	0	Reserved.
10	RETURN_ERR	1	AHB Error Response. Indicates AHB Errors are returned.
9-8	AHB_ENDIAN	2h	Bus Endianness. Indicates that endianness may be configured by input pin.
7	S_HADDR	0	Slave address bus width. Indicates 32-bit wide address bus.
6	M_HADDR	0	Master address bus width. Indicates 32-bit wide address bus.
5-3	S_HDATA	0	Slave Data Bus Width. Indicates 32-bit data bus.
2-0	M_HDATA	0	Master Data Bus Width. Indicates 32-bit data bus.

21.4.15 Global Parameter 2 Register (GPARAM2R)

The global parameter 2 register (GPARAM2R) is a read-only register that contains encoded information about the configuration of the embedded Synopsis AHCI SATA Core.

The GPARAM2R register is shown in [Figure 21-16](#) and described in [Table 21-17](#).

Figure 21-16. Global Parameter 2 Register (GPARAM2R)

LEGEND: R = Read only; -n = value after reset

Table 21-17. Global Parameter 2 Register (GPARAM2R) Field Descriptions

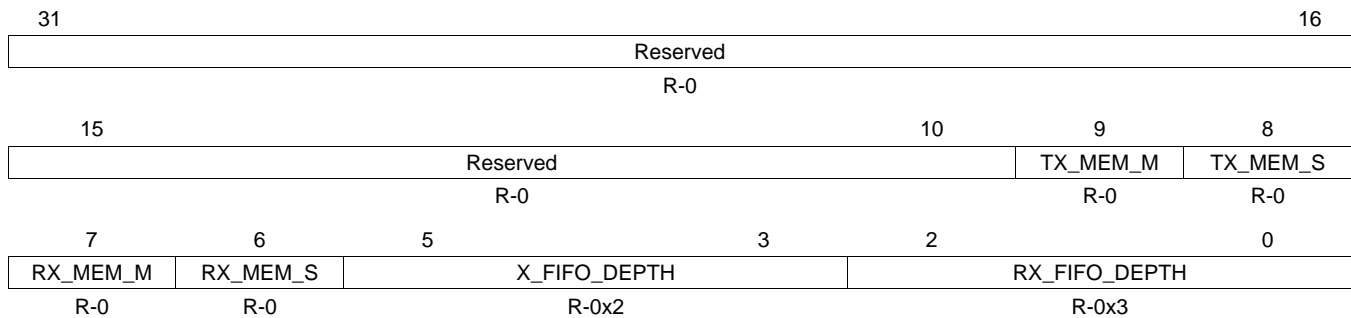

Bit	Field	Value	Description
31-15	Reserved	0	Reserved.
14	DEV_CP	0	Cold Presence Detect. CPD is supported in SATASS.
13	DEV_MP	0	Mechanical Presence Switch. MP is supported in SATASS.
12	ENCODE_M	1	8b/10b Encoding/Decoding. Indicates 8-bit/10-bit encoding and decoding are done in the Synopsis core.
11	RXOOB_CLK_M	0	Rx OOB Clock Mode. Indicates that the Rx OOB Functions are on the Rx Clock.
10	RX_OOB_M	1	Rx OOB Mode. Indicates that Rx Out-of-Band signals are detected in the PHY.
9	TX_OOB_M	1	Tx OOB Mode. Indicates that Tx Out-of-Band signaling is done by the Synopsis Core.
8-0	RXOOB_CLK	96h	Rx OOB Clock Frequency. Reflects the hexadecimal value of the RXOOB_CLK_FREQ parameter.

21.4.16 Port Parameter Register (PPARAMR)

The port parameter register (PPARAMR) is a read-only register that contains encoded information about the selected Port configuration parameters settings. The Port is selected by the TESTR.PSEL field. Note, there are two HBA ports on this sub-system and the configuration setting applies to both ports.

The PPARAMR register is shown in [Figure 21-17](#) and described in [Table 21-18](#).

Figure 21-17. Port Parameter Register (PPARAMR)

LEGEND: R = Read only; -n = value after reset

Table 21-18. Port Parameter Register (PPARAMR) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved.
9	TX_MEM_M	0	Tx FIFO Memory Read Port Type. Indicates that the Tx FIFO memory is asynchronous read.
8	TX_MEM_S	0	Tx FIFO Memory Type. Indicates that the Tx FIFO memory is outside of the core (but still inside the subsystem wrapper).
7	RX_MEM_M	0	Rx FIFO Memory Read Port Type. Indicates that the Rx FIFO memory is asynchronous read.
6	RX_MEM_S	0	Rx FIFO Memory Type. Indicates that the Rx FIFO memory is outside of the core (but still inside the subsystem wrapper).
5-3	TX_FIFO_DEPTH	2h	Tx FIFO Depth. Indicates that the depth of the Tx FIFO is 64 DWORDS.
2-0	RX_FIFO_DEPTH	3h	Rx FIFO Depth. Indicates that the depth of the Rx FIFO is 128 DWORDS.

21.4.17 Version Register (VERSIONR)

The version register (VERSIONR) contains the 32-bit SATASS version.

The VERSIONR register is shown in [Figure 21-18](#) and described in [Table 21-19](#).

Figure 21-18. Version Register (VERSIONR)

LEGEND: R = Read only; -n = value after reset

Table 21-19. Version Register (VERSIONR) Field Description

Bit	Field	Value	Description
31-0	VERSION	3134 302Ah	32-bit version of SATASS.

21.4.18 ID Register (IDR)

The ID register (IDR) contains the 32-bit SATASS ID.

The IDR register is shown in [Figure 21-19](#) and described in [Table 21-20](#).

Figure 21-19. ID Register (IDR)

LEGEND: R = Read only; -n = value after reset

Table 21-20. ID Register (IDR) Field Description

Bit	Field	Value	Description
31-0	ID	4E41 1901h	32-bit ID of SATASS.

21.4.19 Port Command List Base Address Register (P0CLB)

The port command list base address register (P0CLB) contains the 32-bit base address of the command list.

The P0CLB register is shown in [Figure 21-20](#) and described in [Table 21-21](#).

Figure 21-20. Port Command List Base Address Register (P0CLB)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-21. Port Command List Base Address Register (P0CLB) Field Description

Bit	Field	Value	Description
31-10	CLB	0-3F FFFFh	Command List Base Address. Indicates the 32-bit base physical address for the command list for this port. This base is used when fetching commands to execute. The structure pointed to by this address range is 1Kbyte in length. This address must be 1Kbyte-aligned as indicated by bits [9:0] being read-only.
9-0	Reserved	0	Reserved.

21.4.20 Port FIS Base Address Register (P0FB)

The port FIS base address register (P0FB) contains the 32-bit base address of the destination for incoming received FISes.

The P0FB register is shown in [Figure 21-21](#) and described in [Table 21-22](#).

Figure 21-21. Port FIS Base Address Register (P0FB)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-22. Port FIS Base Address Register (P0FB) Field Description

Bit	Field	Value	Description
31-8	FB	0-FF FFFFh	FIS Base Address. Indicates the 32-bit base physical address for received FISes. The structure pointed to by this address range is 256 bytes in length. This address must be 256 byte-aligned as indicated by bits [7:0] being read-only.
7-0	Reserved	0	Reserved.

21.4.21 Port Interrupt Status Register (POIS)

The port interrupt status register (POIS) is used to generate SATASS interrupts when any of the bits are set. Bits in this register are set by some internal conditions, and cleared by software writing ones in the positions it wants to clear. This register is reset on Global reset.

The POIS register is shown in [Figure 21-22](#) and described in [Table 21-23](#).

Figure 21-22. Port Interrupt Status Register (POIS)

31	30	29	28	27	26	25	24	23	22	21	Reserved					16

15	Reserved						8	7	6	5	4	3	2	1	0	
	Reserved						DMPS	PCS	DPS	UFS	SDBS	DSS	PSS	DHRS		
	R-0						RW1C-0	R-0	RW1C-0	R-0	RW1C-0	RW1C-0	RW1C-0	RW1C-0	RW1C-0	

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -n = value after reset

Table 21-23. Port Interrupt Status Register (POIS) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved. Since no dedicated pins for CPD detection/control exist for the device, this bit is reserved. If need to support this feature, use of GPIO is recommended.
30	TFES	0-1	Task File Error Status. This bit is set whenever the P0TFD register is updated by the device and the error bit (P0TFD.STS[0]) is set.
29	HBFS	0-1	Host Bus Fatal Error Status. This bit is set when SATASS bus master detects an ERROR response from the slave.
28	HBDS	0-1	Host Bus Data Error Status. This bit is always cleared to 0.
27	IFS	0-1	Interface Fatal Error Status. This bit is set if any of the following conditions is detected: <ul style="list-style-type: none"> • SYNC escape is received from the device during H2D Register or Data FIS transmission. • One or more of the following errors are detected during Data FIS transfer: Protocol (POSERR.ERR_P), CRC (POSERR.DIAG_C), Handshake (POSERR.DIAG_H), PHY Not Ready (POSERR.ERR_C). • Unknown FIS is received with good CRC, but the length exceeds 64 bytes. • PRD table byte count is zero. Port DMA transitions to a fatal state until software clears P0CMD.ST bit or resets the interface by way of Port or Global reset.
26	INFS	0-1	Interface Non-fatal Error Status. This bit is set if any of the following conditions is detected: <ul style="list-style-type: none"> • One or more of the following errors are detected during non-data FIS transfer: Protocol (POSERR.ERR_P), CRC (POSERR.DIAG_C), Handshake (POSERR.DIAG_H), PHY Not Ready (POSERR.ERR_C). • Command list underflow during read operation (DMA read) when software builds command table that has more total bytes than the transaction given to the device. In both cases, Port operation continues normally. If error is detected during non-data FIS transmission, this FIS is retransmitted continuously until it succeeds or software times out and resets the interface.
25	Reserved	0	Reserved.
24	OFS	0-1	Overflow Status. This bit is set if command list overflow is detected during read or write operation when software builds a command table that has fewer total bytes than the transaction given to the device. Port DMA transitions to a fatal state until software clears P0CMD.ST bit or resets the interface by way of Port or Global reset.
23	IPMS	0-1	Incorrect Port Multiplier Status. Indicates that the HBA received a FIS from a device whose Port Multiplier field did not match what was expected. This bit may be set during enumeration of devices on a Port Multiplier due to the normal Port Multiplier enumeration process. The software should only use the IPMS bit after enumeration is complete on the Port Multiplier.
22	PRCS	0-1	PHY Ready Change Status. When set to 1, indicates the internal PHY Ready signal changed state. This bit reflects the state of the POSERR.DIAG_N bit. To clear this bit, the software must clear the POSERR.DIAG_N bit to 0.
21-8	Reserved	0	Reserved.

Table 21-23. Port Interrupt Status Register (P0IS) Field Descriptions (continued)

Bit	Field	Value	Description
7	DMPS	0-1	Device Mechanical Presence Status. This bit is set when the state of SATA_MP_SWITCH input pin changes as a result of a mechanical switch attached to this port being opened or closed. This bit is only valid if both CAP.SMPS and POCMD.MPSP are set to 1.
6	PCS	0 1	Port Connect Change Status. This bit reflects the state of the P0SERR.DIAG_X bit. This bit is only cleared when P0SERR.DIAG_X is cleared. 0 No change in Current Connect Status 1 Change in Current Connect Status
5	DPS	0-1	Descriptor Processed. A PRD with the I bit set has transferred all of its data. Note: This is an opportunistic interrupt and should not be used to definitely indicate the end of a transfer. Two PRD interrupts could happen close in time together such that the second interrupt is missed when the first PRD interrupt is being cleared.
4	UFS	0-1	Unknown FIS Interrupt. When set to 1, indicates that an unknown FIS was received and has been copied into system memory. This bit is cleared to 0 by software clearing the P0SERR.DIAG_F bit to 0. Note: The UFS bit does not directly reflect the P0SERR.DIAG_F bit. P0SERR.DIAG_F bit is set immediately when an unknown FIS is detected, whereas the UFS bit is set when that FIS is posted to memory. Software should wait to act on an unknown FIS until the UFS bit is set to 1 or the two bits may become out of sync.
3	SDBS	0-1	Set Device Bits Interrupt. A Set Device Bits FIS has been received with the I bit set and has been copied into system memory.
2	DSS	0-1	DMA Setup FIS Interrupt. A DMA Setup FIS has been received with the I bit set and has been copied into system memory.
1	PSS	0-1	PIO Setup FIS Interrupt. A PIO Setup FIS has been received with the I bit set, it has been copied into system memory, and the data related to that FIS has been transferred.
0	DHRS	0-1	Device to Host Register FIS Interrupt. A D2H Register FIS has been received with the I bit set, and has been copied into system memory.

21.4.22 Port Interrupt Enable Register (P0IE)

The port interrupt enable register (P0IE) enables and disables the reporting of the corresponding interrupt to system software. When a bit is set (1), and the corresponding interrupt condition is active, then the SATASS intrq output is asserted. Interrupt sources that are disabled (0) are still reflected in the status registers. This register is symmetrical with the P0IS register. This register is reset on Global reset.

The P0IE register is shown in [Figure 21-23](#) and described in [Table 21-24](#).

Figure 21-23. Port Interrupt Enable Register (P0IE)

31	30	29	28	27	26	25	24	23	22	21	16

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-24. Port Interrupt Enable Register (P0IE) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved. No CPD capability exist since CPD related pins are not bonded out for the device. If need this feature, use of GPIO is recommended.
30	TFEE	0-1	Task File Error Enable. When set to 1, GHC.IE = 1, and P0IS.HBFS = 1, the intrq output is asserted.
29	HBFE	0-1	Host Bus Fatal Error Enable. When set to 1, GHC.IE = 1, and P0IS.HBFS = 1, the interq output is asserted.
28	HBDE	0-1	Host Bus Data Error Enable. When set to 1, GHC.IE = 1, and P0IS.HBDS = 1, the intrq output is asserted.
27	IFE	0-1	Interface Fatal Error Enable. When set to 1, GHC.IE = 1, and P0IS.IFS = 1, the intrq output is asserted.
26	INFE	0-1	Interface Non-fatal Error Enable. When set to 1, GHC.IE = 1, and P0IS.INFS = 1, the intrq output is asserted.
25	Reserved	0	Reserved.
24	OFE	0-1	Overflow Enable. When set to 1, GHC.IE = 1, and P0IS.OFS = 1, the intrq output is asserted.
23	IPME	0-1	Incorrect Port Multiplier Enable. When set to 1, GHC.IE = 1, and P0IS.IPMS = 1, the intrq output is asserted.
22	PRCE	0-1	PHY Ready Change Enable. When set to 1, GHC.IE = 1, and P0IS.PRCS = 1, the intrq output is asserted.
21-8	Reserved	0	Reserved.
7	DMPE	0-1	Device Mechanical Presence Enable. When set to 1, GHC.IE = 1, and P0IS.DMPS = 1, the intrq output is asserted.
6	PCE	0-1	Port Change Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.PCS = 1, the intrq output is asserted.
5	DPE	0-1	Descriptor Processed Interrupt Enable. When set to 1, GHC.IE = 1 and P0IS.DPS = 1, the intrq output is asserted.
4	UFE	0-1	Unknown FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.UFS = 1, the intrq output is asserted.
3	SDBE	0-1	Set Device Bits FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.SDBS = 1, the intrq output is asserted.
2	DSE	0-1	DMA Setup FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.PSS = 1, the intrq output is asserted.
1	PSE	0-1	PIO Setup FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.PSS = 1, the intrq output is asserted.
0	DHRE	0-1	Device Host Register FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.DHRS = 1, the intrq output is asserted.

21.4.23 Port Command Register (POCMD)

The port command register (POCMD) contains bits controlling various Port functions. All read/write bits are reset on Global reset.

The POCMD register is shown in [Figure 21-24](#) and described in [Table 21-25](#).

Figure 21-24. Port Command Register (POCMD)

31		28	27	26	25	24	23	22	21	20	19	18	17	16

LEGEND: R/W = Read/Write; R = Read only; W = Write; W/RO: written once after hard reset by firmware, then remain as read-only; -n = value after reset

Table 21-25. Port Command Register (POCMD) Field Descriptions

Bit	Field	Value	Description
31-28	ICC	0-Fh	Interface Communication Control. Controls power management states of the interface. If the Link layer is currently in the L_IDLE state, writes to this bit field causes the Port to initiate a transition to the interface power management state requested. If the Link layer is not currently in the L_IDLE state, writes to this bit field have no effect. When system software writes a nonreserved value other than No-Op (0), the Port performs the action and updates this bit field back to Idle (0). If software writes to this bit field to change the state to a state the link is already in (that is, interface is in the active state and a request is made to go to the active state), the Port takes no action and returns this bit field to Idle. If the interface is in a low power state and software wants to transition to a different low power state, software must first bring the link to active and then initiate the transition to the desired low power state.
		0	No-Op/ Idle: When software reads this value, it indicates the Port is ready to accept a new interface control command, although the transition to the previously selected state may not yet have occurred.
		1h	Active: Causes the Port to request a transition of the interface into the active state.
		2h	Partial: Causes the Port to request a transition of the interface to the Partial state. The SATA device may reject the request and the interface remains in its current state.
		3h-5h	Reserved
		6h	Slumber: Causes the Port to request a transition of the interface to the Slumber state. The SATA device may reject the request and the interface remains in its current state.
		7h-Fh	Reserved
27	ASP	0	Aggressive Slumber/Partial. When cleared to 0 and POCMD.ALPE = 1, the Port aggressively enters the PARTIAL state when it clears the POCI register, and the P0SACT register is cleared when it clears the P0SACT register and POCI is cleared.
		1	When set to 1 and POCMD.ALPE = 1, the Port aggressively enters the SLUBMER state when it clears the POCI register and the P0SACT register is cleared, or when it clears the P0SACT register and POCI is cleared.
26	ALPE	0	Aggressive Link Power Management Enable. Aggressive power management state transition is disabled.
		1	Port aggressively enters a lower link power state (PARTIAL or SLUBMER) based on the setting of the POCMD.ASP bit.
25	DLAE	0-1	Drive LED on ATAPI Enable. When set to 1, POCMD.ATAPI = 1, and commands are active, the Port asserts P0_act_led output.
24	ATAPI	0-1	Device is ATAPI. When set to 1, the connected device is an ATAPI device. This bit is used by the Port to control whether or not to assert P0_act_led output when commands are active.
23-22	Reserved	0	Reserved.
21	ESP	0	External SATA Port. The ESP bit is mutually exclusive with the POCMD.HPCP bit. Ports signal only connector is not externally accessible.
		1	Ports signal only connector is externally accessible. When set to 1, CAP.SXS is also set to 1.

Table 21-25. Port Command Register (P0CMD) Field Descriptions (continued)

Bit	Field	Value	Description
20	Reserved	0	Reserved. Since no CPD pins are bonded out for the device, this bit should be written with a zero value. If need to implement CPD functionality, GPIO usage is recommended.
19	MPSP	0 1	Mechanical Presence Switch Attached to Port. 0 Platform does not support a mechanical presence switch on this port. 1 Platform supports a mechanical presence switch attached to this port. When this bit is set to 1, P0CMD.HPCP should also be set to 1.
18	HPCP	0 1	Hot Plug. 0 Ports signal and power connectors are not externally accessible. 1 Ports signal and power connectors are externally accessible via a joint signal-power connector for blindmate device hot plug.
17	PMA	0 1	Port Multiplier Attached. Note: Software is responsible for detecting whether a Port Multiplier is present. There is no auto detection. 0 When cleared to 0 by software, indicates that a Port Multiplier is not attached to this Port. 1 When set to 1 by software, indicates that a Port Multiplier is attached to this Port.
16	CPD	0	Since no CPD pins are bonded out for the device, this bit is always zero. if need to implement CPD usage of GPIO is recommended.
15	CR	0-1	Command List Running. When this bit is set to 1, the command list DMA engine for this Port is running. See Synopsys spec for more detail.
14	FR	0-1	FIS Receive Running. When set to 1, the FIS Receive DMA engine for this port is running. Refer to the AHCI specification section 10.3.2 for details on when this bit is set and cleared by the Port.
13	MPSS	0 1	Mechanical Presence Switch State. Reports the state of a mechanical presence switch attached to this port as indicated by the P0_mp_switch input state (assuming CAP.SMPS = 1 and P0CMD.MPSP = 1). If CAP.SMPS = 0, then this bit is cleared to 0. Software should only use this bit if both CAP.SMPS and P0CMD.MPSP are set to 1. Note: The reset of this bit may change based on the SATA_MP_SWITCH state at reset. 0 Switch is closed. 1 Switch is open.
12-8	CCS	0-1Fh	Current Command Slot. This field is valid when P0CMD.ST is set to 1 and is set to the command slot value of the command that is currently being issued by the Port. When P0CMD.ST transitions from 1 to 0, this field is reset to 0x00. After P0CMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command has been issued, the highest priority slot to issue from next is P0CMD.CCS+1. For example, after the Port has issued its first command, if CCS=0x00 and P0CI is set to 0x3, the next command that will be issued is from command slot 1.
7-5	Reserved	0	Reserved.
4	FRE	0-1	FIS Receive Enable. When set to 1, the Port may post received FISes into the FIS receive area pointed to by P0FB. When cleared, received FISes are not accepted by the Port, except for the first D2H register FIS after the initialization sequence, and no FISes are posted to the FIS receive area. System software must not set this bit until P0FB has been programmed with a valid pointer to the FIS receive area, and if software wishes to move the base, this bit must first be cleared, and software must wait for the P0CMD.FR bit to be cleared. Refer to the Synopsis spec for important restrictions on changing P0CMD.FRE.
3	CLO	1	Command List Override. Setting this bit to 1 causes P0TFD.STS.BSY and P0TFD.STS.DRQ to be cleared to 0. This allows a software reset to be transmitted to the device regardless of whether the BSY and DRQ bits are still set in the P0TFD.STS register. This bit is cleared to 0 when P0TFD.STS.BSY and P0TFD.STS.DRQ have been cleared to 0. A write to this register with a value of 0 has no effect. This bit should only be set to 1 immediately prior to setting P0CMD.ST bit to 1 from a previous value of 0. Setting this bit to 1 at any other time is not supported and results in indeterminate behavior.
2	POD	0-1	Power On Device. This bit is RW if cold presence detection is supported on this port as indicated by P0CMD.CPD=1. This bit is RO 1 if cold presence detection is not supported and P0CMD.CPD=0. Note: Since no CPD control/status related pins are bonded out on the device, this bit is read only. Usage of GPIO is recommended if need to supplement CPD feature.
1	SUD	0-1	Spin-Up Device. This bit is read/write if staggered spin-up is supported as indicated by the CAP.SSS = 1. This bit is read-only 1 if staggered spin-up is not supported and CAP.SSS = 0. On an edge detect from 0 to 1, the Port starts a COMRESET initialization sequence to the device. Clearing this bit causes no action on the interface. Note: the SUD bit is read-only 0 on power-up until CAP.SSS bit is written with the required value.

Table 21-25. Port Command Register (P0CMD) Field Descriptions (continued)

Bit	Field	Value	Description
0	ST	0-1	Start. When set to 1, the Port processes the command list. When cleared, the Port does not process the command list. Whenever this bit is changed from a 0 to a 1, the Port starts processing the command list at entry 0. Whenever this bit is changed from a 1 to a 0, the P0CI register is cleared by the Port upon transition into an idle state. Refer to the AHCI specification for important restrictions on when this bit can be set to 1.

21.4.24 Port Task File Data Register (P0TFD)

The port task file data register (P0TFD) contains Error and Status registers updated every time a new Register FIS.

The P0TFD register is shown in [Figure 21-25](#) and described in [Table 21-26](#).

Figure 21-25. Port Task File Data Register (P0TFD)

LEGEND: R = Read only; -n = value after reset

Table 21-26. Port Task File Data Register (P0TFD) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-8	ERR	0-FFh	Error. Contains the latest copy of the task file error register.
7-0	STS	0-FFh	Status. Contains the latest copy of the task file status register. Note: the HBA updates the entire 8-bit field not just the bits listed.
		0	ERR – Indicates an error during the transfer
		1h-2h	Reserved
		3h	DRQ – Indicates a data transfer is requested
		4h-6h	Reserved
		7h	BSY – Indicates the interface is busy
		8h-FFh	Reserved

21.4.25 Port Signature Register (P0SIG)

The port signature register (P0SIG) contains the Device Signature information.

The P0SIG register is shown in [Figure 21-26](#) and described in [Table 21-27](#).

Figure 21-26. Port Signature Register (P0SIG)

LEGEND: R = Read only; -n = value after reset

Table 21-27. Port Signature Register (P0SIG) Field Description

Bit	Field	Value	Description
31-0	SIG	0-FFFF FFFFh	Signature. Contains the signature received from a device on the first D2H Register FIS. This register is updated once after a reset sequence. Reset on Global or Port reset. The bit order as is: Bits 31-24: LBA High (Cylinder High) Register Bits 23-16: LBA Mid (Cylinder Low) Register Bits 15-8: LBA Low (Sector Number) Register Bits 7-0: Sector Count Register

21.4.26 Port Serial ATA Status Register (P0SSTS)

The port serial ATA status register (P0SSTS) conveys the current state of the interface and host. The Port updates it continuously and asynchronously. When the Port transmits a COMRESET to the device, this register is updated to its reset values (i.e., Global reset, Port reset, or COMINIT from the device).

The P0SSTS register is shown in [Figure 21-27](#) and described in [Table 21-28](#).

Figure 21-27. Port Serial ATA Status Register (P0SSTS)

LEGEND: R = Read only; -n = value after reset

Table 21-28. Port Serial ATA Status Register (P0SSTS) Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reserved.
11-8	IPM	0-Fh	Interface Power Management. Indicates the current interface state.
		0	Device is not present or communication is not established.
		1h	Interface in active state
		2h	Interface in Partial power management state.
		3h-5h	Reserved
		6h	Interface in Slumber power management state.
		7h-Fh	Reserved

Table 21-28. Port Serial ATA Status Register (POSSTS) Field Descriptions (continued)

Bit	Field	Value	Description
7-4	SPD	0-Fh 0 1h 2h 3h-Fh	Current Interface Speed. Indicates the negotiated interface communication speed. Device is not present or communication is not established. Generation 1 (1.5 Gbps) negotiated Generation 2 (3 Gbps) negotiated Reserved
3-0	DET	0-Fh 0 1h 2h 3h 4h 5h-Fh	Device Detection. Indicates the interface device detection and PHY state. No device detected and PHY communication is not established. Device presence detected but PHY communication is not established (COMINIT is detected). Reserved Device presence detected and PHY communication is established (PHY Ready is detected). PHY in offline mode as a result of the interface being disabled or running in BIST loopback mode. Reserved

21.4.27 Port Serial ATA Control Register (P0SCTL)

The port serial ATA control register (P0SCTL) is used by software to control SATA interface capabilities. Writes to this register result in an action being taken by the Port PHY interface. Reads from the register return the last value written to it. Reset on Global reset.

These bits are static and should not be changed frequently due to the clock crossing between the Transport and Link Layers. Software must wait for at least seven periods of the slower clock (clk_asic or OCP clock) before changing this register.

The P0SCTL register is shown in [Figure 21-28](#) and described in [Table 21-29](#).

Figure 21-28. Port Serial ATA Control Register (P0SCTL)

31	Reserved	16
	R-0	
15	12 11 8 7 4 3 0	
	Reserved IPM SPD DET	
	R-0 R/W-0 R/W-0 R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-29. Port Serial ATA Control Register (P0SCTL) Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reserved.
11-8	IPM	0-Fh	Interface Power Management Transitions Allowed. Indicates which power states the Port PHY interface is allowed to transition to. If an interface power management state is disabled, the Port does not initiate that state and any request from the device to enter that state is rejected via PMNAKp.
		0	No interface power management state restrictions.
		1h	Transitions to the Partial state are disabled.
		2h	Transitions to the Slumber state are disabled.
		3h	Transitions to both Partial and Slumber states are disabled.
		4h-Fh	Reserved
7-4	SPD	0-Fh	Speed Allowed. Indicates the highest allowable speed of the Port PHY interface. Note: When host software must change this bit field value, the host must also reset the Port (DET = 1) at the same time to ensure proper speed negotiation.
		0	No speed negotiation restrictions.
		1h	Limit speed negotiation to Generation 1 (1.5 Gbps) communication rate.
		2h	Limit speed negotiation to Generation 2 (3 Gbps) communication rate.
		3h-Fh	Reserved
3-0	DET	0-Fh	Device Detection Initialization. Controls the Ports device detection and interface initialization. Note: This bit field may only be modified when P0CMD.ST = 0; changing this bit field while P0CMD.ST = 1 results in undefined behavior. When P0CMD.ST is set to 1, this bit field should have a value of 0.
		0	No device detection or initialization action is requested.
		1h	Perform interface initialization sequence to establish communication. This results in the interface being reset and communication re-initialized.
		2h-3h	Reserved
		4h	Disable the Serial ATA interface and put the Port PHY in offline mode.
		5h-Fh	Reserved

21.4.28 Port Serial ATA Error Register (P0SERR)

The port serial ATA error register (P0SERR) represents all the detected interface errors accumulated since the last time it was cleared. The set bits in the P0SERR register indicate that the corresponding error condition became true one or more times since the last time the bit was cleared. The set bits in this register are explicitly cleared by a write operation to the register, Global reset, or Port reset (COMRESET). The value written to clear the set error bits should have ones encoded in the bit positions corresponding to the bits that are to be cleared. All bits in the following table have a reset value of 0.

The P0SERR register is shown in [Figure 21-29](#) and described in [Table 21-30](#).

Figure 21-29. Port Serial ATA Error Register (P0SERR)

Table 21-30. Port Serial ATA Error Register (P0SERR) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reserved.
26	DIAG_X	0-1	Exchanged. This bit is set to 1 when PHY COMINIT signal is detected. This bit is reflected in the POIS.PCS bit.
25	DIAG_F	0-1	Unknown FIS Type. Indicates that one or more FISes were received by the Transport layer with good CRC, but had a type field that was not recognized/known and the length was less than or equal to 64 bytes. Note: If the Unknown FIS length exceeds 64 bytes, the DIAG_F bit is not set and the DIAG_T bit is set instead.
24	DIAG_T	0-1	Transport State Transition Error. Indicates that a Transport Layer protocol violation was detected.
23	DIAG_S	0-1	Link Sequence Error. Indicates that one or more Link state machine error conditions was encountered. One of the conditions that cause this bit to be set is the device doing SYNC escape during FIS transmission.
22	DIAG_H	0-1	Handshake Error. Indicates that one or more R-ERRp was received in response to frame transmission. Such errors may be the result of a CRC error detected by the device, a disparity or 8-bit/10-bit decoding error, or other error condition leading to a negative handshake on a transmitted frame.
21	DIAG_C	0-1	CRC Error. Indicates that one ore more CRC errors were detected by the Link layer during FIS reception.
20	DIAG_D	0	Disparity Error. This bit is always 0 since it is not used by the AHCI specification.
19	DIAG_B	0-1	10B to 8B Decode Error. Indicates errors were detected by 10b8b decoder. Note: This bit is set only when an error is detected on the received FIS data word. This bit is not set when an error is detected on the primitive, regardless of whether it is inside or outside the FIS.
18	DIAG_W	0-1	Comm Wake. This bit is set when the PHY COMWAKE signal is detected.
17	DIAG_I	0-1	PHY Internal Error. This bit is set when the PHY detects some internal error. Note: The TI PHY does not support any errors so this bit will never be set.
16	DIAG_N	0-1	PHY Ready Change. Indicates that the PHY Ready signal changed state. This bit is reflected in the POIS.PRCs bit.
15-12	Reserved	0	Reserved.

Table 21-30. Port Serial ATA Error Register (P0SERR) Field Descriptions (continued)

Bit	Field	Value	Description
11	ERR_E	0-1	Internal Error. This bit is set to 1 when one or more AHB bus ERROR responses are detected on the master or the slave interfaces.
10	ERR_P	0-1	Protocol Error. This bit is set to 1 when any of the following conditions are detected: <ul style="list-style-type: none"> • Transport state transition error (DIAG_T) • Link sequence error (DIAG_S) • RxFIFO overflow • Link bad end error (WTRM instead of EOF is received)
9	ERR_C	0-1	Non-recovered Persistent Communication Error. This bit is set to 1 when the PHY Ready signal is negated due to the loss of communication with the device or problems with the interface, but not after transition from active to Partial or Slumber power management state.
8	ERR_T	0-1	Non-recovered Transient Data Integrity Error. This bit is set if any of the following P0SERR register bits is set during Data FIS transfer: <ul style="list-style-type: none"> • ERR_P (Protocol) • DIAG_C (CRC) • DIAG_H (Handshake) • ERR_C (PHY Ready negation)
7-2	Reserved	0	Reserved.
1	ERR_M	0-1	Recovered Communication Error. This bit is set to 1 when the PHY Ready condition is detected after interface initialization, but not after transition from partial or Slumber power management state to active state.
0	ERR_I	0-1	Recovered Data Integrity. This bit is set if any of the following P0SERR register bits is set during non-Data FIS transfer: <ul style="list-style-type: none"> • ERR_P (Protocol) • DIAG_C (CRC) • DIAG_H (Handshake) • ERR_C (PHY Ready negation)

21.4.29 Port Serial ATA Active Register (POSACT)

The port serial ATA active register (POSACT) is used to indicate what command slots have commands in them.

The POSACT register is shown in [Figure 21-30](#) and described in [Table 21-31](#).

Figure 21-30. Port Serial ATA Active Register (POSACT)

LEGEND: R/W = Read/Write; W1S = Write 1 to set; -n = value after reset

Table 21-31. Port Serial ATA Active Register (POSACT) Field Description

Bit	Field	Value	Description
31-0	DS[n]	0-1	<p>This field is bit significant. Each bit n corresponds to the TAG and command slot of a native queued command, where bit 0 corresponds to TAG 0 and command slot 0. This field is set by software prior to issuing a native queued command for a particular command slot. Prior to writing POCI[TAG] to 1, software will set DS[TAG] to 1 to indicate that a command with that TAG is outstanding. The device clears bits in this field by sending a Set Device Bits FIS to the Port. The Port clears bits in this field that are set to 1 in the SActive field of the Set Device Bits FIS. The Port only clears bits that correspond to native queued commands that have completed successfully.</p> <p>Software should only write to this bit field when POCMD.ST bit is set to 1. This bit field is cleared when POCMD.ST is written from a 1 to a 0 by software. This bit field is not cleared by a Port reset (COMRESET) or a software reset.</p>

21.4.30 Port Command Issue Register (POCI)

The port command issue register (POCI) is used to indicate what that a command has been constructed and may be carried out.

The POCI register is shown in [Figure 21-31](#) and described in [Table 21-32](#).

Figure 21-31. Port Command Issue Register (POCI)

LEGEND: R/W = Read/Write; W1S = Write 1 to set; -n = value after reset

Table 21-32. Port Command Issue Register (POCI) Field Description

Bit	Field	Value	Description
31-0	CI[n]	0-1	<p>Command Issued. This field is bit significant. Each bit n corresponds to a command slot, where bit 0 corresponds to command slot 0. This bit field is set by software to indicate to the Port that a command has been built in system memory for a command slot and may be sent to the device. When the Port receives a FIS that clears the BSY, DRQ, and ERR bits for the command, it clears the corresponding bit n in this register for that command slot. Bits in this field can only be set to 1 by software when POCMD.ST is set to 1.</p>

21.4.31 Port Serial ATA Notification Register (P0SNTF)

The port serial ATA notification register (P0SNTF) is used to determine if asynchronous notification events have occurred for directly connected devices and devices connected to a Port Multiplier.

The P0SNTF register is shown in [Figure 21-32](#) and described in [Table 21-33](#).

Figure 21-32. Port Serial ATA Notification Register (P0SNTF)

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 21-33. Port Serial ATA Notification Register (P0SNTF) Field Description

Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	PMN[<i>n</i>]	0-1	<p>PM Notify. Indicates whether a particular device with the corresponding PM Port number issued a Set Device Bits FIS to the SATASS Port with the Notification bit set. Individual bits are cleared by software writing 1s to the corresponding bit <i>n</i> positions. This bit field is reset on Global reset, but it is not reset by Port reset (COMRESET) or software reset.</p> <ul style="list-style-type: none"> • PM Port 0 sets bit 0 • PM Port 1 sets bit 1 <p>Note that two different types of ports exist. HBA Port (the device has the support for 2 HBA Ports) and Port Multiplier Port (PMP). A Port of a Port Multiplier (PMP) connects a single device to a PM. As many as 15 devices can be connected to a single HBA Port.</p>

21.4.32 Port DMA Control Register (P0DMACR)

The port DMA control register (P0DMACR) contains bits for controlling the Port DMA engine. The software can change the fields of this register only when P0CMD.ST=0. Power-up (system reset), Global reset, or Port reset (COMRESET) reset this register to the default value.

The P0DMACR register is shown in [Figure 21-33](#) and described in [Table 21-34](#).

Figure 21-33. Port DMA Control Register (P0DMACR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-34. Port DMA Control Register (P0DMACR) Field Description

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-12	RXABL	0-Fh 0 1h 2h 3h 4h 5h 6h 7h 9h-Fh	Receive Burst Limit. Allows software to limit the OCP master write burst size. Note: SATASS master breaks the burst at 1Kbyte address boundaries regardless of the RXABL value. Limit OCP burst size to 256 DWORDS Limit OCP Burst size to 1 DWORD Limit OCP Burst size to 2 DWORDS Limit OCP Burst size to 4 DWORDS Limit OCP Burst size to 8 DWORDS Limit OCP Burst size to 16 DWORDS Limit OCP Burst size to 32 DWORDS Limit OCP Burst size to 64 DWORDS Limit OCP Burst size to 256 DWORDS Note: The maximum sized burst that will be issued on the OCP is 64 bytes; for this reason higher programmed values than 0x7 will still result with 64 bytes burst. Note: This field is read-write when P0CMD.ST=0 and read-only when P0CMD.ST=1.
11-8	TXABL	0-Fh 0 1h 2h 3h 4h 5h 6h 7h 9h-Fh	Transmit Burst Limit. This field allows software to limit the OCP master read burst size. This bit field is read/write when P0CMD.ST = 0 and read-only when P0CMD.ST = 1. Note: SATASS master breaks the burst at 1Kbyte address boundaries regardless of the TXABL value. Limit OCP burst size to 256 DWORDS Limit OCP Burst size to 1 DWORD Limit OCP Burst size to 2 DWORDS Limit OCP Burst size to 4 DWORDS Limit OCP Burst size to 8 DWORDS Limit OCP Burst size to 16 DWORDS Limit OCP Burst size to 32 DWORDS Limit OCP Burst size to 64 DWORDS Limit OCP Burst size to 256 DWORDS Note: The maximum sized burst that will be issued on the OCP is 64 bytes; for this reason higher programmed values than 0x7 will still result with 64 bytes burst.

Table 21-34. Port DMA Control Register (P0DMACR) Field Description (continued)

Bit	Field	Value	Description
7-4	RXTS	0-Fh	Receive Transaction Size (RX_TRANSACTION_SIZE). This field defines the Port DMA transaction size in DWORDs for receive (system bus write, device read) operation. This bit field is read/write when P0CMD.ST = 0 and read-only when P0CMD.ST = 1. The maximum value of this bit field is determined by the Rx FIFO Depth (P0_RXFIFO_DEPTH). If software attempts to write a value exceeding this maximum value, the maximum value would be set instead.
		0	1 DWORD
		1h	2 DWORDs
		2h	4 DWORDs

13	RXTRIM_CALIB	0 1	RX trimming control to the calibration block In function mode eFuse training mode
12	RXTRIM_BYPASS_CTRL	0 1	res_nwell settings are controlled by fuse/calib settings RXTRIM[4:0] res_nwell settings are controlled by cfg_ctrl[11:7](CFGRX_1[11:7])
11-7	RXTRIM_BYPASS_BITS	0 1	Bypass bits for RXTRIM[4:0] when CFGRX_1[12]=1
6	BYPASS_CALOUT_AVG	0 1	For calibration --> Bypasses the averaging filter for the calout signal inside digital Use the output of the digital filter for CALOUT Ignore the output of the digital filter and use the output from the bubble removal circuit for CALOUT
5	CTG_DIG_RSVD1		Clock inversion for rpclk. In X2256, this was mapped to ctl_dig_rsvd[1]. This is a temporary mapping.
4	CTG_DIG_RSVD0		Clock inversion for fclk. In X2256, this was mapped to ctl_dig_rsvd[0]. This is a temporary mapping.
3	ENTEST		Read-only and reflects the value on the serdes_testpatt_p0_entestrx input. The value of the input is driven to the phy's ENTEST field
2-0	TESTPATT		Read-only and reflects the value on the serdes_testpatt_p0_testpatt input. The value of the input is driven to the phy's TESTPATT field

21.4.36 PHY Configuration Receive 2 Register (CFGRX2)

The PHY configuration receive 2 register (CFGRX2) is used to program the phy CFGRX2 bus. It is shown and described in the figure and table below.

Figure 21-37. PHY Configuration Receive 2 Register (CFGRX2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-38. PHY Configuration Receive 2 Register (CFGRX2) Field Descriptions

Bit	Field	Value	Description
31-27	SAMP_BYPASS_SAD1		Bypass bits for SAD1[4:0] when CFG_CTRL[94](CFGRX_3[30]) = 1
26-22	SAMP_BYPASS_SAT0		Bypass bits for SAT0[4:0] when CFG_CTRL[94](CFGRX_3[30]) = 1
21-17	SAMP_BYPASS_SAD0		Bypass bits for SAD0[4:0] when CFG_CTRL[94](CFGRX_3[30]) = 1
16-12	SAMP_BYPASS_SAT1		Bypass bits for SAT1[4:0] when CFG_CTRL[94](CFGRX_3[30]) = 1
11-0	RESERVED		Reserved

21.4.37 PHY Configuration Receive 3 Register (CFGRX3)

The PHY configuration receive 3 register (CFGRX3) is used to program the phy CFGRX3 bus. It is shown and described in the figure and table below.

Figure 21-38. PHY Configuration Receive 3 Register (CFGRX3)

21.4.39 Receive Bus PHY-to-Controller Status Register (Phy STSRX)

The receive bus PHY-to-controller status register (Phy STSRX) is used to observe the phy STSRX bus. It is shown and described in the figure and table below.

Figure 21-40. Receive Bus PHY-to-Controller Status Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-41. Receive Bus PHY-to-Controller Status Register Field Descriptions

Bit	Field	Value	Description
31-16	Reserved		Reserved; driven low
15-11	RX_RTRIM		Trim bits for RX resistor
10	RX_CALOUT_D		CalOut after the digital filter
9	RX_CALOUT_A		CalOut coming from analog
8-7	Reserved		Reserved, driven low.
6	OCIP		Offset Compensation in Progres. Driven high asynchronously during offset compensation
5	BSRXN		Boundary scan data. Reflects the state of the comparator attached to RXNi when IEEE1149.6 boundary scan is enabled. Driven low otherwise.
4	BSRXP		Boundary scan data. Reflects the state of the comparator attached to RXPi when IEEE1149.6 boundary scan is enabled. Driven low otherwise.
3	LOSDTCT		Loss of Signal detect. Driven high asynchronously when a loss of signal (electrical idle) condition is detected for channel i.
2	ODDCG		Odd code group. Low when SYNC is high. Thereafter, it toggles every cycle, so that it is high during odd numbered code groups (the code group output when SYNC is high is defined as code group 0). Synchronous to RXBCLKIN[i].
1	SYNC		Symbol alignment. When comma detection is enabled, this output is high when an aligned comma is received, in the same cycle that the comma pattern is output on RD _i . Alternatively, when an alignment jog is requested, it is high to indicate that the request has been completed. Synchronous to RXBCLKIN[i].
0	TESTFAIL		Test failure. Driven high when an error is encountered during a test sequence executed on channel i. Synchronous to RXBCLKIN[i].

21.4.40 PHY Configuration Transmit 0 Register (CFGTX0)

The PHY configuration transmit 0 register (CFGTX0) is used to program the phy CFGTX0 bus. It is shown and described in the figure and table below.

Figure 21-41. PHY Configuration Transmit 0 Register (CFGTX0)

Table 21-42. PHY Configuration Transmit 0 Register (CFGTX0) Field Descriptions

Bit	Field	Value	Description
31-30	LOOPBACK		Not Used. The RX has similar settings, hence this field is not used.
29-28	CAL_FILTER_DEPTH	00 01 10 11	For calibration --> Average engine can be programmed to have depth of 7,15, 31. Depth of 7 samples Depth of 15 samples Depth of 31 samples Depth of 7 samples
27	RESERVED		Reserved
26-25	DET_CTL		Receiver detect control. Controls PCI-E receiver detect.
24	ENIDL		Read-only and reflects the value being driven to the phy's ENIDL field. This bit is 0 during normal operation and 1 when idle is enabled by either partial mode, no valid data, or for OOB signaling.
23-22	RESERVED		Reserved ; driven low
21-19	TM_EXTRA_LOAD	0 1	TestMode. Default is 000 : auto program dummy load based on mode. [19] -> '1': Enable different extraload resistors to make driver constant current at speed. Current level defined in CFGTX_2[26:25] [20] -> '1': Enable static dummy load during electrical idle. Load current level defined in CFGTX_2[28:27] [21] -> '1': Enable switching dummy load during electrical idle. Load current level defined in CFGTX_2[30:29]
18	RESERVED		Reserved- drive low

Table 21-42. PHY Configuration Transmit 0 Register (CFGTX0) Field Descriptions (continued)

Bit	Field	Value	Description
17-13	DEEMP		De-emphasis. Selects one of output de-emphasis settings from 0 to 50.2% For PCIE Value --> Amplitude Reduction (%) --> Amplitude Reduction (dB) 00000 --> 0 --> 0 00001 to 01111 --> 33.7 --> -3.57 10000 to 11111 --> 50.2 --> -6.05 For eSATA - FULL RATE (CFGTX_0[6:5]=00) Value --> Amplitude Reduction (%) --> Amplitude Reduction (dB) 00000 --> 0 --> 0 00001 to 01111 --> 10 --> -1 10000 to 11111 --> 25 --> -2.5 For eSATA - HALF RATE (CFGTX_0[6:5]=01) Value --> Amplitude Reduction (%) --> Amplitude Reduction (dB) 00000 --> 0 --> 0 00001 to 01111 --> 10 --> -1 10000 to 11111 --> RESERVED --> RESERVED
12-9	SWING		TX Output swing selection. Selects one of output amplitude settings. For PCIE Value --> Amplitude (mVdftp) --> ANA {swingsel,swing[1:0]} 0000 --> 148 (half) --> 111 0001 --> 148 (half) --> 111 0010 --> 258 (half) --> 110 0011 --> 258 (half) --> 110 0100 --> 295 (full/half) --> 101 0101 --> 295 (full/half) --> 101 0110 --> 516 (full/half) --> 100 0111 --> 516 (full/half) --> 100 1000 --> 774 (full/half) --> 001 1001 --> 774 (full/half) --> 001 1010 --> 1069 (full/half) --> 000 1011 --> 1069 (full/half) --> 000 1100 --> 1069 (full/half) --> 000 1101 --> 1069 (full/half) --> 000 1110 --> 1069 (full/half) --> 000 1111 --> 1069 (full/half) --> 000 For eSATA Only 516mV (for Gen1) and 590mV (for Gen2) swing value is supported in SATA mode and all the codes above will map to this in TXA
8	RESERVED		Reserved
7	INVPAIR	0 1	Inverts polarity of TXPi and TXNi. 0 Normal Polarity. TXP is positive data 1 Inverted Polarity. TXN is positive data
6-5	RATE		Read-only and reflects the value being driven to the phy's RATE field. Controlled by hardware and determined by the speed at which the link is operating.

Table 21-42. PHY Configuration Transmit 0 Register (CFGTX0) Field Descriptions (continued)

Bit	Field	Value	Description
4-2	BUSWIDTH	000	Selects the parallel interface width (8 or 10 bit). Only 10-bit mode will be used. 10-bit operation Any value other than 000 is reserved.
1	ENTXLDO	0 1	Enables TX Analog LDO when high. When ENTXLDO='0', TX Analog circuits will be powered down. TXLDO has to be enabled and allowed to settle prior to enabling the transmitter with ENTX. 0 Disabled 1 Enabled
0	ENTX	0 1	Read-only and reflects the value being driven to the ENTX of the phy. This bit is controlled by hardware. 0 Transmit domain is in reset or when in slumber mode 1 Transmitter enabled

21.4.41 PHY Configuration Transmit 1 Register (CFGTX1)

The PHY configuration transmit 1 register (CFGTX1) is used to program the phy CFGTX1 bus. It is shown and described in the figure and table below.

Table 21-43. PHY Configuration Transmit 1 Register (CFGTX1) Field Descriptions

Bit	Field	Value	Description
31-28	TRIM_HIGH_THRESHOLD		For calibration --> 4-b programmable threshold Unless the difference between the previous and new trim code required exceeds 4-b threshold, trim bit will be updated in one shot. Otherwise the trim bits will be updated in steps determined by TRIM_STEP_CHANGE.
27	TX_DISABLE_ON_THE_FLY	0 1	For calibration --> Disables the pattern match. Updates can only be made through electrical idle or TX_FORCE_UPDATE bit. Enables pattern match Disables pattern match
26	TX_FORCE_UPDATE	0 1	For calibration --> Forces the update to be made to the Analog trim bits without looking for any specific data pattern or electrical idle. Disables forced update. Enables forced update Can be written DYNAMIC.
25	TX_TRIM_BYPASS	0 1	For calibration --> Bypasses the trim bits generated from the calibration algorithm Use the trim code generated by trx_dig Bypass the trim code generated by trx_dig
24	TRIM_2B_MODE	0 1	For calibration --> Enables 2-b data pattern detection mode for trim updates. 2-b detection mode, e.g. "00" or "11" 3-b detection mode, e.g. "00" or "111"
23	RESERVED		Reserved
22-21	TRIM_STEP_CHANGE	00 01 10 11	For calibration --> Step change value for staircase logic make updates in steps of 1 make updates in steps of 2 make updates in steps of 4 make updates in steps of 8

Table 21-43. PHY Configuration Transmit 1 Register (CFGTX1) Field Descriptions (continued)

Bit	Field	Value	Description
20-19	TRIM_LOW_THRESHOLD	00	For calibration --> 2-b programmable threshold. make updates only when diff is >= 1
		01	make updates only when diff is >= 2
		10	make updates only when diff is >= 3
		11	make updates only when diff is >= 4
			Unless the difference between the previous and current trim code exceeds or equals above mentioned threshold, no updates trim bit updates are made in Analog.
18-17	CALIB_WAIT_CYCLES	0	For calibration --> 2-b programmable number of wait cycles before polling the calout signal Additional clock cycle delay of 1 MHz clock
		1	Additional clock cycle delay of 1 MHz clock
		2	Additional clock cycle delay of 1 MHz clock
		3	Additional clock cycle delay of 1 MHz clock
16	ENABLE_LOOP_DELAY	0	For calibration --> Enables the additional loop delay of 40 clock cycles before sweeping the trim code during the calibration Disables the loop delay
			1 Enables the loop delay, ensures at least 32-clock cycles between two full cycles of trim code sweep
15	BYPASS_CALOUT_AVG	0	For calibration --> Bypasses the averaging filter for the callout signal inside digital Use the output of the digital filter for CALOUT
		1	Ignore the output of the digital filter and use the output from the bubble removal circuit for CALOUT.
14	Reserved		Reserved; driven low.
13	ENBSPLS		This field is read only and reflects the value on the serdes_bscan_ctrl_p0_enspspt input. The value of the input is what is driven to the phy's ENBSPT field
12	ENBSRX		This field is read only and reflects the value on the serdes_bscan_ctrl_p0_ensbrx input. The value of the input is what is driven to the phy's ENBSRX field.
11	ENBSTX		This field is read only and reflects the value on the serdes_bscan_ctrl_p0_ensbtx input. The value of the input is what is driven to the phy's ENBSTX field.
10	BSINITCLK		This field is read only and reflects the value on the serdes_bscan_clk_p0_bsinitclk input. The value of the input is what is driven to the phy's BSINITCLK field.
9	BSINRXN		This field is read only and reflects the value on the serdes_bscan_p0_bsinrxn input. The value of the input is what is driven to the phy's BSINRXN field.
8	BSINRXP		This field is read only and reflects the value on the serdes_bscan_p0_bsinrxp input. The value of the input is what is driven to the phy's BSINRXP field.
7	TSYNC_ENABLE		In x2256: was mapped to CFGTX_0 [21] In x2282: DO NOT USE
6	ENTEST		This field is read only and reflects the value on the serdes_testpatt_p0_entesttx input. The value of the input is what is driven to the phy's ENTST field.
5	BSTX		This field is read only and reflects the value on the serdes_bscan_p0_bstx input. The value of the input is what is driven to the phy's BSTX field.
4-2	TESTPATT		Not Used. The RX has similar settings, hence this field is not used.
1	USE_STAIRCASE	0	For calibration Disables staircase logic for trim code change
		1	Enables staircase logic for trim code change
0	ENLFPS		DO NOT USE: Drive Low

21.4.42 PHY Configuration Transmit 2 Register (CFGTX2)

The PHY configuration transmit 2 register (CFGTX2) is used to program the phy CFGTX2 bus. It is shown and described in the figure and table below.

Figure 21-43. PHY Configuration Transmit 2 Register (CFGTX2)

3-1	TRIM_MODE		TRIM_MODE[2:0]
0	HYST_DISABLE		HYST_DISABLE_Z and CALOUT_TX

21.4.45 Transmit Bus Controller-to-PHY Status Register

The transmit bus controller-to-PHY status register is shown and described in the figure and table below.

Figure 21-46. Transmit Bus Controller-to-PHY Status Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-47. Transmit Bus Controller-to-PHY Status Register Field Descriptions

Bit	Field	Value	Description
31-10	Reserved		Reserved; driven low.
9	TX_CALOUT_D		CalOut after the digital filter
8	TX_CALOUT_A		CalOut coming from analog
7-3	TX_RTRIM		Trim bits for TX resistor
2	Reserved		Reserved; driven low.
1	RDTCTIP		Receiver detect in progress. Driven high synchronous to TXBCLKIN[i] when PCI-E receiver detection starts for channel i, and deasserted synchronous to TXBCLKIN[i] when the TXPi and TXNi common mode returns to normal (or when receiver detection disabled).
0	TESTFAIL		Test failure. Driven high when an error is encountered during a test sequence executed on channel i, or if an over or underflow occurs in the Tx serializer when ENFTP = 0. Synchronous to TXBCLKIN[i].

21.5 SATA PLL Registers

The PLL that clocks the SERDES is controlled through a register space that is different from the SATA Controller and the PHY. Dedicated registers that pertain to SATA exist within the control module space.

The Base address for the SATA PLL configuration registers is 4814_0000h.

Table 21-48. SATA PLL Controller Registers

Address Offset	Acronym	Register Description	Section
720h	SATA_PLLCFG0	SATA SerDes PLL Configuration Register 0	Section 21.5.1

21.5.1 SATA PLL Configuration 0 Register (SATA_PLLCFG0)

The register access is determined by the state of the lock bit. When the lock bit is 0 and the module is in NonSec Priv mode, bit access is Read/Write as shown in [Figure 21-47](#). Otherwise, bit access is read only. When the lock bit is set to 1, the register is not accessible.

The SATA_PLLCFG0 register is shown in [Figure 21-47](#) and described in [Table 21-49](#).

21.5.6 SATA PLL Status (SATA_PLLSTATUS)

The SATA PLL status register (SATA_PLLSTATUS) is used to reflect the SATA PLL status.

The register access is affected by the state of the lock bit. When the lock bit is set to 0, access is read only. When the lock bit is set to 1, the register is not accessible.

The SATA_PLLSTATUS register is shown in [Figure 21-52](#) and described in [Table 21-54](#).

Figure 21-52. SATA PLL Status (SATA_PLLSTATUS)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-54. SATA PLL Status (SATA_PLLSTATUS) Field Description

Bit	Field	Value	Description
31-12	Reserved		Reserved
11-8	RTRIMSTS		Value of the rtrim loop (may not be static in Continuous mode of operation)
7-4	VTUNESTS		Value of the vtune control loop (may not be static in Continuous mode of operation)
3	APLLDIGSTS5		Not used
2	APLLDIGSTS4		Not used
1	APLLDIGSTS1		SSC is engaged
0	APLLDIGSTS0		APLL is locked

21.5.7 SATA Receive Status (SATA_RXSTATUS)

The SATA receive status register (SATA_RXSTATUS) is used to reflect the SATA receive status.

The register access is affected by the state of the lock bit. When the lock bit is set to 0, access is read only. When the lock bit is set to 1, the register is not accessible.

The SATA_RXSTATUS register is shown in [Figure 21-53](#) and described in [Table 21-55](#).

Figure 21-53. SATA Receive Status (SATA_RXSTATUS)

Table 21-55. SATA Receive Status (SATA_RXSTATUS) Field Description

Bit	Field	Value	Description
31-1	Reserved		Reserved
0	TESTFAIL		Test failure. Driven high when an error is encountered during a test sequence executed on channel i. Synchronous to RXBCLKIN[j].

21.5.8 SATA Transmit Status (SATA_TXSTATUS)

The SATA transmit status register (SATA_TXSTATUS) is used to reflect the SATA transmit status.

The register access is affected by the state of the lock bit. When the lock bit is set to 0, access is read only. When the lock bit is set to 1, the register is not accessible.

The SATA_TXSTATUS register is shown in [Figure 21-54](#) and described in [Table 21-56](#).

Figure 21-54. SATA Transmit Status (SATA_TXSTATUS)

Bit	Field	Value	Description
31-1	Reserved		Reserved
0	TESTFAIL		Test failure. Driven high when an error is encountered during a test sequence executed on channel i, or if an over or underflow occurs in the Tx serialiser when ENFTP = 0 (see section 7.3.3). Synchronous to TXBCLKIN[i].

21.5.9 SATA TEST Configuration (SATA_TESTCFG)

The SATA test configuration register (SATA_TESTCFG) is used to control ??.

The register access is determined by the state of the lock bit. When the lock bit is 0 and the module is in NonSec Priv mode, bit access is Read/Write as shown in [Figure 21-55](#). Otherwise, bit access is read only. When the lock bit is set to 1, the register is not accessible.

The SATA_TESTCFG register is shown in [Figure 21-55](#) and described in [Table 21-57](#).

6-3	Reserved		Reserved
0	RX_TESTPATT		Enables and selects test patterns.
		000	Reserved
		001	An alternating 0/1 pattern with a period of 2 UI.
		010	Uses a 7-bit LFSR with feedback polynomial x^7+x^6+1 .
		011	Uses a 23-bit LFSR with feedback polynomial $x^{23}+x^{18}+1$.
		100	Uses a 31-bit LFSR with feedback polynomial $x^{31}+x^{28}+1$.
		101	Reserved
		110	Reserved
		111	Reserved

21.6 SATA Subsystem Registers

The following PRCM Registers are used to release the SATA Controller from Reset. These registers are found within the PRCM module.

The Base address for the PRCM module is 4818_0000h.

Table 21-58. SATA Subsystem Controller Registers

Address Offset	Acronym	Register Description	Section
504h	CM_DEFAULT_L3_MED_CLKSTCTRL	Clock Domain Power Control Register	Section 21.6.1
560h	CM_ALWON2_SATA_CLKCTRL	SATA Clock Management/Control Register	Section 21.6.2

21.6.1 Clock Domain Power Control Register (CM_DEFAULT_L3_MED_CLKSTCTRL)

The clock domain power control register (CM_DEFAULT_L3_MED_CLKSTCTRL) enables the domain power state transition. It controls the software-supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also holds one status bit per clock input of the domain.

The CM_DEFAULT_L3_MED_CLKSTCTRL register is shown in [Figure 21-56](#) and described in [Table 21-59](#).

			R/W-1h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

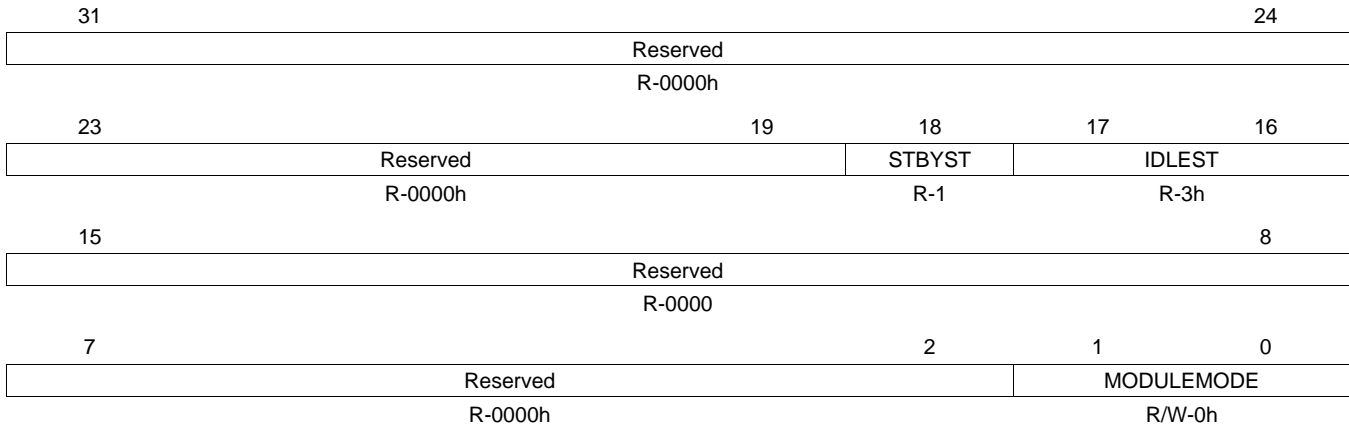

Table 21-59. Clock Domain Power Control Register (CM_DEFAULT_L3_MED_CLKSTCTRL) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved		Reserved
8	CLKACTIVITY_L3_MED_GCLK	0 1	This field indicates the state of the L3_SLOW_GCLK clock in the domain. Corresponding clock is gated. Corresponding clock is active.
7-2	Reserved		Reserved
1-0	CLKTRCTRL	0h 1h 2h 3h	Controls the clock state transition of the L3_MED clock domain in DEFAULT power domain. NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. SW_SLEEP: Start a software forced sleep transition on the domain. SW_WKUP: Start a software forced wake-up transition on the domain. HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions

21.6.2 Clock Domain SATA Control Register (CM_DEFAULT_SATA_CLKCTRL)

The clock domain SATA control register (CM_DEFAULT_SATA_CLKCTRL) manages the SATA clocks. The CM_DEFAULT_SATA_CLKCTRL register is shown in [Figure 21-57](#) and described in [Table 21-60](#).

Figure 21-57. Clock Domain SATA Control Register (CM_DEFAULT_SATA_CLKCTRL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 21-60. Clock Domain SATA Control Register (CM_DEFAULT_SATA_CLKCTRL) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved		Reserved
18	STBYST	0 1	Module standby status Module is functional (not in standby). Module is in standby.
17-16	IDLEST	0h 1h 2h 3h	Module idle status Module is fully functional, including OCP. Module is performing transition: wakeup, or sleep, or sleep abortion. Module is in Idle mode (only OCP part). It is functional if using separate functional clock. Module is disabled and cannot be accessed.
15-2	Reserved		Reserved
1-0	MODULEMODE	0h 1h 2h 3h	Controls the way mandatory clocks are managed. Module is disable by software. Any OCP access to the module results in an error, except if resulting from a module wakeup (asynchronous wakeup). Reserved Module is explicitly enabled. Interface clock (if not used for functions) can be gated according to the clock domain state. Functional clocks will stay present. As long as in this configuration, power domain sleep transition cannot happen. Reserved

Serial Port Interface (SPI)

This chapter describes the master/slave multichannel serial port interface (SPI) module.

22.2 Architecture	2521
22.3 SPI Registers	2559

22.1 Introduction

22.1.1 Overview

SPI is a general-purpose receive/transmit master/slave controller that can interface with up to four slave external devices or one single external master. It allows a duplex, synchronous, serial communication between a CPU and SPI compliant external devices (slaves and masters). Figure 22-1 shows a high-level overview of a SPI system.

Figure 22-1. SPI System Overview

22.1.2 Features

The SPI includes these distinctive features:

- Serial clock with programmable frequency, polarity and phase
- It supports maximum frequency of 48 MHz.
- Clock frequency granularity can be changed: power of two or one single clock cycle.
- SPI enable generation programmable
- SPI enable with programmable polarity
- Wide selection of SPI word lengths ranging from 4 bits to 32 bits
- Master / Slave modes
- Master multichannel mode:
 - SPI interface provides supports for up to four SPI channels
 - SPI word Transmit / Receive slot assignment based on round robin arbitration
 - SPI configuration per channel (clock definition, enable polarity and word width)
 - Full duplex/half duplex
 - Transmit-only/receive-only/transmit-and-receive modes
 - Flexible I/O port controls per channel
 - Programmable clock granularity
- Independent DMA requests (read/write) per channel

- Single interrupt line for multiple interrupt source events
- 32-bit-wide bus, for system configuration and data transfer
- Programmable delay before the first SPI word transmitted
- No dead cycle between two successive words in slave mode
- Multiple SPI word access with a channel using a FIFO enabled
- Programmable timing control between chip select and external clock generation
- Support DMA providing 256 bit aligned addresses when FIFO is used
- Built-in FIFO available for a single channel. FIFO size of up to 64 bytes is supported.

22.2 Architecture

22.2.1 SPI Interface

This section lists the name and description of the SPI interface used for connection to external SPI compliant devices. SPI has a total of seven external SPI signals shown in [Table 22-1](#).

Table 22-1. SPI Interface Pins

Pin	Type	Description
SPI_SCLK	I/O	SPI serial clock (output when master, input when slave)
SPI_D[0]	I/O	Can be configured as either input or output (MOSI or MISO)
SPI_D[1]	I/O	Can be configured as either input or output (MOSI or MISO)
SPI_SCS[0]	I/O	SPI chip select 0 output when master, input when slave (active low)
SPI_SCS[1]	I/O	SPI chip select 1 output when master, input when slave (active low)
SPI_SCS[2]	I/O	SPI chip select 2 output when master, input when slave (active low)
SPI_SCS[3]	I/O	SPI chip select 3 output when master, input when slave (active low)

22.2.2 SPI Transmission

This section describes the transmissions supported by SPI. The SPI protocol is a synchronous protocol that allows a master device to initiate serial communication with a slave device. Data is exchanged between these devices. A slave select line ($SPI_SCS[n]$) can be used to allow selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities. Connected to multiple external devices, SPI exchanges data with a single SPI device at a time through two main modes:

- Two data pins interface mode. (See [Section 22.2.2.1](#))
- Single data pin interface mode (recommended for half-duplex transmission). (See [Section 22.2.2.2](#))

The flexibility of SPI allows exchanging data with several formats through programmable parameters described in [Section 22.2.2.3](#).

22.2.2.1 Two Data Pins Interface Mode

The two data pins interface mode, allows a full duplex SPI transmission where data is transmitted (shifted out serially) and received (shifted in serially) simultaneously on separate data lines SPI_D[0] and SPI_D[1]. Data leaving the master exits on transmit serial data line also known as MOSI: MasterOutSlaveIn. Data leaving the slave exits on the receive data line also known as MISO: MasterInSlaveOut.

SPI has a unified SPI port control: SPI_D[1:0] can be independently configured as receive or transmit lines. The user has the responsibility to program which data line to use and in which direction (receive or transmit), according to the external slave/master connection.

The serial clock (SPI_SCLK) synchronizes shifting and sampling of the information on the two serial data lines (SPI_D[1:0]). Each time a bit is transferred out from the Master, one bit is transferred in from Slave.

Figure 22-2 shows an example of a full duplex system with a Master device on the left and a Slave device on the right. After 8 cycles of the serial clock SPI_SCLK, the WordA has been transferred from the master to the slave. At the same time, the WordB has been transferred from the slave to the master.

When referring to the master device, the control block transmits the clock SPI_SCLK and the enable signal (SPI_SCS[n]) (optional depends on MCSPI_MODULECTRL[PIN34] bit field).

Figure 22-2. SPI Full-Duplex Transmission

22.2.2.2 Single Data Pin Interface Mode

In single data pin interface mode, under software control, a single data line is used to alternatively transmit and receive data (Half duplex transmission).

SPI has a unified SPI port control: SPI_D[1:0] can be independently configured as receive or transmit lines. The user has the responsibility to program which data line to use and in which direction (receive or transmit), according to the external slave/master connection.

As for a full duplex transmission, the serial clock (SPI_SCLK) synchronizes shifting and sampling of the information on the single serial data line.

22.2.2.2.1 Example With a Receive-Only Slave

Figure 22-3 shows a half duplex system with a Master device on the left and a receive-only Slave device on the right. Each time a bit is transferred out from the Master, one bit is transferred in the Slave. After 8 cycles of the serial clock SPI_SCLK, the WordA has been transferred from the master to the slave.

Figure 22-3. SPI Half-Duplex Transmission (Receive-only Slave)

22.2.2.2.2 Example With a Transmit-Only Slave

Figure 22-4 shows a half duplex system with a Master device on the left and a transmit-only Slave device on the right. Each time a bit is transferred out from the Slave, one bit is transferred in the Master. After 8 cycles of the serial clock SPI_SCLK, the WordA has been transferred from the slave to the master.

Figure 22-4. SPI Half-Duplex Transmission (Transmit-Only Slave)

22.2.2.3 Transfer Formats

This section describes the transfer formats supported by SPI.

The flexibility of SPI allows setting the parameters of the SPI transfer:

- SPI word length
- SPI enable generation programmable
- SPI enable assertion
- SPI enable polarity
- SPI clock frequency
- SPI clock phase
- SPI clock polarity

The consistency between SPI word length, clock phase and clock polarity of the master SPI device and the communicating slave device remains under software responsibility.

22.2.2.3.1 Programmable Word Length

SPI supports any SPI word from 4 to 32 bits long.

The SPI word length can be changed between transmissions to allow a master device to communicate with peripheral slaves having different requirements.

22.2.2.3.2 Programmable SPI Enable Generation

SPI is able to generate or not the SPI enable, if management of chip select is de-asserted a point to point connection is mandatory. Only a single master of slave device can be connected to the SPI bus.

22.2.2.3.3 Programmable SPI Enable ($\overline{\text{SPI_SCS}}[n]$)

The polarity of the $\overline{\text{SPI_SCS}}[n]$ signals is programmable. $\overline{\text{SPI_SCS}}[n]$ signals can be active high or low.

The assertion of the $\overline{\text{SPI_SCS}}[n]$ signals is programmable: $\overline{\text{SPI_SCS}}[n]$ signals can be manually asserted or can be automatically asserted.

Two consecutive words for two different slave devices may go along with active $\overline{\text{SPI_SCS}}[n]$ signals with different polarity.

22.2.2.3.4 Programmable SPI Clock (SPI_SCLK)

The phase and the polarity of the SPI serial clock are programmable when SPI is a SPI master device or a SPI slave device. The baud rate of the SPI serial clock is programmable when it is a SPI master.

When SPI is operating as a slave, the serial clock SPI_SCLK is an input from the master.

22.2.2.3.5 Bit Rate

In Master Mode, an internal reference clock CLKSPIREF is used as an input of a programmable divider to generate bit rate of the serial clock SPI_SCLK . Granularity of this clock divider can be changed.

22.2.2.3.6 Polarity and Phase

SPI supports four sub-modes of the SPI format transfer that depend on the polarity (POL) and the phase (PHA) of the SPI serial clock (SPI_SCLK). Table 22-2 and Figure 22-5 show a summary of the four sub-modes. Software selects one of four combinations of serial clock phase and polarity.

Two consecutive SPI words for two different slave devices may go along with active SPI_SCLK signal with different phase and polarity.

Table 22-2. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	mode0	SPI_SCLK active high and sampling occurs on the rising edge.
0	1	mode1	SPI_SCLK active high and sampling occurs on the falling edge.
1	0	mode2	SPI_SCLK active low and sampling occurs on the falling edge.
1	1	mode3	SPI_SCLK active low and sampling occurs on the rising edge.

Figure 22-5. Phase and Polarity Combinations

22.2.2.3.7 Transfer Format With PHA = 0

This section describes the concept of a SPI transmission with the SPI mode0 and the SPI mode2.

In the transfer format with PHA = 0, $\overline{\text{SPI_SCS}}[n]$ is activated a half cycle of SPI_SCLK ahead of the first SPI_SCLK edge.

In both master and slave modes, SPI drives the data lines at the time of $\overline{\text{SPI_SCS}}[n]$ is asserted.

Each data frame is transmitted starting with the MSB. At the extremity of both SPI data lines, the first bit of SPI word is valid a half cycle of SPI_SCLK after the $\overline{\text{SPI_SCS}}[n]$ assertion.

Therefore, the first edge of the SPI_SCLK line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next SPI_SCLK edge, the received data bit is shifted into the shift register, and a new data bit is transmitted on the serial data line.

This process continues for a total of pulses on the SPI_SCLK line defined by the SPI word length programmed in the master device, with data being latched on odd numbered edges and shifted on even numbered edges.

Figure 22-6 is a timing diagram of a SPI transfer for the SPI mode0 and the SPI mode2, when SPI is master or slave, with the frequency of SPI_SCLK equals to the frequency of CLKSPIREF. It should not be used as a replacement for SPI timing information and requirements.

When SPI is in slave mode, if the $\overline{\text{SPI_SCS}}[n]$ line is not de-asserted between successive transmissions then the content of the Transmitter register is not transmitted, instead the last received SPI word is transmitted.

In master mode, the $\overline{\text{SPI_SCS}}[n]$ line must be negated and reasserted between each successive SPI word. This is because the slave select pin freezes the data in its shift register and does not allow it to be altered if PHA bit equals 0.

In 3-pin mode without using the $\overline{\text{SPI_SCS}}[n]$ signal, the controller provides the same waveform but with $\overline{\text{SPI_SCS}}[n]$ forced to low state. In this mode, $\overline{\text{SPI_SCS}}[n]$ is useless.

Figure 22-6. Full Duplex Single Transfer Format with PHA = 0

22.2.2.3.8 Transfer Format With PHA = 1

This section describes SPI full duplex transmission with the SPI mode1 and the SPI mode 3.

In the transfer format with PHA = 1, $\overline{\text{SPI_SCS}}[n]$ is activated a delay (t_{LEAD}) ahead of the first SPI_SCLK edge.

In both master and slave modes, SPI drives the data lines on the first SPI_SCLK edge.

Each data frame is transmitted starting with the MSB. At the extremity of both SPI data lines, the first bit of SPI word is valid on the next SPI_SCLK edge, a half cycle of SPI_SCLK later. It is the sampling edge for both the master and slave.

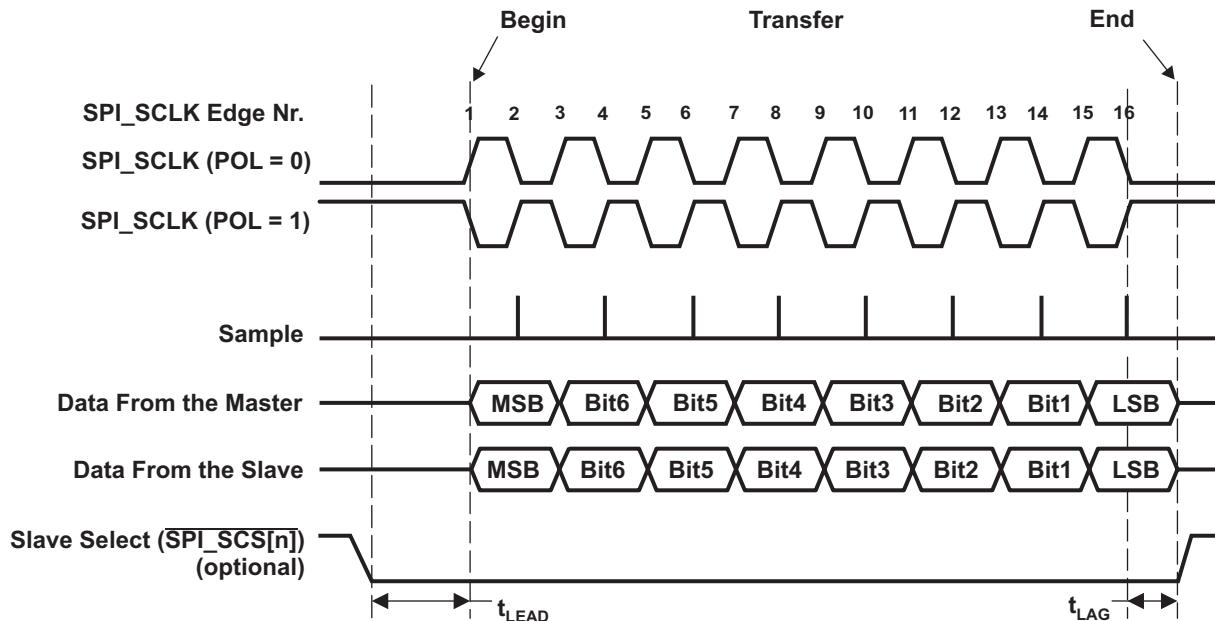

When the third edge occurs, the received data bit is shifted into the shift register. The next data bit of the master is provided to the serial input pin of the slave.

This process continues for a total of pulses on the SPI_SCLK line defined by the word length programmed in the master device, with data being latched on even numbered edges and shifted on odd numbered edges.

Figure 22-7 is a timing diagram of a SPI transfer for the SPI mode1 and the SPI mode3, when SPI is master or slave, with the frequency of SPI_SCLK equals to the frequency of CLKSPIREF. It should not be used as a replacement for SPI timing information and requirements.

The $\overline{\text{SPI_SCS}}[n]$ line may remain active between successive transfers. In 3-pin mode without using the $\overline{\text{SPI_SCS}}[n]$ signal, the controller provides the same waveform but with $\overline{\text{SPI_SCS}}[n]$ forced to low state. In this mode, $\overline{\text{SPI_SCS}}[n]$ is useless.

Figure 22-7. Full Duplex Single Transfer Format With PHA = 1

22.2.3 Master Mode

SPI is in master mode when the MS bit of the register MCSPI_MODULCTRL is cleared.

In master mode SPI supports multi-channel communication with up to four independent SPI communication channel contexts. SPI initiates a data transfer on the data lines (SPI_D[1:0]) and generates clock (SPI_SCLK) and control signals (SPI_SCS[n]) to a single SPI slave device at a time.

22.2.3.1 Dedicated Resources Per Channel

In the following sections, the letter “I” indicates the channel number that can be 0, 1, 2, or 3. Each channel has the following dedicated resources:

- Its own channel enable, programmable with the bit EN of the register MCSPI_CH(I)CTRL. Disabling the channel, outside data word transmission, remains under user responsibility.
- Its own transmitter register MCSPI_TX on top of the common shift register. If the transmitter register is empty, the status bit TXS of the register MCSPI_CH(I)STAT is set.
- Its own receiver register MCSPI_RX on top of the common shift register. If the receiver register is full, the status bit RXS of the register MCSPI_CH(I)STAT is set.
- A fixed SPI ENABLE line allocation (SPI_SCS[I] port for channel I), SPI enable management is optional.
- Its own communication configuration with the following parameters via the register (I)CONF
 - Transmit/Receive modes, programmable with the bit TRM.
 - Interface mode (Two data pins or Single data pin) and data pins assignment, both programmable with the bits IS and DPE.
 - SPI word length, programmable with the bits WL.
 - SPI_SCS[n] polarity, programmable with the bit EPOL.
 - SPI_SCS[n] kept active between words, programmable with the bit FORCE.
 - Turbo mode, programmable with the bit TURBO.
 - SPI_SCLK frequency, programmable with the bit CLKD, the granularity of clock division can be changed using CLKG bit, the clock ratio is then concatenated with MCSPI_CHCTRL[EXTCLK] value.
 - SPI_SCLK polarity, programmable with the bit POL.
 - SPI_SCLK phase, programmable with the bit PHA.
 - Start bit extension enable, programmable with the bit SBE to support LoSSI transfer specification.
 - Start bit polarity, programmable with the bit SBPOL.
 - Use a FIFO Buffer or not(), programmable with FFER and FFEW, depending on transfer mode TRM.
- Two DMA requests events, read and write, to synchronize read/write accesses of the DMA controller with the activity of SPI. The DMA requests are enabled with the bits DMAR and DMAW.
- Three interrupts events

The transfers will use the latest loaded parameters of the register (I)CONF.

The configuration parameters SPI_SCS[n] polarity, Turbo mode, SPI_SCLK phase and SPI_SCLK polarity can be loaded in the (I)CONF register only when the channel is disabled. The user has the responsibility to change the other parameters of the (I)CONF register when no transfer occurs on the SPI interface.

22.2.3.2 Interrupt Events in Master Mode

In master mode, the interrupt events related to the transmitter register state are TX_empty and TX_underflow. The interrupt event related to the receiver register state is RX_full.

22.2.3.2.1 TX_empty

The event TX_empty is activated when a channel is enabled and its transmitter register becomes empty (transient event). Enabling channel automatically raises this event, except for the Master receive only mode. (See [Section 22.2.3.5](#)). When FIFO buffer is enabled (MCSPi_CH(I)CONF[FFEW] set to 1), the TX_empty is asserted as soon as there is enough space in buffer to write a number of byte defined by MCSPi_XFERLEVEL[AEL].

Transmitter register must be loaded to remove the source of the interrupt and the TX_empty interrupt status bit must be cleared for interrupt line de-assertion (if event enabled as interrupt source) . (See [Section 22.2.5](#)).

When FIFO is enabled, no new TX_empty event will be asserted as soon as CPU has not performed the number of write into transmitter register defined by MCSPi_XFERLEVEL[AEL]. It is the responsibility of CPU to perform the right number of writes.

22.2.3.2.2 TX_underflow

The event TX_underflow is activated when the channel is enabled and if the transmitter register or FIFO is empty (not updated with new data) at the time of shift register assignment.

The TX_underflow is a harmless warning in master mode.

To avoid having TX_underflow event at the beginning of a transmission, the event TX_underflow is not activated when no data has been loaded into the transmitter register since channel has been enabled.

To avoid having TX_underflow event the Transmitter register must be loaded seldom.

TX_underflow interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

Note: Be careful, when more than one channel have a FIFO enable bit field FFER or FFEW set, the module force no use of FIFO, software must take care that only one enabled channel is configured to use the FIFO buffer.

22.2.3.2.3 RX_full

The event RX_full is activated when channel is enabled and receiver register becomes filled (transient event). When FIFO buffer is enabled (MCSPi_CH(I)CONF[FFER] set to 1), the RX_full is asserted as soon as there is a number of bytes holds in buffer to read defined by MCSPi_XFERLEVEL[AFL].

Receiver register must be read to remove source of interrupt and RX_full interrupt status bit must be cleared for interrupt line de-assertion (if event enabled as interrupt source).

When FIFO is enabled, no new RX_full event will be asserted as soon as CPU has not performed the number of read into receive register defined by MCSPi_XFERLEVEL[AFL]. It is the responsibility of CPU to perform the right number of reads.

22.2.3.2.4 End of Word Count

The event end of word count (EOW) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in MCSPi_XFERLEVEL[WCNT] register. If the value was programmed to 0000h, the counter is not enabled and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as MCSPi_XFERLEVEL[WCNT] is not reloaded and channel re-enabled.

End of Word interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

22.2.3.3 Master Transmit and Receive Mode

This mode is programmable per channel (bits TRM of the register (I)CONF).

The channel access to the shift registers, for transmission/reception, is based on its transmitter and receiver register state and round robin arbitration.

The channel that meets the rules below is included in the round robin list of already active channels scheduled for transmission and/or reception. The arbiter skips the channel that does not meet the rules and search for the next following enabled channel, in rotation.

Rule 1: Only enabled channels (bit EN of the register MCSPI_CH(I)CTRL), can be scheduled for transmission and/or reception.

Rule 2: An enabled channel can be scheduled if its transmitter register is not empty (bit TXS of the register MCSPI_CH(I)STAT) or its FIFO is not empty in case of buffer use for the corresponding channel (bit FFE of the register MCSPI_CH(I)STAT), that is updated with new data, at the time of shift register assignment. If the transmitter register or FIFO is empty, at the time of shift register assignment, the event TX_underflow is activated and the next enabled channel with new data to transmit is scheduled. (See also transmit only mode).

Rule 3: An enabled channel can be scheduled if its receive register is not full (bit RXS of the register MCSPI_CH(I)STAT) or its FIFO is not full in case of buffer use for the corresponding channel (bit FFF of the register MCSPI_CH(I)STAT) at the time of shift register assignment. (See also receive only mode). Therefore the receiver register of FIFO cannot be overwritten. The RX_overflow bit, in the MCSPI_IRQSTATUS register is never set in this mode.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) the updated transmitter register of the next scheduled channel is loaded into the shift register. This bit is meaningless when using the Buffer for this channel. The serialization (transmit and receive) starts according to the channel communication configuration. On serialization completion the received data is transferred to the channel receive register.

The built-in FIFO is available in this mode and can be configured in one data direction Transmit or Receive, then the FIFO is seen as a unique FFNBYTE bytes buffer, or it can also be configured in both data direction Transmit and Receive, then the FIFO is split into two separate FFNBYTE/2 bytes buffer with their own address space management, in this last case the definition of AEL and AFL levels is based on FFNBYTE/2 bytes and is under CPU responsibility.

22.2.3.4 Master Transmit-Only Mode

This mode avoids the CPU to read the receiver register (minimizing data movement) when only transmission is meaningful.

The master transmit only mode is programmable per channel (bits TRM of the register (I)CONF).

In master transmit only mode, transmission starts after data is loaded into the transmitter register.

Rule 1 and **Rule 2**, defined in [Section 22.2.3.3](#), are applicable in this mode.

Rule 3, defined in [Section 22.2.3.3](#), is not applicable: In master transmit only mode, the receiver register or FIFO state “full” does not prevent transmission, and the receiver register is always overwritten with the new SPI word. This event in the receiver register is not significant when only transmission is meaningful. So, the RX_overflow bit, in the MCSPI_IRQSTATUS register is never set in this mode.

The SPI module automatically disables the RX_full interrupt status. The corresponding interrupt request and DMA Read request are not generated in master transmit only mode.

The status of the serialization completion is given by the bit EOT of the register MCSPI_CH(I)STAT. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFEW bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE bytes buffer.

22.2.3.5 Master Receive-Only Mode

This mode avoids the CPU to refill the transmitter register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (bits TRM of the register (I)CONF).

The master receive only mode enables channel scheduling only on empty state of the receiver register.

Rule 1 and **Rule 3**, defined in [Section 22.2.3.3](#), are applicable in this mode.

Rule 2, defined in [Section 22.2.3.3](#), is not applicable: In master receive only mode, after the first loading of the transmitter register of the enabled channel, the transmitter register state is maintained as full. The content of the transmitter register is always loaded into the shift register, at the time of shift register assignment. So, after the first loading of the transmitter register, the bits TX_empty and TX_underflow, in the MCSPI_IRQSTATUS register are never set in this mode.

The status of the serialization completion is given by the bit EOT of the register MCSPI_CH(I)STAT. The bit RX_full in the MCSPI_IRQSTATUS register is set when a received data is loaded from the shift register to the receiver register. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFERBYTE bytes buffer.

22.2.3.6 Single-Channel Master Mode

When the SPI is configured as a master device with a single enabled channel, the assertion of the SPIM_CSX signal can be controlled in two different ways:

- In 3 pin mode : MCSPI_MODULCTRL[1] PIN34 and MCSPI_MODULCTRL[0] SINGLE bits are set to 1, the controller transmit SPI word as soon as transmit register or FIFO is not empty.
- In 4 pin mode : MCSPI_MODULCTRL[1] PIN34 bit is cleared to 0 and MCSPI_MODULCTRL[0] SINGLE bit is set to 1, SPI_SCS[n] assertion/deassertion controlled by Software. (See [Section 22.2.3.6.1](#)) using the MCSPI_CHxCONF[20] FORCE bit.

22.2.3.6.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) before disabling the current channel and enabling a different channel.
- Disable the current channel first, and then enable the other channel.

22.2.3.6.2 Keep $\overline{\text{SPI_SCS}}[n]$ Active Mode (Force $\overline{\text{SPI_SCS}}[n]$)

Continuous transfers are manually allowed by keeping the $\overline{\text{SPI_SCS}}[n]$ signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the $\overline{\text{SPI_SCS}}[n]$ line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the $\overline{\text{SPI_SCS}}[n]$ active mode is supported when:

- A single channel is used (MCSPI_MODULCTRL[Single] bit is set to 1).
- Transfer parameters of the transfer are loaded in the configuration register (MCSPI_CH(I)CONF) in the appropriate channel.

The state of the $\overline{\text{SPI_SCS}}[n]$ signal is programmable.

- Writing 1 into the bit FORCE of the register MCSPI_CH(I)CONF drives high the $\overline{\text{SPI_SCS}}[n]$ line when MCSPI_CHCONF(I)[EPOL] is cleared to 0, and drives it low when MCSPI_CHCONF(I)[EPOL] is set.
- Writing 0 into the bit FORCE of the register MCSPI_CH(I)CONF drives low the $\overline{\text{SPI_SCS}}[n]$ line when MCSPI_CHCONF(I)[EPOL] is cleared to 0, and drives it high when MCSPI_CHCONF(I)[EPOL] is set.
- A single channel is enabled (MCSPI_CH(I)CTRL[En] set to 1) . The first enabled channel activates the $\overline{\text{SPI_SCS}}[n]$ line.

Once the channel is enabled, the $\overline{\text{SPI_SCS}}[n]$ signal is activated with the programmed polarity.

As in multi-channel master mode, the start of the transfer depends on the status of the transmitter register, the status of the receiver register and the mode defined by the bits TRM in the configuration register (transmit only, receive only or transmit and receive) of the enabled channel.

The status of the serialization completion of each SPI word is given by the bit EOT of the register MCSPI_CH(I)STAT. The bit RX_full in the MCSPI_IRQSTATUS register is set when a received data is loaded from the shift register to the receiver register.

A change in the configuration parameters is propagated directly on the SPI interface. If the $\overline{\text{SPI_SCS}}[n]$ signal is activated the user must insure that the configuration is changed only between SPI words, in order to avoid corrupting the current transfer.

NOTE: The $\overline{\text{SPI_SCS}}[n]$ polarity, the SPI_SCLK phase and SPI_SCLK polarity must not be modified when the $\overline{\text{SPI_SCS}}[n]$ signal is activated. The Transmit/Receive mode, programmable with the bit TRM can be modified only when the channel is disabled. The channel can be disabled and enabled while the $\overline{\text{SPI_SCS}}[n]$ signal is activated.

The delay between SPI words that requires the connected SPI slave device to switch from one configuration (Transmit only for instance) to another (receive only for instance) must be handled under software responsibility.

At the end of the last SPI word, the channel must be deactivated (MCSPI_CH(I)CTRL[En] is cleared to 0) and the $\overline{\text{SPI_SCS}}[n]$ can be forced to its inactive state (MCSPI_CH(I)CONF[Force]).

Figure 22-8 and Figure 22-9 show successive transfers with $\overline{\text{SPI_SCS}}[n]$ kept active low with a different configuration for each SPI word in respectively single data pin interface mode and two data pins interface mode. The arrows indicate when the channel is disabled before a change in the configuration parameters and enabled again.

Figure 22-8. Continuous Transfers With $\overline{\text{SPI_SCS}}[n]$ Maintained Active (Single-Data-Pin Interface Mode)

Figure 22-9. Continuous Transfers With $\overline{\text{SPI_SCS}}[n]$ Maintained Active (Dual-Data-Pin Interface Mode)

-
- NOTE:** The turbo mode is also supported for the Keep `SPI_SCS[n]` active mode when the following conditions are met:
- A single channel will be explicitly used (MCSPi_MODULCTRL[Single] bit is set to 1).
 - The turbo mode is enabled in the configuration of the channel (Turbo bit of the register (i)CONF).
-

22.2.3.6.3 Turbo Mode

The purpose of the Turbo mode is to improve the throughput of the SPI interface when a single channel is enabled, by allowing transfers until the shift register and the receiver register are full.

This mode is programmable per channel (bit Turbo of the register (I)CONF). When several channels are enabled, the bit Turbo of the registers MCSPI_CH(I)CONF has no effect, and the channel access to the shift registers remains as described in [Section 22.2.3.3](#).

In Turbo mode, **Rule 1** and **Rule 2** defined in [Section 22.2.3.3](#) are applicable, but Rule 3 is not applicable. An enabled channel can be scheduled if its receive register is full (bit RXS of the register MCSPI_CH(I)STAT) at the time of shift register assignment until the shift register is full.

The receiver register cannot be overwritten in turbo mode. In consequence the RX_overflow bit, in MCSPI_IRQSTATUS register is never set in this mode.

22.2.3.7 Start Bit Mode

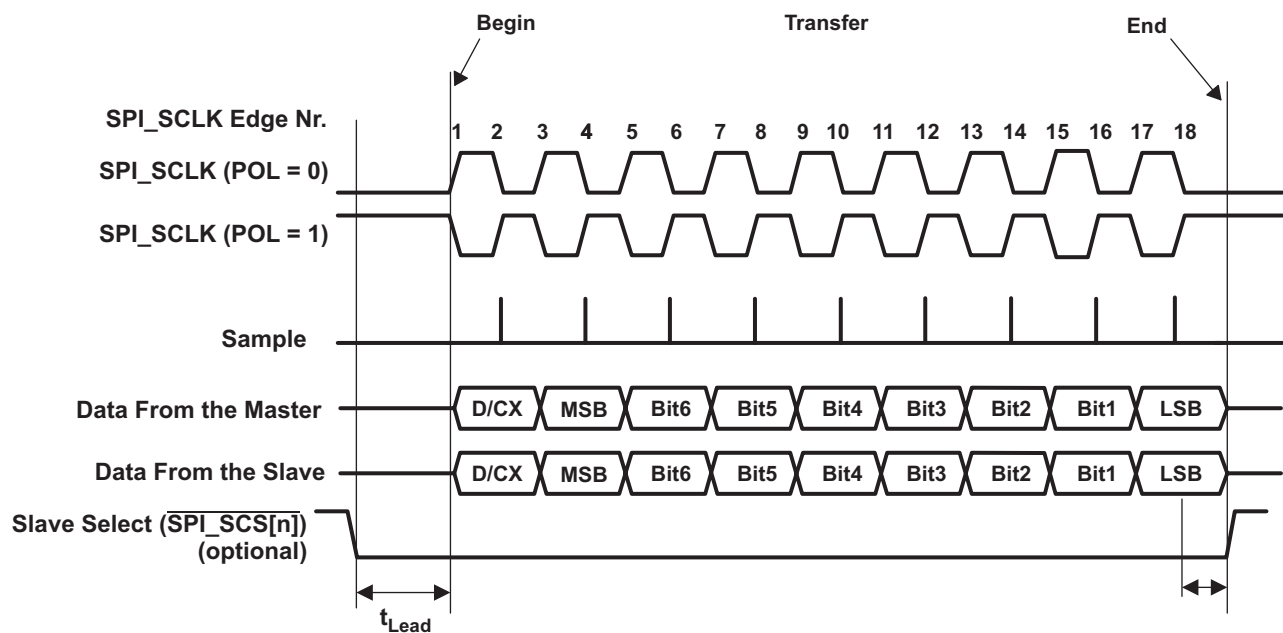

The purpose of the start bit mode is to add an extended bit before the SPI word transmission specified by word length WL (see [Figure 22-10](#)). This feature is only available in master mode. This mode is compliant with write command/data format as specified in LoSSI protocol.

This mode is programmable per channel (Start bit enable (SBE) bit of the register MCSPI_CH(I)CONF).

The polarity of the extended bit is programmable per channel and it indicates whether the next SPI word must be handled as a command when SBPOL is cleared to 0 or as a data or a parameter when SBPOL is set to 1. Moreover, start bit polarity SBPOL can be changed dynamically during start bit mode transfer without disabling the channel for reconfiguration, in this case you have the responsibility to configure the SBPOL bit before writing the SPI word to be transmitted in TX register.

The start bit mode could be used at the same time as turbo mode and/or manual chip select mode. In this case, only one channel could be used, no round-robin arbitration is possible.

Figure 22-10. Extended SPI Transfer With Start Bit PHA = 1

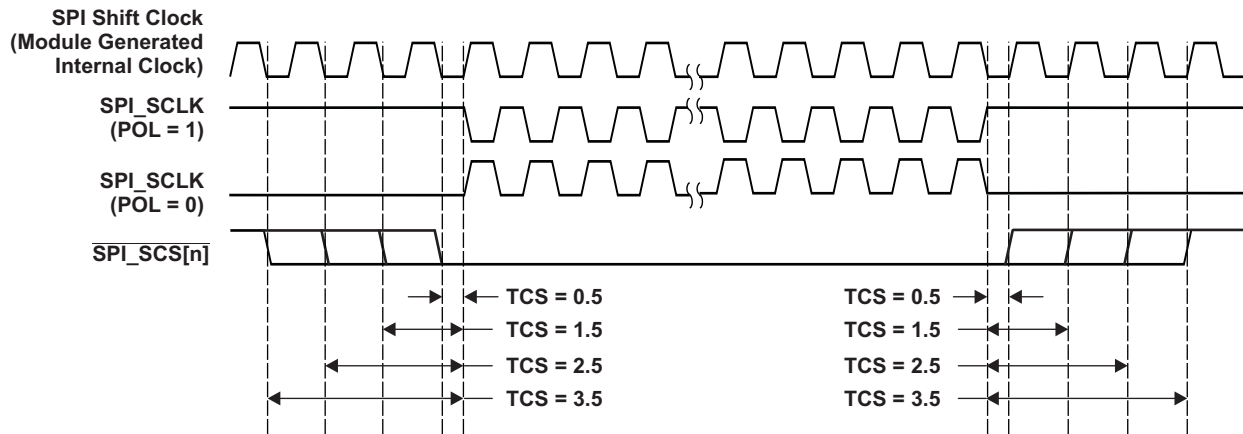

22.2.3.8 Chip-Select Timing Control

The chip select timing control is only available in master mode with automatic chip select generation (FORCE bit field is cleared to 0), to add a programmable delay between chip select assertion and first clock edge or chip select removal and last clock edge. The option is available only in 4 pin mode MCSPI_MODULCTRL[1] PIN34 is cleared to 0.

This mode is programmable per channel (TCS bit of the register MCSPI_CH(I)CONF). Figure 22-11 shows the chip-select SPI_SCS[n] timing control.

Figure 22-11. Chip-Select SPI_SCS[n] Timing Controls

NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between chip-select assertion and the first clock edge with PHA = 1 or between chip-select removal and the last clock edge with PHA = 0.

With an odd clock divider ratio which occurs when granularity is one clock cycle, that means that MCSPI_CH(I)CONF[CLKG] is set to 1 and MCSPI_CH(I)CONF[CLKD] has an even value, the clock duty cycle is not 50%, then one of the high level or low level duration is selected to be added to TCS delay.

Table 22-3 summarizes all delays between chip select and first (setup) or last (hold) clock edge.

In 3-pin mode this option is useless, the chip select SPI_SCS[n] is forced to low state.

T_{ref} = CLKSPIREF period in ns

F_{ratio} = SPI clock division ratio

Table 22-3. Chip Select ↔ Clock Edge Delay Depending on Configuration

Clock Ratio F_{ratio}	Clock Phase PHA	Chip Select ↔ Clock Edge Delay	
		Setup	Hold
1	0	$T_{ref} \times (TCS + \frac{1}{2})$	$T_{ref} \times (TCS + 1)$
	1	$T_{ref} \times (TCS + 1)$	$T_{ref} \times (TCS + \frac{1}{2})$
Even ≥ 2	x	$T_{ref} \times F_{ratio} \times (TCS + \frac{1}{2})$	$T_{ref} \times F_{ratio} \times (TCS + \frac{1}{2})$
Odd ≥ 3 (only with MCSPI_CH(I)CONF[CLKG] set to 1)	0	$T_{ref} \times \{[F_{ratio} \times TCS] + (F_{ratio} + \frac{1}{2})\}$	$T_{ref} \times \{[F_{ratio} \times TCS] + (F_{ratio} + \frac{1}{2})\}$
	1	$T_{ref} \times \{[F_{ratio} \times TCS] + (F_{ratio} - \frac{1}{2})\}$	$T_{ref} \times \{[F_{ratio} \times TCS] + (F_{ratio} - \frac{1}{2})\}$

The clock divider ratio depends on divider granularity MCSPI_CH(I)CONF[CLKG]:

- MCSPI_CH(I)CONF[CLKG] = 0 : granularity is power of 2.

$$F_{ratio} = 2^{MCSPI_CH(I)CONF[CLKD]}$$
- MCSPI_CH(I)CONF[CLKG] = 1 : EXTCLK concatenated with CLKD + 1.

$$F_{ratio} = MCSPI_CH(I)CNTRL[EXTCLK].MCSPI_CH(I)CONF[CLKD] + 1$$

22.2.3.9 Clock Ratio Granularity

By default the clock division ratio is defined by the register MCSPI_CH(I)CONF[CLKD] with power of 2 granularity leading to a clock division in range 1 to 32768, in this case the duty cycle is always 50%. With bit MCSPI_CH(I)CONF[CLKG] the clock division granularity can be changed to one clock cycle, in that case the register MCSPI_CH(I)CNTRL[EXTCLK] is concatenated with MCSPI_CH(I)CONF[CLKD] to give a 12-bit width division ratio in range 1 to 4096.

When granularity is one clock cycle (MCSPI_CH(I)CONF[CLKG] set to 1), for odd value of clock ratio the clock duty cycle is kept to 50-50 using falling edge of clock reference CLKSPIREF.

Table 22-4. CLKSPPIO High/Low Time Computation

Clock Ratio F_{ratio}	CLKSPPIO High Time	CLKSPPIO Low Time
1	T_{high_ref}	T_{low_ref}
Even ≥ 2	$t_{ref} \times (F_{ratio}/2)$	$t_{ref} \times (F_{ratio}/2)$
Odd ≥ 3	$t_{ref} \times (F_{ratio}/2)$	$t_{ref} \times (F_{ratio}/2)$

T_{ref} = CLKSPIREF period in ns. T_{high_ref} = CLKSPIREF high Time period in ns. T_{low_ref} = CLKSPIREF low Time period in ns. F_{ratio} = SPI clock division ratio

$$F_{ratio} = MCSPI_CH(I)CNTRL[EXTCLK].MCSPI_CH(I)CONF[CLKD] + 1$$

For odd ratio value the duty cycle is calculated as:

$$Duty_cycle = \frac{1}{2}$$

Granularity examples: With a clock source frequency of 48 MHz:

Table 22-5. Clock Granularity Examples

MCSPI_CH(I) CNTRL	MCSPI_CH(I) CONF	MCSPI_CH(I) CONF	F_{ratio}	MCSPI_CH(I) CONF	MCSPI_CH(I) CONF	Thigh (ns)	Tlow (ns)	Tperiod (ns)	Duty Cycle	Fout (MHz)

22.2.3.10 FIFO Buffer Management (Optional USEFIFO = 1)

The SPI controller has a built-in FFNBYTE bytes buffer in order to unload DMA or interrupt handler and improve data throughput. The instantiation of this Buffer is optional it depends on a generic parameter USEFIFO, the FIFO is instantiated when it is set to 1. Allowed FIFO depth up to 64 bytes is supported and is defined by generic parameter FFNBYTE. When the FIFO is not instantiated writes in registers MCSPI_XFERLEVEL, MCSPI_CH(I)CONF[FFER] and MCSPI_CH(I)CONF[FFEW] have no functional effect, nevertheless read back is allowed to check written value.

This buffer can be used by only one channel at once and is selected by setting MCSPI_CH(I)CONF[FFER] or MCSPI_CH(I)CONF[FFEW] to 1.

If several channel are selected and several FIFO enable bit fields set to 1, the controller forces buffer not to be used, it is the responsibility of the driver to set only one FIFO enable bit field.

The buffer can be used in the modes defined:

- Master or Slave mode.
- Transmit only, Receive only or Transmit/Receive mode.
- Single channel or turbo mode, or in normal round robin mode. In round robin mode the buffer is used by only one channel.
- Every word length MCSPI_CH(I)CONF[WL] are supported.

Two levels AEL and AFL located in MCSPI_XFERLEVEL register rule the buffer management. The granularity of these levels is one byte, then it is not aligned with SPI word length. It is the responsibility of the driver to set these values as a multiple of SPI word length defined in MCSPI_CH(I)CONF[WL]. The number of byte written in the FIFO depends on word length (see [Table 22-6](#)).

Table 22-6. FIFO Writes, Word Length Relationship

	SPI Word Length WL		
	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of byte written in the FIFO	1 byte	2 bytes	4 byte

22.2.3.10.1 Split FIFO

The FIFO can be split into two parts when the module is configured in transmit/receive mode MCSPI_CH(I)CONF[TRM] is cleared to 0 and MCSPI_CH(I)CONF[FFER] and MCSPI_CH(I)CONF[FFEW] asserted. Then system can access a FFNBYTE/2 byte depth FIFO per direction.

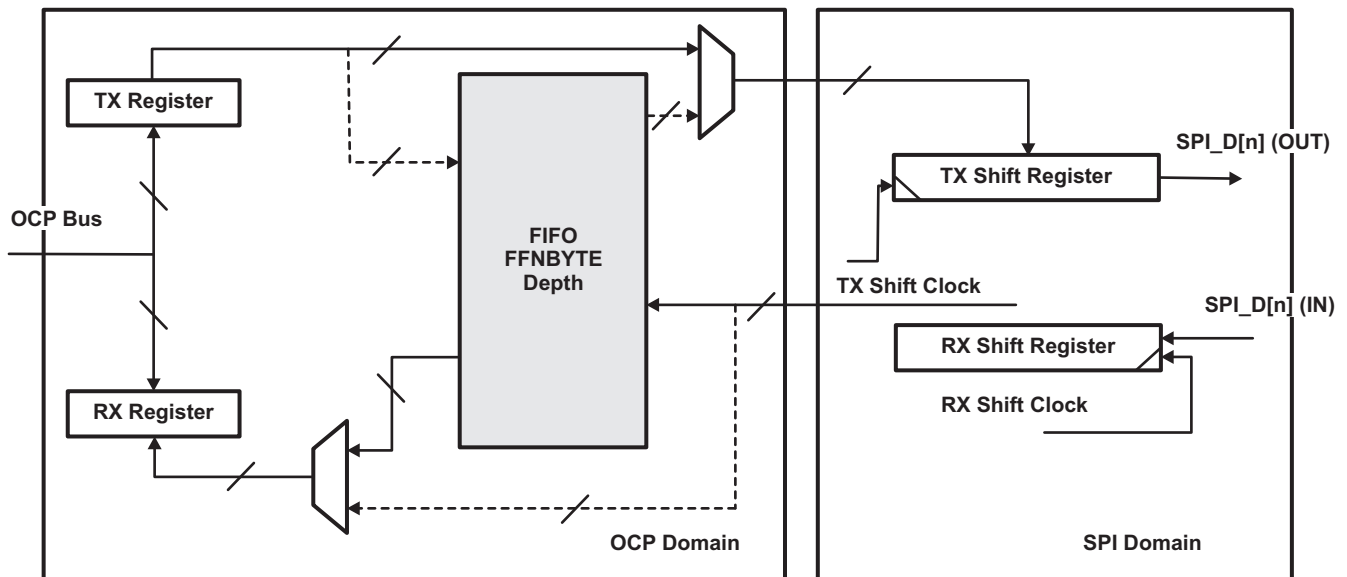

The FIFO buffer pointers are reset when the corresponding channel is enabled or FIFO configuration changes.

Figure 22-12. Transmit/Receive Mode With No FIFO Used

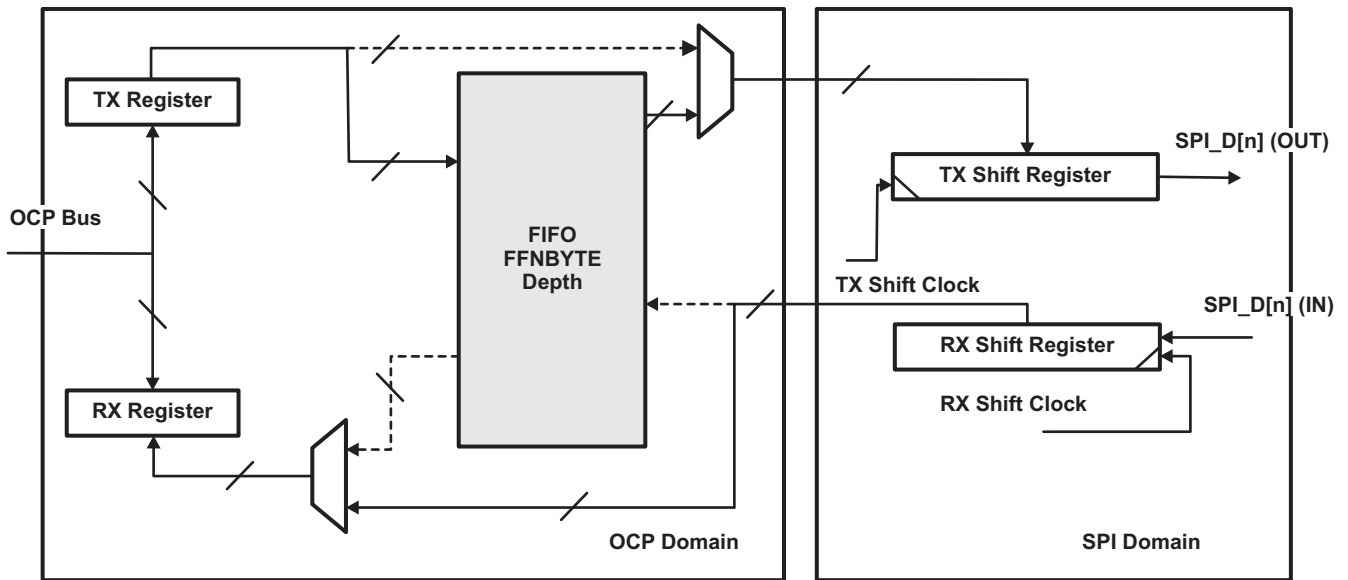

Configuration:
 MCSPI_CH(i)CONF[TRM] = 0 (Transmit/receive mode)
 MCSPI_CH(i)CONF[FFER] = 0 (FIFO disabled on receive path)
 MCSPI_CH(i)CONF[FEW] = 0 (FIFO disabled on transmit path)

Figure 22-13. Transmit/Receive Mode With Only Receive FIFO Enabled

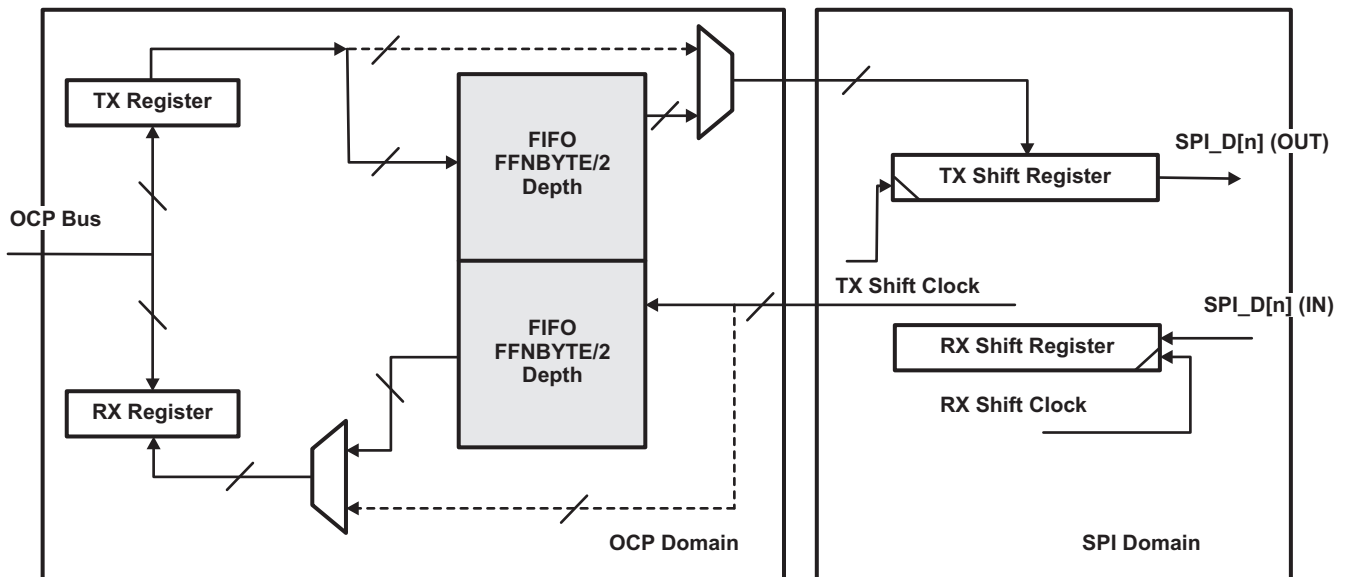

Configuration:
 MCSPI_CH(i)CONF[TRM] = 0 (Transmit/receive mode)
 MCSPI_CH(i)CONF[FFER] = 1 (FIFO enabled on receive path)
 MCSPI_CH(i)CONF[FEW] = 0 (FIFO disabled on transmit path)

Figure 22-14. Transmit/Receive Mode With Only Transmit FIFO Used

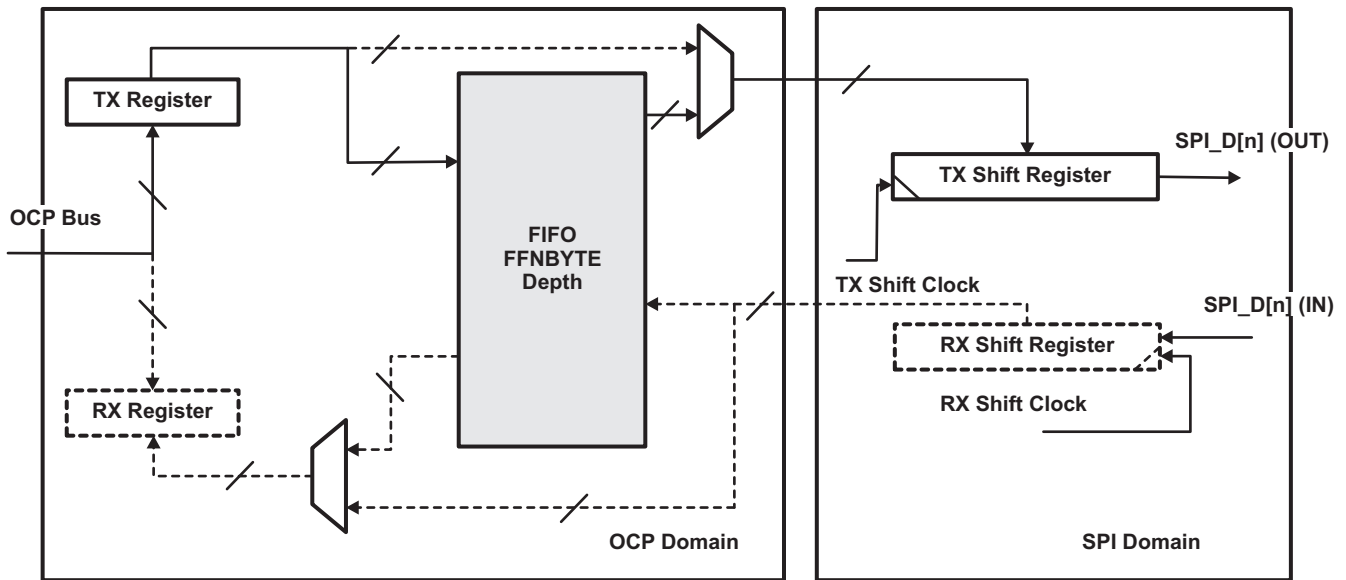

Configuration:
 MCSPI_CH(i)CONF[TRM] = 0 (Transmit/receive mode)
 MCSPI_CH(i)CONF[FFER] = 0 (FIFO disabled on receive path)
 MCSPI_CH(i)CONF[FEW] = 1 (FIFO enabled on transmit path)

Figure 22-15. Transmit/Receive Mode With Both FIFO Direction Used

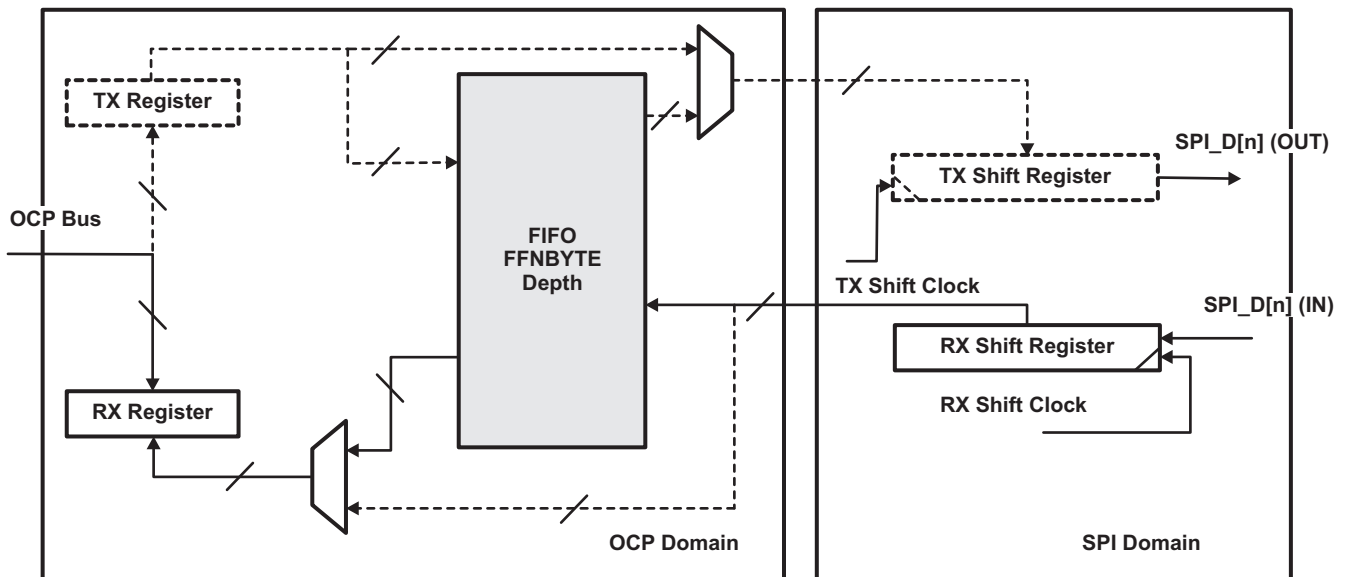

Configuration:
 MCSPI_CH(i)CONF[TRM] = 0 (Transmit/receive mode)
 MCSPI_CH(i)CONF[FFER] = 1 (FIFO enabled on receive path)
 MCSPI_CH(i)CONF[FEW] = 0 (FIFO disabled on transmit path)

Figure 22-16. Transmit-Only Mode With FIFO Used

Configuration:
 MCSPI_CH(i)CONF[TRM] = 2h (Transmit-only mode)
 MCSPI_CH(i)CONF[FFER] = 1 (FIFO enabled on transmit path)
 MCSPI_CH(i)CONF[FFEW] (not applicable)

Figure 22-17. Receive-Only Mode With FIFO Used

Configuration:
 MCSPI_CH(i)CONF[TRM] = 1 (Receive-only mode)
 MCSPI_CH(i)CONF[FFER] = 1 (FIFO enabled on receive path)
 MCSPI_CH(i)CONF[FFEW] (not applicable)

22.2.3.10.2 Buffer Almost Full

The bit field MCSPI_XFERLEVEL[AFL] is needed when the buffer is used to receive SPI word from a slave (MCSPI_CH(I)CONF[FFER] must be set to 1) and register width depends on the generic parameter FFNBYTE value. It defines the almost full buffer status.

When FIFO pointer reaches this level, an interrupt or a DMA request is sent to the CPU to enable the system to read AFL + 1 bytes from receive register. Be careful, AFL + 1 must correspond to a multiple value of MCSPI_CH(I)CONF[WL].

When DMA is used, the request is de-asserted after the first receive register read.

No new request will be asserted again as long as system has not performed the right number of read accesses.

Figure 22-18. Buffer Almost Full Level (AFL)

* non-DMA mode only. In DMA mode, the DMA RX request is asserted to its active level under identical conditions.

NOTE: SPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPI_m_DMA_RX_n request is asserted on the same conditions than the SPI_IRQSTATUS RX_n_FULL flag.

22.2.3.10.3 Buffer Almost Empty

The bit field `MCSPi_XFERLEVEL[AEL]` is needed when the buffer is used to transmit SPI word to a slave (`MCSPi_CH(I)CONF[FFEW]` bit must be set to 1) and register width depends on the generic parameter `FFNBYTE` value. It defines the almost empty buffer status.

When FIFO pointer has not reached this level, an interrupt or a DMA request is sent to the CPU to enable the system to write `AEL + 1` bytes to transmit register. Be careful, `AEL + 1` must correspond to a multiple value of `MCSPi_CH(I)CONF[WL]`.

When DMA is used, the request is de-asserted after the first transmit register write.

No new request will be asserted again as long as system has not performed the right number of write accesses.

* non-DMA mode only. In DMA mode, the DMA TX request is asserted to its active level under identical conditions.

22.2.3.10.4 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user shall previously configure the `MCSPi_XFERLEVEL` register the AEL and AFL levels and especially the `WCNT` bit field to define the number of Spi word to be transferred using the FIFO before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of Spi word transfer. If `WCNT` is cleared to 0, the counter is not used and the user must stop the transfer manually by disabling the channel, in this case the user doesn't know how many SPI transfers have been done. For receive transfer, software shall poll the corresponding `FFE` bit field and read the Receive register to empty the FIFO buffer.

When End Of Word count interrupt is generated, the user can disable the channel and poll on `MCSPi_CH(I)STAT[FFE]` register to know if SPI word is still there in FIFO buffer and read last words.

NOTE: If the FIFO buffer is enabled, the module is configured to use the `WCNT` feature in the master mode, and the software uses the `TX_EMPTY` interrupt to load data into the FIFO, then the `WCNT` value must be a multiple of the Almost Empty Level (AEL).

22.2.3.10.5 Multiple SPI Word Access

The CPU has the ability to perform multiple SPI word access to the receive or transmit registers within a single 32-bit OCP access by setting the bit field `MCSPi_MODULCTRL[MOA]` to 1 under specific conditions:

- The channel selected has the FIFO enable.
- Only FIFO sense enabled support the kind of access.
- The bit field `MCSPi_MODULCTRL[MOA]` is set to 1.
- Only 32-bit OCP access and data width can be performed to receive or transmit registers, for other

kind of access the CPU must de-assert MCSPI_MODULCTRL[MOA] bit fields.

- The Level MCSPI_XFERLEVEL[AEL] and MCSPI_XFERLEVEL[AFL] must be 32-bit aligned , it means that $AEL[0] = AEL[1] = 1$ or $AFL[0] = AFL[1] = 1$.
- If MCSPI_XFERLEVEL[WCNT] is used it must be configured according to SPI word length.
- The word length of SPI words allows to perform multiple SPI access, that means that $MCSPI_CH(l)CONF[WL] < 16$

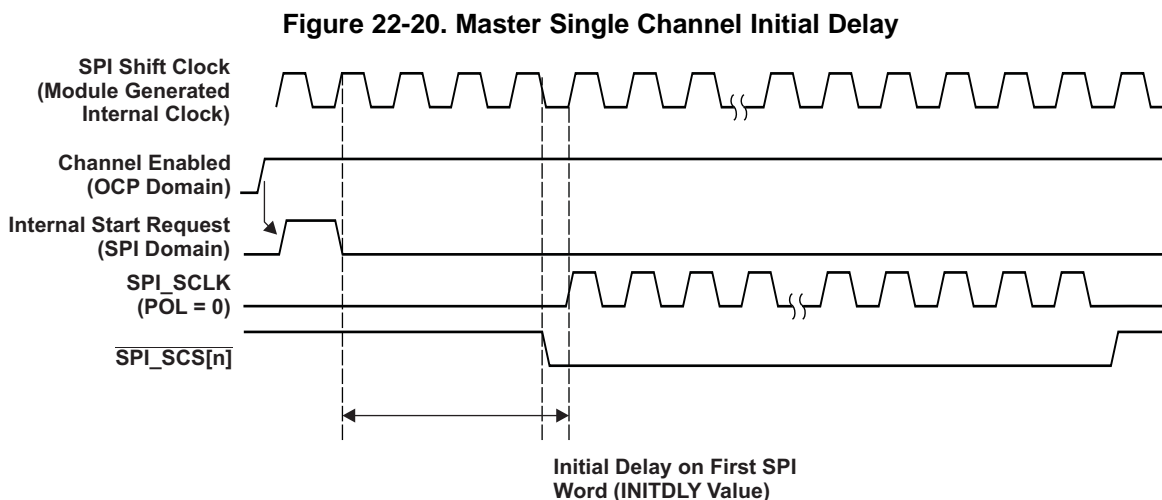

Number of SPI word access depending on SPI word length:

- $3 \leq WL \leq 7$, SPI word length smaller or equal to byte length, four SPI words accessed per 32-bit OCP read/write. If word count is used (MCSPI_XFERLEVEL[WCNT]), set the bit field to $WCNT[0] = WCNT[1] = 0$
- $8 \leq WL \leq 15$, SPI word length greater than byte or equal to 16-bit length, two SPI words accessed per 32-bit OCP read/write. If word count is used (MCSPI_XFERLEVEL[WCNT]), set the bit field to $WCNT[0] = 0$
- $16 \leq WL$ multiple SPI word access not applicable.

22.2.3.11 First SPI Word Delayed

The SPI controller has the ability to delay the first SPI word transfer to give time for system to complete some parallel processes or fill the FIFO in order to improve transfer bandwidth. This delay is applied only on first SPI word after SPI channel enabled and first write in Transmit register. It is based on output clock frequency.

This option is meaningful in master mode and single channel mode MCSPI_MODULECTRL[SINGLE] asserted.

Few delay values are available: No delay, 4/8/16/32 SPI cycles.

Its accuracy is half cycle in clock bypass mode and depends on clock polarity and phase.

22.2.3.12 3-Pin or 4-Pin Mode

External SPI bus interface can be configured to use a restricted set of pin using the bit field MCSPI_MODULECTRL[1] PIN34 and depending on targeted application:

- If MCSPI_MODULECTRL[34] is cleared to 0 (default value), the controller is in 4-pin mode using the SPI pins: SPI_SCLK, SPI_D[0], SPI_D[1], and SPI_SCS[n].
- If MCSPI_MODULECTRL[34] is set to 1, the controller is in 3-pin mode using the SPI pins: SPI_SCLK, SPI_D[0], and SPI_D[1].

In this mode it is mandatory to put the controller in single channel master mode (MCSPI_MODULECTRL[SINGLE] asserted) and to connect only one SPI device on the bus.

Figure 22-21. 3-Pin Mode System Overview

In 3-pin mode all options related to chip select management are useless:

- MCSPI_CHxCONF[EPOL]
- MCSPI_CHxCONF[TCS0]
- MCSPI_CHxCONF[FORCE]

The chip select pin $\overline{\text{SPI_SCS}}[n]$ is forced to 0 in this mode.

22.2.4 Slave Mode

SPI is in slave mode when the bit MS of the register MCSPI_MODULCTRL is set.

In slave mode, SPI can be connected to up to 4 external SPI master devices. SPI handles transactions with a single SPI master device at a time.

In slave mode, SPI initiates data transfer on the data lines (SPI_D[1:0]) when it receives an SPI clock (SPI_SCLK) from the external SPI master device.

The controller is able to work with or without a chip select $\overline{\text{SPI_SCS}}[n]$ depending on MCSPI_MODULCTRL[1] PIN34 bit setting. It also support transfers without dead cycle between two successive words.

22.2.4.1 Dedicated Resources

In slave mode, enabling a channel that is not channel 0 has no effect. Only channel 0 can be enabled. The channel 0, in slave mode has the following resources:

- Its own channel enable, programmable with the bit EN of the register MCSPI_CH0CTRL. This channel should be enabled before transmission and reception. Disabling the channel, outside data word transmission, remains under user responsibility.
- Any of the 4 ports $\overline{\text{SPI_SCS}}[3:0]$ can be used as a slave SPI device enable. This is programmable with the SPIENSLV bits of the register MCSPI_CH0CONF.
- Its own transmitter register MCSPI_TX on top of the common shift register. If the transmitter register is empty, the status bit TXS of the register MCSPI_CH0STAT is set. When SPI is selected by an external master (active signal on the $\overline{\text{SPI_SCS}}[n]$ port assigned to channel 0), the transmitter register content of channel0 is always loaded in shift register whether it has been updated or not. The transmitter register should be loaded before SPI is selected by a master.
- Its own receiver register MCSPI_RX on top of the common shift register. If the receiver register is full, the status bit RXS of the register MCSPI_CH0STAT is set.

NOTE: The transmitter register and receiver registers of the other channels are not used. Read from or Write in the registers of a channel that is not channel 0 has no effect.

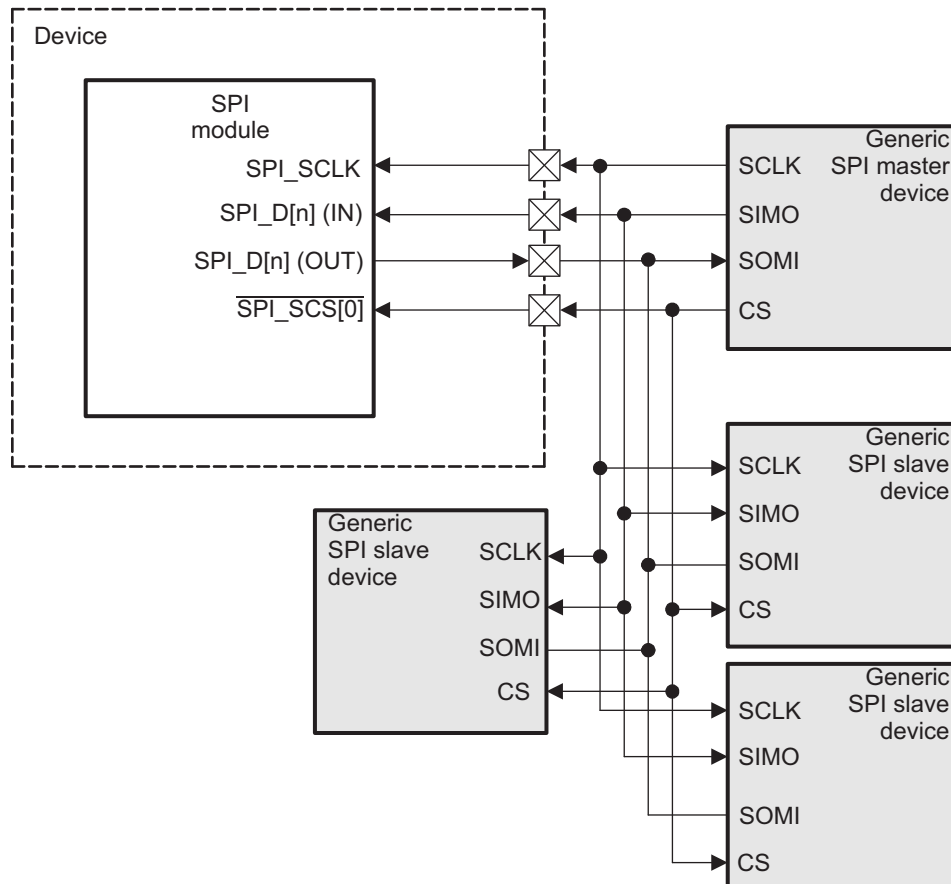

- Its own communication configuration with the following parameters via the register MCSPI_CH0CONF:
 - Transmit/Receive modes, programmable with the bit TRM.
 - Interface mode (Two data pins or Single data pin) and data pins assignment, both programmable with the bits IS and DPE.
 - SPI word length, programmable with the bits WL.
 - $\overline{\text{SPI_SCS}}[n]$ polarity, programmable with the bit EPOL.
 - SPI_SCLK polarity, programmable with the bit POL.
 - SPI_SCLK phase, programmable with the bit PHA.
 - Use a FIFO buffer or not, programmable with FFER and FFEW, depending on transfer mode TRM.

The SPI_SCLK frequency of a transfer is controlled by the external SPI master connected to SPI. The bits CLKD0 of the register 0CONF are not used in slave mode.

NOTE: The configuration of the channel can be loaded in the 0CONF register only when the channel is disabled.

- Two DMA requests events, read and write, to synchronize read/write accesses of the DMA controller with the activity of SPI. The DMA requests are enabled with the bits DMAR and DMAW of the register 0CONF.
- Four interrupts events.

Figure 22-22 shows an example of four slaves wired on a single master device.

Figure 22-22. Example of SPI Slave with One Master and Multiple Slave Devices on Channel 0

22.2.4.2 Interrupt Events in Slave Mode

The interrupt events related to the transmitter register state are TX_empty and TX_underflow. The interrupt events related to the receiver register state are RX_full and RX_overflow.

22.2.4.2.1 TX_EMPTY

The event TX_empty is activated when the channel is enabled and its transmitter register becomes empty. Enabling channel automatically raises this event. When FIFO buffer is enabled (MCSPi_CH(l)CONF[FFEW] set to 1), the TX_empty is asserted as soon as there is enough space in buffer to write a number of byte defined by MCSPi_XFERLEVEL[AEL].

Transmitter register must be load to remove source of interrupt and TX_empty interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

When FIFO is enabled, no new TX_empty event will be asserted as soon as Local Host has not performed the number of write into transmitter register defined by MCSPi_XFERLEVEL[AEL]. It is the responsibility of Local Host to perform the right number of writes.

22.2.4.2.2 TX_UNDERFLOW

The event TX_underflow is activated when channel is enabled and if the transmitter register or FIFO (if use of buffer is enabled) is empty (not updated with new data) when an external master device starts a data transfer with SPI (transmit and receive).

When FIFO is enabled the data emitted while underflow event is raised is not the last data written in the FIFO.

The TX_underflow indicates an error (data loss) in slave mode.

To avoid having TX_underflow event at the beginning of a transmission, the event TX_underflow is not activated when no data has been loaded into the transmitter register since channel has been enabled.

TX_underflow interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

22.2.4.2.3 RX_FULL

The event RX_full is activated when channel is enabled and receiver becomes filled (transient event). When FIFO buffer is enabled (MCSPI_CH(I)CONF[FFER] set to 1), the RX_full is asserted as soon as there is a number of bytes holds in buffer to read defined by MCSPI_XFERLEVEL[AFL].

Receiver register must be read to remove source of interrupt and RX_full interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

When FIFO is enabled, no new RX_full event will be asserted as soon as Local Host has not performed the number of read into receive register defined by MCSPI_XFERLEVEL[AFL]. It is the responsibility of Local Host to perform the right number of reads.

22.2.4.2.4 RX_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the SPI_RX n register or FIFO is full when a new SPI word is received. The SPI_RX n register is always overwritten with the new SPI word. If the FIFO is enabled data within the FIFO are overwritten, it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW indicates an error (data loss) in slave mode.

The SPI_IRQSTATUS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

22.2.4.2.5 End of Word Count

The event EOW (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in MCSPI_XFERLEVEL[WCNT] register. If the value was programmed to 0000h, the counter is not enabled and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[WCNT] is not reloaded and channel re-enabled.

End of Word interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

22.2.4.3 Slave Transmit-and-Receive Mode

The slave transmit and receive mode is programmable (bits TRM cleared to 0 in the register MCSPI_CH(I)CONF).

After the channel is enabled, transmission and reception proceed with interrupt and DMA request events.

In slave transmit and receive mode, transmitter register should be loaded before SPI is selected by an external SPI master device.

Transmitter register or FIFO (if use of buffer enabled) content is always loaded in shift register whether it has been updated or not. The event TX_underflow is activated accordingly, and does not prevent transmission.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) the received data is transferred to the channel receive register. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured in one data direction Transmit or Receive, then the FIFO is seen as a unique FFNBYTE bytes buffer, or it can also be configured in both data direction Transmit and Receive, then the FIFO is split into two separate FFNBYTE/2 bytes buffer with their own address space management, in this last case the definition of AEL and AFL levels is based on FFNBYTE bytes and is under Local Host responsibility.

22.2.4.4 Slave Receive-Only Mode

The slave receive mode is programmable (bits TRM set to 01 in the register (I)CONF).

In receive only mode, the Transmitter register should be loaded before SPI is selected by an external SPI master device. Transmitter register or FIFO (if use of buffer enabled) content is always loaded in shift register whether it has been updated or not. The event TX_underflow is activated accordingly, and does not prevent transmission.

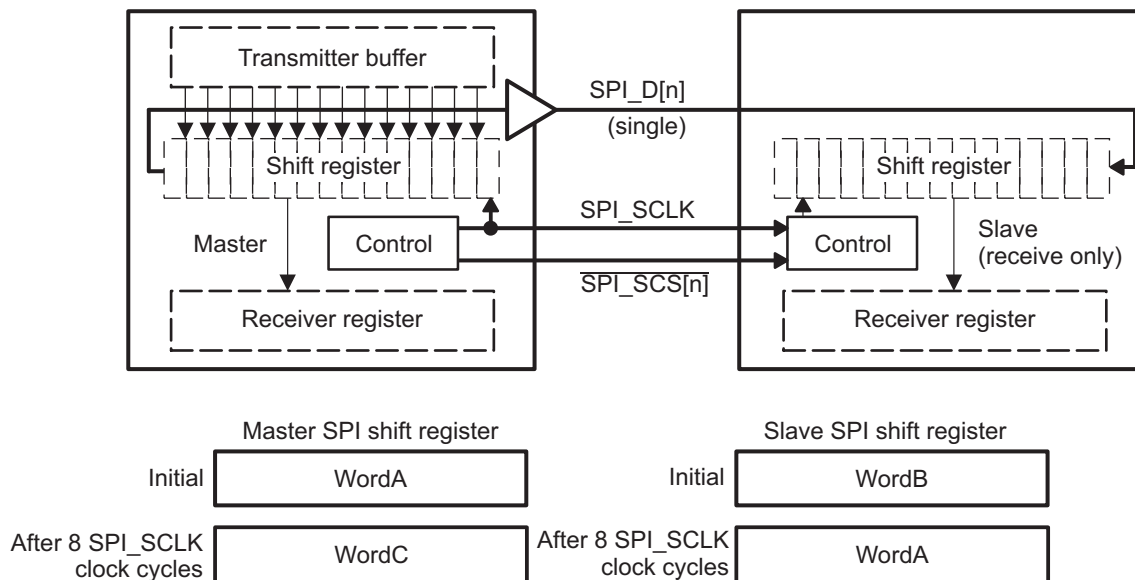

When an SPI word transfer completes (the SPI_m.SPI_CH_nSTAT0[2] EOT bit (with *n* = 0) is set to 1), the received data is transferred to the channel receive register.

To use SPI as a slave receive only device with MCSPI_CH(I)CONF[TRM] = 00, the user has the responsibility of the inhibition of the TX_empty and TX_underflow interrupts and DMA write requests due to the transmitter register state.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) the received data is transferred to the channel receive register. This bit is meaningless when using the Buffer for this channel. The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE bytes buffer.

Figure 22-23 shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock spim_clk, Word A transfers from the master to the slave.

Figure 22-23. SPI Half-Duplex Transmission (Receive-Only Slave)

22.2.4.5 Slave Transmit-Only Mode

The slave transmit only mode is programmable (TRM bit set to 10 in the register MCSPI_CH(I)CONF). This mode avoids the CPU to read the receiver register (minimizing data movement) when only transmission is meaningful.

To use SPI as a slave transmit only device with (I)CONF[TRM] = 00, the user should inhibit the RX_full and RX_overflow interrupts and DMA read requests due to the receiver register state.

On completion of SPI word transfer the bit EOT of the register MCSPI_CH(I)STAT is set. This bit is meaningless when using the buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE bytes buffer.

Figure 22-24 shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, 1 bit transfers in the master. After eight cycles of the serial clock spim_clk, WordB transfers from the slave to the master.

Figure 22-24. SPI Half-Duplex Transmission (Transmit-Only Slave)

22.2.5 Interrupts

According to its transmitter register state and its receiver register state each channel can issue interrupt events if they are enabled.

The interrupt events are listed in the [Section 22.2.3.2](#) and in [Section 22.2.4.2](#).

Each interrupt event has a status bit, in the MCSPI_IRQSTATUS register, which indicates service is required, and an interrupt enable bit, in the MCSPI_IRQENABLE register, which enables the status to generate hardware interrupt requests.

When an interrupt occurs and later a mask is applied on it (IRQENABLE), the interrupt line is not asserted again even if the interrupt source has not been serviced.

SPI supports interrupt driven operation and polling.

22.2.5.1 Interrupt-Driven Operation

Alternatively, an interrupt enable bit, in the MCSPI_IRQENABLE register, can be set to enable each of the events to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the CPU must:

- Read the MCSPI_IRQSTATUS register to identify which event occurred,
- Read the receiver register that corresponds to the event, to remove the source of an RX_full event, or Write into the transmitter register that corresponds to the event, to remove the source of a TX_empty event. No action is needed to remove the source of the events TX_underflow and RX_overflow.
- Write a 1 into the corresponding bit of MCSPI_IRQSTATUS register to clear the interrupt status, and release the interrupt line.

The interrupt status bit should always be reset after channel enabling and before event are enabled as interrupt source.

22.2.5.2 Polling

When the interrupt capability of an event is disabled in the MCSPI_IRQENABLE register, the interrupt line is not asserted and:

- The status bits in the MCSPI_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.
- Once the expected event occurs, CPU must: Read the receiver register that corresponds to the event, to remove the source of an RX_full event, or write into the transmitter register that corresponds to the event, to remove the source of a TX_empty event. No action is needed to remove the source of the events TX_underflow and RX_overflow.
- Writing a 1 into the corresponding bit of MCSPI_IRQSTATUS register clears the interrupt status and does not affect the interrupt line state.

22.2.6 DMA Requests

SPI can be interfaced with a DMA controller. At system level, the advantage is to discharge the local host of the data transfers.

According to its transmitter register state, its receiver register state or FIFO level (if use of buffer for the channel) each channel can issue DMA requests if they are enabled.

The DMA requests need to be disabled in order to get TX and RX interrupts, in order to define either the end of the transfer or the transfer of the last words for the modes listed below:

- Master Transmit On
- Master normal receive only mode
- Master turbo receive only mode
- Slave Transmit Only

There are 2 DMA request lines per channel. The management of DMA requests differ according to use of FIFO buffer or not:

22.2.6.1 FIFO Buffer Disabled

The DMA Read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. DMA Read request can be individually masked with the bit DMAR of the register MCSPI_CH(I)CONF. The DMA Read request line is de-asserted (OCP compliant) on read completion of the receive register of the channel.

The DMA Write request line is asserted when the channel is enabled and the transmitter register of the channel is empty. DMA Write request can be individually masked with the bit DMAW of the register MCSPI_CH(I)CONF. The DMA Write request line is deasserted (OCP compliant) on load completion of the transmitter register of the channel.

Only one SPI word can be transmitted/received per OCP bus access to write/read the transmit or receive register.

22.2.6.2 FIFO Buffer Enabled

The DMA Read request line is asserted when the channel is enabled and a number of bytes defined in MCSPI_XFERLEVEL[AFL] bit field is hold in FIFO buffer for the receive register of the channel. DMA Read request can be individually masked with the bit DMAR of the register MCSPI_CH(I)CONF. The DMA Read request line is de-asserted (OCP compliant) on the first SPI word read completion of the receive register of the channel. No new DMA request will be asserted again as soon as user has not performed the right number of read accesses defined by MCSPI_XFERLEVEL[AFL] it is under user responsibility.

The DMA Write request line is asserted when the channel is enabled and the number of bytes hold in FIFO buffer is below the level defined by the MCSPI_XFERLEVEL[AEL] bit field. DMA Write request can be individually masked with the bit DMAW of the register MCSPI_CH(I)CONF. The DMA Write request line is de-asserted (OCP compliant) on load completion of the first SPI word in the transmitter register of the channel. No new DMA request will be asserted again as soon as user has not performed the right number of write accesses defined by MCSPI_XFERLEVEL[AEL] it is under user responsibility.

Only one SPI word can be transmitted/received per OCP bus access to write/read the transmit or receive FIFO.

22.2.6.3 DMA 256 Bit Aligned Addresses

The controller has two registers, MCSPI_DAFTX and MCSPI_DAFRX, used only with an enabled channel that manages the FIFO to be compliant the a DMA handler providing only 256-bit aligned addresses.

This features is activated when the bit field MCSPI_MODULCTRL[8] FDAA is set to 1 and only one enabled channel has its bit field MCSPI_CH(I)CONF[27] FFE(I)W or MCSPI_CH(I)CONF[28] FFE(I)R enabled.

In this case, the registers MCSPI_TX(I) and MCSPI_RX(I) are not used and data are managed through registers MCSPI_DAFTX and MCSPI_DAFRX.

22.2.7 Emulation Mode

The MReqDebug input differentiates a regular access of a processor (application access), from an emulator access.

Application access: MReqDebug = 0

In functional mode, the consequences of a read of a receiver register MCSPI_RX(i) are the following:

- The source of an RXi_Full event in the MCSPI_IRQSTATUS register is removed, if it was enabled in the MCSPI_IRQENABLE register.
- The RXiS status bit in the MCSPI_IRQSTATUS register is cleared.
- In master mode, depending on the round robin arbitration, and the transmitter register state, the channel may access to the shift register for transmission/reception.

Emulator access: MReqDebug = 1

In emulation mode, SPI behavior is the same as in functional mode but a read of a receiver register MCSPI_RX(i) is not intrusive:

- MCSPI_RX(i) is still considered as not read. When the FIFO buffer is enabled, pointers are not updated.
- The source of an RXi_Full event in the MCSPI_IRQSTATUS register is not removed. The RXiS status bit in the MCSPI_CH(i)STAT register is held steady.

In emulation mode, as in functional mode, based on the ongoing data transfers, the status bits of the MCSPI_CH(i)STAT register may be optionally updated, the interrupt and DMA request lines may be optionally asserted.

22.2.8 Power Saving Management

Independently of the module operational modes (Transmit and/or Receive), two modes of operations are defined from a power management perspective: normal and idle modes.

The two modes are temporally fully exclusive.

SPI is compliant with the profile “IdleReq / SIdleAck / Swakup” in the Idle mode.

22.2.8.1 Normal Mode

Both the OCP clock and SPI clock (CLKSPIREF) provided to SPI must be active for both master and slave modes. The auto-gating of the module OCP clock and SPI clock occurs when the following conditions are met:

- The bit Autoidle of the register MCSPI_SYSCONFIG is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the SPI is not selected by the external SPI master device and no OCP accesses.

Autogating of the module OCP clock and SPI clock stops when the following conditions are met:

- In master mode, an OCP access occurs.
- In slave mode, an OCP access occurs or SPI is selected by an external SPI master device.

22.2.8.2 Idle Mode

The OCP clock and SPI clock provided to SPI may be switched off on system power manager request and switched back on module request.

SPI is compliant with the power management handshaking protocol: idle request from the system power manager, idle acknowledgment from SPI.

The idle acknowledgment in response to an idle request from the system power manager varies according to a programmable mode in the MCSPI_SYSCONFIG register: No idle mode, force idle mode, and smart idle mode.

- When programmed for no idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is set to 01), the module ignores the system power manager request, and behaves normally, as if the request was not asserted.
- When programmed for smart idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is set to 10), the module acknowledges the system power manager request according to its internal state.
- When programmed for force idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is cleared to 00), the module acknowledges the system power manager request unconditionally.

The OCP clock will be optionally switched off, during the smart idle mode period, if the bit ClockActivity of the register MCSPI_SYSCONFIG is set.

The SPI clock will be optionally switched off, during the smart idle mode period, if the second bit ClockActivity of the register MCSPI_SYSCONFIG is set.

SPI assumes that both clocks may be switched off whatever the value set in the field ClockActivity of the register MCSPI_SYSCONFIG.

22.2.8.2.1 Transitions from Normal Mode to Smart-Idle Mode

The module detects an idle request when the synchronous signal IdleReq is asserted.

When IdleReq is asserted, any access to the module will generate an error as long as the OCP clock is alive.

When configured as a slave device, SPI responds to the idle request by asserting the SIdleAck signal (idle acknowledgement) only after completion of the current transfer (SPI_SCS[n]) slave selection signal deasserted by the external master) and if interrupt or DMA request lines are not asserted.

As a master device, SPI responds to the idle request by asserting the SIdleAck signal (idle acknowledgement) only after completion of all the channel data transfers and if interrupt or DMA request lines are not asserted.

As long as SIdleAck is not asserted, if an event occurs, the module can still generate an interrupt or a DMA request after IdleReq assertion. In this case, the module ignores the idle request and SIdleAck will not get asserted: The system power manager will abort the power mode transition procedure. It is then the responsibility of the system to de-assert IdleReq before attempting to access the module.

When SIdleAck is asserted, the module does not assert any new interrupt or DMA request.

22.2.8.2.2 Transition From Smart-Idle Mode to Normal mode

SPI detects the end of the idle period when the idle request signal (IdleReq) is deasserted.

Upon IdleReq de-assertion, the module switches back to normal mode and de-asserts SIdleAck signal. The module is fully operational.

22.2.8.2.3 Force-Idle Mode

Force-idle mode is enabled as follows:

- The bit SIdleMode of the register MCSPI_SYSCONFIG is cleared to 00 (Force Idle).
The force idle mode is an idle mode where SPI responds unconditionally to the idle request by asserting the SIdleAck signal and by deasserting unconditionally the interrupt and DMA request lines if asserted.

The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI_IRQSTATUS register.

In force-idle mode, the module is supposed to be disabled at that time, so the interrupt and DMA request lines are likely deasserted. OCP clock and SPI clock provided to SPI can be switched off.

An idle request during an SPI data transfer can lead to an unexpected and unpredictable result, and is under software responsibility.

Any access to the module in force idle mode will generate an error as long as the OCP clock is alive and IdleReq is asserted.

The module exits the force idle mode when:

- The idle request signal (IdleReq) is de-asserted.
Upon IdleReq de-assertion, the module switches back to normal mode and de-asserts SIdleAck signal. The module is fully operational. The interrupt and DMA request lines are optionally asserted a clock cycle later.

22.2.9 System Test Mode

SPI is in system test mode (SYSTEST) when the bit System_Test of the register MCSPI_MODULCTRL is set.

The SYSTEST mode is used to check in a very simple manner the correctness of the system interconnect either internally to interrupt handler, or power manager, or externally to SPI I/Os.

I/O verification can be performed in SYSTEST mode by toggling the outputs and capturing the logic state of the inputs. (See MCSPI_SYST register definition in [Section 22.3.10](#))

22.2.10 Reset

22.2.10.1 Internal Reset Monitoring

The module is reset by the hardware when an active-low reset signal, synchronous to the OCP interface clock is asserted on the input pin RESETN.

This hardware reset signal has a global reset action on the module. All configuration registers and all state machines are reset, in all clock domains.

Additionally, the module can be reset by software through the bit SoftReset of the register MCSPI_SYSCONFIG. This bit has exactly the same action on the module logic as the hardware RESETN signal. The register MCSPI_SYSCONFIG is not sensitive to software reset. The SoftReset control bit is active high. The bit is automatically reset to 0 by the hardware.

A global ResetDone status bit is provided in the status register MCSPI_SYSSTATUS. This bit is set to 1 when all the different clock domains resets (OCP domain and SPI domains) have been released (logical AND).

The global ResetDone status bit can be monitored by the software to check if the module is ready-to-use following a reset (either hardware or software).

The clock CLKSPIREF must be provided to the module, in order to allow the ResetDone status bit to be set.

When used in slave mode, the clock CLKSPIREF is needed only during the reset phase. The clock CLKSPIREF can be switched off after the ResetDone status is set.

22.2.10.2 Reset values of registers

The reset values of registers and signals are described in [Section 22.3](#).

22.2.11 Access to Data Registers

This section details the supported data accesses (read or write) from/to the data receiver registers MCSPI_RX(i) and data transmitter registers MCSPI_TX(i).

Supported access:

SPI supports only one SPI word per register (receiver or transmitter) and does not support successive 8-bit or 16-bit accesses for a single SPI word.

The SPI word received is always right justified on LSB of the 32-bit register MCSPI_RX(i), and the SPI word to transmit is always right justified on LSB of the 32-bit register MCSPI_TX(i).

The upper bits, above SPI word length, are ignored and the content of the data registers is not reset between the SPI data transfers.

The coherence between the number of bits of the SPI Word, the number of bits of the access and the enabled byte remains under the user's responsibility. Only aligned accesses are supported.

In Master mode, data should not be written in the transmit register when the channel is disabled.

22.2.12 Programming Aid

22.2.12.1 Module Initialization

- Hard or soft reset.
- Read MCSPI_SYSSTATUS.
- Check if reset is done.
- Module configuration: (a) Write into MCSPI_MODULCTRL (b) Write into MCSPI_SYSCONFIG.
- Before the ResetDone bit is set, the clocks CLK and CLKSPIREF must be provided to the module.
- To avoid hazardous behavior, it is advised to reset the module before changing from MASTER mode to SLAVE mode or from SLAVE mode to MASTER mode.

22.2.12.2 SPI Operational Modes Configuration

The selection of the working mode is done through the MCSPI_CHxCONF register (where x = 0, 1, 2 and 3). [Table 22-7](#) through [Table 22-9](#) list the possible operating modes and their configurations.

Table 22-7. SPI Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set receive mode.	MCSPI_CHxCONF[13:12] TRM	0x1
Set the word length.	MCSPI_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	MCSPI_MODULCTRL[2] MS MCSPI_CHxCTRL[0] EN	0x0 0x1
Channels activated low during active state	MCSPI_CHxCONF[6] EPOL	0x1
Clock held high during active state	MCSPI_CHxCONF[1] POL	0x0
Data latched on odd-numbered edges of the SPI clock	MCSPI_CHxCONF[0] PHA	0x0
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 22-8. SPI Transmit Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit mode.	MCSPI_CHxCONF[13:12] TRM	0x2
Set the word length.	MCSPI_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	MCSPI_MODULCTRL[2] MS MCSPI_CHxCTRL[0] EN	0x0 0x1
Channels activated low during active state	MCSPI_CHxCONF[6] EPOL	0x1
Clock held high during active state	MCSPI_CHxCONF[1] POL	0x0

22.2.12.2.1 Common Transfer Procedures Without FIFO – Polling Method

22.2.12.2.1.1 Receive-Only Procedure – Polling Method

Table 22-10 lists the receive-only procedure using the polling method. The SPI is acting as slave.

Table 22-10. Receive-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode	See Table 22-7.	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Wait until receive register is full?	MCSPi_RXx	= 0x1
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0

22.2.12.2.1.2 Receive-Only Procedure – Interrupt Method

Table 22-11 lists the receive-only procedure using the interrupt method. The SPI is acting as slave. Channel 0 is used. For the rest channels (1, 2 and 3) the same logic applies.

Table 22-11. Receive-Only Procedure – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 22-7.	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Enable the interrupt for the receiver register.	MCSPi_IRQENABLE[2] RX0_FULL_ENABLE	0x1
Read the status register.	MCSPi_IRQSTATUS[2] RX0_FULL	0x0
Disable the interrupt.	MCSPi_IRQENABLE[2] RX0_FULL_ENABLE	0x0
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0
Read the receiver register.	MCSPi_RX0	xxxx

22.2.12.2.1.3 Transmit-Only Procedure – Polling Method

Table 22-12 lists the transmit-only procedure using the polling method. The SPI is acting as master.

Table 22-12. Transmit-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 22-8	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Wait until end of transfer?	MCSPi_CHxSTAT[2:1]	= 0x2
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0

22.2.12.2.1.4 Transmit-and-Receive Procedure – Polling Method

Table 22-12 lists the transmit-and-receive procedure using the polling method. The SPI is acting as master and slave.

Table 22-13. Transmit-and-Rceive Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 22-9 .	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Wait until transmit/receive word?	MCSPi_CHxSTAT[2:0]	= 0x3
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0

22.2.12.2.2 Common Transfer Procedures With FIFO – Polling Method

When using FIFO the SPI module can start the transfer only after the first write request is released by writing the MCSPi_TXx register (where x = 0, 1, 2 and 3). The first write request can be managed by the IRQ routine or DMA handler. The end of transfer is more complex and depends on the transfer type. See [Table 22-12](#) through [Table 22-19](#).

In multi-channel master mode, be careful not to overwrite the bits of the other channels when initializing the MCSPi_IRQSTATUS and MCSPi_IRQENABLE registers.

22.2.12.2.2.1 Receive-Only Procedure With Word Count – Polling Method

Table 22-14. Receive-Only Procedure With Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 22-7 .	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Wait until end of word count?	MCSPi_IRQSTATUS[17] EOW	= 0x1
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0
Read from the receiver register.	MCSPi_RXx	xxxx

22.2.12.2.2.2 Transmit-Only Procedure With and Without Word Count – Polling Method

Table 22-15. Transmit-Only Procedure Without Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 22-8 .	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Wait until end of word count?	MCSPi_IRQSTATUS[17] EOW	= 0x1
Wait until end of transfer?	MCSPi_CHxSTAT[2] EOT MCSPi_CHxSTAT[3] TXFFE	= 0x1 = 0x1
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0

22.2.12.2.2.3 Transmit-Only Procedure With and Without Word Count – Interrupt Method

Table 22-16. Transmit-Only Procedure With Word Count – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 22-8 .	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Enable the interrupt for the transmit register.	MCSPi_IRQENABLE[4] TX1_EMPTY_ENABLE	0x1
End of word count.	MCSPi_IRQSTATUS[17] EOW	= 0x1
End of transfer	MCSPi_CHxSTAT[2] EOT MCSPi_CHxSTAT[3] TXFFE	= 0x1 = 0x1
Clear the interrupt.	MCSPi_IRQENABLE[17] EOWKE	= 0x0

Table 22-16. Transmit-Only Procedure With Word Count – Interrupt Method (continued)

Step	Register/Bit Field/Programming Model	Value
Disable the interrupt for the transmit register.	MCSPi_IRQENABLE[4] TX1_EMPTY_ENABLE	0x0
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0

22.2.12.2.2.4 Transmit-and-Receive Procedure With Word Count – Polling Method

Table 22-17. Transmit-and-Receive Procedure With Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 22-9 .	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Wait until end of word count?	MCSPi_IRQSTATUS[17] EOW	= 0x1
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0
Read from the receiver register.	MCSPi_RXx	xxxx

22.2.12.2.2.5 Transmit-and-Receive Procedure with Word Count – Interrupt Method

Table 22-18. Transmit-and-Receive Procedure With Word Count – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 22-9 .	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Enable the interrupt for the receiver register.	MCSPi_IRQENABLE[2] RX0_FULL_ENABLE	0x1
Enable the interrupt for the transmit register.	MCSPi_IRQENABLE[4] TX1_EMPTY_ENABLE	0x1
End of word count?	MCSPi_IRQSTATUS[17] EOW	= 0x1
Clear the interrupt.	MCSPi_IRQENABLE[17] EOWKE	= 0x0
Disable the interrupt for the receiver register.	MCSPi_IRQENABLE[2] RX0_FULL_ENABLE	0x0
Disable the interrupt for the transmit register.	MCSPi_IRQENABLE[4] TX1_EMPTY_ENABLE	0x0
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0
Read from the receiver register.	MCSPi_RXx	xxxx

22.2.12.2.2.6 Transmit-and-Receive Procedure Without Word Count – Polling Method

Table 22-19. Transmit-and-Receive Procedure Without Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 22-9 .	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Wait until end of transfer?	MCSPi_CHxSTAT[2] EOT MCSPi_CHxSTAT[3] TXFFE	= 0x1 = 0x1
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0
Read from the receiver register.	MCSPi_RXx	xxxx

22.2.13 Interrupt and DMA Events

SPI has two DMA requests (Rx and Tx) per channel. It also has one interrupt line for all the interrupt requests.

22.3 SPI Registers

Table 22-20 lists the SPI registers.

Table 22-20. SPI Registers

Offset Address	Acronym	Register Name	Section
0h	MCSPi_HL_REV	McSPI IP revision register	Section 22.3.1
4h	MCSPi_HL_HWINFO	McSPI IP hardware information register	Section 22.3.2

22.3.1 McSPI IP Revision Register (MCSPI_HL_REV)

The McSPI IP revision register (MCSPI_HL_REV) holds the IP revision identifier information. The MCSPI_HL_REV is shown in [Figure 22-25](#) and described in [Table 22-21](#).

Figure 22-25. McSPI IP Revision Register (MCSPI_HL_REV)

LEGEND: R = Read only; -n = value after reset

Table 22-21. McSPI IP Revision Register (MCSPI_HL_REV) Field Descriptions

Bit	Field	Value	Description
31-30	SCHEME	0-3h	Identifies scheme.
29-28	Reserved	0	Reserved for module specific status information. Read returns 0.
27-16	FUNC	0-FFFh	Indicates a software compatible module family.
15-11	R_RTL	0-1Fh	RTL version (R).
10-8	X_MAJOR	0-7h	Major revision (X).
7-6	CUSTOM	0-3h	Indicates a special version for a particular device.
5-0	Y_MINOR	0-3Fh	Minor revision (Y).

22.3.2 McSPI IP Hardware Information Register (MCSPI_HL_HWINFO)

The McSPI IP hardware information register (MCSPI_HL_HWINFO) provides information about the IP hardware configuration. The MCSPI_HL_HWINFO is shown in [Figure 22-26](#) and described in [Table 22-22](#).

Figure 22-26. McSPI IP Hardware Information Register (MCSPI_HL_HWINFO)

LEGEND: R = Read only; -n = value after reset

Table 22-22. McSPI IP Hardware Information Register (MCSPI_HL_HWINFO) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved.
5-1	FFNBYTE	0	FIFO number of byte generic parameter. Defines the value of FFNBYTE generic parameter.
		1h	Reserved
		2h	FIFO 16 bytes depth
		3h	FIFO 32 bytes depth
		4h	Reserved
		5h-7h	FIFO 64 bytes depth
		8h	Reserved
		9h-Fh	FIFO 128 bytes depth
		10h	Reserved
		11h-1Fh	FIFO 256 bytes depth
		11h-1Fh	Reserved
0	USEFIFO	0	Use of a FIFO enable.
		0	FIFO not implemented in design
		1	FIFO and its management implemented in design with depth defined by FFNBYTE generic.

22.3.3 McSPI IP System Configuration Register (MCSPI_HL_SYSCONFIG)

The McSPI IP system configuration register (MCSPI_HL_SYSCONFIG) allows control of the clock management. The MCSPI_HL_SYSCONFIG is shown in Figure 22-27 and described in Table 22-23.

Figure 22-27. McSPI IP System Configuration Register (MCSPI_HL_SYSCONFIG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 22-23. McSPI IP System Configuration Register (MCSPI_HL_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved.
3-2	IDLEMODE	0	Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, that is, regardless of the IP module's internal requirements.
		1h	No-idle mode: local target never enters idle state.
		2h	Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events.
		3h	Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.
1	FREEEMU	0	Sensitivity to emulation (debug) suspend input signal.
		1	IP module is sensitive to emulation suspend.
		1	IP module is not sensitive to emulation suspend.
0	SOFTRESET	Write 0	Software reset.
		Read 0	No action
		Write 1	Reset done, no pending action
		Read 1	Initiate software reset
		Read 1	Reset (software or other) ongoing

22.3.4 McSPI Revision Register (MCSPI_REVISION)

The McSPI revision register (MCSPI_REVISION) contains the hard-coded RTL revision number. The MCSIPI_REVISION is shown in [Figure 22-28](#) and described in [Table 22-24](#).

Figure 22-28. McSPI Revision Register (MCSPI_REVISION)

LEGEND: R = Read only; -n = value after reset

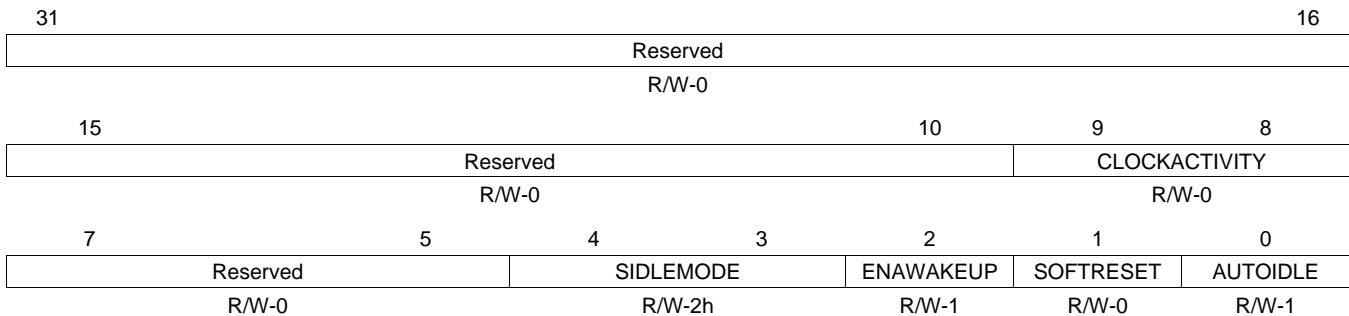

Table 22-24. McSPI Revision Register (MCSPI_REVISION) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved.
7-0	REV	0-FFh	Identifies revision of peripheral.

22.3.5 McSPI System Configuration Register (MCSPI_SYSCONFIG)

The McSPI system configuration register (MCSPI_SYSCONFIG) allows control of various parameters of the module interface. It is not sensitive to software reset. The MCSPI_SYSCONFIG is shown in Figure 22-29 and described in Table 22-25.

Figure 22-29. McSPI System Configuration Register (MCSPI_SYSCONFIG)

LEGEND: R/W = Read/Write; -n = value after reset

Table 22-25. McSPI System Configuration Register (MCSPI_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads returns 0
9-8	CLOCKACTIVITY	0	Clocks activity during wake-up mode period. OCP and Functional clocks may be switched off.
		1h	OCP clock is maintained. Functional clock may be switched-off.
		2h	Functional clock is maintained. OCP clock may be switched-off.
		3h	OCP and Functional clocks are maintained.
7-5	Reserved	0	Reads returns 0
4-3	SIDLEMODE	0	Power management If an idle request is detected, the McSPI acknowledges it unconditionally and goes in Inactive mode. Interrupt, DMA requests are unconditionally de-asserted.
		1h	If an idle request is detected, the request is ignored and keeps on behaving normally.
		2h	Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements.
		3h	Reserved
2	ENAWAKEUP	0	Enable Wakeup. Wakeup capability is disabled.
		1	Wakeup capability is enabled.
1	SOFTRESET	0	Software reset. During reads it always returns 0. (write) Normal mode
		1	(write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware.
0	AUTOIDLE	0	Internal OCP Clock gating strategy OCP clock is free-running
		1	Automatic OCP clock gating strategy is applied, based on the OCP interface activity

22.3.6 McSPI System Status Register (MCSPI_SYSSTATUS)

The McSPI system status register (MCSPI_SYSSTATUS) provides status information about the module excluding the interrupt status information. The MCSI_SYSSTATUS is shown in [Figure 22-30](#) and described in [Table 22-26](#).

Figure 22-30. McSPI System Status Register (MCSPI_SYSSTATUS)

LEGEND: R = Read only; -n = value after reset

Table 22-26. McSPI System Status Register (MCSPI_SYSSTATUS) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved for module specific status information. Read returns 0.
0	RESETDONE	0	Internal Reset Monitoring
		1	Internal module reset is on-going
		1	Reset completed

22.3.7 McSPI Interrupt Status Register (MCSPI_IRQSTATUS)

The McSPI interrupt status register (MCSPI_IRQSTATUS) regroups all the status of the module internal events that can generate an interrupt. The MCSPI_IRQSTATUS is shown in [Figure 22-31](#) and described in [Table 22-27](#).

NOTE: In SYSTEST mode, the bits of this register have no meaning and always read 0.

Figure 22-31. McSPI Interrupt Status Register (MCSPI_IRQSTATUS)

LEGEND: R/W = Read/Write; -n = value after reset

Table 22-27. McSPI Interrupt Status Register (MCSPI_IRQSTATUS) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads returns 0
17	EOW	Write 0 Read 0 Write 1 Read 1	End of word (EOW) count event when a channel is enabled using the FIFO buffer and the channel has sent the number of McSPI words defined by the MCSPI_XFERLEVEL[WCNT]. Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
16	Reserved	0	Reserved
15	Reserved	0	Reads returns 0
14	RX3_FULL	Write 0 Read 0 Write 1 Read 1	Receiver register is full or almost full. Only when Channel 3 is enabled. This bit indicate FIFO almost full status when built-in FIFO is used for receive register (MCSPI_CH3CONF[FFE3R] is set). Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
13	TX3_UNDERFLOW	Write 0 Read 0 Write 1 Read 1	Transmitter register underflow. Only when Channel 3 is enabled. The transmitter register is empty (not updated by Host or DMA with new data) before its time slot assignment. Exception: No TX_underflow event when no data has been loaded into the transmitter register since channel has been enabled. Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.

Table 22-27. McSPI Interrupt Status Register (MCSPi_IRQSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
12	TX3_EMPTY	Write 0 Read 0 Write 1 Read 1	Transmitter register is empty or almost empty. This bit indicate FIFO almost full status when built-in FIFO is used for transmit register (MCSPi_CH3CONF[FFE3W] is set). Note: Enabling the channel automatically raises this event. Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
11	Reserved	0	Reads returns 0
10	RX2_FULL	Write 0 Read 0 Write 1 Read 1	Receiver register full or almost full. Channel 2 This bit indicate FIFO almost full status when built-in FIFO is used for receive register (MCSPi_CH3CONF[FFE2R] is set). Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
9	TX2_UNDERFLOW	Write 0 Read 0 Write 1 Read 1	Transmitter register underflow. Channel 2 Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
8	TX2_EMPTY	Write 0 Read 0 Write 1 Read 1	Transmitter register empty or almost empty. Channel 2. This bit indicate FIFO almost full status when built-in FIFO is used for transmit register (MCSPi_CH3CONF[FFE2W] is set). Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
7	Reserved	0	Reads returns 0
6	RX1_FULL	Write 0 Read 0 Write 1 Read 1	Receiver register full or almost full. Channel 1. This bit indicate FIFO almost full status when built-in FIFO is use for receive register (MCSPi_CH3CONF[FFE1R] is set). Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
5	TX1_UNDERFLOW	Write 0 Read 0 Write 1 Read 1	Transmitter register underflow. Channel 1. Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
4	TX1_EMPTY	Write 0 Read 0 Write 1 Read 1	Transmitter register empty or almost empty. Channel 1. This bit indicate FIFO almost full status when built-in FIFO is use for transmit register (MCSPi_CH3CONF[FFE1W] is set). Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
3	RX0_OVERFLOW	Write 0 Read 0 Write 1 Read 1	Receiver register overflow (slave mode only). Channel 0. Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.

Table 22-27. McSPI Interrupt Status Register (MCSPi_IRQSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
2	RX0_FULL	Write 0 Read 0 Write 1 Read 1	Receiver register full or almost full. Channel 0. Receiver register full or almost full. Channel 0. Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
1	TX0_UNDERFLOW	Write 0 Read 0 Write 1 Read 1	Transmitter register underflow. Channel 0. Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.
0	TX0_EMPTY	Write 0 Read 0 Write 1 Read 1	Transmitter register empty or almost empty. Channel 0. This bit indicate FIFO almost full status when built-in FIFO is use for transmit register (MCSPi_CH3CONF[FFE0W] is set). Event status bit is unchanged. Event false. Event status bit is reset. Event is pending.

22.3.8 McSPI Interrupt Enable Register (MCSPi_IRQENABLE)

This McSPI interrupt enable register (MCSPi_IRQENABLE) enables/disables the module internal sources of interrupt, on an event-by-event basis. The MCSPi_IRQENABLE is shown in [Figure 22-32](#) and described in [Table 22-28](#).

Figure 22-32. McSPI Interrupt Enable Register (MCSPi_IRQENABLE)

Bit	Field	Value	Description
31-18	Reserved	0	Reads return 0
17	EOWKE	0	End of word count interrupt enable. Interrupt is disabled.
		1	Interrupt is enabled.
16	Reserved		Reserved
15	Reserved	0	Reads return 0
14	RX3_FULL_ENABLE	0	MCSPi_RX3 receiver register full or almost full interrupt enable (channel 3). Interrupt is disabled.
		1	Interrupt is enabled.
13	TX3_UNDERFLOW_ENABLE	0	MCSPi_TX3 transmitter register underflow interrupt enable (channel 3). Interrupt is disabled.
		1	Interrupt is enabled.
12	TX3_EMPTY_ENABLE	0	MCSPi_TX3 transmitter register empty or almost empty interrupt enable (channel 3). Interrupt is disabled.
		1	Interrupt is enabled.
11	Reserved	0	Reads return 0
10	RX2_FULL_ENABLE	0	MCSPi_RX2 receiver register full or almost full interrupt enable (channel 2). Interrupt is disabled.
		1	Interrupt is enabled.
9	TX2_UNDERFLOW_ENABLE	0	MCSPi_TX2 transmitter register underflow interrupt enable (channel 2). Interrupt is disabled.
		1	Interrupt is enabled.
8	TX2_EMPTY_ENABLE	0	MCSPi_TX2 transmitter register empty or almost empty interrupt enable (channel 2). Interrupt is disabled.
		1	Interrupt is enabled.
7	Reserved	0	Reads return 0

Table 22-28. McSPI Interrupt Enable Register (MCSPi_IRQENABLE) Field Descriptions (continued)

Bit	Field	Value	Description
6	RX1_FULL_ENABLE	0	MCSPi_RX1 receiver register full or almost full interrupt enable (channel 1) Interrupt is disabled.
		1	Interrupt is enabled.
5	TX1_UNDERFLOW_ENABLE	0	MCSPi_TX1 transmitter register underflow interrupt enable (channel 1). Interrupt is disabled.
		1	Interrupt is enabled.
4	TX1_EMPTY_ENABLE	0	MCSPi_TX1 transmitter register empty or almost empty interrupt enable (channel 1). Interrupt is disabled.
		1	Interrupt is enabled.
3	RX0_OVERFLOW_ENABLE	0	MCSPi_RX0 receiver register overflow interrupt enable (channel 0). Interrupt is disabled.
		1	Interrupt is enabled.
2	RX0_FULL_ENABLE	0	MCSPi_RX0 receiver register full or almost full interrupt enable (channel 0). Interrupt is disabled.
		1	Interrupt is enabled.
1	TX0_UNDERFLOW_ENABLE	0	MCSPi_TX0 transmitter register underflow interrupt enable (channel 0). Interrupt is disabled.
		1	Interrupt is enabled.
0	TX0_EMPTY_ENABLE	0	MCSPi_TX0 transmitter register empty or almost empty interrupt enable (channel 0). Interrupt is disabled.
		1	Interrupt is enabled.

22.3.9 McSPI Wakeup Enable Register (MCSPI_WAKEUPENABLE)

The McSPI wakeup enable register (MCSPI_WAKEUPENABLE) allows you to enable/disable the module internal sources of wakeup on an event-by-event basis. The MCSIPI_WAKEUPENABLE is shown in [Figure 22-33](#) and described in [Table 22-29](#).

Figure 22-33. McSPI Wakeup Enable Register (MCSPI_WAKEUPENABLE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 22-29. McSPI Wakeup Enable Register (MCSPI_WAKEUPENABLE) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. Read returns 0.
0	WKEN	0	Wakeup functionality in slave mode when an active control signal is detected on the SPI_SCS[n] line programmed in MCSIPI_CH(i)CONF[SPIENSLV]. The event is not allowed to wakeup the system, even if MCSIPI_SYSCONFIG[ENAWAKEUP] is set.
		1	The event is allowed to wakeup the system if MCSIPI_SYSCONFIG[ENAWAKEUP] is set.

22.3.10 McSPI System Test Register (MCSPY_SYST)

This McSPI system test register (MCSPY_SYST) is used to configure the system interconnect either internally to the peripheral bus or externally to the device I/O pads, when the module is configured in the system test (SYSTEST) mode. The MCSPY_SYST is shown in Figure 22-34 and described in Table 22-30.

Figure 22-34. McSPI System Test Register (MCSPY_SYST)

Reserved								
R/W-0								
31							16	
15	Reserved			12	11	10	9	8

LEGEND: R/W = Read/Write; -n = value after reset

Table 22-30. McSPI System Test Register (MCSPY_SYST) Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reads returns 0
11	SSB	0	Set status bit. This bit must be cleared prior attempting to clear a status bit of the MCSPY_IRQSTATUS register.
		1	No action. Writing 0 does not clear already set status bits. This bit must be cleared prior attempting to clear a status bit of the <MCSPY_IRQSTATUS> register. Writing 1 sets to 1 all status bits contained in the MCSPY_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits contained in the <MCSPY_IRQSTATUS> register.
10	SPIENDIR	0	Sets the direction of the SPI_SCS[3:0] lines and SPI_SCLK line.
		1	Output (as in master mode). Input (as in slave mode).
9	SPIDATDIR1	0	Sets the direction of the SPI_D[1].
		1	Output Input
8	SPIDATDIR0	0	Sets the direction of the SPI_D[0].
		1	Output Input
7	Reserved	0	Reserved
6	SPICLK		SPI_SCLK line (signal data value) If MCSPY_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If MCSPY_SYST[SPIENDIR] = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this register.
5	SPIDAT_1		SPI_D[1] line (signal data value) If MCSPY_SYST[SPIDATDIR1] = 0 (output mode direction), the SPI_D[1] line is driven high or low according to the value written into this register. If MCSPY_SYST[SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the SPI_D[1] line (high or low), and a write into this bit has no effect.
4	SPIDAT_0		SPI_D[0] line (signal data value) If MCSPY_SYST[SPIDATDIR0] = 0 (output mode direction), the SPI_D[0] line is driven high or low according to the value written into this register. If MCSPY_SYST[SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the SPI_D[0] line (high or low), and a write into this bit has no effect.

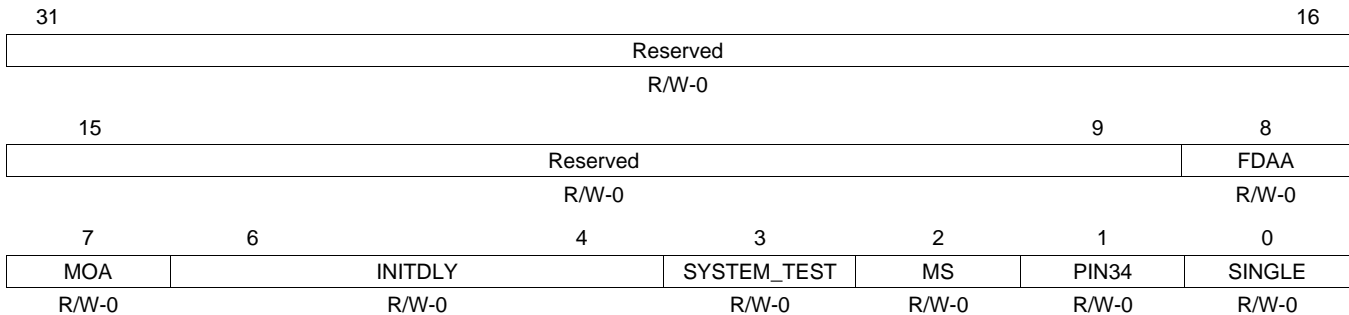

Table 22-30. McSPI System Test Register (MCSPY_SYST) Field Descriptions (continued)

Bit	Field	Value	Description
3	SPIEN_3		<p>$\overline{\text{SPI_SCS}}[3]$ line (signal data value)</p> <p>If MCSPY_SYST[SPIENDIR] = 0 (output mode direction), the $\overline{\text{SPI_SCS}}[3]$ line is driven high or low according to the value written into this register.</p> <p>If MCSPY_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the $\overline{\text{SPI_SCS}}[3]$ line (high or low), and a write into this bit has no effect.</p>
2	SPIEN_2		<p>$\overline{\text{SPI_SCS}}[2]$ line (signal data value)</p> <p>If MCSPY_SYST[SPIENDIR] = 0 (output mode direction), the $\overline{\text{SPI_SCS}}[2]$ line is driven high or low according to the value written into this register.</p> <p>If MCSPY_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the $\overline{\text{SPI_SCS}}[2]$ line (high or low), and a write into this bit has no effect.</p>
1	SPIEN_1		<p>$\overline{\text{SPI_SCS}}[1]$ line (signal data value)</p> <p>If MCSPY_SYST[SPIENDIR] = 0 (output mode direction), the $\overline{\text{SPI_SCS}}[1]$ line is driven high or low according to the value written into this register.</p> <p>If MCSPY_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the $\overline{\text{SPI_SCS}}[1]$ line (high or low), and a write into this bit has no effect.</p>
0	SPIEN_0		<p>$\overline{\text{SPI_SCS}}[0]$ line (signal data value)</p> <p>If MCSPY_SYST[SPIENDIR] = 0 (output mode direction), the $\overline{\text{SPI_SCS}}[0]$ line is driven high or low according to the value written into this register.</p> <p>If MCSPY_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the $\overline{\text{SPI_SCS}}[0]$ line (high or low), and a write into this bit has no effect.</p>

22.3.11 McSPI Module Control Register (MCSPI_MODULCTRL)

This McSPI module control register (MCSPI_MODULCTRL) is used to configure the serial port interface. The MCSPI_MODULCTRL is shown in [Figure 22-35](#) and described in [Table 22-31](#).

Figure 22-35. McSPI Module Control Register (MCSPI_MODULCTRL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 22-31. McSPI Module Control Register(MCSPI_MODULCTRL) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	
8	FDAA	0 1	FIFO DMA Address 256-bit aligned. This register is used when a FIFO is managed by the module and DMA connected to the controller provides only 256 bit aligned address. If this bit is set the enabled channel which uses the FIFO has its datas managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TX(i) and MCSPI_RX(i) registers. 0 FIFO data managed by MCSPI_TX(i) and MCSPI_RX(i) registers. 1 FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.
7	MOA	0 1	Multiple word ocp access. This register can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit OCP word access. This is possible for WL < 16. 0 Multiple word access disabled 1 Multiple word access enabled with FIFO
6-4	INITDLY	0 1h 2h 3h 4h 5h-Fh	Initial SPI delay for first transfer. This register is an option only available in single master mode, The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock, No clock output provided to the boundary and chip select is not active in 4 pin mode within this period. 0 No delay for first SPI transfer 1h The controller wait 4 SPI bus clock 2h The controller wait 8 SPI bus clock 3h The controller wait 16 SPI bus clock 4h The controller wait 32 SPI bus clock 5h-Fh Reserved
3	SYSTEM_TEST	0 1	Enables the system test mode 0 Functional mode 1 System test mode (SYSTEST)
2	MS	0 1	Master/ Slave 0 Master - The module generates the SPI_SCLK and $\overline{\text{SPI_SCS}}[3:0]$ 1 Slave - The module receives the SPI_SCLK and $\overline{\text{SPI_SCS}}[3:0]$
1	PIN34	0 1	Pin mode selection. This register is used to configure the SPI pin mode, in master or slave mode. If asserted, the controller only use SPI_D[0], SPI_D[1], and SPI_SCLK clock pin for SPI transfers. 0 $\overline{\text{SPI_SCS}}[n]$ is used as a chip select. 1 $\overline{\text{SPI_SCS}}[n]$ is not used. In this mode all related option to chip select have no meaning.

Table 22-31. McSPI Module Control Register(MCSPI_MODULCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
0	SINGLE	0	Single channel / Multichannel (master mode only) For master mode, the user has to set this bit to 0 for Multi or 1 for Single. For Slave mode, this bit has to be set to 0. More than one channel will be used in master mode.
		1	Only one channel will be used in master mode. This bit must be set in Force $\overline{\text{SPI_SCS}}[n]$ mode.

22.3.12 McSPI Channel (i) Configuration Register (MCSPI_CH(i)CONF)

The McSPI channel *i* configuration register (MCSPI_CH(i)CONF) is used to configure channel *i*. The (MCSPI_CH(i)CONF) is shown in [Figure 22-36](#) and described in [Table 22-32](#).

Figure 22-36. McSPI Channel (i) Configuration Register (MCSPI_CH(i)CONF)

Bit	Field	Value	Description
31-30	Reserved	0	Read returns 0
29	CLKG	0 1	Clock divider granularity. This register defines the granularity of channel clock divider: power of two or one clock cycle granularity. When this bit is set the register MCSPI_CHCTRL[EXTCLK] must be configured to reach a maximum of 4096 clock divider ratio. Then The clock divider ratio is a concatenation of MCSPI_CHCONF[CLKD] and MCSPI_CHCTRL[EXTCLK] values. 0 Clock granularity of power of 2 1 1 clock cycle granularity
28	FFER	0 1	FIFO enabled for receive. Only one channel can have this bit set. 0 The buffer is not used to receive data. 1 The buffer is used to receive data.
27	FFEW	0 1	FIFO enabled for transmit. Only one channel can have this bit set. 0 The buffer is not used to transmit data. 1 The buffer is used to transmit data.
26-25	TCS	0 1h 2h 3h	Chip select time control. This 2-bit field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock. 0 0.5 clock cycles 1h 1.5 clock cycles 2h 2.5 clock cycles 3h 3.5 clock cycles
24	SBPOL	0 1	Start bit polarity. 0 Start bit polarity is held to 0 during SPI transfer. 1 Start bit polarity is held to 1 during SPI transfer.
23	SBE	0 1	Start bit enable for SPI transfer. 0 Default SPI transfer length as specified by WL bit field. 1 Start bit D/CX added before SPI transfer. Polarity is defined by MCSPI_CH(i)CONF[SBPOL].

Table 22-32. McSPI Channel (i) Configuration Register (MCSPI_CH(i)CONF) Field Descriptions (continued)

Bit	Field	Value	Description	
22-21	SPIENSLV		Channel 0 only and slave mode only: SPI slave select signal detection.	
		0	Detection enabled only on $\overline{\text{SPI_SCS}}[0]$	
		1h	Detection enabled only on $\overline{\text{SPI_SCS}}[1]$	
		2h	Detection enabled only on $\overline{\text{SPI_SCS}}[2]$	
		3h	Detection enabled only on $\overline{\text{SPI_SCS}}[3]$	
		20	FORCE	Manual $\overline{\text{SPI_SCS}}[n]$ assertion to keep $\overline{\text{SPI_SCS}}[n]$ active between SPI words. (single channel master mode only)
		0	Writing 0 into this bit drives the $\overline{\text{SPI_SCS}}[n]$ line when MCSPI_CHCONF(i)[EPOL] = 0, and drives it high when MCSPI_CHCONF(i)[EPOL] = 1.	
		1	Writing 1 into this bit drives the $\overline{\text{SPI_SCS}}[n]$ line when MCSPI_CHCONF(i)[EPOL] = 0, and drives it low when MCSPI_CHCONF(i)[EPOL] = 1.	
19	TURBO		Turbo mode.	
		0	Turbo is deactivated (recommended for single SPI word transfer).	
		1	Turbo is activated to maximize the throughput for multi-SPI word transfers.	
		18	IS	Input select
		0	Data line 0 (SPI_D[0]) selected for reception.	
		1	Data line 1 (SPI_D[1]) selected for reception.	
17	DPE1		Transmission enable for data line 1 (SPIDATAGZEN[1])	
		0	Data line 1 (SPI_D[1]) selected for transmission	
		1	No transmission on data line 1 (SPI_D[1])	
		16	DPE0	Transmission enable for data line 0 (SPIDATAGZEN[0])
		0	Data line 0 (SPI_D[0]) selected for transmission	
		1	No transmission on data line 0 (SPI_D[0])	
15	DMAR		DMA read request. The DMA read request line is asserted when the channel is enabled and new data is available in the receive register of the channel. The DMA read request line is deasserted on read completion of the receive register of the channel.	
		0	DMA read request is disabled.	
		1	DMA read request is enabled.	
		14	DMAW	DMA write request. The DMA write request line is asserted when the channel is enabled and the MCSPI_TXn register of the channel is empty. The DMA write request line is deasserted on load completion of the MCSPI_TXn register of the channel.
		0	DMA write request is disabled.	
		1	DMA write request is enabled.	
13-12	TRM		Transmit/receive modes.	
		0	Transmit and receive mode	
		1h	Receive-only mode	
		2h	Transmit-only mode	
		3h	Reserved	

Table 22-32. McSPI Channel (i) Configuration Register (MCSPI_CH(i)CONF) Field Descriptions (continued)

22.3.13 McSPI Channel (i) Status Register (MCSPi_CH(i)STAT)

The McSPI channel *i* status register register (MCSPi_CH(i)STAT) provides status information about the McSPI channel *i* FIFO transmit buffer register (MCSPi_TX*n*) and the McSPI channel *i* FIFO receive buffer register (MCSPi_RX*n*) of channel *i*. The (MCSPi_CH(i)STAT) is shown in [Figure 22-37](#) and described in [Table 22-34](#).

Figure 22-37. McSPI Channel (i) Status Register (MCSPi_CH(i)STAT)

31	Reserved							8
R-0								
7	6	5	4	3	2	1	0	
Reserved	RXFFF	RXFFE	TXFFF	TXFFE	EOT	TXS	RXS	
R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 22-34. McSPI Channel (i) Status Register (MCSPi_CH(i)STAT) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Read returns 0
6	RXFFF	0 1	Channel <i>i</i> FIFO receive buffer full status. FIFO receive buffer is not full. FIFO receive buffer is full.
5	RXFFE	0 1	Channel <i>i</i> FIFO receive buffer empty status. FIFO receive buffer is not empty. FIFO receive buffer is empty.
4	TXFFF	0 1	Channel <i>i</i> FIFO transmit buffer full status. FIFO transmit buffer is not full. FIFO transmit buffer is full.
3	TXFFE	0 1	Channel <i>i</i> FIFO transmit buffer empty status. FIFO transmit buffer is not empty. FIFO transmit buffer is empty.
2	EOT	0 1	Channel <i>i</i> end-of-transfer status. The definitions of beginning and end of transfer vary with master versus slave and the transfer format (transmit/receive mode, turbo mode). 0 This flag is automatically cleared when the shift register is loaded with the data from the transmitter register (beginning of transfer). 1 This flag is automatically set to one at the end of an SPI transfer.
1	TXS	0 1	Channel <i>i</i> transmitter register status. The bit is cleared when the host writes the most significant byte of the SPI word in the MCSPi_TX(i) register. The bit is set when enabling the channel <i>i</i> , and also when the SPI word is transferred from the MCSPi_TX(i) register to the shift register. 0 Register is full. 1 Register is empty.
0	RXS	0 1	Channel <i>i</i> receiver register status. The bit is cleared when enabling the channel <i>i</i> , and also when the host reads the most significant byte of the received SPI word from the MCSPi_RX(i) register. The bit is set when the received SPI word is transferred from the shift register to the MCSPi_RX(i) register. 0 Register is empty. 1 Register is full.

22.3.14 McSPI Channel (*i*) Control Register (MCSPI_CH(I)CTRL)

The McSPI channel *i* control register (MCSPI_CH*i*CTRL) is used to enable channel *i*. The MCSPI_CH*i*CTRL is shown in [Figure 22-38](#) and described in [Table 22-35](#).

Figure 22-38. McSPI Channel (*i*) Control Register (MCSPI_CH(I)CTRL)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-35. McSPI Channel (*i*) Control Register (MCSPI_CH(I)CTRL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-8	EXTCLK	0	Clock ratio extension. Used to concatenate with the CLKD bit field in MCSPI_CH <i>n</i> CONF for clock ratio only when granularity is 1 clock cycle (CLKG bit in MCSPI_CH <i>n</i> CONF set to 1). Then the maximum value reached is a 4096 clock divider ratio.
		1h	Clock ratio is CLKD + 1
	
		FFh	Clock ratio is CLKD + 1 + 4080
7-1	Reserved	0	Reserved
0	EN	0	Channel <i>n</i> enable.
		0	Channel <i>n</i> is not active.
		1	Channel <i>n</i> is active.

22.3.15 McSPI Channel *i* Transmit Register (MCSPI_TX(*i*))

The McSPI channel *i* transmit register (MCSPI_TX(*i*)) contains a single McSPI word to transmit on the serial link. The (MCSPI_TX(*i*)) is shown in [Figure 22-39](#) and described in [Table 22-36](#).

- Little endian host access SPI 8 bit word on 0; big endian host accesses on 3h.
- The SPI words are transferred with MSB first.

Figure 22-39. McSPI Channel *i* Transmit Register (MCSPI_TX(*i*))

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 22-36. McSPI Channel *i* Transmit Register (MCSPI_TX(*i*)) Field Descriptions

Bit	Field	Value	Description
31-0	TDATA	0-FFFF FFFFh	Channel <i>i</i> data to transmit.

22.3.16 McSPI Channel *i* Receive Register (MCSPI_RX(*i*))

The McSPI channel *i* FIFO receive buffer register (MCSPI_RX(*i*)) contains a single McSPI word received through the serial link. The (MCSPI_RX(*i*)) is shown in [Figure 22-40](#) and described in [Table 22-37](#).

- Little endian host access SPI 8 bit word on 0; big endian host accesses on 3h.

Figure 22-40. McSPI Channel *i* Receive Register (MCSPI_RX(*i*))

Table 22-37. McSPI Channel *i* Receive Register (MCSPI_RX(*i*)) Field Descriptions

Bit	Field	Value	Description
31-0	RDATA	0-FFFF FFFFh	Channel <i>i</i> received data.

22.3.17 McSPI Transfer Levels Register (MCSPI_XFERLEVEL)

The McSPI transfer levels register (MCSPI_XFERLEVEL) provides the transfer levels needed while using the FIFO buffer during transfer. The MCSIPI_XFERLEVEL is shown in [Figure 22-41](#) and described in [Table 22-38](#).

Figure 22-41. McSPI Transfer Levels Register (MCSPI_XFERLEVEL)

LEGEND: R/W = Read/Write; -n = value after reset

Table 22-38. McSPI Transfer Levels Register (MCSPI_XFERLEVEL) Field Descriptions

Bit	Field	Value	Description
31-16	WCNT	0 1 ... FFFEh FFFFh	SPI word counter. Holds the programmable value of the number of SPI words to be transferred on the channel that is using the FIFO buffer. When the transfer has started, a read back of this register returns the current SPI word transfer index. Counter not used 1 SPI word ... 65534 SPI word 65535 SPI word
15-8	AFL	0 1 ... FFh	Buffer almost full. Holds the programmable almost full level value used to determine almost full buffer condition. If you want an interrupt or a DMA read request to be issued during a receive operation when the data buffer holds at least <i>n</i> bytes, then the buffer MCSIPI_XFERLEVEL[AFL] must be set with <i>n</i> - 1. 1 byte 2 bytes ... 256 bytes
7-0	AEL	0 1 ... FFh	Buffer almost empty. Holds the programmable almost empty level value used to determine almost empty buffer condition. If you want an interrupt or a DMA write request to be issued during a transmit operation when the data buffer is able to receive <i>n</i> bytes, then the buffer MCSIPI_XFERLEVEL[AEL] must be set with <i>n</i> - 1. 1 byte 2 bytes ... 256 bytes

22.3.18 DMA Address Aligned FIFO Transmitter Register (MCSPI_DAFTX)

The DMA address aligned FIFO transmitter register (MCSPI_DAFTX) contains the SPI words to transmit on the serial link when the FIFO used and the DMA address is aligned on 256 bits. MCSPI_DAFTX is an image of one of MCSPI_TX(*i*) register corresponding to the channel that has its FIFO enabled. The MCSPI_DAFTX is shown in [Figure 22-42](#) and described in [Table 22-39](#).

- Little endian host access SPI 8 bit word on 0; big endian host accesses on 3h.
- The SPI words are transferred with MSB first.

Figure 22-42. DMA Address Aligned FIFO Transmitter Register (MCSPI_DAFTX)

LEGEND: R/W = Read/Write; -n = value after reset

Table 22-39. DMA Address Aligned FIFO Transmitter Register (MCSPI_DAFTX) Field Descriptions

Bit	Field	Value	Description
31-0	DAFTDATA	0-FFFF FFFFh	FIFO data to transmit with DMA 256 bit aligned address. This register is only is used when MCSPI_MODULCTRL[FDAA] is set to 1 and only one of the MCSPI_CH(i)CONF[FFEW] of enabled channels is set. If these conditions are not respected, any access to this register returns a null value.

22.3.19 DMA Address Aligned FIFO Receiver Register (MCSPI_DAFRX)

The DMA address aligned FIFO receiver register (MCSPI_DAFRX) contains the SPI words to receive on the serial link when the FIFO used and the DMA address is aligned on 256 bits. MCSPI_DAFRX is an image of one of MCSPI_RX(*i*) register corresponding to the channel that has its FIFO enabled. The MCSPI_DAFRX is shown in [Figure 22-43](#) and described in [Table 22-40](#).

- Little endian host access SPI 8 bit word on 0; big endian host accesses on 3h.

Figure 22-43. DMA Address Aligned FIFO Receiver Register (MCSPI_DAFRX)

LEGEND: R/W = Read/Write; -n = value after reset

Table 22-40. DMA Address Aligned FIFO Receiver Register (MCSPI_DAFRX) Field Descriptions

Bit	Field	Value	Description
31-0	DAFRDATA	0-FFFF FFFFh	FIFO received data with DMA 256 bit aligned address. This register is only is used when MCSPI_MODULCTRL[FDAA] is set to 1 and only one of the MCSPI_CH(i)CONF[FFER] of enabled channels is set. If these conditions are not respected, any access to this register returns a null value.

Timers

This chapter describes the operation of the software-programmable timer.

Topic	Page
23.1 Introduction	2586
23.2 Architecture	2589

23.1 Introduction

23.1.1 Overview

The timer module contains a free running upward counter with auto reload capability on overflow. The timer counter can be read and written in real-time (while counting). The timer module includes compare logic to allow an interrupt event on a programmable counter matching value.

A dedicated output signal can be pulsed or toggled on overflow and a matched event. This output can be used as a timing stamp trigger signal or PWM (pulse-width modulation) signal source. An additional dedicated output signal (PORGPOCFG) can be used for general-purpose IO, directly driven by bit 14 of the Timer Control Register (TCLR). Based on the programmable input signal transition type, a dedicated signal can be used to trigger an automatic timer counter capture event and generate an interrupt. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged in one module interrupt line and one wake-up line. Each internal interrupt source can be independently enabled or disabled.

This module is controllable through the OCP peripheral bus.

As two clock domains are managed inside this module, resynchronization is done by special logic between the OCP clock domain and the Timer clock domain. At reset, synchronization logic allows utilization of all ratios between the OCP clock and the Timer clock. A drawback of this mode is that the full-resynchronization path is used with access latency performance impact in terms of OCP clock cycles. In order to improve module access latency, and under restricted conditions on clock ratios, write-posted mode can be used by setting the POSTED bit of the Timer Synchronous Interface Control Register (TSICR). Under posted mode, the OCP write command is granted before the write process is complete in the timer clock domain. This mode allows software to do concurrent writes on Dual Mode timer registers and to observe write process completion (synchronization) at the software level by reading independent write posted status bits in the Write Posted Status Register (TWPS).

23.1.2 Features

The timer consists of the following features:

- Counter timer with compare and capture modes
- Auto-reload mode
- Start-stop mode
- Programmable divider clock source
- 16-32 bit addressing
- “On the fly” read/write registers
- Interrupts generated on overflow, compare and capture
- Interrupt enable
- Wake-up enable
- Write posted mode
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general purpose use PORGPOCFG
- OCP interface compatible

The Timer resolution and interrupt period are dependent on the selected input clock and clock prescale value. Example resolutions for common clock values are shown in [Table 23-1](#).

Table 23-1. Timer Resolution and Maximum Range

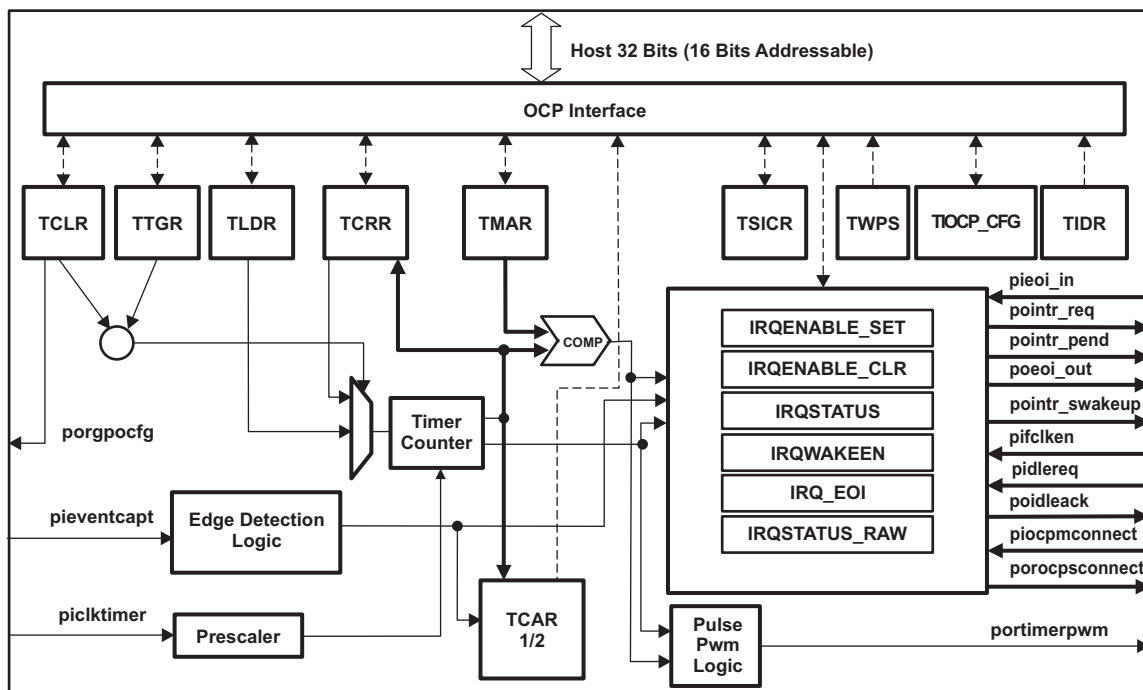

Clock	Prescaler	Resolution	Interrupt Period Range ⁽¹⁾
32 KHz	1 (min)	31.25 us	62.5 us to ~37h 17m
	256 (max)	8 ms	16 ms to ~397d 16h 22m
27 MHz	1 (min)	~37 ns	~74 ns to ~159s
	256 (max)	~9.48 us	~18.9 us to ~11h 18m
38.4 MHz	1 (min)	~26 ns	~52 ns to ~112 s
	256 (max)	~6.7 us	~13.3 us to ~7h 57m

⁽¹⁾ Minimum calculation adheres to recommendation of 2 clock cycle minimum between interrupts.

23.1.3 Functional Block Diagram

Figure 23-1 shows a block diagram of the timer.

Figure 23-1. Timer Block Diagram

23.1.4 GP Timer External System Interface

The general-purpose (GP) timer can send or receive stimulus to/from the external (off-chip) system. In the device, however, only certain timers are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count. See the device-specific data manual details on which timers have IO capabilities.

Figure 23-2 shows the external system interface for the GP timers.

NOTE: For the timers with IO capabilities, the PORGPOCFG output signal selects the timer PWM output or the timer capture input signal to the TIMn_IO pad at the top level. When $TCLR[GPO_CFG] = 1$, TIMn_IO functions as a capture input. When $TCLR[GPO_CFG] = 0$, TIMn_IO functions as a PWM output.

23.2 Architecture

23.2.1 Functional Description

The general-purpose timer is an upward counter. It supports 3 functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

23.2.1.1 Timer Mode Functionality

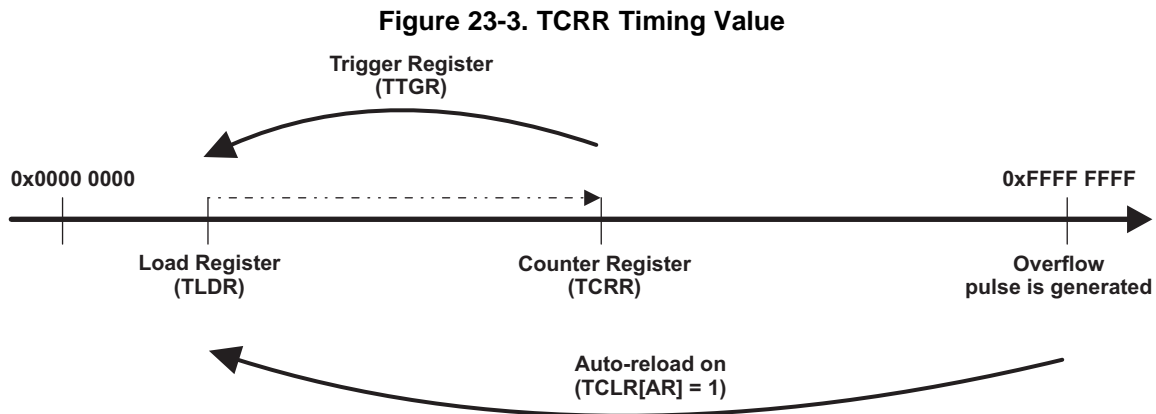

The timer is an upward counter that can be started and stopped at any time through the ST bit of the Timer Control Register (TCLR). The Timer Counter Register (TCRR) can be loaded when stopped or on the fly (while counting). TCRR can be loaded directly by a TCRR write access with the new timer value. TCRR can also be loaded with the value held in the Timer Load Register (TLDR), due to a write access to the Timer Trigger Register (TTGR). TCRR is loaded regardless of the TTGR written value. The TCRR value can be read when stopped or captured on-the-fly by a TCRR read access. The timer is stopped and the counter value is cleared to "0" when the module's reset is asserted. The timer is maintained in a stopped state after reset is released. When the timer is stopped, TCRR does not increment. The counter can be restarted from the frozen value unless TCRR has been reloaded with a new value.

When the one-shot mode is enabled (TCLR[AR] = 0), the counter is stopped after a counting overflow (counter value remains at zero).

When the auto-reload mode is enabled (TCLR[AR] = 1), TCRR is reloaded with the Timer Load Register (TLDR) value after a counting overflow.

It is not recommended to put the overflow value (FFFF FFFFh) in TLDR because it can lead to undesired results.

An interrupt can be issued on overflow, if the overflow interrupt enable bit is set in the Timer IRQENABLE Set Register (IRQENABLE_SET[OVF_EN_FLAG] = 1). In addition, a dedicated output pin can be used to generate one positive pulse (picktimer duration) or to invert the current value (toggle mode) when an overflow occurs. Refer to [Section 23.2.1.5](#) for more details related to the dedicated pulse-width modulation (PWM) output pin.

23.2.1.2 Capture Mode Functionality

The timer value in TCRR can be captured and saved in TCAR1 or TCAR2 function of the mode selected in TCLR through the field CAPT_MODE when a transition is detected on the module input pin (PIEVENTCAPT). The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

Rising transition, falling transition or both can be selected in TCLR (TCM bit) to trig the timer counter capture. The module sets the IRQSTATUS (TCAR_IT_FLAG bit) when an active transition is detected and at the same time the counter value TCRR is stored in one of the timer capture registers TCAR1 or TCAR2 as follows:

- If TCLR's CAPT_MODE field is 0 then, on the first enabled capture event, the value of the counter register is saved in TCAR1 register and all the next events are ignored (no update on TCAR1 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR's position writing a 1 in it.
- If TCLR's CAPT_MODE field is 1 then, on the first enabled captured event, the counter value is saved in TCAR1 register and, on the second enabled capture event, the value of the counter register is saved in TCAR2 register. All the other events are ignored (no update on TCAR1/2 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR's position writing a 1 in it. This mechanism is useful for period calculation of a clock if that clock is connected to the PIEVENTCAPT input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served - TCAR_IT_FLAG bit of IRQSTATUS (previously 1) is cleared. The timer functional clock (input to prescaler) is used to sample the input pin (PIEVENTCAPT). Input negative or positive pulse can be detected when pulse time is above functional clock period. An interrupt can be issued on transition detection if the capture interrupt enable bit is set in the Timer Interrupt Enable Register IRQENABLE_SET (TCAR_IT_FLAG bit).

In [Figure 23-4](#), the TCM value is 01 and CAPT_MODE is 0 - only rising edge of the PIEVENTCAPT will trigger a capture in TCAR and only TCAR1 will update.

In [Figure 23-5](#), the TCM value is 01 and CAPT_MODE is 1 - only rising edge of the PIEVENTCAPT will trigger a capture in TCAR1 on first enabled event and TCAR2 will update on the second enabled event.

Figure 23-4. Capture Wave Example for CAPT_MODE = 0

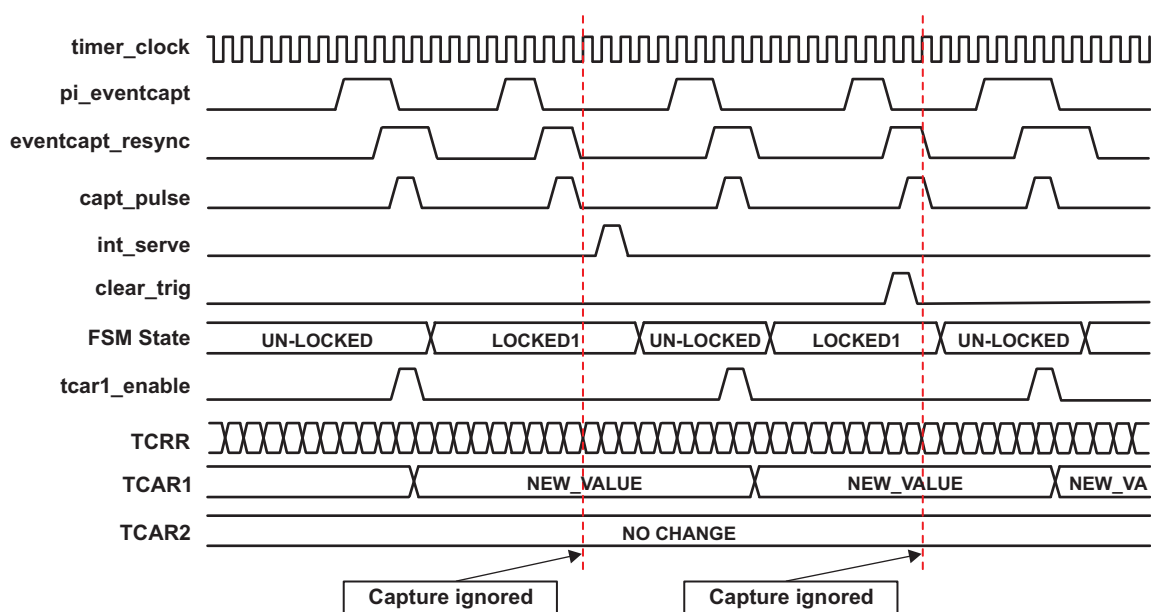

Figure 23-5. Capture Wave Example for CAPT_MODE = 1

23.2.1.3 Compare Mode Functionality

When the Compare Enable bit of the Timer Control Register (TCLR[CE]) is set to 1, the timer value in the Timer Counter Register (TCRR) is permanently compared to the value held in the Timer Match Register (TMAR). The TMAR value can be loaded at any time (timer counting or stopped). When the TCRR and the TMAR values match, an interrupt can be issued if the match interrupt enable bit is set in the Timer IRQENABLE Set Register (IRQENABLE_SET[MAT_EN_FLAG] = 1). Software should write a compare value in the TMAR register before setting the TCLR[CE] bit to avoid any unwanted interrupt due to a reset value matching effect.

A dedicated output pin can be used to generate one positive pulse (piclktimer duration) or to invert the current value (toggle mode) when an overflow and a match occur. Refer to [Section 23.2.1.5](#) for more details related to the dedicated pulse-width modulation (PWM) output pin.

23.2.1.4 Prescaler Functionality

A prescaler counter can be used to divide the timer counter input clock frequency. The prescaler is enabled when the PRE bit of the Timer Control Register (TCLR[PRE]) is set. The 2ⁿ division ratio value (PTV) can be configured in the TCLR register. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly. Refer to [Section 23.2.1.6](#) for more details on the prescaler clock ratio values.

Table 23-2. Prescaler Functionality

Contexts	Prescaler Counter	Timer Counter
Overflow (when Auto-reload on)	Reset	TLDR
TCRR Write	Reset	TCRR
TTGR Write	Reset	TLDR
Stop	Reset	Frozen

23.2.1.5 Pulse-Width Modulation

The timer can be configured to provide a programmable pulse-width modulation (PWM) output on a dedicated output pin (PORTIMERPWM). The PORTIMERPWM output pin can be configured to toggle on a specified event. The TRG field of the Timer Control Register (TCLR[TRG]) determines the trigger event when the PORTIMERPWM pin toggles. Either overflow or the combination of both overflow and match can be used to toggle the PORTIMERPWM pin.

When both overflow and match are configured to trigger the PWM pin, the matched event will be ignored from the moment the mode was set-up until the first overflow event occurs (see [Figure 23-7](#)).

The SCPWM bit in the TCLR register can be programmed to set or clear the PORTIMERPWM output signal only while the counter is stopped or the triggering is disabled. This allows fixing a deterministic state of the output pin while modulation is stopped. The modulation is synchronously stopped when the TRG bit is cleared and overflow occurs.

In the following timing diagrams, the internal overflow pulse is set each time an overflow occurs in the Timer Counter Register (TCRR), and the internal match pulse is set when the counter reaches the Timer Match Register (TMAR) value. Depending on the configured value of the TRG and PT bits of the TCLR register, the timer generates one pulse or inverts the current value on the output pin (PORTIMERPWM).

The Timer Load Register (TLDR) and Timer Match Register (TMAR) must keep values smaller than the overflow value (FFFF FFFFh) with at least 2 units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the TLDR and TMAR registers must be at least 2 units. When match event is used, the CE bit of the TCLR register must be set.

In [Figure 23-6](#), TCLR[SCPWM] is cleared to 0. In [Figure 23-7](#), TCLR[SCPWM] is set to 1.

Figure 23-6. Timing Diagram of Pulse-Width Modulation with SCPWM = 0

Figure 23-7. Timing Diagram of Pulse-Width Modulation with SCPWM = 1

23.2.1.6 Timer Counting Rate

The timer counter is composed of a prescaler stage and a timer counter. The prescaler stage is clocked with the timer input clock and acts as a clock divider for the timer counter stage. The ratio can be managed by accessing the ratio definition field of the control register (PTV and PRE of TCLR). See [Table 23-3](#).

The timer rate is defined by:

- The value of the prescaler fields (PRE and PTV of TCLR register)
- The value loaded into the Timer Load Register (TLDR).

Table 23-3. Prescaler Clock Ratios Value

PRE	PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

The timer rate equation is as follows:

$$(FFFF\ FFFFh - TLDR + 1) \times \text{timer Clock period} \times \text{Clock Divider (PS)}$$

With timer Clock period = 1/ timer Clock frequency and PS = $2^{(PTV + 1)}$.

As an example, if we consider a timer clock input of 32 kHz, with a PRE field equal to 0, the timer output period is:

Table 23-4. Value and Corresponding Interrupt Period

TLDR	Interrupt period
0000 0000h	~37 h
FFFF 0000h	~2 s
FFFF FFF0h	500 μ s
FFFF FFFEh	62.5 μ s

23.2.1.7 Dual Mode Timer Under Emulation

During emulation mode (when PINSUSPENDN signal is active), the timer can/cannot continue running according to the value of the EmuFree bit of the timer OCP configuration register (TIOCP_CFG).

If EmuFree is 1, timer execution is not stopped and, regardless of the value of PINSUSPENDN signal, and the interrupt assertion is still generated when overflow is reached.

If EmuFree is 0, counters (prescaler/timer) are frozen and an increment start occurs again as soon as PINSUSPENDN becomes inactive. The asynchronous input pin is internally synchronized on 2 TIMER clock rising edges.

23.2.2 Accessing Registers

All registers are 32-bit wide, accessible via OCP interface with 16-bit or 32-bit OCP access (Read/Write). The 32-bit registers write update in 16 bits access must be LSB16 first and the second write access must be MSB16. For the write operation, the module allows skipping the MSB access if the user does not need to update the 16 MSB bits of the register, but only for the OCP registers (TIDR, TIOCP_CFG, IRQ_EOI, IRQSTATUS_RAW, IRQSTATUS, IRQENABLE_SET, IRQENABLE_CLR, IRQWAKEEN and TSICR). The write operation on any functional register (TCLR, TCRR, TLDR, TTGR and TMAR) must be complete (the MSB must be written even if the MSB data is not used).

23.2.2.1 Programming the Timer Registers

The TLDR, TCRR, TCLR, TIOCP_CFG, IRQ_EOI, IRQSTATUS, IRQENABLE_SET, IRQENABLE_CLR, IRQWAKEEN, TTGR, TSICR and TMAR registers write is done synchronously with OCP clock, by the host, using the OCP bus protocol.

23.2.2.2 Reading the Timer Registers

The counter register (TCRR) is a 32-bit “atomic datum” and 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. Atomic capture is also performed for the TCAR1 and TCAR2 registers as they may change due to internal processes.

23.2.2.3 OCP Error Generation

The timer module responds with error indication in the following cases:

Error on write transactions

- Assert the PORSRESP = ERR signal in the same cycle as PORSCMDACCEPTED.
- Use the ERR code for PORSRESP during the response phase.

Error on read transactions

- Assert the PORSRESP = ERR signal in the same cycle as PORSCMDACCEPTED.
- Use the ERR code for PORSRESP during the response phase. PORSDATA in this case is not valid.

Table 23-5. OCP Error Reporting

Error Type	Response: SRESP = ERR
Unsupported PIOCPMCMDCMD command	Yes
Address error: Read or write to a non-existing internal address	No
Read to write-only registers and write to read-only registers	No
Unaligned address (PIOCPMADDR ≠ 00) on read/write transaction	Yes
Unsupported PIOCPMBYTEEN on read/write transaction	Yes

NOTE: Byte enable “0000” is a supported byte enable.

23.2.3 Posted Mode Selection

A choice between the two synchronization modes will be made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to functional registers that require synchronization on/from timer clock domain. For write operation the registers affected by this posted/non-posted selection are: TCLR, TLDR, TCRR, TTGR and TMAR. For read operation the register affected by this posted/non-posted selection are: TCRR, TCAR1 and TCAR2.

The OCP clock domain synchronous registers TIDR, TIOCP_CFG, TISTAT, IRQ_EOI, IRQSTATUS, IRQSTATUS_RAW, IRQENABLE_SET, IRQENABLE_CLR, IRQWAKEEN, TWPS and TSICR are not affected by the posted/non-posted mode selection; the write/read operation is effective and acknowledged (command accepted) after one OCP clock cycle from the command assertion.

The configuration posted/non-posted is made by setting the PIFREQRATIO when the module is integrated. The PIFREQRATIO signal should be tied to '1' when the freq (timer) < freq (OCP)/4 frequency, and tied to 0 when it is the opposite frequency ratio. The PIFREQRATIO represent the reset value of the TSICR (POSTED bit). The configuration can be changed (overwritten) by software, writing the TSICR (POSTED bit) register.

The following cases are possible:

- Posted Mode can be used when the functional frequency range is: freq (timer) < freq (OCP)/4.
- Non-Posted Mode can be used regardless of the frequency range. Recommended frequency is: freq (timer) >= freq (OCP)/4.

NOTE: The Non-Posted Mode can be also used when freq (timer) < freq (OCP)/4, but it is recommended to use the Posted Mode. Using Non-Posted Mode will delay the command accept and the transaction latency will be as described in the below chapters. Posted mode offers an OCP interface latency improvement and can be used only if the frequencies respect the freq (timer) < freq (OCP)/4 formula.

23.2.4 Write Registers Access

23.2.4.1 Write Posted

This mode can be used only if the functional frequency range is freq (timer) < freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is set to 1 in the timer control register.

This mode uses a posted-write scheme to update any internal register. The write transaction is immediately acknowledged on the OCP interface, although the effective write operation will occur later, due to a resynchronisation in the timer clock domain. This has the advantage of not stalling either the interconnect system, or the CPU that requested the write transaction. For each register, a status bit is provided, that is set if there is a pending write access to this register.

In this mode, it is mandatory that the CPU checks the status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can lead to unexpected results also).

There is one status bit per register, accessible in the Timer Write Posted Status Register. When the timer module operates in this mode, there is an automatic sampling of the current timer counter value, in an OCP-synchronized capture register. Consequently, any read access to the timer counter register does not add any re-synchronization latency; the current value is always available.

A register read following a write posted register (on the same register) is not insured to read the previous write value if the write posted process is not completed. Software synchronization should be used to avoid non-coherent read.

The drawback of this automatic update mechanism is that it assumes a given relationship between the OCP interface frequency and the timer functional frequency.

This posted period is defined as the interval between the posted write access request and the reset of the posted bit in TWPS register, and can be quantified:

$$T \text{ (reset posted max.)} = 3 \text{ OCP clock} + 2.5 \text{ TIMER clock}$$

The time when the write accomplishes is:

$$T \text{ (write accomplish)} = 1 \text{ OCP clock} + 2.5 \text{ TIMER clock}$$

23.2.4.2 Write Non-Posted

This mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is $\text{freq}(\text{timer}) \geq \text{freq}(\text{OCP})/4$.

This mode is used if TSICR (POSTED bit) is cleared to 0 in the timer control register.

This mode uses a non posted-write scheme to update any internal register. That means the write transaction will not be acknowledged on the OCP interface, until the effective write operation occurs, after the resynchronisation in the timer clock domain. The drawback is that both the interconnect system and the CPU are stalled during this period.

- The latency of the interrupt serving is increased, as the interconnect system and CPU are stalled.
- An interconnect logic, including time-out logic to detect erroneous transactions, can generate an unwanted system abort event.

The stall period is defined as the interval between the non-posted write access request and the rise of the command accept signal and can be quantified:

$$T(\text{stall max.}) = 3 \text{ OCP clock} + 2.5 \text{ TIMER clock}$$

The time when the write accomplishes is:

$$T(\text{write accomplish}) = 1 \text{ OCP clock} + 2.5 \text{ TIMER clock}$$

A register read following a write to the same register is always coherent.

23.2.5 Read Registers Access

23.2.5.1 Read Posted

This mode can be used only if the functional frequency range is $\text{freq}(\text{timer}) < \text{freq}(\text{OCP})/4$.

This mode is used if TSICR (POSTED bit) is set to 1 in the timer control register.

This mode uses a posted-read scheme, for reading any internal register. The read transaction is immediately acknowledged on the OCP interface, and the value to be read has been previously resynchronised. This has the advantage of not stalling either the interconnect system, or the CPU that requested the read transaction.

23.2.5.2 Read Non-Posted

This mode is functional whatever the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is $\text{freq}(\text{timer}) \geq \text{freq}(\text{OCP})/4$.

This mode is used if TSICR (POSTED bit) is cleared to 0 in the timer control register.

This mode uses a non posted-read scheme, for reading any internal register. The read transaction will not be acknowledged on the OCP interface, until the effective read operation occurs, after the resynchronisation in the timer clock domain. The drawback is that both the interconnect system and the CPU are stalled during this period.

- The latency of the interrupt serving is increased, as the interconnect system and the CPU are stalled.
- An interconnect system including time-out logic to detect erroneous transactions can generate an unwanted system abort event.

This mode only applies only to three registers: TCRR, TCAR1 and TCAR2, which need resynchronisation from functional to OCP clock domains.

The stall period is defined as the interval between the non-posted read access request and the rise of the command accept signal and can be quantified:

$$T(\text{stall max.}) = 3 \text{ OCP clock} + 2.5 \text{ TIMER clock}$$

The time when the value is sampled is:

$$T(\text{read sample}) = 1 \text{ OCP clock} + 2.5 \text{ TIMER clock}$$

Timer Registers

The timer registers are listed in [Table 23-6](#). All registers are:

- 32-bit register accessible in 16-bit mode
- Little-endian addressing

Table 23-6. Timer Registers

Offset	Acronym	Register Name	Section
00h	TIDR	Identification Register	Section 23.2.6
10h	TIOCP_CFG	Timer OCP Configuration Register	Section 23.2.7

23.2.6 TIDR Register

This read only register contains the revision number of the module. A write to this register has no effect. This register is used by software to track features, bugs, and compatibility.

Figure 23-8. TIDR Register

LEGEND: R = Read only; -n = value after reset

Table 23-7. TIDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1	Used to distinguish between old scheme and current.
29-28	Reserved	R	0	Reads return 0
27-16	FUNC	R	FFFh	Function indicates a software compatible module family.
15-11	R_RTL	R	2h	RTL Version (R).
10-8	X_MAJOR	R	3h	Major Revision (X).
7-6	CUSTOM	R	0	Indicates a special version for a particular device.
5-0	Y_MINOR	R	1	Minor Revision (Y).

23.2.7 TIOCP_CFG Register

This register allows controlling various parameters of the OCP interface.

Figure 23-9. TIOCP_CFG Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-8. TIOCP_CFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	Reserved	R	0	Reserved
3-2	IDLEMODE	R/W	0	Power management, req/ack control 0 = Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements. Backup mode, for debug only. 1h = No-idle mode: local target never enters idle state. Backup mode, for debug only. 2h = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events. 3h = Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.
1	EMUFREE	R/W	0	Emulation mode 0 = The timer is frozen in emulation mode (PINSUSPENDN signal active). 1 = The timer runs free, regardless of PINSUSPENDN value.
0	SOFTRESET	R/W	0	Software reset Read 0 = Reset done, no pending action Write 0 = No action Read 1 = Reset ongoing Write 1 = Initiate software reset

23.2.8 IRQ_EOI Register

Software End-Of-Interrupt: Allows the generation of further pulses on the interrupt line, if a new interrupt event is pending, when using the pulsed output.

Unused when using the level interrupt line (depending on module integration).

Figure 23-10. IRQ_EOI Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-9. IRQ_EOI Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0	Reserved
0	LINE_NUMBER	R/W	0	Write the number of the interrupt line to apply a SW EOI to it. Note that there is only a single line (that is, number 0) Read 0 = Always returns 0 Write 0 = SW EOI on interrupt line Write 1 = No action

23.2.9 IRQSTATUS_RAW Register

Component interrupt request status.

Check the corresponding secondary status register. Raw status is set even if event is not enabled. Write 1 to set the (raw) status, mostly for debug.

Figure 23-11. IRQSTATUS_RAW Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-10. IRQSTATUS_RAW Register Field Descriptions

Bit	Field	Type	Reset	Description

4-2	PTV	R/W	0	Pre-scale clock Timer value. See Table 23-3 for more details.
1	AR	R/W	0	0 = One shot timer 1 = Auto-reload timer
0	ST	R/W	0	In the case of one-shot mode selected (AR = 0), this bit is automatically reset by internal logic when the counter is overflowed. 0 = Stop timer: Only the counter is frozen 1 = Start timer

23.2.15 TCRR Register

The TCRR register is a 32-bit register, 16-bit addressable. The MCU can perform a 32-bit access or two 16-bit accesses to access the register. Note that since the OCP clock is completely asynchronous with the timer clock, some synchronization is done in order to make sure that the TCRR value is not read while it is being incremented.

In 16-bit mode the following sequence must be followed to read the TCRR register properly:

First, perform an OCP Read Transaction to Read the lower 16-bit of the TCRR register (offset = 3Ch). When the TCRR is read and synchronized, the lower 16-bit LSBs are driven onto the output OCP data bus and the upper 16-bit MSBs of the TCRR register are stored in a temporary register.

Second, perform an OCP Read Transaction to read the upper 16-bit of the TCRR register (offset = 3Eh). During this Read, the value of the upper 16-bit MSBs that has been temporary register is forwarded onto the output OCP data bus.

So, to read the value of TCRR correctly, the first OCP read access has to be to the lower 16-bit (offset = 3Ch), followed by OCP read access to the upper 16-bit (offset = 3Eh).

As the TCRR is updated using more sources (shadow_in_tcrr, incremented value of tcrr, TLDR and "0"), a priority order will be defined:

The first priority is the OCP update.

The second is the reload way (triggered through TTGR reg. or following an auto-reload overflow).

The third is the one-shot overflow reset to 0.

The last is the incremented value.

Figure 23-17. TCRR Register

Table 23-17. TLDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	LOAD_VALUE	R/W	0	Timer counter value loaded on overflow in auto-reload mode or on TTGR write access

23.2.17 TTGR Register

The read value of this register is always FFFF FFFFh.

Figure 23-19. TTGR Register

31	TTGR_VALUE	0
R/W-FFFF FFFFh		

LEGEND: R = Read only; -n = value after reset

Table 23-18. TTGR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TTGR_VALUE	R/W	FFFF FFFFh	Any write to the TTGR register will load the value from TLDR into TCRR and clear the prescaler counter. This will occur regardless of the AR field value in the TCLR register. A read access of TTGR will always return FFFF FFFFh.

23.2.18 TWPS Register

In posted mode the software must read the pending write status bits (Timer Write Posted Status register bits [4:0]) to insure that following write access will not be discarded due to on going write synchronization process. These bits are automatically cleared by internal logic when the write to the corresponding register is acknowledged.

4	W_PEND_TMAR	R	0	When equal to 1, a write is pending to the TMAR register
3	W_PEND_TTGR	R	0	When equal to 1, a write is pending to the TTGR register
2	W_PEND_TLDR	R	0	When equal to 1, a write is pending to the TLDR register
1	W_PEND_TCRR	R	0	When equal to 1, a write is pending to the TCRR register
0	W_PEND_TCLR	R	0	When equal to 1, a write is pending to the TCLR register

23.2.19 TMAR Register

The TMAR register stores the value to be compared against the counter's current value using the timer's compare logic.

Figure 23-21. TMAR Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 23-20. TMAR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	COMPARE_VALUE	R/W	0	Value to be compared to the timer counter

23.2.20 TCAR1 Register

When the appropriate (rising, falling or both) transition is detected in the edge detection logic the current counter value is stored to the TCAR1 register. Note that since the OCP clock is completely asynchronous with the timer clock, some synchronization is done in order to make sure that the TCAR1 value is not read while it is being updated due to some capture event.

In 16-bit mode the following sequence must be followed to read the TCAR1 register properly:

First, perform an OCP Read Transaction to Read the lower 16-bits of the TCAR1 register.

Second, perform an OCP Read Transaction to read the upper 16-bits of the TCAR1 register.

Figure 23-22. TCAR1 Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 23-21. TCAR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	CAPTURED_VALUE	R	0	Timer counter value captured on an external event trigger

23.2.21 TSICR Register

Access to this register is not stalled even if the timer is in non-posted mode configuration. To abort any wrong behavior, software can permanently reset the functional part of the module. Also in case of a wrong hardware PIFREQRATIO tied the POSTED field can be reprogrammed on the fly, so deadlock situation cannot happen.

Reset value of POSTED depends on hardware integration module at design time. Software must read POSTED field to get the hardware module configuration.

Figure 23-23. TSICR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-22. TSICR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-3	Reserved	R	0	Reserved
2	POSTED	R/W	0	PIFREQRATIO 0 = Posted mode inactive: will delay the command accept output signal. 1 = Posted mode active (clocks ratio needs to fit freq (timer) less than freq (OCP)/4 frequency requirement)
1	SFT	R/W	0	This bit resets all the function parts of the module. During reads it always returns 0. 0 = Software reset is disabled 1 = Software reset is enabled
0	Reserved	R	0	Reserved

23.2.22 TCAR2 Register

When the appropriate (rising, falling or both) transition is detected in the edge detection logic and the capture on second event is activated from the control register (TCLR), the current counter value is stored to the TCAR2 register. Note that since the OCP clock is completely asynchronous with the timer clock, some synchronization is done in order to make sure that the TCAR2 value is not read while it is being updated due to some capture event.

In 16-bit mode the following sequence must be followed to read the TCAR2 register properly:

First, perform an OCP Read Transaction to Read the lower 16-bits of the TCAR2 register.

Second, perform an OCP Read Transaction to read the upper 16-bits of the TCAR2 register.

Figure 23-24. TCAR2 Register

UART/IrDA/CIR Module

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module.

Topic	Page
24.1 Introduction	2613
24.2 Architecture	2615
24.3 UART Registers	2647

24.1 Introduction

24.1.1 Main Features

The main features of each of the UARTs are:

- Selectable UART/IrDA/CIR modes
- 16C750 compatibility
- Dual 64 entry FIFOs for received and transmitted data payload
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- Complete status reporting capabilities in both normal and sleep mode
- Frequency prescaler values from 0 to 16383 to generate the appropriate baud rates
- Internal system clock reference for baud setting (In this document, a 48 MHz reference clock is considered. For more information on reference clock support, see your device-specific data manual)
- Two DMA requests, 1 interrupt request to the system
- Break character detection and generation
- Configurable data format
 - Data bit: 5, 6, 7, or 8 bits
 - Parity bit: Even, odd, none
 - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)

The UART/IrDA module can operate in six different modes:

- UART 16x mode
- UART 16x mode with autobauding (greater than or equal to 1200 bits/s and less than or equal to 115.2 Kbits/s)
- UART 13x mode
- IrDA SIR mode (less than or equal to 115.2 Kbits/s)
- IrDA MIR mode (0.576 and 1.152 Mbits/s)
- IrDA FIR mode (4 Mbits/s)
- CIR mode (programmable modulation rates specific to remote control applications)

24.1.2 UART/Modem Functions

The UART/Modem has the following functions:

- Baud-rate from 300 bits/s up to 3.6864 Mb/s (with a 48 MHz reference clock)
- Auto-baud between 1200 bits/s and 115.2 Kbits/s
- Software/Hardware flow control
 - Programmable Xon/Xoff characters
 - Programmable auto-RTS and auto-CTS
- Programmable serial interface characteristics
 - 5, 6, 7, or 8 bit characters
 - Even, odd, mark (always = 1), space (always = 0) or no parity (non parity bit frame) bit generation and detection
 - 1, 1.5, or 2 stop bit generation
- False start bit detection
- Line break generation and detection
- Fully prioritized interrupt system controls
- Internal test and loopback capabilities
- Modem control functions ($\overline{\text{CTS}}$, $\overline{\text{RTS}}$, $\overline{\text{DSR}}$, $\overline{\text{DTR}}$, RIN, and $\overline{\text{DCD}}$)

24.1.3 IrDA Functions

The IrDA has the following functions:

- Slow infrared (SIR 115.2 KBAUD), medium infrared (MIR 0.576 MBAUD) and fast infrared (FIR 4.0 MBAUD) operations (very fast infrared (VFIR) is not supported)
- Framing error, cyclic redundancy check (CRC) error, illegal symbol (FIR), abort pattern (SIR, MIR) detection
- 8-entry status FIFO (with selectable trigger levels) available to monitor frame length and frame errors

24.1.4 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR includes the following key features to provide CIR support for remote control applications:

- Consumer Infrared remote control mode with programmable data encoding
- Transmit and receive modes supported
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

24.2 Architecture

24.2.1 UART Signal Descriptions

Table 24-1 describes the UART interface.

Table 24-1. UART Signal Description

Signal	I/O	Description	Reset
RX	I	Serial data input for all modes.	Unknown
TX	O	Serial data output in UART modes. In other modes, this pin is set to the reset value (inactive state).	1
IRTX	O	Serial data output in IrDA modes (SIR, MIR and FIR). In other modes, this pin is set to the reset value (inactive state).	0
RCTX	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
$\overline{\text{CTS}}$	I	Clear to send. Active-low modem status signal. Reading bit 4 of the modem status register checks the condition of $\overline{\text{CTS}}$. Reading bit 0 of that register checks a change of state of $\overline{\text{CTS}}$ since the last read of the modem status register. $\overline{\text{CTS}}$ is used in auto-CTS mode to control the transmitter.	Unknown
$\overline{\text{RTS}}$	O	Request to send. When active (low), the module is ready to receive data. Setting modem control register bit 1 activates $\overline{\text{RTS}}$. It becomes inactive as a result of a module reset, loop back mode or by clearing the MCR[1]. In auto-RTS mode, it becomes inactive as a result of the receiver threshold logic.	1
SD	O	SD mode is used to configure the transceivers. The SD pin out is an inverted value of ACREG[6].	1
$\overline{\text{DSR}}$	I	Data set ready: Active-low modem status signal. Reading bit 5 of the modem status register checks the condition of $\overline{\text{DSR}}$. Reading bit 1 of that register checks a change of state of $\overline{\text{DSR}}$ since the last read of the modem status register.	Unknown
$\overline{\text{DTR}}$	O	Data terminal ready: When active (low), this signal informs the modem that the module is ready to communicate. It is activated by setting bit 0 of the modem control register.	1
$\overline{\text{DCD}}$	I	Data carrier detect: Active-low modem status signal. The condition of $\overline{\text{DCD}}$ can be checked by reading bit 7 of the modem status register and any change in its state can be detected by reading bit 3 of that register.	Unknown
RIN	I	Ring indicator: Active-low modem status signal. The condition of RIN can be checked by reading bit 6 of the modem status register and any change in its state can be detected by reading bit 2 of that register.	Unknown

NOTE: Not all UART instances on a specific device support the full pinout shown here. Refer to the device data manual for details

24.2.2 UART/IrDA/CIR Mode Selection

To select a mode, set the MODESELECT field in MDR1[2:0] (see Table 24-2).

Table 24-2. UART Mode Selection

MDR1[2:0] Value	Mode
0h	UART 16x mode
1h	SIR mode
2h	UART 16x auto-baud
3h	UART 13x mode
4h	MIR mode
5h	FIR mode
6h	CIR mode
7h	Disable (default state)

24.2.3 UART Mode

This section describes how the UART functions in UART wired mode. [Figure 24-1](#) shows how to connect the UART operating in UART mode to another UART on an external device.

Figure 24-1. UART to UART Connection With Full Handshaking

The UART uses a wired interface for serial communication with a remote device. It can use hardware or software flow control to manage transmission/reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals. Software flow control automatically controls data flow by using programmable XON/XOFF characters.

The UART modem module is enhanced with an autobauding functionality, which in control mode allows to automatically set the speed, the number of bit per character, and the parity selected. [Figure 24-2](#) shows the UART frame data format. Each frame consists of a start bit, 5 to 8 data bits (user configurable), an optional parity bit (user configurable), and 1 or 2 stop bits (user configurable).

Figure 24-2. UART Frame Data Format

uart-005

24.2.3.1 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled/disabled independently by programming EFR[7:6]. With auto-CTS, $\overline{\text{CTS}}$ must be active before the module can transmit data.

Auto-RTS only activates the $\overline{\text{RTS}}$ output when there is enough room in the RX FIFO to receive data and de-activates the $\overline{\text{RTS}}$ output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the TCR determine the levels at which $\overline{\text{RTS}}$ is activated/de-activated.

If both auto-CTS and auto-RTS are enabled, data transmission does not occur unless the receiver FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If not enabled, overrun errors occur if the transmit data rate exceeds the receive FIFO latency.

24.2.3.1.1 Auto-RTS

Auto-RTS data flow control originates in the receiver block (see functional block diagram). The receiver FIFO trigger levels used in auto-RTS are stored in the TCR. $\overline{\text{RTS}}$ is active if the RX FIFO level is below the HALT trigger level in TCR[3:0]. When the receiver FIFO HALT trigger level is reached, $\overline{\text{RTS}}$ is de-asserted. The sending device (for example, another UART) may send an additional byte after the trigger level is reached because it may not recognize the de-assertion of $\overline{\text{RTS}}$ until it has begun sending the additional byte. $\overline{\text{RTS}}$ is automatically reasserted once the receiver FIFO reaches the RESUME trigger level programmed via TCR[7:4]. This reassertion requests the sending device to resume transmission.

24.2.3.1.2 Auto-CTS

The transmitter circuitry checks $\overline{\text{CTS}}$ before sending the next data byte. When $\overline{\text{CTS}}$ is active, the transmitter sends the next byte. To stop the transmitter from sending the following byte, $\overline{\text{CTS}}$ must be de-asserted before the middle of the last stop bit that is currently being sent. The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the $\overline{\text{CTS}}$ state changes need not trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO and a receiver overrun error can result.

24.2.3.2 Software Flow Control

Software flow control is enabled through the enhanced feature register (EFR) and the modem control register (MCR). Different combinations of software flow control can be enabled by setting different combinations of EFR[3:0]. There are two other enhanced features relating to software flow control:

- XON any function (MCR[5]): operation will resume after receiving any character after recognizing the XOFF character. The XON-any character is written into the RX FIFO even if it is a software flow character.
- Special character (EFR[5]): Incoming data is compared to XOFF2. Detection of the special character sets the XOFF interrupt (IIR[4]) but does not halt transmission. The XOFF interrupt is cleared by a read of the IIR. The special character is transferred to the RX FIFO.

24.2.3.2.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission is halted after completing transmission of the current character. XOFF detection also sets IIR[4] (if enabled via IER[5]) and causes the interrupt line to go low. To resume transmission a XON1/2 character must be received (in certain cases XON1 and XON2 must be received sequentially). When the correct XON characters are received IIR[4] is cleared and the XOFF interrupt disappears.

NOTE: If a parity, framing or break error occurs while receiving a software flow control character, this character will be treated as normal data and will be written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled no valid XON or XOFF characters are written to the RX FIFO. For example, EFR[1:0] = 10, if XON1 and XOFF1 characters are received they do not get written to the RX FIFO. In the case where pairs of software flow characters are programmed to be received sequentially (EFR[1:0] = 11) the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

24.2.3.2.2 Transmit (TX)

- XOFF1: Two characters are transmitted when the RX FIFO has passed the programmed trigger level TCR[3:0].
- XON1: Two characters are transmitted when the RX FIFO reaches the trigger level programmed via TCR[7:4].

NOTE: If after an XOFF character has been sent, software flow control is disabled, the module transmits XON characters automatically to enable normal transmission to proceed.

The transmission of XOFF/XON (s) follows the exact same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is set to be 5, 6 or 7 characters then the 5, 6 or 7 least significant bits of XOFF1,2/XON1,2 are transmitted. Note that the transmission of 5, 6, or 7 bits of a character is seldom done but this functionality is included to maintain compatibility with earlier designs. It is assumed that software flow control and hardware flow control will never be enabled simultaneously.

24.2.3.3 Break and Time-Out Conditions

24.2.3.3.1 Time-Out Counter

An RX idle condition is detected when the receiver line, RX, has been high for a time equivalent to 4X programmed word length+12 bits. The receiver line is sampled midway through each bit. For sleep mode the counter is reset when there is activity on the RX line. For the timeout interrupt, the counter only counts when there is data in the RX FIFO and the count is reset when there is activity on the RX line or when the RHR is read.

24.2.3.3.2 Break Condition

When a break condition occurs, the TX line is pulled low. A break condition is activated by setting LCR[6]. Be aware that the break condition is not aligned on word stream; that is, a break condition can occur in the middle of a character. The only way to send a break condition on a full character, is:

- Reset transmit FIFO (if enabled)
- Wait for transmit shift register becomes empty (LSR[6] = 1)
- Take a guard time according to stop bit definition
- Set LCR[6] to 1

A break condition is asserted as long as LCR[6] is set to 1. The above functionality (timeout counter and break condition) only applies to the UART Modem operation and does not extend to the IrDA/CIR modes of operation.

NOTE: A break condition is asserted irrespective of CTS state when auto-CTS is programmed.

24.2.3.4 UART Configuration Example

This section proposes outlines the programming stages to operate one UART module with FIFO, interrupt and no DMA capabilities. This is a three-step procedure that ensures quick start of these modules (obviously it does not cover every UART module feature). The first stage covers SW reset of the module (interrupts, status and controls); the second stage deals with FIFO configuration and enable. Finally, last stage deals with the baud rate data and stop configuration. The procedure below is programming language agnostic.

24.2.3.4.1 UART Software Reset

Goal: To clear IER and MCR registers: remove UART breaks (LCR[6] = 0) and put module in reset (MDR1[2:0] = 7h).

Procedure: To write into both the IER and MCR register, EFR[4] must first be set to 1. To be able to access the EFR register, BFh must first be written to LCR register. Hence LCR = BFh; first write to the LCR register EFR[4] = 1. When LCR = BFh, enable the enhanced feature register LCR[7] = 0. Here, access to IER and MCR is allowed. IER = 0; disable interrupt MCR = 0. Force control signals inactive LCR[6] = 0. Here, UART breaks are removed MDR1 = 7h. Here, UART is in reset or disabled. Alternatively, the SYSC[1] can be set to 1 to start a hardware reset from the generic synchronous reset module. The reset progress can be monitored via the SYSS[0]. Once complete the above sequence should ensure the UART is in the equivalent disabled mode with reference to MDR1[2:0].

24.2.3.4.2 UART FIFO Configuration

Goal: To set trigger level for halt/restore (TCR register), set trigger level for transmit/receive (TLR register), and configure FIFO (FCR register).

Procedure: To write into both the TLR and TCR registers, EFR[4] must be set to 1 and MCR[6] to 1. To write into FCR, EFR[4] must be set to 1. Note that EFR[4] = 1 has already been done in the previous section, hence a write to MCR[6] is necessary. MCR[6] = 1; set TCR, TLR, and FCR to the desired value. Here, accesses to TCR, TLR, and FCR must be disabled to avoid any further undesired writes to these registers. Hence, LCR = BFh, provides access to EFR, EFR[4] = 0; LCR[7] = 0; MCR[6] = 0.

24.2.3.4.3 Baud Rate Data and Stop Configuration

Goal: To configure UART data and stop (LCR register). baud rate (DLH and DLL registers), and enable UART operation. In case interrupt capability is added, configuration must be added right before UART enable.

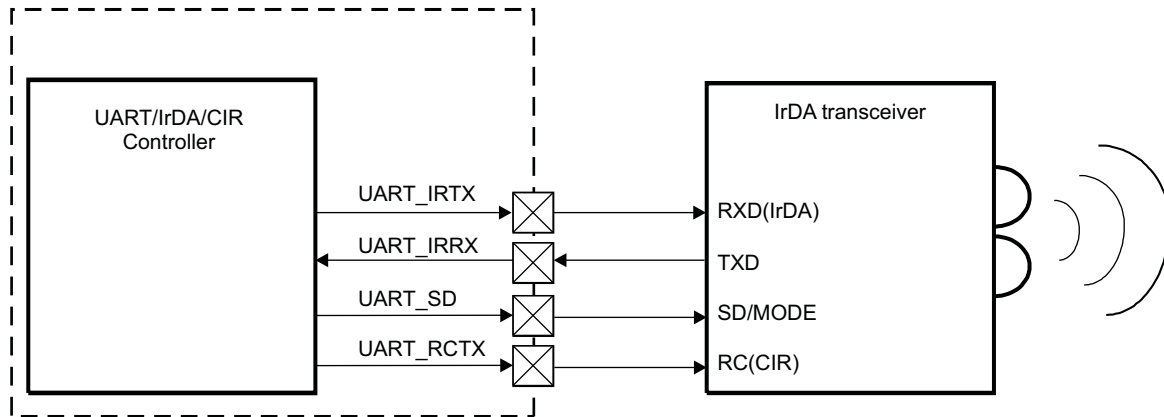

Procedure: Set LCR to desired value; LCR[7] to 1, gives access to DLH and DLL registers. Set DLH and DLL; LCR[7] = 0, removes access to DLH and DLL registers. Set IER to desired value. Set interrupts MDR1[2:0] = 0; enables UART without autobauding.

The UART module is operational.

24.2.4 IrDA Mode

This section describes the IrDA connection with an external device. Figure 24-3 shows how UART3 can be connected to an external infrared transceiver in the IrDA mode.

Figure 24-3. UART IrDA to External IR Device

The module performs serial-to-parallel conversion on received data characters and parallel-to-serial conversion on transmitted data characters by the processor. The complete status of each channel of the module and each received character/frame can be read at any time during functional operation via the line status register (LSR).

The module can be placed in an alternate mode (FIFO mode) relieving the processor of excessive software overhead by buffering received/transmitted characters. Both the receiver and transmitter FIFOs can store up to 64 bytes of data (plus three additional bits of error status per byte for the receiver FIFO) and have selectable trigger levels. Both interrupts and DMA are available to control the data-flow between the LH and the module.

24.2.4.1 SIR Mode

In slow infrared (SIR) mode, data transfer takes place between the LH and peripheral devices at speeds of up to 115200 bauds speed. A SIR transmit frame starts with start flags (either a single C0h, multiple C0h, or a single C0h preceded by a number of FFh flags), followed by frame data, CRC-16 and ends with a stop flag (C1h). The bit format for a single word uses a single start bit, eight data bits and one stop bit and is unaffected by the use and settings of the LCR register.

Note that BLR[6] is used to select whether C0h or FFh start patterns is to be used, when multiple start flags are required. The SIR transmit state machine attaches start flags, CRC-16 and stop flags. It checks the outgoing data to establish if data transparency is required. SIR transparency is carried out if the outgoing data, between the start and stop flags, contains C0h, C1h, or 7Dh. If one of these is about to be transmitted, then the SIR state machine sends an escape character (7Dh) first, then inverts the fifth bit of the real data to be sent, and sends this data immediately after the 7Dh character.

The SIR receive state machine recovers the receive clock, removes the start flags, removes any transparency from the incoming data and determines frame boundary with reception of the stop flag. It also checks for errors such as: frame abort (0x7D character followed immediately by a C1h stop flag, without transparency), CRC error and frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find out possible errors of the received frame.

NOTE: Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the UART3.ACREG[5] DIS_IR_RX bit description. This applies to all three modes: SIR, MIR, and FIR.

The infrared output in SIR mode can either be 1.6 μ s or 3/16 encoding, selected by the PULSETYPE bit of the auxiliary control register (ACREG[7]). In 1.6 μ s encoding, the infrared pulse width is 1.6 μ s and in 3/16 encoding the infrared pulse width is 3/16 of a bit duration (1/ baud-rate). The transmitting device must send at least two start flags at the start of each frame for back-to-back frames.

NOTE: Reception supports variable-length stop-bits.

24.2.4.1.1 Frame Format

Figure 24-4 shows the IrDA SIR frame format.

uart-006

The CRC is applied on the address (A), control (C), and information (I) bytes.

NOTE: The two words of CRC are written to the FIFO in reception.

24.2.4.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to C0h (BOF), C1h (EOF), or 7Dh (control escape), the controller performs certain tasks:

- In transmission:
 - Inserts a control escape (CE) byte preceding the byte
 - Complements bit 5 of the byte (that is, exclusive ORs the byte with 20h)

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 20h).
- In reception:

For the A, C, I, CRC field:

 - Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO
 - If the byte is equal to the CE byte, discards the CE byte
 - Complements bit 5 of the byte following the CE
 - Sends the complemented byte to the CRC detector and stores it in the RX FIFO

24.2.4.1.3 Abort Sequence

The transmitter may decide to prematurely close a frame. The transmitter aborts by sending following sequence: 7DC1h. The abort pattern closes the frame without a CRC field or an ending flag. It is possible to abort a transmission frame by programming the ABORTEN bit of the auxiliary control register (ACREG[1]). When this bit is set to 1, 7Dh and C1h are transmitted and the frame is not terminated with CRC or stop flags. The receiver treats a frame as an aborted frame when a 7Dh character followed immediately by a C1h character have been received without transparency.

24.2.4.1.4 Pulse Shaping

The SIR mode supports both the 3/16th and the 1.6- μ s pulse duration methods. The PULSETYPE bit of the auxiliary control register (ACREG[7]) selects the pulse width method in transmit mode.

24.2.4.1.5 Encoder

Serial data from transmit state-machine is encoded to transmit data to the optoelectronics. While the serial data input to the (TXD) is high, the output (IRTX) is always low, and the counter used to form a pulse on IRTX is continuously cleared. After TXD resets to 0, IRTX rises on the falling edge of the 7th 16XCLK. On the falling edge of the 10th 16XCLK pulse, IRTX falls, creating a 3-clock-wide pulse. While TXD stays low, a pulse is transmitted during the 7th to the 10th clock of each 16-clock bit cycle.

Figure 24-5 shows the IrDA SIR encoding mechanism.

24.2.4.1.6 Decoder

After reset, RXD is high and the 4-bit counter is cleared. When a rising edge is detected on RX, RXD falls on the next rising edge of 16XCLK with sufficient setup time. RXD stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, RXD remains high.

Figure 24-6 shows the IrDA SIR decoding mechanism.

Figure 24-6. IrDA SIR Decoding Mechanism

The operation of the RX input can be disabled with DISIRRX bit of the auxiliary control register (ACREG[5]). Furthermore, the MDR2[6] can be used to invert the signal from the transceiver (RX output) pin to the IRRX logic inside the UART.

24.2.4.1.7 IR Address Checking

In all IR modes, if address checking is enabled, only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multi-point infrared environment. It is possible to program two frame addresses that the UART IrDA receives with XON1/ADDR1 and XON2/ADDR2 registers.

Selecting address1 checking is done by setting EFR[0] to 1; selecting address2 checking is done by setting EFR[1] to 1. Clearing EFR[1:0] to 0 disables all address checking operations. If both bits are set, then the incoming frame is checked for both private and public addresses. If address checking is disabled, then all received frames are written into the reception FIFO.

24.2.4.1.8 SIR Free Format Mode

To allow complete software flexibility in the transmission and reception of Infrared data packets, the SIR Free Format mode is a sub function of the existing SIR mode such that all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values. In transmission phase, it uses the IRTX pin as in SIR mode.

This mode corresponds to a UART mode with a pulse modulation of 3/16 of baud-rate pulse width. For example, a normal SIR packet has BOF control and CRC error checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs. In SIR Free Format mode only the data termed the FIFO DATA area as shown in Figure 24-7 (and in Figure 24-4) would be transmitted and received.

Figure 24-7. SIR Free Format Mode

uart-009

In this mode, the entire FIFO data packet is to be constructed (encoded and decoded) by the LH software.

The SIR Free Format mode is selected by setting the module in UART mode ($MDR1[2:0] = 000$) and the $MDR2[3]$ register bit to one to allow the pulse shaping.

As the bit format is to remain the same, some UART mode configuration register need to be set at specific value:

- $LCR[1:0] = 11$ (8 data bits)
- $LCR[2] = 0$ (1 stop bit)
- $LCR[3] = 0$ (no parity)
- $ACREG[7] = 0$ (3/16 of baud-rate pulse width)

The features defined through $MDR2[6]$ and $ACREG[5]$ are also supported.

NOTE: All other configuration registers need to be at the reset value.

The UART mode interrupts are used for the SIR Free Format mode but many of them are not relevant (XOFF, RTS, CTS, Modem status register,).

24.2.4.1.9 Programming Models

Example 24-1. Receive IrDA

Receive IrDA frame with parity forced to 1, baud-rate = 112.5Kbs, FIFOs disabled.

- $MDR1 = 01h$
 - $MDR1[2:0] = 001b$: SIR mode
- $LCR = A8h$
 - $LCR[7] = 1$: access to write DLL and DLH
 - $LCR[5:3] = 101$: set parity type to forced 1 (default: no parity).
 - optional: $LCR[2] = 1$: set number of stop bits to 2 (default: 1)
 - optional: $LCR[1:0] = 11b$: set word length to 8 bits (default: 5)
- $DLL = 1Ah$: 115.2 Kbs
- $DLH = 0h$: 115.2 Kbs
- $LCR = 28h$: $LCR[7] = 0$ disables access to DLL and DLH and gives access to MCR, FCR, IER, BLR, EBLR, RHR
- optional: $IER = 1$: enable RHR interrupt

Example 24-2. Transmit IrDA

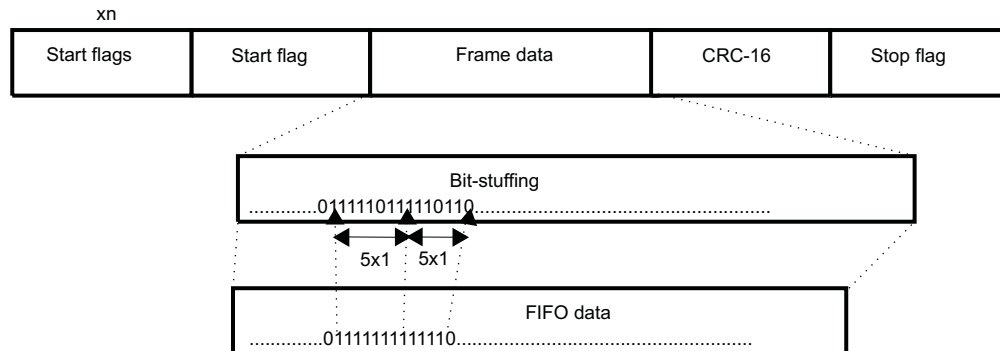

Transmit IrDA 6bytes frame with no parity, baud-rate = 112.5Kbs, FIFOs disabled, 3/16 encoding.

- MDR1 = 41h
 - MDR1[2:0] = 001b: SIR mode
 - MDR1[6] = 1: SIP is generated automatic after each transmission
- LCR = BFh: gives you access to EFR
- EFR = 10h: enhanced functions write enable
- LCR = 86h
 - LCR[7] = 1: access to write DLL and DLH
 - LCR[2] = 1: set number of stop bits to 2 (default: 1)
 - LCR[1:0] = 10b: set word length to 7 bits (default: 5)
- DLL = 1Ah: 115.2 Kbs
- DLH = 0h: 115.2 Kbs
- LCR = 06h: LCR[7] = 0 disables access to DLL and DLH and gives access to MCR, FCR, IER, BLR, EBLR, THR
- MCR = 01h: force \overline{DTR} output to active (low)
- optional: IER = 02h: enable THR interrupt
- TXFLL = 06h: transmit frame length is 6 bytes
- EBLR = 08: transmit 7 starts of frame
- optional: set ACREG[7] = 1: selects SIR pulse width to be 1.6 μ s (default 3/16 bit period).
- THR = desired data to be transmitted

24.2.4.2 MIR Mode

In medium infrared (MIR) mode, data transfer takes place between LH and peripheral devices at 0.576 or 1.152 Mb/s speed. A MIR transmit frame starts with start flags (at least two), followed by a frame data, CRC-16 and ends with a stop flag (see [Figure 24-8](#)).

Figure 24-8. MIR Transmit Frame Format

uart-010

On transmit, the MIR state machine attaches start flags, CRC-16, and stop flags. It also looks for 5 consecutive 1s in the frame data and automatically inserts 0 after 5 consecutive 1s (this is called bit stuffing).

On receive, the MIR receive state machine recovers the receive clock, removes the start flags, de-stuffs the incoming data and determines frame boundary with reception of the stop flag. It also checks for errors such as: frame abort, CRC error or frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find out possible errors of received frame.

Data can be transferred both ways by the module but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. Refer to the DISIRRX bit of the auxiliary control register (ACREG[5]) for a description of the logical operation.

NOTE: This applies to all three modes SIR, MIR, and FIR.

24.2.4.2.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of ± 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by the IrDA specifications.

[Figure 24-9](#) shows the MIR baud rate adjustment mechanism.

Figure 24-9. MIR Baud Rate Adjustment Mechanism

uart-011

24.2.4.2.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is currently occupied.

When the SIPMODE bit of the mode definition register 1 (MDR1[6]) equals 1, the TX state machine always sends one SIP at the end of a transmission frame. But when MDR1[6] = 0, the transmission of the SIP depends on the SENDSIP bit of the auxiliary control register (ACREG[3]). The system (LH) can set ACREG[3] at least once every 500 ms. The advantage of this approach over the default approach is that the TX state machine does not need to send the SIP at the end of each frame which may reduce the overhead required.

Figure 24-10 shows the SIP.

Figure 24-10. Serial Infrared Interaction Pulse (SIP)

108-012

24.2.4.2.3 Programming Models

Example 24-3. Receive IrDA

Receive IrDA frame with no parity, baud-rate = 1.152 Mbs, FIFOs disabled.

- MDR1 = 04h
 - MDR1[2:0] = 100b: MIR mode
- LCR = 86h
 - LCR[7] = 1: access to write DLL and DLH
 - LCR[2] = 1: set number of stop bits to 2 (default: 1)
 - LCR[1:0] = 10b: set word length to 7 bits (default: 5)
- DLL = 01h: 1.152 Mbs
- DLH = 0h: 1.152 Mbs
- LCR = 06h: LCR[7] = 0 disables access to DLL and DLH and gives access to MCR, FCR, IER, BLR, EBLR, RHR
- MCR = 03h: forces $\overline{\text{DTR}}$ and $\overline{\text{RTS}}$ output to active (low).
- optional: IER = 1: enable RHR interrupt

Example 24-4. Transmit IrDA

Transmit IrDA 60 bytes frame with no parity, baud-rate = 1.152 Mbs, FIFOs disabled.

- MDR1 = 04h
 - MDR1[2:0] = 100b: MIR mode
- LCR = 82h
 - LCR[7] = 1: access to write DLL and DLH
 - LCR[1:0] = 10b: set word length to 7 bits (default: 5)
 - optional: LCR[2] = 1: set number of stop bits to 2 (default: 1)
- DLL = 01h: 1.152 Mbs
- DLH = 0h: 1.152 Mbs
- LCR = 02h: LCR[7] = 0 disables access to DLL and DLH and gives access to MCR, FCR, IER, BLR, EBLR, THR
- MCR = 01h: force $\overline{\text{DTR}}$ output to active (low)
- optional: IER = 02h: enable THR interrupt
- TXFLL = 3Ch: transmit frame length is 60 bytes
- optional: EBLR = 08: transmit 8 additional starts of frame (MIR mode requires 2 starts anyway)
- optional: set ACREG[3] = 1: SIP sends at the end of transmission
- THR = desired data to be transmitted

24.2.4.3 FIR Mode

In fast infrared mode (FIR), data transfer takes place between LH and peripheral devices at 4 Mbits/s speed. A FIR transmit frame starts with preamble, followed by a start flag, frame data, CRC-32 and ends with a stop flag.

Table 24-3 shows the FIR transmit frame format.

Table 24-3. FIR Transmit Frame Format

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag
-------------------	------------	------------	--------	-----------

On transmit, the FIR transmit state machine attaches the preamble, start flag, CRC-32, and stop flag. It also encodes the transmit data into 4PPM format. It also generates the serial infrared interaction pulse (SIP).

On receive, the FIR receive state machine recovers the receive clock, removes start flag, decodes the 4PPM incoming data and determines frame boundary with reception of stop flag. It also checks for errors such as: illegal symbol, CRC error and frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find out possible errors of the received frame.

Data can be transferred both ways by the module but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. Refer to the DISIRRX bit of the auxiliary control register (ACREG[5]) for a description of the logical operation.

NOTE: This applies to all three modes SIR, MIR, and FIR.

24.2.5 CIR Mode

In consumer infrared (CIR) mode, the infrared operation is designed to function as a programmable (universal) remote control. By setting the MDR1 register, the UART can be set to CIR mode in the same way as the other IrDA modes are set using the MDR1 register. The CIR mode uses a variable pulse width modulation technique (based on multiples of a programmable T period) to encompass the various formats of infrared encoding for remote control applications. The CIR logic is to transmit and receive data packets according to the user definable frame structure and packet content.

24.2.5.1 Consumer IR Encoding

There are two distinct methods of encoding for remote control applications. The first uses time extended bit forms, that is, a variable pulse distance (or duration) whereby the difference between a logic 1 and logic 0 is the length of the pulse width; and the second is the use of a bi-phase where the encoding of the logic 0 and logic 1 is in the change of signal level from 1 -> 0 or 0 -> 1, respectively. Japanese manufacturers tend to favor the use of pulse duration encoding whereas European manufacturers favor the use of bi-phase encoding.

The CIR mode is designed to use a completely flexible free format encoding where a digit '1' from the TX/RX FIFO is to be transmitted/received as a modulated pulse with duration T. Equally, a '0' is to be transmitted/received as a blank duration T. The protocol of the data is to be constructed and deciphered by the host CPU. For example, the RC-5 protocol (Figure 24-11) using Manchester encoding can be emulated as using a "01" pair for one and "10" pair for a zero.

Figure 24-11. RC-5 Bit Encoding

Since the CIR mode logic does not impose a fixed format for infrared packets of data, the CPU software is at liberty to define the format through the use of simple data structures that will then be modulated into an industry standard such as RC-5 or SIRC to name a few. To send a sequence of “0101” in RC-5, the host software must write an eight bit binary character of “10011001” to the data TX FIFO of the UART.

For SIRC, the modulation length (multiples of T) is the method to distinguish between a “1” or a “0”. The following SIRC digits show the difference in encoding between this and RC-5 for example.

NOTE: The pulse width is extended for “1” digits.

Figure 24-12 shows SIRC bit encoding.

Figure 24-12. SIRC Bit Encoding

To construct comprehensive packets that constitute remote control commands, the host software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 24-13 shows a standard RC-5 frame as detected by the UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two T pulses (digital bits) from the TX and RX FIFOs.

Figure 24-13. RC-5 Standard Packet Format

uart-018

Where:

- S1, S2: Start bits (always 1)
- T: Toggle bit
- A4..A0: Address (or system) bits
- C5..C0: Command bits

The toggle bit T changes each time a new command is transmitted to allow detection of pressing the same key twice (or effectively receiving the same data from the host consecutively). Since a code is being sent as long as the CPU transmits characters to the UART for transmission, a brief delay in the transmission of the same command would be detected by the use of the toggle bit. The address bits define the machine or device that the Infrared transmission is intended for and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that allows the command range to increase to 7 bits. This format is known as the extended RC-5 format.

The SIRC encoding uses the duration of modulation for mark and space; hence the duration of data bits inside the standard frame length will vary depending upon the logic 1 content. Figure 24-14 shows the packet format and bit encoding. As Figure 24-14 shows, 1 start bit of 2 ms and control codes are followed by data that constitute the entire frame.

Figure 24-14. SIRC Packet Format

uart-019

NOTE: The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for emitting and receiving data packets must exercise a scheme of interpacket delay, where the emission of successive packets can be done only after a real-time delay has expired.

Figure 24-15. SIRC Bit Transmission Example

uart-020

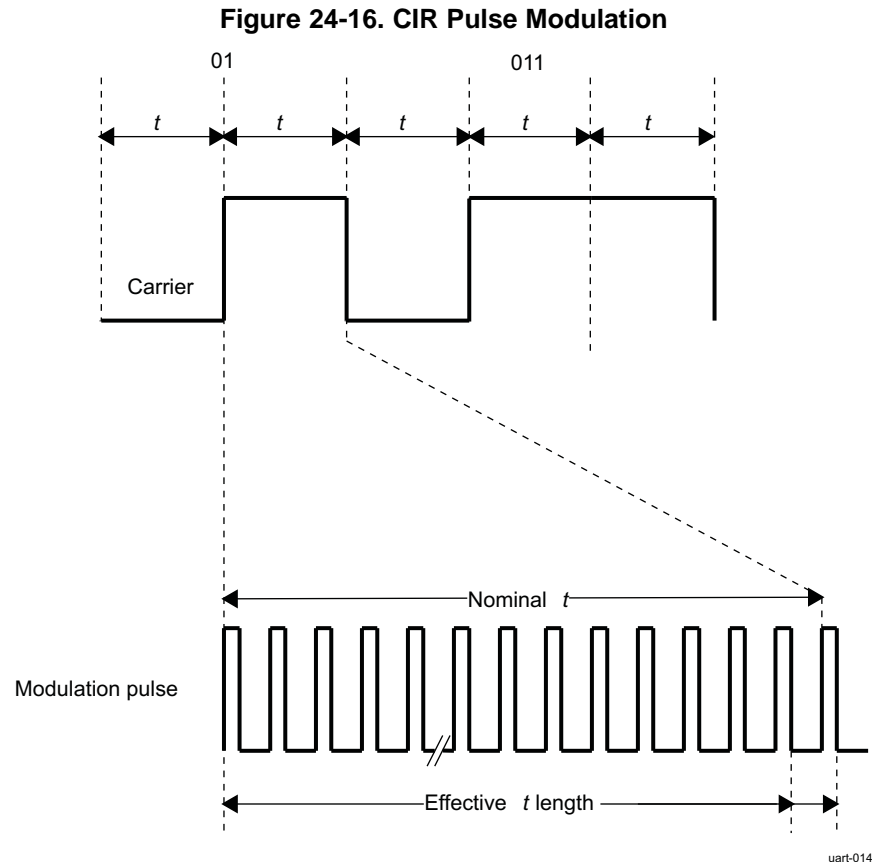

This document does not describe all encoding methods and techniques; the preceding information shows the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol usage.

24.2.5.2 CIR Mode Operation

In CIR mode, the infrared operation functions as a programmable (universal) remote control. CIR mode uses a variable PWM technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on user-defined frame structure and packet content.

24.2.5.3 Carrier Modulation

Looking closely at the actual modulation pulses of the infrared data stream, each modulated pulse that constitutes a digit is a train of on/off pulses (see [Figure 24-16](#)).

A minimum of 4 modulation pulses per bit is required by the module. Based on the requested modulation frequency, the CFPS register must be set with the correct dividing value to provide the more accurate pulse frequency:

$$\text{Dividing value} = (FCLK/12)/MODfreq$$

Where:

- FCLK = System clock frequency (48 MHz)
- 12 = real value of BAUD multiple
- MODfreq = Effective frequency of the modulation (MHz)

For example, for a targeted modulation frequency of 36 kHz, the CFPS value must be set to 111 in decimal, which provides a modulation frequency of 36.04 kHz.

NOTE: The CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the CIRCULSEMODE field in the mode definition register 2 (MDR2[5:4]).

Figure 24-17 shows the CIR modulation duty cycles.

Figure 24-17. CIR Modulation Duty Cycle

The transmission logic ensures that all pulses are transmitted completely (that is, no cutoff during transmission). Furthermore, while transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes.

NOTE: The CIR RX demodulation can be bypassed by setting the MDR3[0] register bit. This bit will not affect the transmission modulation.

24.2.5.4 Frequency Divider Values

As previously explained, the data transferred is a succession of pulses with a T period. Depending on the standards used, the T period is defined through the DLL and DLH registers, which defined the value to divide the functional clock (48 MHz):

$$\text{Dividing value} = (FCLK/16)/Tfreq$$

Where:

- FCLK = System clock frequency (48 MHz)
- 16 = real value of BAUD multiple
- Tfreq = Effective frequency of the T pulse (MHz)

24.2.6 FIFO Management

The FIFO is accessed by reading/writing the RHR and THR registers. Parameters are controlled using the FIFO control register (FCR) and supplementary control register (SCR). Reading the TXFIFOFULL bit in SSR[0] as 1 means the FIFO is full.

The TLR register controls the FIFO trigger level, which enables the DMA and interrupt generation. After reset, both transmitter and receiver FIFOs are disabled; so, in effect, the trigger level is the default value of 1 byte. [Figure 24-18](#) shows the FIFO management registers.

NOTE: Data in the RHR register is not overwritten when an overflow occurs.
The SFLSR, SFREGL, and SFREGH status registers are used in IrDA mode only.

Figure 24-18. FIFO Management

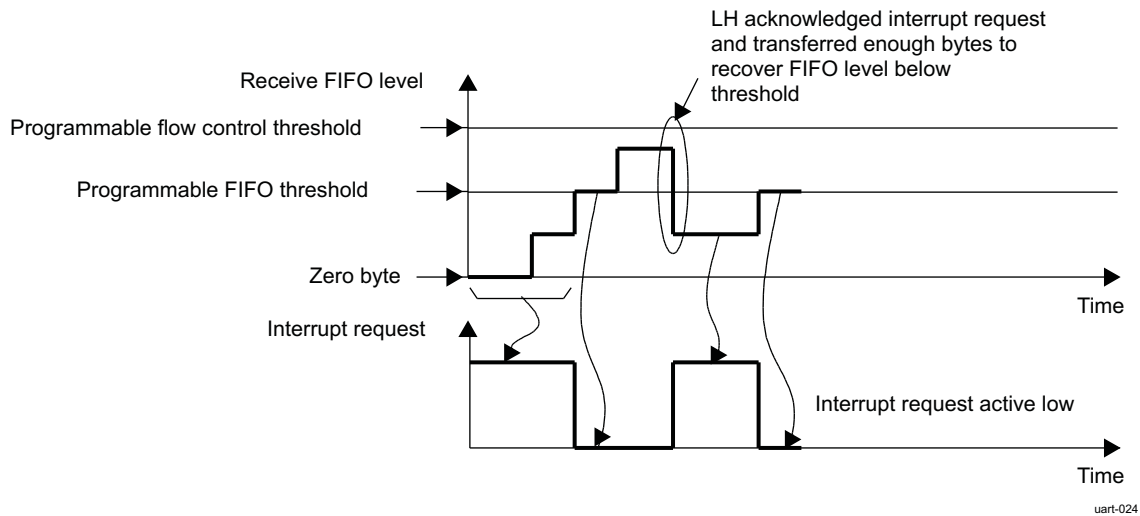

uart-023

24.2.6.1 FIFO Interrupt Mode

In the FIFO interrupt mode (FIFO_EN bit in the FIFO control register (FCR[0]) is set to 1 and relevant interrupts are enabled via the interrupt enable register (IER)), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the receive/transmit FIFO threshold (TLR[7:4] and TLR[3:0] fields or the FCR[7:6] and FCR[5:4] fields, respectively) are reached; the interrupt signals instruct the Local Host to transfer data to the destination (from the UART module in receive mode and/or from any source to the UART FIFO in transmit mode). Note also that in the case of the UART flow control being enabled along with the interrupt capabilities, the user must ensure that the UART flow control FIFO threshold (TCR[3:0]) is greater than or equal to the receive FIFO threshold.

Figure 24-19 shows the generation of the receive FIFO interrupt request.

Figure 24-19. Receive FIFO Interrupt Request Generation

In receive mode, no interrupt is generated until the receive FIFO reaches its threshold. Once low, the interrupt can be de-asserted only when the Local Host has handled enough bytes to make the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 24-20 shows the generation of the transmit FIFO interrupt request.

Figure 24-20. Transmit FIFO Interrupt Request Generation

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is de-asserted when the TX FIFO crosses the threshold level. The interrupt line is de-asserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

24.2.6.2 FIFO Polled Mode Operation

In FIFO polled mode (FCR[0] = 0, relevant interrupts disabled via interrupt enable register (IER)) the status of the receiver and transmitter can then be checked by polling the line status register (LSR). This mode is an alternative to the FIFO interrupt mode of operation where the status of the receiver and transmitter is automatically known by means of interrupts sent to the LH.

24.2.6.3 FIFO DMA Mode Operation

24.2.6.3.1 DMA Signaling

There are four modes of DMA operation, DMA mode 0/1/2/3. They can be selected as follows:

- When SCR[0] = 0: setting FCR[3] to 0 enables DMA mode 0, setting FCR[3] to 1 enables DMA mode 1.
- When SCR[0] = 1: SCR[2:1] determines DMA mode 0 to 3, according to supplementary control register (SCR).

So for instance:

- if no DMA operation is desired: set SCR[0] to 1 and SCR[2:1] to 00 (FCR[3] is discarded)
- if DMA mode 1 is desired: either set SCR[0] to 0 and FCR[3] to 1 or set SCR[0] to 1 and SCR[2:1] to 01 (FCR[3] is discarded)

If the FIFOs are disabled (FCR[0] = 0), DMA occurs in single character transfers.

NOTE: Note that when DMA mode 0 has been programmed, the signals associated with DMA operation are not active.

24.2.6.3.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 24-21, Figure 24-22, Figure 24-23, and Figure 24-24 show the supported DMA operations.

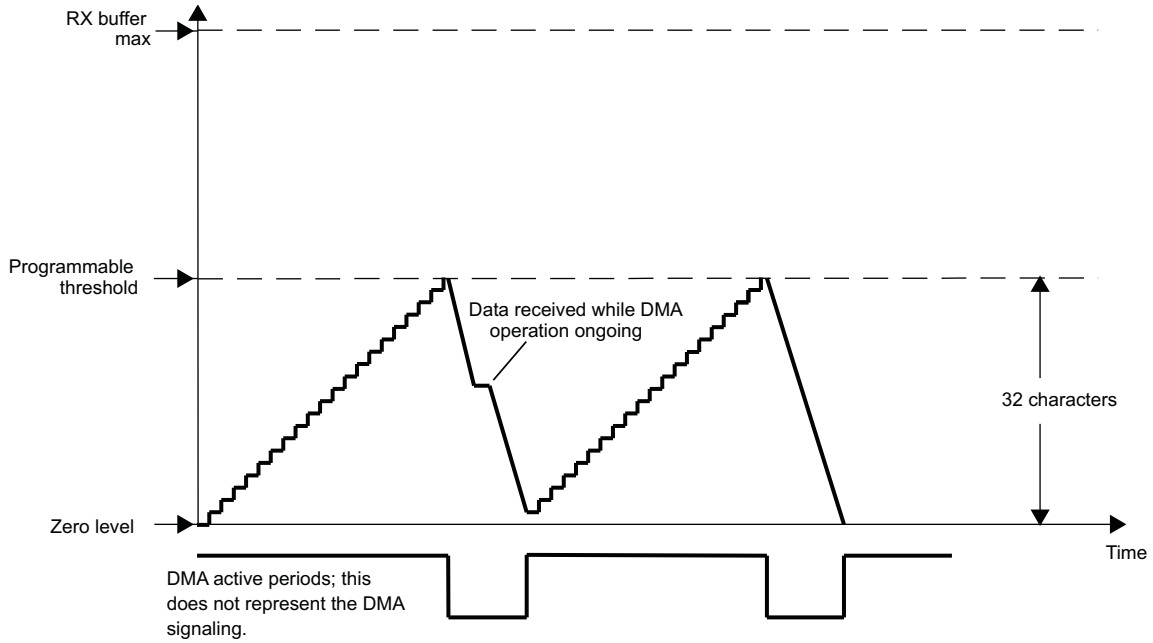

In receive mode, a DMA request is generated as soon as the receive FIFO reaches its threshold level defined in the trigger level register (TLR). This request is de-asserted when the number of bytes defined by the threshold level has been read by the system DMA.

In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request is de-asserted when the number of bytes defined by the number of spaces in the trigger level register (TLR) has been written by the system DMA. If an insufficient number of characters are written, then the DMA request will remain active.

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the TLR register.

There are a number of ways the threshold can be programmed. The example in Figure 24-22 is of a DMA transfer that operates with a space setting of 56, which could arise from the use of the auto settings in the FCR[5:4] or the use of the TLR[3:0] concatenated with the FCR[5:4]. The setting of 56 spaces in the UART/IrDA/CIR module should correlate with settings of the system DMA so that the buffer does not overflow (program the DMA request size of the Local Host controller to be equal to the number of spaces value in the UART/IrDA/CIR module).

Figure 24-21. Receive FIFO DMA Request Generation (32 Characters)

uart-026

Figure 24-22. Transmit FIFO DMA Request Generation (56 Spaces)

uart-027

Figure 24-23 shows an example with 8 spaces to show the buffer level crossing the space threshold. Again, the Local Host DMA controller settings must correspond to that of the UART/IrDA/CIR module.

Figure 24-23. Transmit FIFO DMA Request Generation (8 Spaces)

uart-028

The final example illustrates the setting of one space which uses the DMA for each transfer of one character to the transmit buffer (see Figure 24-24). The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer. There are two occasions where the buffer holds the maximum amount of data words, shortly after this, the DMA is disabled to illustrate the slower transmission of the data words to the TX pin. Eventually, the buffer will be emptied at the rate specified by the BAUD Rate Settings of the DLL and DLH registers. Again, the DMA settings should correspond to the system's Local Host DMA controller settings in order to ensure the correct operation of this logic.

Figure 24-24. Transmit FIFO DMA Request Generation (1 Space)

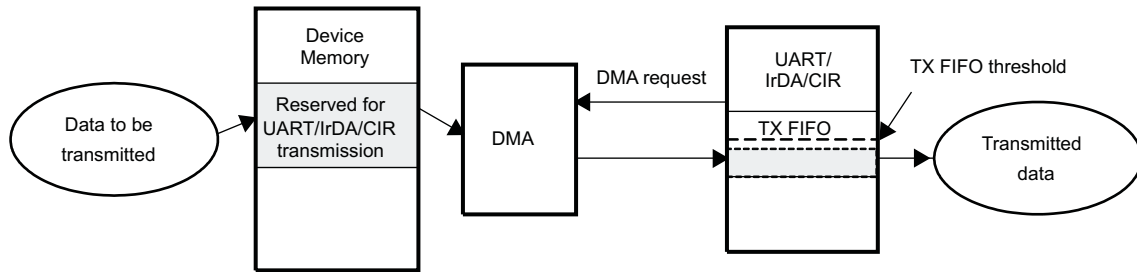

uart-029

24.2.6.3.3 DMA Transmission

Figure 24-25 shows the DMA transmission process.

Figure 24-25. Transmission Process

uart-030

- Data to be transmitted are put in the memory reserved for UART/IrDA/CIR transmission by the DMA:
 - Until the TX FIFO trigger level is not reached, a DMA request is generated.
 - An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
- Data in the TX FIFO are automatically transmitted.
- The end of the transmission is signaled by the UARTi.THR empty (TX FIFO empty).

NOTE: In IrDA mode, the transmission is not ended immediately after the TX FIFO empties, at which point there are still the last data byte, the CRC field, and the stop flag to be transmitted; thus, the end of transmission is a few milliseconds after the UARTi.THR register empties.

24.2.6.3.4 DMA Reception

Figure 24-26 shows the DMA reception process.

Figure 24-26. Reception Process

uart-031

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA.
 - At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
 - An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

24.2.6.4 IrDA Status FIFO

In IrDA modes, a status FIFO is used to record the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written into the status FIFO. The frame length and error status can be read by reading SFREGL/H and SFLSR. Reading the SFLSR causes the read pointer to be incremented. The status FIFO is eight entries deep and therefore can hold the status of eight frames. The LH uses the frame-length information to locate the frame-boundary in the received frame data. The LH can screen bad frames using the error-status information and later request the sender to resend only the bad frames. This status FIFO can be used very effectively in DMA as the LH need not be interrupted every time a frame is received but only whenever the programmed status FIFO trigger level is reached.

24.2.6.5 Frame Closing

There are two ways by which a transmission-frame can be properly terminated:

- **Frame-length method:** Frame-length method is selected when MDR1[7] = 0. The LH writes the frame-length value to TXFLH and TXFLL registers. The device automatically attaches end flags to the frame once the number of bytes transmitted becomes equal to the frame-length value.
- **Set-EOT bit Method:** Set-EOT bit method is selected when MDR1[7] = 1. The LH writes 1 to ACREG[0] (EOT bit) just before it writes the last byte to the TX FIFO. When the LH writes the last byte to the TX FIFO, the device internally sets the tag bit for that particular character in the TX FIFO. As the TX state machine reads data from the TX FIFO it uses this tag-bit information to attach end flags and properly terminate the frame.

24.2.6.6 Store and Controlled Transmission (SCT)

In SCT the LH first starts writing data into the TX FIFO. Then, after it writes a part of a frame (for a bigger frame) or a whole frame (a small frame, that is, supervisory frame), it writes a 1 to ACREG[2] (deferred TX start) to start transmission. SCT is enabled when MDR1[5] = 1. This method of transmission is different from the normal mode, where transmission of data starts immediately after data is written to the TX FIFO. SCT is useful to send short frames without TX underrun.

24.2.6.7 Underrun During Transmission

Underrun in transmission occurs when the TX FIFO becomes empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end-flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a re-transmission. Underrun also causes an internal flag to be set which disables further transmission. Before the next frame can be transmitted the system (LH) must:

- Reset the TX FIFO
- Read the RESUME register. This clears the internal flag.

This functionality can be disabled with ACREG[4], compensated by the extension of the stop bit in transmission in case the TX FIFO is empty.

24.2.6.8 Overrun During Receive

Overrun occurs during receive if the RX state machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the LH with IIR[3] and discards the remaining portion of the frame. Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received the system (LH) must:

- Reset the RX FIFO
- Read the RESUME register. This clears the internal flag.

24.2.7 Interrupts

The UART/IrDA/CIR module generates interrupts. All interrupts can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (IER). The interrupt status of the device can be checked at any time by reading the interrupt identification register (IIR). The UART, IrDA and CIR modes have different interrupts in the UART/IrDA/CIR module and therefore different IER and IIR mappings according to the selected mode.

24.2.7.1 Trigger Levels

The UART provides programmable trigger levels for both receiver and transmitter DMA and Interrupt generation. After reset, both transmitter and receiver FIFOs are disabled; so, in effect, the trigger level is the default value of one byte. The programmable trigger levels are an enhanced feature available via the trigger level register (TLR).

24.2.7.2 UART Mode Interrupts

In UART modes, there are seven possible interrupts. These interrupts are prioritized to six different levels. When an interrupt is generated, the interrupt identification register (IIR) indicates that an interrupt is pending by bringing IIR[0] to 0 and provides the type of interrupt through IIR[5-1]. [Table 24-4](#) summarizes the interrupt control functions.

It is important to note that for the receiver line status interrupt, RX_FIFO_STS bit (LSR[7]) generates the interrupt. For the XOFF interrupt, if a XOFF flow character detection caused the interrupt, the interrupt is cleared by a XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the IIR.

Table 24-4. UART Mode Interrupts

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
00 0001	None	None	None	None
00 0110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read RHR register. OE: Read LSR register.
00 1100	2	RX time-out	Stale data in RX FIFO	Read RHR register.
00 0100	2	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR register until interrupt condition disappears.
00 0010	3	THR interrupt	TFE (THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR register until interrupt condition disappears.
00 0000	4	Modem status	See the MSR register.	Read MSR register.
01 0000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt. Read IIR register, if special character interrupt.
10 0000	6	CTS, RTS, DSR	RTS pin, CTS pin, or DSR pin changes state from active (low) to inactive (high).	Read IIR register.

24.2.7.3 IrDA Mode Interrupts

In IrDA modes, there are eight possible interrupts. The interrupt line is activated when any of the eight interrupts is generated (there is no priority). For IIR[5], interrupt source 1 is used with interrupt reset method 1 and interrupt source 2 is used with interrupt reset method 2. [Table 24-5](#) summarizes the interrupt control functions.

Table 24-5. IrDA Mode Interrupts

IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR register until interrupt condition disappears.
1	THR interrupt	TFE (THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR register until interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read RHR register.
3	RX overrun	Write to RHR register when RX FIFO full.	Read RESUME register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read SFREGL/H, SFLSR. Status FIFO read pointer is incremented only when reading SFLSR.
5	TX status (indicated by MDR2[0] (IRTX_UNDERRUN))	1. THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read RESUME register. OR 2. Read IIR register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into STATUS FIFO.	Read STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame.	Read IIR register.

24.2.7.4 CIR Mode Interrupts

The CIR mode uses a subset of the existing IrDA mode interrupts. [Table 24-6](#) summarizes the interrupt modes that are to be maintained. In CIR mode, IIR bit 5 has a single purpose of indicating that the last bit of infrared data has been passed to the IR TX pin.

Table 24-6. CIR Mode Interrupts

IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR register until interrupt condition disappears.
1	THR interrupt	TFE (THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR register until interrupt condition disappears.
2	RXSTOPIT interrupt	Receive stop interrupt (depending on value set in the BOF length register (EBLR))	Read IIR register.
3	RXOEIT interrupt	Write to RHR register when RX FIFO full.	Read RESUME register.
4	N/A for CIR mode		
5	TX status	Transmission of the last bit of the frame is completed successfully.	Read IIR register.
6-7	N/A for CIR mode		

24.2.7.5 Wake-Up Interrupt

Wake-up interrupt is a special interrupt, which is not designed in the same way than previous ones. This interrupt is enabled when the RX_CTS_DSR_WAKE_UP_ENABLE bit of the supplementary control register (SCR[4]) is set to one. The IIR register is not modified when it occurs, SSR[1] must be checked to detect a wake-up-event. When wake-up interrupt occurs, the only way to clear it, is to reset SCR[4] to 0. Wake-up can also occur if the WER[7] TX_WAKEUP_EN is set to 1 and one of the followings occurred:

- THR interrupt occurred if it is enabled (omitted if TX DMA request is enabled)
- TX DMA request occurred if it is enabled
- TX_STATUS_IT occurred if it is enabled (only IrDA and CIR modes). Can not be used with THR interrupt

24.2.8 Sleep Modes

24.2.8.1 When in UART Mode

In UART modes, sleep mode is enabled by writing a 1 to IER[4] (when EFR[4] = 1). Sleep mode is entered when:

- The serial data input line, RX is idle
- The TX FIFO and TX shift register are empty
- The RX FIFO is empty
- There are no interrupts pending except THR interrupts

It should be noted that sleep mode is a good way to lower power consumption of UART but this state can be achieved only when the UART is set in modem mode. Therefore, even if the UART has no functional key role, it must be initialized in a functional mode to take advantage of sleep mode. In sleep mode the module clock and baud rate clock are stopped internally. Because most registers are clocked using these clocks the power consumption is greatly reduced. The module wakes up when any change is detected on the RX line, if data is written to the TX FIFO, when there is any change in the state of the modem input pins. Note that an interrupt can be generated on a wake up event by setting SCR[4] to 1. See interrupt section to know how to manage it.

NOTE: Writing to the divisor latches, DLL and DLH, to set the baud clock, BCLK, must not be done during sleep mode. Therefore, it is advisable to disable sleep mode using IER[4] before writing to DLL or DLH.

24.2.8.2 When in IR-IrDA and CIR Modes

In IrDA/CIR modes, sleep mode is enabled by writing a 1 to MDR1[3]. Sleep mode is entered when:

- The serial data input line, RX is idle
- The TX FIFO and TX shift register are empty
- The RX FIFO is empty
- There are no interrupts pending except THR interrupts

The module wakes up when any change is detected on the RX line or if data is written to the TX FIFO.

24.2.9 Idle Modes

Sleep and Autoidle modes are embedded power-saving features. At the system level, power reduction techniques can be applied by shutting down certain internal clock and power domains of the device.

- The UART supports an idle req - idle ack handshaking protocol. This protocol is used at system level to shut down clocks of the UART in a clean and controlled manner and to switch the UART from the interrupt generation mode to a wakeup generation mode for unmasked events (Refer to SYSC[2] and WER).
- In the wakeup generation mode, interrupt request generation and DMA request generation are disabled.

24.2.10 Programmable Baud Rate Generator

The UART/rRDA/CIR module contains a programmable baud generator and a set of fixed dividers that takes the 48 MHz clock input and divides it down to the expected baud-rate. The baud rate generator and associated controls is shown in [Figure 24-27](#).

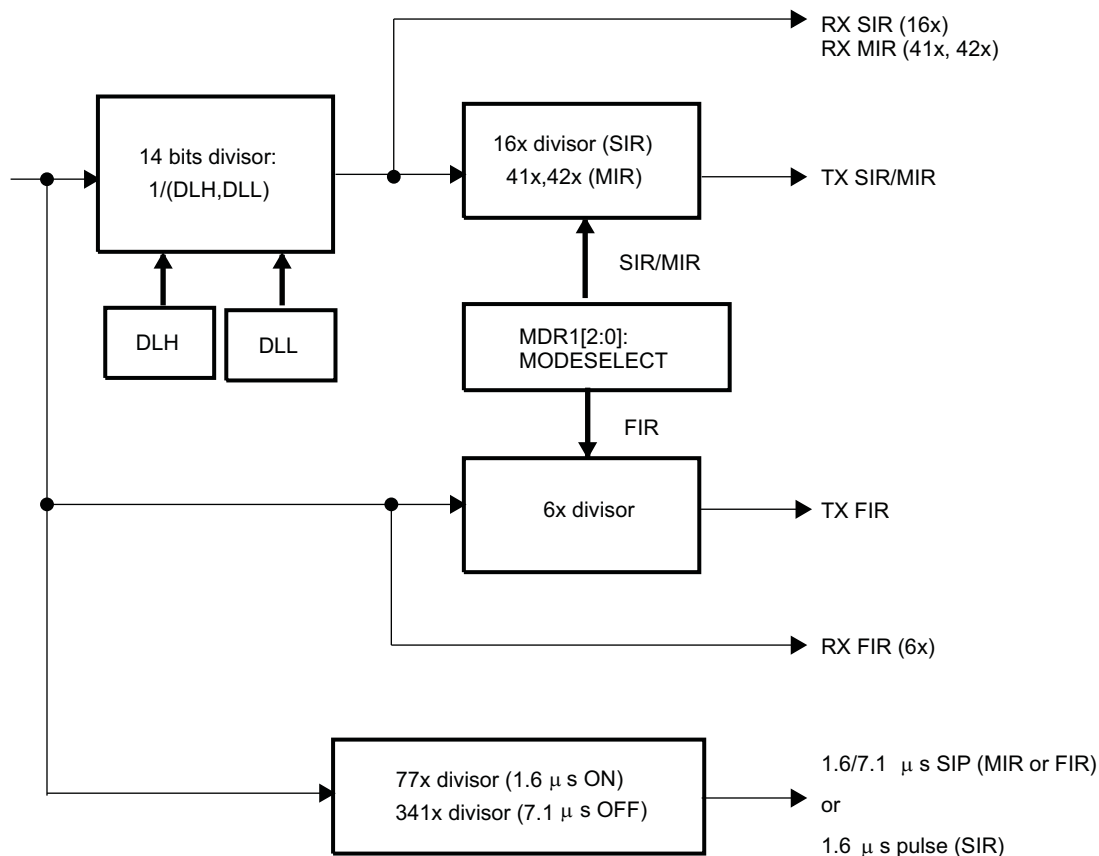

CAUTION

It is mandatory that the MODESELECT bit in MDR1[2:0] = 7h (disable) before initializing or modifying clock parameter controls (DLH and DLL). Failure to observe this rule can result in unpredictable module behavior.

Choosing the appropriate divisor value:

- UART 16x mode: Divisor value = Operating Frequency/(16x baud rate)
- UART 13x mode: Divisor value = Operating Frequency/(13x baud rate)
- SIR mode: Divisor value = Operating Frequency/(16x baud-rate)
- MIR mode: Divisor value = Operating Frequency/(41x/42x baud-rate)
- FIR mode: Divisor value = none

Figure 24-27. BAUD Rate Generator

uart-033

24.2.10.1 UART Baud Rates (48 MHz Clock)

Table 24-7 describes the UART baud rate settings.

Table 24-7. UART Baud Rate Settings (48-MHz Clock)

Baud Rate	Baud Multiple	DLH, DLL (Decimal)	DLH, DLL (Hex)	Actual Baud Rate	Error (%)
0.3 Kbps	16x	10000	27h, 10h	0.3 Kbps	0
0.6 Kbps	16x	5000	13h, 88h	0.6 Kbps	0
1.2 Kbps	16x	2500	09h, C4h	1.2 Kbps	0

⁽²⁾ Average value

24.2.10.3 Autobauding Modes

In autobauding mode, the UART extracts transfer characteristics (speed, length, and parity) from an AT command. These characteristics are used to receive data after an “at” (AT) and to send data.

The valid AT commands follow:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and echo functionality is not implemented in hardware. A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. Either A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0Dh), are saved to RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved into RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UASR register reflects the correct settings for the baud rate detected. The interrupt activity continues in this way each time a subsequent character is received. Therefore, it is recommended that the software enables the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed: 115.2k baud, 57.6k baud, 38.4k baud, 28.8k baud, 19.2k baud, 14.4k baud, 9.6k baud, 4.8k baud, 2.4k baud, or 1.2k baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character + space parity is not supported.

The method used to identify the speed is:

- Detect the transition 1->0 on the received data. This happens as soon as a stop to start bit transition occurs. The transition is valid after a majority vote on 3 sampling period.
- Sample the start bit duration with $115\,200 \times 16$ Hz clock frequency as long as there is no rising edge. A transition 0->1 is considered as valid after a majority vote on 3 sampling period.
- Compare the sampled value with a table. If the sampled value is outside a valid range an error is reported (no speed identified). And the hardware goes back to the first state (1).
- Else store the first data bit in the received register (for serial to parallel conversion) and go to frame format identification.

The next received bits are sampled according to the programmed baud rate. However, after seven bits reception, the speed identification must be restarted since we may receive several “a” or “A” character before a valid “t” or “T” character.

Autobauding mode is selected when the MODESELECT field in MDR1[2:0] is set to 2h. In the UART autobauding mode, DLL, DLH, and LCR[5:0] settings are not used; instead, UASR is updated with the configuration detected by the autobauding logic.

24.3 UART Registers

Each register is selected using a combination of address and, for some, LCR register bit settings as shown in [Table 24-9](#). The following registers are accessible by the local host (LH) at address = module base address + address offset. The module base address is the module start address. Note that register address offsets depends upon the module address alignment at the system top level.

Table 24-9. UART Registers

Address Offset	Registers					
	LCR[7] = 0		LCR[7:0] ≠ BFh		LCR[7:0] = BFh	
	Read	Write	Read	Write	Read	Write
0h	RHR	THR	DLL	DLL	DLL	DLL
4h	IER ⁽¹⁾	IER ⁽¹⁾	DLH	DLH	DLH	DLH
8h	IIR	FCR ⁽²⁾	IIR	FCR ⁽²⁾	EFR	EFR
Ch	LCR	LCR	LCR	LCR	LCR	LCR

28h	SFLSR	TXFLL	SFLSR	TXFLL	SFLSR	TXFLL
2Ch	RESUME	TXFLH	RESUME	TXFLH	RESUME	TXFLH
30h	SFREGL	RXFLL	SFREGL	RXFLL	SFREGL	RXFLL
34h	SFREGH	RXFLH	SFREGH	RXFLH	SFREGH	RXFLH
38h	BLR	BLR	UASR	-	UASR	-
3Ch	ACREG	ACREG	-	-	-	-
40h	SCR	SCR	SCR	SCR	SCR	SCR
44h	SSR	SSR[2]	SSR	SSR[2]	SSR	SSR[2]
48h	EBLR	EBLR	-	-	-	-
50h	MVR	-	MVR	-	MVR	-
54h	SYSC	SYSC	SYSC	SYSC	SYSC	SYSC
58h	SYSS	-	SYSS	-	SYSS	-
5Ch	WER	WER	WER	WER	WER	WER
60h	CFPS	CFPS	CFPS	CFPS	CFPS	CFPS
80h	MDR3	MDR3	MDR3	MDR3	MDR3	MDR3

⁽¹⁾ In UART modes, IER[7:4] can only be written when EFR[4] = 1; in IrDA/CIR modes, EFR[4] has no impact on the access to IER[7:4].

⁽²⁾ MCR[7:5] and FCR[5:4] can only be written when EFR[4] = 1.

⁽³⁾ Transmission control register (TCR) and trigger level register (TLR) are accessible only when EFR[4] = 1 and MCR[6] = 1.

24.3.1 Receiver Holding Register (RHR)

The receiver section consists of the receiver holding register and the receiver shift register. The RHR is actually a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location zero of the FIFO is used to store the single data character.

NOTE: If an overflow occurs, the data in the RHR is not overwritten.

The receiver holding register (RHR) register is shown in [Figure 24-28](#) and described in [Table 24-10](#).

Figure 24-28. Receiver Holding Register (RHR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-10. Receiver Holding Register (RHR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	RHR	0-FFh	Receive holding register.

24.3.2 Transmit Holding Register (THR)

The transmitter section consists of the transmit holding register and the transmit shift register. The transmit holding register is a 64-byte FIFO. The MPU writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location zero of the FIFO is used to store the data.

The transmit holding register (THR) is shown in [Figure 24-29](#) and described in [Table 24-11](#).

Figure 24-29. Transmit Holding Register (THR)

LEGEND: R/W = Read/Write; W = Write only; -n = value after reset

Table 24-11. Transmit Holding Register (THR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	THR	0-FFh	Transmit holding register.

24.3.3 Interrupt Enable Register (IER) - UART Mode

The interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are seven types of interrupt in this mode: receiver error, RHR interrupt, THR interrupt, XOFF received and $\overline{\text{CTS}}/\overline{\text{RTS}}$ change of state from low to high. Each interrupt can be enabled/disabled individually. There is also a sleep mode enable bit. The UART interrupt enable register (IER) is shown in Figure 24-30 and described in Table 24-12.

Figure 24-30. UART Interrupt Enable Register (IER)

Reserved

Table 24-12. UART Interrupt Enable Register (IER) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	CTSIT		Can be written only when EFR[4] = 1.
		0	Disables the $\overline{\text{CTS}}$ interrupt.
		1	Enables the $\overline{\text{CTS}}$ interrupt.
6	RTSIT		Can be written only when EFR[4] = 1.
		0	Disables the $\overline{\text{RTS}}$ interrupt.
		1	Enables the $\overline{\text{RTS}}$ interrupt.
5	XOFFIT		Can be written only when EFR[4] = 1.
		0	Disables the XOFF interrupt.
		1	Enables the XOFF interrupt.
4	SLEEPMODE		Can be only written when EFR[4] = 1.
		0	Disables sleep mode.
		1	Enables sleep mode (stop baud rate clock when the module is inactive).
3	MODEMSTSIT	0	Disables the modem status register interrupt.
		1	Enables the modem status register interrupt
2	LINESIT	0	Disables the receiver line status interrupt.
		1	Enables the receiver line status interrupt.
1	THRIT	0	Disables the THR interrupt.
		1	Enables the THR interrupt.
0	RHRIT	0	Disables the RHR interrupt and time out interrupt.
		1	Enables the RHR interrupt and time out interrupt.

24.3.4 Interrupt Enable Register (IER) - IrDA Mode

The IrDA interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are 8 types of interrupt in these modes, received EOF, LSR interrupt, TX status, status FIFO interrupt, RX overrun, last byte in RX FIFO, THR interrupt, and RHR interrupt. Each interrupt can be enabled/disabled individually. The IrDA interrupt enable register (IER) is shown in Figure 24-31 and described in Table 24-13.

NOTE: The TXSTATUSIT interrupt reflects two possible conditions. The MDR2[0] bit should be read to determine the status in the event of this interrupt.

Figure 24-31. IrDA Interrupt Enable Register (IER)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-13. IrDA Interrupt Enable Register (IER) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	EOFIT	0	Disables the received EOF interrupt.
		1	Enables the received EOF interrupt.
6	LINESTSIT	0	Disables the receiver line status interrupt.
		1	Enables the receiver line status interrupt.
5	TXSTATUSIT	0	Disables the TX status interrupt.
		1	Enables the TX status interrupt.
4	STSFIFOTRIGIT	0	Disables status FIFO trigger level interrupt.
		1	Enables status FIFO trigger level interrupt.
3	RXOVERRUNIT	0	Disables the RX overrun interrupt.
		1	Enables the RX overrun interrupt.
2	LASTRXBYTEIT	0	Disables the last byte of frame in RX FIFO interrupt.
		1	Enables the last byte of frame in RX FIFO interrupt.
1	THRIT	0	Disables the THR interrupt.
		1	Enables the THR interrupt.
0	RHRIT	0	Disables the RHR interrupt.
		1	Enables the RHR interrupt.

24.3.5 Interrupt Enable Register (IER) - CIR Mode

The CIR interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are 5 types of interrupt in these modes, TX status, RX overrun, RX stop interrupt, THR interrupt, and RHR interrupt. Each interrupt can be enabled/disabled individually. The CIR interrupt enable register (IER) is shown in Figure 24-32 and described in Table 24-14.

NOTE: In CIR mode, the TXSTATUSIT bit has only one meaning corresponding to the case MDR2[0] = 0.

The RXSTOPIT interrupt is generated based on the value set in the BOF Length register (EBLR).

Figure 24-32. CIR Interrupt Enable Register (IER)

2	RXSTOPIT	0	Disables the RX stop interrupt.
		1	Disables the RX stop interrupt.
1	THRIT	0	Disables the THR interrupt.
		1	Enables the THR interrupt.
0	RHRIT	0	Disables the RHR interrupt.
		1	Enables the RHR interrupt.

24.3.6 Interrupt Identification Register (IIR) - UART Mode

The UART interrupt identification register (IIR) is a read-only register that provides the source of the interrupt. The UART interrupt identification register (IIR) is shown in [Figure 24-33](#) and described in [Table 24-15](#).

NOTE: An interrupt source can be flagged only if enabled in the IER register.

Figure 24-33. UART Interrupt Identification Register (IIR)

5	TX_STATUS_IT	0	TX status interrupt inactive.
		1	TX status interrupt active.
4	STS_FIFO_IT	0	Status FIFO trigger level interrupt inactive.
		1	Status FIFO trigger level interrupt active.
3	RX_OE_IT	0	RX overrun interrupt inactive.
		1	RX overrun interrupt active.
2	RX_FIFO_LAST_BYTE_IT	0	Last byte of frame in RX FIFO interrupt inactive.
		1	Last byte of frame in RX FIFO interrupt active.
1	THR_IT	0	THR interrupt inactive.
		1	THR interrupt active.
0	RHR_IT	0	RHR interrupt inactive.
		1	RHR interrupt active.

24.3.8 Interrupt Identification Register (IIR) - CIR Mode

The CIR interrupt identification register (IIR) is a read-only register that provides the source of the interrupt. The CIR interrupt identification register (IIR) is shown in [Figure 24-35](#) and described in [Table 24-17](#).

NOTE: An interrupt source can be flagged only if enabled in the IER register.

Figure 24-35. CIR Interrupt Identification Register (IIR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-6	RX_FIFO_TRIG	0-3h	Sets the trigger level for the RX FIFO: If SCR[7] = 0 and TLR[7:4] ≠ 0000, RX_FIFO_TRIG is not considered. If SCR[7] = 1, RX_FIFO_TRIG is 2 LSB of the trigger level (1 to 63 on 6 bits) with the granularity 1. If SCR[7] = 0 and TLR[7:4] = 0000: 0 8 characters 1h 16 characters 2h 56 characters 3h 60 characters
5-4	TX_FIFO_TRIG	0-3h	Can be written only if EFR[4] = 1. Sets the trigger level for the TX FIFO: If SCR[6] = 0 and TLR[3:0] ≠ 0000, TX_FIFO_TRIG is not considered. If SCR[6] = 1, TX_FIFO_TRIG is 2 LSB of the trigger level (1 to 63 on 6 bits) with a granularity of 1. If SCR[6] = 0 and TLR[3:0] = 0000: 0 8 characters 1h 16 characters 2h 32 characters 3h 56 characters
3	DMA_MODE		Can be changed only when the baud clock is not running (DLL and DLH cleared to 0). If SCR[0] = 0, this register is considered. 0 DMA_MODE 0 (No DMA). 1 DMA_MODE 1 (UART_NDMA_REQ[0] in TX, UART_NDMA_REQ[1] in RX).
2	TX_FIFO_CLEAR	0 1	0 No change. 1 Clears the transmit FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.
1	RX_FIFO_CLEAR	0 1	0 No change. 1 Clears the receive FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.
0	FIFO_EN	0 1	Can be changed only when the baud clock is not running (DLL and DLH cleared to 0). 0 Disables the transmit and receive FIFOs. The transmit and receive holding registers are 1-byte FIFOs. 1 Enables the transmit and receive FIFOs. The transmit and receive holding registers are 64-byte FIFOs.

24.3.10 Line Control Register (LCR)

The line control register (LCR) is shown in [Figure 24-37](#) and described in [Table 24-19](#).

NOTE: As soon as LCR[6] is set to 1, the TX line is forced to 0 and remains in this state as long as LCR[6] = 1.

Figure 24-37. Line Control Register (LCR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-19. Line Control Register (LCR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	DIV_EN	0 1	Divisor latch enable. Normal operating condition. Divisor latch enable. Allows access to DLL and DLH.
6	BREAK_EN	0 1	Break control bit. Note: When LCR[6] is set to 1, the TX line is forced to 0 and remains in this state as long as LCR[6] = 1. Normal operating condition. Forces the transmitter output to go low to alert the communication terminal.
5	PARITY_TYPE2	0 1 1	If LCR[3] = 1: If LCR[5] = 0, LCR[4] selects the forced parity format. If LCR[5] = 1 and LCR[4] = 0, the parity bit is forced to 1 in the transmitted and received data. If LCR[5] = 1 and LCR[4] = 1, the parity bit is forced to 0 in the transmitted and received data.
4	PARITY_TYPE1	0 1	If LCR[3] = 1: Odd parity is generated. Even parity is generated.
3	PARITY_EN	0 1	Parity bit. No parity. A parity bit is generated during transmission, and the receiver checks for received parity.
2	NB_STOP	0 1	Specifies the number of stop bits. 1 stop bit (word length = 5, 6, 7, 8). 1.5 stop bits (word length = 5) or 2 stop bits (word length = 6, 7, 8).
1-0	CHAR_LENGTH	0-3h 0 1h 2h 3h	Specifies the word length to be transmitted or received. 5 bits 6 bits 7 bits 8 bit

24.3.11 Modem Control Register (MCR)

Bits 3-0 control the interface with the modem, data set, or peripheral device that is emulating the modem. The modem control register (MCR) is shown in [Figure 24-38](#) and described in [Table 24-20](#).

Figure 24-38. Modem Control Register (MCR)

Reserved							
R-0							
7	6	5	4	3	2	1	0
Reserved	TCRTLR	XONEN	LOOPBACKEN	CDSTSCH	RISTSCH	RTS	DTR
R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-20. Modem Control Register (MCR) Field Descriptions

Bit	Field	Value	Description
15-7	Reserved	0	Reserved.
6	TCRTLR	0	No action.
		1	Enables access to the TCR and TLR registers.
5	XONEN	0	Disable XON any function.
		1	Enable XON any function.
4	LOOPBACKEN	0	Normal operating mode.
		1	Enable local loopback mode (internal). In this mode, the MCR[3:0] signals are looped back into MSR[7:4]. The transmit output is looped back to the receive input internally.
3	CDSTSCH	0	In loopback mode, forces $\overline{\text{DCD}}$ input high and IRQ outputs to INACTIVE state.
		1	In loopback mode, forces $\overline{\text{DCD}}$ input low and IRQ outputs to INACTIVE state.
2	RISTSCH	0	In loopback mode, forces $\overline{\text{RT}}$ input inactive (high).
		1	In loopback mode, forces $\overline{\text{RT}}$ input active (low).
1	RTS	0	In loopback mode, controls MSR[4]. If auto-RTS is enabled, the $\overline{\text{RTS}}$ output is controlled by hardware flow control.
		1	Force $\overline{\text{RTS}}$ output to active (low).
0	DTR	0	Force $\overline{\text{DTR}}$ output (used in loopback mode) to inactive (high).
		1	Force $\overline{\text{DTR}}$ output (used in loopback mode) to active (low).

24.3.12 Line Status Register (LSR) - UART Mode

When the UART line status register (LSR) is read, LSR[4:2] reflect the error bits (BI, FE, PE) of the character at the top of the RX FIFO (next character to be read). Therefore, reading the LSR and then reading the RHR identifies errors in a character. Reading RHR updates BI, FE, and PE. LSR [7] is set when there is an error anywhere in the RX FIFO and is cleared only when there are no more errors remaining in the RX FIFO. The UART line status register (LSR) is shown in [Figure 24-39](#) and described in [Table 24-21](#).

NOTE: Reading the LSR does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the RHR. Reading LSR clears OE if set.

Figure 24-39. UART Line Status Register (LSR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-21. UART Line Status Register (LSR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	RXFIFOSTS	0	Normal operation.
		1	At least one parity error, framing error, or break indication in the RX FIFO. Bit 7 is cleared when no errors are present in the RX FIFO.
6	TXSRE	0	Transmitter hold (TX FIFO) and shift registers are not empty.
		1	Transmitter hold (TX FIFO) and shift registers are empty.
5	TXFIFOE	0	Transmit hold register (TX FIFO) is not empty.
		1	Transmit hold register (TX FIFO) is empty. The transmission is not necessarily completed.
4	RXBI	0	No break condition.
		1	A break was detected while the data being read from the RX FIFO was being received (RX input was low for one character + 1 bit time frame).
3	RXFE	0	No framing error in data being read from RX FIFO.
		1	Framing error occurred in data being read from RX FIFO (received data did not have a valid stop bit).
2	RXPE	0	No parity error in data being read from RX FIFO.
		1	Parity error in data being read from RX FIFO.
1	RXOE	0	No overrun error.
		1	Overrun error occurred. Set when the character held in the receive shift register is not transferred to the RX FIFO. This case occurs only when receive FIFO is full.
0	RXFIFOE	0	No data in the receive FIFO.
		1	At least one data character in the RX FIFO.

24.3.13 Line Status Register (LSR) - IrDA Mode

When the IrDA line status register (LSR) is read, LSR[4:2] reflect the error bits (FL, CRC, ABORT) of the frame at the top of the status FIFO (next frame status to be read). The IrDA line status register (LSR) is shown in Figure 24-40 and described in Table 24-22.

Figure 24-40. IrDA Line Status Register (LSR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-22. IrDA Line Status Register (LSR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	THR_EMPTY	0	Transmit holding register (TX FIFO) is not empty.
		1	Transmit hold register (TX FIFO) is empty. The transmission is not necessarily completed.
6	STS_FIFO_FULL	0	Status FIFO is not full.
		1	Status FIFO is full.
5	RX_LAST_BYTE	0	The RX FIFO (RHR) does not contain the last byte of the frame to be read.
		1	The RX FIFO (RHR) contains the last byte of the frame to be read. This bit is set to 1 only when the last byte of a frame is available to be read. It is used to determine the frame boundary. It is cleared on a single read of the LSR register.
4	FRAME_TOO_LONG	0	No frame-too-long error in frame.
		1	Frame-too-long error in the frame at the top of the status FIFO (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by RXFLH and RXFLR registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected.
3	ABORT	0	No abort pattern error in frame.
		1	Abort pattern received. SIR and MIR: abort pattern. FIR: Illegal symbol.
2	CRC	0	No CRC error in frame.
		1	CRC error in the frame at the top of the status FIFO (next character to be read).
1	STS_FIFO_E	0	Status FIFO is not empty.
		1	Status FIFO is empty.
0	RX_FIFO_E	0	At least one data character in the RX FIFO.
		1	No data in the receive FIFO.

24.3.14 Line Status Register (LSR) - CIR Mode

The CIR line status register (LSR) is shown in [Figure 24-41](#) and described in [Table 24-23](#).

Figure 24-41. CIR Line Status Register (LSR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-23. CIR Line Status Register (LSR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	THREMPY	0	Transmit holding register (TX FIFO) is not empty.
		1	Transmit hold register (TX FIFO) is empty. The transmission is not necessarily completed.
6	Reserved	0	Reserved.
5	RXSTOP	0	The RXSTOP is generated based on the value set in the BOF Length register (EBLR). Reception is on going or waiting for a new frame.
		1	Reception is completed. It is cleared on a single read of the LSR register.
4-1	Reserved	0	Reserved
0	RXFIFOE	0	At least one data character in the RX FIFO.
		1	No data in the receive FIFO.

24.3.15 Modem Status Register (MSR)

The modem status register (MSR) provides information about the current state of the control lines from the modem, data set, or peripheral device to the Local Host. It also indicates when a control input from the modem changes state. The modem status register (MSR) is shown in [Figure 24-42](#) and described in [Table 24-24](#).

Figure 24-42. Modem Status Register (MSR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-24. Modem Status Register (MSR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	NCD_STS		This bit is the complement of the $\overline{\text{DCD}}$ input. In loopback mode, it is equivalent to MCR[3].
6	NRI_STS		This bit is the complement of the $\overline{\text{RT}}$ input. In loopback mode, it is equivalent to MCR[2].
5	NDSR_STS		This bit is the complement of the $\overline{\text{DSR}}$ input. In loopback mode, it is equivalent to MCR[0].
4	NCTS_STS		This bit is the complement of the $\overline{\text{CTS}}$ input. In loopback mode, it is equivalent to MCR[1].
3	DCD_STS	0	No change.
		1	Indicates that $\overline{\text{DCD}}$ input (or MCR[3] in loopback mode) has changed. Cleared on a read.
2	RI_STS	0	No change.
		1	Indicates that $\overline{\text{RT}}$ input (or MCR[2] in loopback mode) changed state from low to high. Cleared on a read.
1	DSR_STS	0	No change.
		1	Indicates that $\overline{\text{DSR}}$ input (or MCR[0] in loopback mode) changed state. Cleared on a read.
0	CTS_STS	0	No change.
		1	Indicates that $\overline{\text{CTS}}$ input (or MCR[1] in loopback mode) changed state. Cleared on a read.

24.3.16 Transmission Control Register (TCR)

The transmission control register (TCR) stores the receive FIFO threshold levels to start/stop transmission during hardware flow control. The transmission control register (TCR) is shown in [Figure 24-43](#) and described in [Table 24-25](#).

NOTE:

- Trigger levels from 0-60 bytes are available with a granularity of 4.
- Trigger level = 4 × [4-bit register value]
- You must ensure that TCR[3:0] > TCR[7:4], whenever auto-RTS or software flow control is enabled to avoid a misoperation of the device. In FIFO interrupt mode with flow control, you have to also ensure that the trigger level to HALT transmission is greater or equal to receive FIFO trigger level (either TLR[7:4] or FCR[7:6]); otherwise, FIFO operation stalls.
- In FIFO DMA mode with flow control, this concept does not exist because the DMA request is sent each time a byte is received.

Figure 24-43. Transmission Control Register (TCR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-25. Transmission Control Register (TCR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-4	RXFIFOTRIGSTART	0-Fh	RX FIFO trigger level to RESTORE transmission (0 to 60).
3-0	RXFIFOTRIGHALT	0-Fh	RX FIFO trigger level to HALT transmission (0 to 60).

24.3.17 Scratchpad Register (SPR)

The scratchpad register (SPR) is a read/write register that does not control the module. It is a scratchpad register used to hold temporary data. The scratchpad register (SPR) is shown in [Figure 24-44](#) and described in [Table 24-26](#).

Figure 24-44. Scratchpad Register (SPR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-26. Scratchpad Register (SPR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	SPR_WORD	0-FFh	Scratchpad register.

24.3.18 Trigger Level Register (TLR)

This register stores the programmable transmit and receive FIFO trigger levels used for DMA and IRQ generation. The trigger level register (TLR) is shown in [Figure 24-45](#) and described in [Table 24-27](#).

Figure 24-45. Trigger Level Register (TLR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-27. Trigger Level Register (TLR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-4	RX_FIFO_TRIG_DMA	0-Fh	Receive FIFO trigger level. See Table 24-28 .
3-0	TX_FIFO_TRIG_DMA	0-Fh	Transmit FIFO trigger level. See Table 24-29 .

Table 24-28. RX FIFO Trigger Level Setting Summary

SCR[7]	TLR[7:4]	Description
0	0	Defined by FCR[7:6] (either 8, 16, 56, 60 characters).
0	≠ 0000	Defined by TLR[7:4] (from 4 to 60 characters with a granularity of 4 characters).
1	any value	Defined by the concatenated value of TLR[7:4] and FCR[7:6] (from 1 to 63 characters with a granularity of 1 character). Note: the combination of TLR[7:4] = 0000 and FCR[7:6] = 00 (all zeros) is not supported (minimum of 1 character is required). All zeros results in unpredictable behavior.

Table 24-29. TX FIFO Trigger Level Setting Summary

SCR[6]	TLR[3:0]	Description
0	0	Defined by FCR[5:4] (either 8, 16, 32, 56 characters).
0	≠ 0000	Defined by TLR[3:0] (from 4 to 60 characters with a granularity of 4 characters).
1	any value	Defined by the concatenated value of TLR[3:0] and FCR[5:4] (from 1 to 63 characters with a granularity of 1 character). Note: the combination of TLR[3:0] = 0000 and FCR[5:4] = 00 (all zeros) is not supported (minimum of 1 character is required). All zeros results in unpredictable behavior.

24.3.19 Mode Definition Register 1 (MDR1)

The mode of operation is programmed by writing to MDR1[2:0]; therefore, the mode definition register 1 (MDR1) must be programmed on startup after configuration of the configuration registers (DLL, DLH, and LCR). The value of MDR1[2:0] must not be changed again during normal operation. The mode definition register 1 (MDR1) is shown in Figure 24-46 and described in Table 24-30.

NOTE: If the module is disabled by setting the MODESELECT field to 7h, interrupt requests can still be generated unless disabled through the interrupt enable register (IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (IIR) shows the UART mode interrupt flags.

Figure 24-46. Mode Definition Register 1 (MDR1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-30. Mode Definition Register 1 (MDR1) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	FRAMEENDMODE	0	IrDA mode only.
		0	Frame-length method.
		1	Set EOT bit method.
6	SIPMODE		MIR/FIR modes only.
		0	Manual SIP mode: SIP is generated with the control of ACREG[3].
		1	Automatic SIP mode: SIP is generated after each transmission.
5	SCT		Store and control the transmission.
		0	Starts the infrared transmission when a value is written to the THR register.
		1	Starts the infrared transmission with the control of ACREG[2]. Note: Before starting any transmission, there must be no reception ongoing.
4	SETTXIR		Used to configure the infrared transceiver.
		0	If MDR2[7] = 0, no action; if MDR2[7] = 1, TXIR pin output is forced low.
		1	TXIR pin output is forced high (not dependant of MDR2[7] value).
3	IRSLEEP		IrDA/CIR sleep mode.
		0	IrDA/CIR sleep mode disabled.
		1	IrDA/CIR sleep mode enabled.
2-0	MODESELECT	0-7h	UART/IrDA/CIR mode selection.
		0	UART 16x mode.
		1	SIR mode.
		2h	UART 16x auto-baud.
		3h	UART 13x mode.
		4h	MIR mode.
		5h	FIR mode.
		6h	CIR mode.
		7h	Disable (default state).

24.3.20 Mode Definition Register 2 (MDR2)

The MDR2[0] bit describes the status of the TX status interrupt in IIR[5]. The IRTXUNDERRUN bit must be read after a TX status interrupt occurs. The MDR2[2:1] bits set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in MDR1[2:0]. The mode definition register 2 (MDR2) is shown in [Figure 24-47](#) and described in [Table 24-31](#).

NOTE: The MDR2[6] bit gives the flexibility to invert the RX pin inside the UART module to ensure that the protocol at the input of the transceiver module has the same polarity at module level. By default, the RX pin is inverted because most of transceiver invert the IR receive pin.

Figure 24-47. Mode Definition Register 2 (MDR2)

Reserved							
R-0							
7	6	5	4	3	2	1	0
SETTXIRALT	IRRXINVERT	CIRPULSEMODE	UARTPULSE	STSFIFOTRIG	IRTXUNDERRUN		
R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R-0		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-31. Mode Definition Register 2 (MDR2) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	SETTXIRALT	0 1	Provides alternate functionality for MDR1[4]. Normal mode Alternate mode for SETTXIR
6	IRRXINVERT	0 1	Only for IR mode (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes. Inversion is performed. No inversion is performed.
5-4	CIRPULSEMODE	0-3h 0 1h 2h 3h	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: Pulse width of 3 from 12 cycles. Pulse width of 4 from 12 cycles. Pulse width of 5 from 12 cycles. Pulse width of 6 from 12 cycles.
3	UARTPULSE	0 1	UART mode only. Used to allow pulse shaping in UART mode. Normal UART mode. UART mode with pulse shaping.
2-1	STSFIFOTRIG	0-3h 0 1h 2h 3h	Only for IrDA mode. Frame status FIFO threshold select: 1 entry 4 entries 7 entries 8 entries
0	IRTXUNDERRUN	0 1	IrDA transmission status interrupt. When the TX status interrupt (IIR[5]) occurs, the meaning of the interrupt is: The last bit of the frame was transmitted successfully without error. An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the RESUME register is read.

24.3.21 Mode Definition Register 3 (MDR3)

The MDR3[0] DISABLE_CIR_RX_DEMOD bit will force the CIR receiver to bypass demodulation of received data if set.

The MDR3[1] NONDEFAULT_FREQ bit allows the user to set sample per bi. Set this bit if non default (48MHz) clock frequency is used to achieve less than 2 % error rate. Changing this bit automatically disables the device by setting MDR1[2:0] to 3h.

MDR3[2] SET_DMA_THRESHOLD bit enables the usage of different TX DMA threshold then 64-trigger, when set to 1h.

The mode definition register 3 (MDR3) is shown in [Figure 24-48](#) and described in [Table 24-32](#).

Figure 24-48. Mode Definition Register 3 (MDR3)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-32. Mode Definition Register 3 (MDR3) Field Descriptions

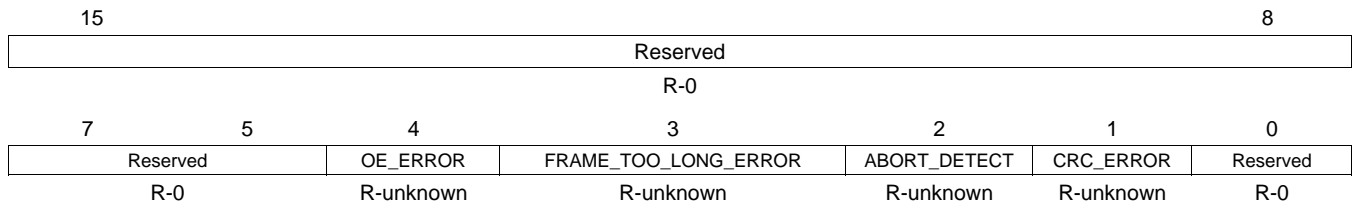

Bit	Field	Value	Description
31-3	Reserved	0	Reserved.
2	SET_DMA_THRE SHOLD	0 1h	Use the value of 64-tx trigger. Sets different TX DMA threshold then 64-trigger
1	NONDEFAULT_F REQ	0 1h	Default fclk frequencies Nondefault fclk frequencies
0	DISABLE_CIR_R X_DEMOD	0 1h	Enalbes CIR RX demodulation Disables CIR RX demodulation

24.3.22 Status FIFO Line Status Register (SFLSR)

Reading the status FIFO line status register (SFLSR) effectively reads frame status information from the status FIFO. This register does not physically exist. Reading this register increments the status FIFO read pointer (SFREGL and SFREGH must be read first). The status FIFO line status register (SFLSR) is shown in [Figure 24-49](#) and described in [Table 24-33](#).

NOTE: Top of RX FIFO = Next frame to be read from RX FIFO.

Figure 24-49. Status FIFO Line Status Register (SFLSR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-33. Status FIFO Line Status Register (SFLSR) Field Descriptions

Bit	Field	Value	Description
15-5	Reserved	0	Reserved.
4	OE_ERROR	0	No error
		1	Overrun error in RX FIFO when frame at top of RX FIFO was received.
3	FRAME_TOO_LONG_ERROR	0	No error
		1	Frame-length too long error in frame at top of RX FIFO.
2	ABORT_DETECT	0	No error
		1	Abort pattern detected in frame at top of RX FIFO.
1	CRC_ERROR	0	No error
		1	CRC error in frame at top of RX FIFO.
0	Reserved	0	Reserved.

24.3.23 RESUME Register

The RESUME register is used to clear internal flags, which halt transmission/reception when an underrun/overrun error occurs. Reading this register resumes the halted operation. This register does not physically exist and always reads as 00. The RESUME register is shown in [Figure 24-50](#) and described in [Table 24-34](#).

Figure 24-50. RESUME Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-34. RESUME Register Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	RESUME	0-FFh	Dummy read to restart the TX or RX.

24.3.24 Status FIFO Register Low (SFREGL)

The frame lengths of received frames are written into the status FIFO. This information can be read by reading the status FIFO register low (SFREGL) and the status FIFO register high (SFREGH). These registers do not physically exist. The LSBs are read from SFREGL and the MSBs are read from SFREGH. Reading these registers does not alter the status FIFO read pointer. These registers must be read before the pointer is incremented by reading the SFLSR. The status FIFO register low (SFREGL) is shown in [Figure 24-51](#) and described in [Table 24-35](#).

Figure 24-51. Status FIFO Register Low (SFREGL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-35. Status FIFO Register Low (SFREGL) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	SFREGL	0-FFh	LSB part of the frame length.

24.3.25 Status FIFO Register High (SFREGH)

The frame lengths of received frames are written into the status FIFO. This information can be read by reading the status FIFO register low (SFREGL) and the status FIFO register high (SFREGH). These registers do not physically exist. The LSBs are read from SFREGL and the MSBs are read from SFREGH. Reading these registers does not alter the status FIFO read pointer. These registers must be read before the pointer is incremented by reading the SFLSR. The status FIFO register high (SFREGH) is shown in [Figure 24-52](#) and described in [Table 24-36](#).

Figure 24-52. Status FIFO Register High (SFREGH)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-36. Status FIFO Register High (SFREGH) Field Descriptions

Bit	Field	Value	Description
15-4	Reserved	0	Reserved.
3-0	SFREGH	0-Fh	MSB part of the frame length.

24.3.26 BOF Control Register (BLR)

The BLR[6] bit is used to select whether C0h or FFh start patterns are to be used, when multiple start flags are required in SIR mode. If only one start flag is required, this is always C0h. If n start flags are required, either $(n - 1)$ C0h or $(n - 1)$ FFh flags are sent, followed by a single C0h flag (immediately preceding the first data byte). The BOF control register (BLR) is shown in [Figure 24-53](#) and described in [Table 24-37](#).

Figure 24-53. BOF Control Register (BLR)

15	8	7	6	5	0
Reserved	STSFIFORESET		XBOFTYPE	Reserved	
R-0	R/W-0		R/W-1	R-0	

LEGEND: R/W = Read/Write; R = Read only; - n = value after reset

Table 24-37. BOF Control Register (BLR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	STSFIFORESET		Status FIFO reset. This bit is self-clearing..
6	XBOFTYPE	0	FFh start pattern is used.
		1	C0h start pattern is used.
0	Reserved	0	Reserved.

24.3.27 Auxiliary Control Register (ACREG)

The auxiliary control register (ACREG) is shown in [Figure 24-54](#) and described in [Table 24-38](#).

NOTE:

- If transmit FIFO is not empty and MDR1[5] = 1, IrDA starts a new transfer with data of previous frame as soon as abort frame has been sent. Therefore, TX FIFO must be reset before sending an abort frame.
- It is recommended to disable TX FIFO underrun capability by masking corresponding underrun interrupt. When disabling underrun by setting ACREG[4] = 1, unknown data is sent over TX line.

Figure 24-54. Auxiliary Control Register (ACREG)

15								8							
Reserved															
R-0															
7		6		5		4		3		2		1		0	
PULSETYPE	SDMOD	DISIRRX	DISTXUNDERRUN	SENDSIP	SCTXEN	ABORTEN	EOTEN								
R/W-0		R/W-0		R/W-0		R/W-0		R/W-0		R/W-0		R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-38. Auxiliary Control Register (ACREG) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	PULSETYPE	0 1	SIR pulse-width select: 0 3/16 of baud-rate pulse width 1 1.6 μ s
6	SDMOD	0 1	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0 SD pin is set to high. 1 SD pin is set to low.
5	DISIRRX	0 1	Disable RX input. 0 Normal operation (RX input automatically disabled during transmit, but enabled outside of transmit operation). 1 Disables RX input (permanent state; independent of transmit).
4	DISTXUNDERRUN	0 1	Disable TX underrun. 0 Long stop bits cannot be transmitted. TX underrun is enabled. 1 Long stop bits can be transmitted.
3	SENDSIP	0 1	MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is automatically cleared at the end of the SIP transmission. 0 No action. 1 Send SIP pulse.
2	SCTXEN		Store and control TX start. When MDR1[5] = 1 and the LH writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.
1	ABORTEN		Frame abort. The LH can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame.
0	EOTEN		EOT (end-of-transmission) bit. The LH writes 1 to this bit just before it writes the last byte to the TX FIFO in the set-EOT bit frame-closing method. This bit is automatically cleared when the LH writes to the THR (TX FIFO).

24.3.28 Supplementary Control Register (SCR)

The supplementary control register (SCR) is shown in [Figure 24-55](#) and described in [Table 24-39](#).

NOTE: Bit 4 enables the wake-up interrupt, but this interrupt is not mapped into the IIR register. Therefore, when an interrupt occurs and there is no interrupt pending in the IIR register, the SSR[1] bit must be checked. To clear the wake-up interrupt, bit SCR[4] must be reset to 0.

Figure 24-55. Supplementary Control Register (SCR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-39. Supplementary Control Register (SCR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	RXTRIGGRANU1	0 1	Disables the granularity of 1 for trigger RX level. Enables the granularity of 1 for trigger RX level.
6	TXTRIGGRANU1	0 1	Disables the granularity of 1 for trigger TX level. Enables the granularity of 1 for trigger TX level.
5	DSRIT	0 1	Disables $\overline{\text{DSR}}$ interrupt. Enables $\overline{\text{DSR}}$ interrupt.
4	RXCTSDSRWAKEUPENABLE	0 1	RX CTS wake-up enable. Disables the WAKE UP interrupt and clears SSR[1]. Waits for a falling edge of RX, $\overline{\text{CTS}}$, or $\overline{\text{DSR}}$ pins to generate an interrupt.
3	TXEMPTYCTLIT	0 1	Normal mode for THR interrupt. THR interrupt is generated when TX FIFO and TX shift register are empty.
2-1	DMAMODE2	0-3h 0 1h 2h 3h	Specifies the DMA mode valid if SCR[0] = 1: DMA mode 0 (no DMA). DMA mode 1 (UARTnDMAREQ[0] in TX, UARTnDMAREQ[1] in RX) DMA mode 2 (UARTnDMAREQ[0] in RX) DMA mode 3 (UARTnDMAREQ[0] in TX)
0	DMAMODECTL	0 1	The DMAMODE is set with FCR[3]. The DMAMODE is set with SCR[2:1].

24.3.29 Supplementary Status Register (SSR)

The supplementary status register (SSR) is shown in [Figure 24-56](#) and described in [Table 24-40](#).

NOTE: Bit 1 is reset only when SCR[4] is reset to 0.

Figure 24-56. Supplementary Status Register (SSR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-40. Supplementary Status Register (SSR) Field Descriptions

Bit	Field	Value	Description
15-3	Reserved	0	Reserved.
2	DMACOUNTERRST	0	The DMA counter will not be reset, if the corresponding FIFO is reset (via FCR[1] or FCR[2]).
		1	The DMA counter will be reset, if the corresponding FIFO is reset (via FCR[1] or FCR[2]).
1	RXCTSDSRWAKEUPSTS	0	Pin falling edge detection: Reset only when SCR[4] is reset to 0. No falling-edge event on RX, \overline{CTS} , and \overline{DSR} .
		1	A falling edge occurred on RX, \overline{CTS} , or \overline{DSR} .
0	TXFIFOFULL	0	TX FIFO is not full.
		1	TX FIFO is full.

24.3.30 BOF Length Register (EBLR)

In IrDA SIR operation, the BOF length register (EBLR) specifies the number of BOF + xBOFs to transmit. The value set into this register must consider the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with n XBOFs, this register must be set to $n + 1$. Furthermore, the value 0 sends 1 BOF plus 255 XBOFs.

In IrDA MIR mode, the BOF length register (EBLR) specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags).

In CIR mode, the BOF length register (EBLR) specifies the number of consecutive zeros to be received before generating the RXSTOP interrupt (IIR[2]). All the received zeros are stored in the RX FIFO. When the register is cleared to 0, this feature is deactivated and always in reception state, which is disabled by setting the ACREG[5] bit to 1.

The BOF length register (EBLR) is shown in [Figure 24-57](#) and described in [Table 24-41](#).

NOTE: If the RX_STOP interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with zeros and then passed into the RX FIFO.

Figure 24-57. BOF Length Register (EBLR)

LEGEND: R/W = Read/Write; R = Read only; - n = value after reset

Table 24-41. BOF Length Register (EBLR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	EBLR	0	IrDA mode: This register allows definition of up to 176 xBOFs, the maximum required by IrDA specification. CIR mode: This register specifies the number of consecutive zeros to be received before generating the RXSTOP interrupt (IIR[2]). Feature disabled.
		1h	Generate RXSTOP interrupt after receiving 1 zero bit.
		...	
		FFh	Generate RXSTOP interrupt after receiving 255 zero bits.

24.3.31 Module Version Register (MVR)

The reset value is fixed by hardware and corresponds to the RTL revision of this module. A reset has no effect on the value returned. The module version register (MVR) is shown in [Figure 24-58](#) and described in [Table 24-42](#).

Figure 24-58. Module Version Register (MVR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-42. Module Version Register (MVR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-4	MAJORREV	0-Fh	Major revision number of the module.
3-0	MINORREV	0-Fh	Minor revision number of the module.

24.3.32 System Configuration Register (SYSC)

The AUTOIDLE bit controls a power-saving technique to reduce the logic power consumption of the module interface; that is, when the feature is enabled, the interface clock is gated off until the module interface is accessed. When the SOFTRESET bit is set high, it causes a full device reset. The system configuration register (SYSC) is shown in [Figure 24-59](#) and described in [Table 24-43](#).

Figure 24-59. System Configuration Register (SYSC)

15	5	4	3	2	1	0

R-0		R/W-0	R/W-0	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-43. System Configuration Register (SYSC) Field Descriptions

Bit	Field	Value	Description
15-5	Reserved	0	Reserved.
4-3	IDLEMODE	0-3h	Power management req/ack control.
		0	Force idle: Idle request is acknowledged unconditionally.
		1h	No-idle: Idle request is never acknowledged.
		2h	Smart idle: Acknowledgement to an idle request is given based in the internal activity of the module.
		3h	Smart idle Wakeup: Acknowledgement to an idle request is given based in the internal activity of the module. The module is allowed to generate wakeup request.
2	ENAWAKEUP		Wakeup control.
		0	Wakeup is disabled.
		1	Wakeup capability is enabled.
1	SOFTRESET		Software reset. Set this bit to 1 to trigger a module reset. This bit is automatically reset by the hardware. Read returns 0.
		0	Normal mode.
		1	Module is reset.
0	AUTOIDLE		Internal interface clock-gating strategy.
		0	Clock is running.
		1	Automatic interface clock-gating strategy is applied based on interface activity.

24.3.33 System Status Register (SYSS)

The system status register (SYSS) is shown in [Figure 24-60](#) and described in [Table 24-44](#).

Figure 24-60. System Status Register (SYSS)

15	1	0
Reserved		RESETDONE
R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Bit	Field	Value	Description
15-1	Reserved	0	Reserved.
0	RESETDONE		Internal reset monitoring.
		0	Internal module reset is ongoing.
		1	Reset complete.

24.3.34 Wake-Up Enable Register (WER)

The wake-up enable register (WER) is used to mask and unmask a UART event that subsequently notifies the system. An event is any activity in the logic that can cause an interrupt and/or an activity that requires the system to wake up. Even if wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART still registers the interrupt as such. The wake-up enable register (WER) is shown in [Figure 24-61](#) and described in [Table 24-45](#).

Figure 24-61. Wake-Up Enable Register (WER)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-45. Wake-Up Enable Register (WER) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	TXWAKEUPEN	0	Event is not allowed to wake up the system.
		1	Event can wake up the system: Event can be: THRIT or TXDMA request and/or TXSATUSIT.
6	RLS_INTERRUPT	0	Event is not allowed to wake up the system.
		1	Event can wake up the system.
5	RHR_INTERRUPT	0	Event is not allowed to wake up the system.
		1	Event can wake up the system.
4	RX_ACTIVITY	0	Event is not allowed to wake up the system.
		1	Event can wake up the system.
3	DCD_ACTIVITY	0	Event is not allowed to wake up the system.
		1	Event can wake up the system.
2	RI_ACTIVITY	0	Event is not allowed to wake up the system.
		1	Event can wake up the system.
1	DSR_ACTIVITY	0	Event is not allowed to wake up the system.
		1	Event can wake up the system.
0	CTS_ACTIVITY	0	Event is not allowed to wake up the system.
		1	Event can wake up the system.

24.3.35 Carrier Frequency Prescaler Register (CFPS)

Since the consumer IR (CIR) works at modulation rates of 30–56.8 kHz, the 48 MHz clock must be prescaled before the clock can drive the IR logic. The carrier frequency prescaler register (CFPS) sets the divisor rate to give a range to accommodate the remote control requirements in BAUD multiples of 12x. The value of the CFPS at reset is 105 decimal (69h), which equates to a 38.1 kHz output from starting conditions. The 48 MHz carrier is prescaled by the CFPS that is then divided by the 12x BAUD multiple. The carrier frequency prescaler register (CFPS) is shown in [Figure 24-62](#) and described in [Table 24-46](#).

Figure 24-62. Carrier Frequency Prescaler Register (CFPS)

24.3.36 Divisor Latches Low Register (DLL)

The divisor latches low register (DLL) with the DLH register stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH stores the most-significant part of the divisor, DLL stores the least-significant part of the divisor. The DLL register is shown in [Figure 24-63](#) and described in [Table 24-47](#).

NOTE: DLL and DLH can be written to only before sleep mode is enabled (before IER[4] is set).

Figure 24-63. Divisor Latches Low Register (DLL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-47. Divisor Latches Low Register (DLL) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	CLOCK_LSB	0-FFh	Divisor latches low. Stores the 8 LSB divisor value.

24.3.37 Divisor Latches High Register (DLH)

The divisor latches high register (DLH) with the DLL register stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH stores the most-significant part of the divisor, DLL stores the least-significant part of the divisor. The DLH register is shown in [Figure 24-64](#) and described in [Table 24-48](#).

NOTE: DLL and DLH can be written to only before sleep mode is enabled (before IER[4] is set).

Figure 24-64. Divisor Latches High Register (DLH)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-48. Divisor Latches High Register (DLH) Field Descriptions

Bit	Field	Value	Description
15-6	Reserved	0	Reserved.
5-0	CLOCK_MSB	0-3Fh	Divisor latches high. Stores the 6 MSB divisor value.

24.3.38 Enhanced Feature Register (EFR)

The enhanced feature register (EFR) enables or disables enhanced features. Most enhanced functions apply only to UART modes, but EFR[4] enables write accesses to FCR[5:4], the TX trigger level, which is also used in IrDA modes. The enhanced feature register (EFR) is shown in [Figure 24-65](#) and described in [Table 24-49](#).

Figure 24-65. Enhanced Feature Register (EFR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-49. Enhanced Feature Register (EFR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	AUTOCTSEN	0 1	Auto-CTS enable bit (UART mode only). Normal operation. Auto-CTS flow control is enabled; transmission is halted when the $\overline{\text{CTS}}$ pin is high (inactive).
6	AUTORTSEN	0 1	Auto-RTS enable bit (UART mode only). Normal operation. Auto-RTS flow control is enabled; $\overline{\text{RTS}}$ pin goes high (inactive) when the receiver FIFO HALT trigger level, TCR[3:0], is reached and goes low (active) when the receiver FIFO RESTORE transmission trigger level is reached.
5	SPECIALCHARDETECT	0 1	Special character detect (UART mode only). Normal operation. Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to RX FIFO and the IIR[4] bit is set to 1 to indicate that a special character was detected.
4	ENHANCEDEN	0 1	Enhanced functions write enable bit. Disables writing to IER[7:4], FCR[5:4], and MCR[7:5]. Enables writing to IER[7:4], FCR[5:4], and MCR[7:5].
3-0	SWFLOWCONTROL	0-Fh	Combinations of software flow control can be selected by programming this bit. XON1 and XON2 should be set to different values if the software flow control is enabled. See Table 24-50 . In IrDA mode, EFR[1:0] selects the IR address to check. See IR Address Checking .

Table 24-50. EFR[3:0] Software Flow Control Options

EFR[3:0]				TX/RX Software Flow Control
Bit 3	Bit 2	Bit 1	Bit 0	
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 ⁽¹⁾
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 ⁽¹⁾

⁽¹⁾ The XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.

24.3.39 XON1/ADDR1 Register

In UART mode, XON1 character; in IrDA mode, ADDR1 address 1. The XON1/ADDR1 register is shown in [Figure 24-66](#) and described in [Table 24-51](#).

Figure 24-66. XON1/ADDR1 Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 24-51. XON1/ADDR1 Register Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	XONWORD1	0-FFh	Stores the 8-bit XON1 character in UART modes and ADDR1 address 1 in IrDA modes.

24.3.40 XON2/ADDR2 Register

In UART mode, XON2 character; in IrDA mode, ADDR2 address 2. The XON2/ADDR2 register is shown in [Figure 24-67](#) and described in [Table 24-52](#).

Figure 24-67. XON2/ADDR2 Register

15-8	Reserved	0	Reserved.
7-0	XOFFWORD2	0-FFh	Stores the 8-bit XOFF2 character in UART modes.

24.3.43 Transmit Frame Length Low Register (TXFLL)

The transmit frame length low register (TXFLL) and the TXFLH register hold the 13-bit transmit frame length (expressed in bytes). TXFLL holds the LSBs and TXFLH holds the MSBs. The frame length value is used if the frame length method of frame closing is used. The transmit frame length low register (TXFLL) is shown in [Figure 24-70](#) and described in [Table 24-55](#).

Figure 24-70. Transmit Frame Length Low Register (TXFLL)

LEGEND: R/W = Read/Write; W = Write only; -n = value after reset

24.3.47 UART Autobauding Status Register (UASR)

The UART autobauding status register (UASR) returns the speed, the number of bits by characters, and the type of parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. The UART autobauding status register (UASR) is shown in Figure 24-74 and described in Table 24-59.

NOTE:

- This register is used to set up transmission according to characteristics of previous reception, instead of LCR, DLL, and DLH registers when UART is in autobauding mode.
- To reset the autobauding hardware (to start a new “AT” detection) or to set the UART in standard mode (no autobaud), MDR1[2:0] must be set to 7h (reset state), then set to 2h (UART in autobaud mode) or cleared to 0 (UART in standard mode).

Usage limitation:

- Only 7 and 8 bits character (5 and 6 bits not supported).
- 7 bits character with space parity not supported.
- Baud rate between 1200 and 115 200 bp/s (10 possibilities).

Figure 24-74. UART Autobauding Status Register (UASR)

Table 24-59. UART Autobauding Status Register (UASR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-6	PARITYTYPE	0-3h	Type of the parity in UART autobauding mode.
		0	No parity identified
		1h	Parity space
		2h	Even parity
		3h	Odd parity
5	BITBYCHAR		Number of bits by characters.
		0	7-bit character identified.
		1	8-bit character identified.
4-0	SPEED	0-1Fh	Speed
		0	No speed identified.
		1h	115 200 baud
		2h	57 600 baud
		3h	38 400 baud
		4h	28 800 baud
		5h	19 200 baud
		6h	14 400 baud
		7h	9600 baud
		8h	4800 baud
		9h	2400 baud
		Ah	1200 baud
		Bh-1Fh	Reserved

Universal Serial Bus Subsystem (USBSS)

The Universal Serial Bus Subsystem (USBSS) contains dual USB 2.0 compliant modules. Both modules are configurable as a USB Host, a USB Device or a dual role OTG Host/Device via the On-The-Go (OTG) supplement of the USB 2.0 Specification. Both USB modules operate independently of each other.

25.1 Introduction

Each USB module is built around the a USB OTG controller and PHY. Each USB controller has 32K Bytes of Endpoint FIFO RAM and support for up to 15 Endpoints in addition to Endpoint 0. The USB subsystem makes use of a Direct Memory Access (DMA) Controller for accelerating endpoint data movement via dedicated DMA hardware with minimal intervention by the CPU.

The two USB modules share a single DMA controller and accompanying Queue Manager, Interrupt Pacer, Power Management module, and PHY clock.

For the remainder of this chapter the term USB controller or USB PHY refers to any of the two USB controllers or PHYs existing within the USB subsystem. The term USB module is used to mean/refer to any of the two USB modules. USB0 is used to refer to the first instantiation of a USB modules and USB1 is used to refer to the other USB module instantiation.

25.2 Features Supported

The main features of the USB Subsystem are:

- Two USB modules where each USB module is built around a USB OTG controller and PHY.
- Supports USB Device operations at High Speed (Up to 480 Mb/s) or Full Speed (Up to 12 Mb/s).
- Supports USB Host operations at High Speed (Up to 480 Mb/s), Full Speed (Up to 12 Mb/s) and Low Speed (Up to 1.5Mb/s).
- USB 2.0 extensions for OTG Session Request Protocol (SRP).
- USB 2.0 extensions for OTG Host Request Protocol (HRP).
- Supports all USB standard transfer types (control, bulk, interrupt, and isochronous) as both a USB Host as well as a USB Device.
- Supports high bandwidth ISO mode.
- Supports 15 Transmit (Tx) and 15 Receive (Rx) Endpoints excluding Endpoint 0.
- Includes a 32KB Endpoint FIFO RAM per USB Module with user programmable Endpoint FIFO sizes.
- Includes RNDIS mode for accelerating RNDIS type protocols using short packet termination over USB.
- Includes CDC Linux mode for accelerating CDC type protocols using short packet termination over USB.
- Includes Generic RNDIS mode, an RNDIS-like mode for terminating RNDIS type protocols without using short packet termination for support for MSC class applications.
- Includes a DMA controller sub-module with 30 Rx and 30 Tx simultaneous data connections/channels.
- Includes DMA scheduler.
- The DMA supports host and packet descriptors formats.
- The DMA supports stall on buffer starvation.
- The DMA supports capability of allocating data buffer sizes up to 4Mbytes per single transfer.
- Provides a Queue Manager Module with 156 Queues for Queuing and De-Queuing packets.
- Supports DMA pacing logic for interrupts.

25.3 Functional Block Diagram

[Figure 25-1](#) displays a high-level functional block diagram covering the major blocks of the USB subsystem. It captures the general data paths and displays the interaction between each blocks of the subsystem at a high level.

Figure 25-1. USB Subsystem Block Diagram

25.3.1 L3 Slow Interconnect

This is the L3 master / slave interface to the device Memory Mapped Registers (MMRs) and system resources. The CPPI DMA and Queue Manager have also their own dedicated interface to the system resource through the master interfaces. CPU accesses the USB peripheral through the slave L3 Interface.

25.3.2 Memory Mapped Registers

The USB register file (USB core and subsystem registers and CPPI DMA registers that are accessible to the CPU) reside in a block within the USBSS.

25.3.3 USB 2.0 Controller

The USB subsystem supports two independent USB Modules. Each USB module comprises of a Dual Role USB 2.0 controllers with the support for OTG extensions.

25.3.4 USB PHY

The PHY is connected to the USB controller via 8-bit USB 2.0 Transceiver Macrocell Interface (UTMI). The PHY does not have a built-in charge pump thus an external power source is required to source the 5V VBUS power when operating as a USB Host. The PHY has built in charge detection for device mode and external charge control capability for a host application.

25.3.5 USB Pins

The USB subsystem external interface signals comprises two differential data lines, two Voltage Buses Level Detection Pins (VBUSIN), and two USB DRVVBUS signals which are used to enable/disable external 5V Power Source. The USB ID pins are used to configure the USB controller's role. Charge detect enable signals are present within both PHYs. For more details about the USB0 and USB1 mode registers, see [Section 25.9.2.1.23](#) and [Section 25.9.2.2.23](#), respectively.

25.3.6 DMA

The DMA alongside with the Queue Manager and the Scheduler are used to perform data transfer for Endpoints 1 to 15.

25.4 Industry Standard(s) Compliance

The USB subsystem complies with the following standards:

- Complies with the USB 2.0 Specification and the On-The-Go Supplement of the USB 2.0 Specification.

25.5 Architecture

Each USB controller within the device supports 15 Transmit (Tx) endpoints and 15 Receive (Rx) endpoints in addition to Endpoint 0. These endpoints are used for IN transactions or OUT transactions depending on the role of the USB Controller.

When used as a USB Device, IN transactions are processed through Tx endpoints and OUT transactions are processed through Rx endpoints. When used as a USB Host, IN transactions are processed through Rx endpoints and OUT transactions is processed through Tx endpoints.

Endpoints can be individually configured in software to handle Bulk, Interrupt, Isochronous, or Control transfers. Further, the endpoints can also be dynamically allocated to different target device functions on the fly – maximizing the number of devices that can be simultaneously supported. Each endpoint requires a block of memory allocated within the Module FIFO to be associated with it.

Each USB module has a single block of FIFO RAM (32 Kbytes in size) that is shared by all endpoints. The FIFO for Endpoint 0 is required to be 64 bytes deep and is single buffered. The first 64 Bytes of the FIFO RAM is reserved by hardware for Endpoint 0 and for this reason user software does not need (nor has the capability) to allocate a FIFO block for Endpoint 0. The rest of the FIFO RAM is user configurable with regard to the other endpoints. The size of an individual endpoint FIFO may range from 8 to 4096 bytes and can either be single or double buffered. Supported sizes must conform to the following sizes:

- FS/LS: 8, 16, 32, 64, 1024 bytes
- HS: 64, 128, 512, 1024, 2048, 4096 bytes.

Separate FIFOs may be associated with each endpoint: alternatively a Tx endpoint and the Rx endpoint with the same Endpoint number can be configured to use the same FIFO memory space, for example to reduce the size of RAM block needed, provided they can never be active at the same time.

The user can process USB transactions entirely from the CPU via the L3 Interconnect or can optionally use the DMA to automatically perform data transfer for endpoints 1-15. A CPU must be used to service Endpoint 0 transactions.

25.5.1 USB Controller Operational Mode

25.5.1.1 USB Controller Role Assuming Method

The two USB modules can be used in a range of different environments. They can be used as a High-Speed or a Full-Speed USB Device attached to a conventional USB Host (such as a PC) in a point-to-point type of arrangement, they can be used as a USB Host in which the USB modules can also be used with another USB Device of any speed (High-, Full-, or Low-speed) in a point-to-point arrangement, or they can be used as a USB Host to a range of USB Devices in a multi-point setup via a USB Hub. Note that the role each USB module operates is independent of each other.

USB transactions from the controller are issued and received during a valid USB Session. A session is defined only when VBUS is above the VBUS_SESS_VLD as specified in the OTG Supplement.

The USB 2.0 controller session starts when one of the following events occurs

- Firmware assumes it will be operating as the USB Host and sets the DEVCTL[SESSION] bit

If the firmware writes to the DEVCTL[SESSION] bit, the USB controller will attempt to determine if it is the 'A-Device', or if it is the 'B-Device' by sensing the resistance on the USBx_ID pin.

An A-Device is a device with a the Standard A Receptacle or a device with a Micro-A plug inserted into it's receptacle. A B-Device is defined as a device with a (mini-)B receptacle, or a Micro-A/B receptacle with the B end of the plug inserted into it's receptacle.

If the USB controller determines it is the A-Device it will turn on VBUS and wait until the USBx_VBUSIN pin is $\geq 4.4V$. Assuming that the voltage level of the USBX_VBUSIN is found to be within the VBUS Valid range according to the USB 2.0 Specification, the controller will then default to the USB Host and wait for a device to connect to the bus before attempting to enumerate the device.

If the controller senses it is a B-Device, it will use the Session Request Protocol as defined in the USB OTG Supplement to request a session from the A-Device and default to operating as a USB Device. If desired, firmware can force the USB Controller to act as an A-Device or a B-Device by writing to IDDIG bit in the USB Mode register before it sets the DEVCTL[SESSION] bit. This will override the ID sense

value and force the controller to operate as the USB Host or a USB Device.

- The USB Controller senses a voltage ($0.8 \leq \text{USBx_VBUSIN} \leq 2.1\text{V}$) on the USBx_VBUSIN pin.

If DEVCTL[SESSION] bit is clear when the USB Controller senses that a voltage of $\geq \text{VBUS_SESS_VLD}$ on the USBx_VBUSIN pin, firmware should assume was another device on the bus has attempted to start a session. The USB controller will assume that it is the B-Device and automatically set DEVCTL[SESSION] bit. When $\text{USBx_VBUSIN} \geq \text{VBUS_SESS_VLD}$, it will enable the 1.5 KOhm D+ pull-up. The subsequent Reset Interrupt received by the USB controller signifies the start of the session and the USB Controller should then proceed to behave as a Full-Speed or High-Speed Capable USB Device during enumeration.

25.5.1.2 Soft Connect

After a Power-on Reset (POR) or software initiated USB Module Reset, the SOFTCONN bit of POWER register is cleared to 0. The controller will therefore appear disconnected from the bus (D+/D- appear as high impedance) until firmware has set the SOFTCONN bit to 1. This feature allows the application software can then choose when to connect to the USB -or- when to remain disconnected. Applications with an overall lengthy initialization procedure may use this to ensure that all other initialization is complete and the CPU is ready to perform enumeration before setting the Soft Connect bit and connecting to the USB. Once the SOFTCONN bit has been set, the software can also simulate a disconnect by clearing this bit to 0.

25.5.1.3 Suspend

When operating as an active USB Host, firmware sets the POWER[SUSPEND] bit to enter into Suspend mode. Following the completion of the current transaction, the controller will disable it's scheduler and stop the frame counter.

When operating as an active USB Device, the controller monitors activity on the D+/D- and automatically transitions into suspend mode when it doesn't detect any valid USB activity for a period of greater than or equal to 3 ms. The USB controller will automatically set the POWER[SUSPEND] bit and then generate an Suspend Interrupt. At this point, the controller can then be left active or the application may arrange to disable the controller by stopping its clock. If the software disabled the USB clock, the controller will not then be able to detect Resume signaling and must rely on external hardware to detect Resume signaling so that the clock to the controller can be restarted.

25.5.1.4 Resume

When operating as a active USB Host, firmware clears the POWER[SUSPEND] bit to exit into Suspend mode and set the POWER[RESUME] bit for 20ms. The controller will automatically send Resume signaling onto the bus . Following the completion of this 20 ms period, firmware should clear the POWER[RESUME] bit to restart the transaction scheduler and frame counter. If remote Wake-up resume signaling is detected while the controller is in suspend mode, the controller will automatically exit suspend and set the POWER[RESUME] bit, take over generating the Resume Signal ,and finally generate an Resume Interrupt

When operating as a active USB Device, if resume signaling is detected on the bus, the clock to the controller must be restarted (if stopped during suspend). The controller will automatically exit Suspend mode and generate an interrupt. If the software wants to initiate a remote wakeup while the controller is in Suspend mode, it should set the POWER[RESUME] bit to 1. The software should leave then this bit set for approximately 10 ms (minimum of 2 ms, a maximum of 15 ms) before resetting it to 0. **NOTE:** No resume interrupt will be generated when the software initiates a remote wakeup.

25.5.1.5 Reset

When the controller is operating as a USB Host, a USB Reset condition will be generated on the bus if the Reset bit is set by firmware. If the High-Speed Enable (HSENA) bit is set, the controller will attempt to negotiate for high-speed operation.

Once the RESET is cleared, the controller will automatically start the frame counter and schedule USB transactions.

When the controller is operating as an USB Device it will automatically perform the following functions when it sees a USB Reset bus condition.

- Functional Address (FADDR) is cleared 0
- Endpoint Index Register (INDEX) is cleared to 0
- All endpoint FIFOs are flushed
- All Endpoint Control/Status registers are cleared
- All Endpoint Interrupts are Enabled at the controller level
- A USB Reset Interrupt is generated.

If the High Speed Enable (HSENA) bit within the POWER register is set, the controller will automatically attempt to negotiate with the USB Host for High-Speed Operation. Whether high-speed operation is selected is indicated by HSMODE bit of POWER register. When the application software receives a reset interrupt, it should close any open pipes and wait for bus enumeration to begin.

25.5.1.6 USB Controller Endpoint Control / Status Register Access

The USB controller provides two mechanisms for accessing endpoint control and status registers; Indexed and Non-Indexed method.

- **Indexed Endpoint Control/Status Register Space.**

This register space can be thought of as a region populated with Proxy Registers. The endpoint register space mapped at this region is selected by programming the corresponding INDEX register of the controller. By programming the INDEX register with the corresponding endpoint number, the control and status register corresponding to that particular endpoint is accessible from this Indexed Region. In other words, Index Register region behaves as a proxy to access a selected endpoint registers. Indexed access enables the controller to access different endpoints without reconfiguring addressing..

- **Non-indexed Endpoint Control/Status Register Space.**

The Endpoint Control / Status registers are located at dedicated endpoint registers in the respective USB Controllers

This use of Index / Non Indexed access modes allows the firmware to access an endpoint register region directly from its unique space (as specified within a non-indexed region), or from a proxy space by programming the corresponding Index register.

Note: The control and status registers/regions apply to both Tx and Rx of a given Endpoint. That is, Endpoint 1 Tx and Endpoint 1 Rx registers occupy the same register space.

25.5.1.7 Dynamic Endpoint FIFO Sizing

Each USB module supports a total of 32K bytes of FIFO RAM to dynamically allocate FIFO to all endpoints in use. Each endpoint requires a FIFO RAM block to be associated with it. There is one set of registers per endpoint available for FIFO allocation, excluding endpoint 0. FIFO configuration registers are Indexed registers and cannot be accessed directly; configuration takes place via accessing proxy registers. The INDEX register at addresses must be set to the appropriate endpoint before writing to the respective Endpoint FIFO configuration registers. The Endpoint FIFO configuration registers do not have non-indexed registers.

The allocation of FIFO space to the different endpoints requires programming for each Tx and Rx endpoint with the following information:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether the FIFO is single buffered or double buffered

The maximum packet size and double buffering together define the total of space that needs to be allocated to the FIFO per Endpoint

It is the responsibility of the firmware to ensure that all the Tx and Rx endpoints that are active in the current USB configuration have a block of FIFO RAM allocated for their use. The first 64 bytes of FIFO memory is statically configured for Endpoint 0 use and should be treated as reserved for all other endpoints. For endpoints other than endpoint 0, the FIFO RAM interface is configurable and must have a minimum size of 8 bytes and should be capable of buffering either 1 or 2 packets. Separate FIFOs may be associated with each endpoint: alternatively a Tx endpoint and the Rx endpoint with the same Endpoint number can be configured to use the same FIFO to reduce the size of RAM block needed, provided they are never active at the same time.

NOTE: The option of dynamically setting FIFO sizes only applies to Endpoints 1-15. Endpoint 0 FIFO has a fixed size (64 bytes) and a fixed location which is the first 64 Bytes of FIFO (FIFO addresses 0-63).

25.5.1.8 USB 2.0 Test Modes

Each USB2.0 controller supports the four USB 2.0 test modes (Test_SE0_NAK, Test_J, Test_K, and Test_Packet) defined for high-speed functions. It also supports an additional "FIFO access" test mode that can be used to test the operation of the CPU interface, the DMA controller and the FIFO RAM block.

The test modes are entered by writing to the TESTMODE register. A test mode is usually requested by the host sending a SET_FEATURE request to Endpoint 0. When the software receives the request, it should wait until the Endpoint 0 transfer has completed (when it receives the Endpoint 0 interrupt indicating the status phase has completed) then write to the TESTMODE register.

Note: These test modes have no purpose in normal operation.

25.5.1.8.1 TEST_SE0_NAK

To enter the Test_SE0_NAK test mode, the software should set the TEST_SE0_NAK bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it responds to any valid IN token with a NAK.

25.5.1.8.2 TEST_J

To enter the Test_J test mode, the software should set the TEST_J bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it transmits a continuous J on the bus.

25.5.1.8.3 TEST_K

To enter the Test_K test mode, the software should set the TEST_K bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it transmits a continuous K on the bus.

25.5.1.8.4 TEST_PACKET

To execute the Test_Packet, the software should:

1. Start a session (if the core is being used in Host mode).
2. Write the standard test packet (shown below) to the Endpoint 0 FIFO.
3. Write 8h to the TESTMODE register (TEST_PACKET = 1) to enter Test_Packet test mode.
4. Set the TxPktRdy bit in the HOST/PERI_CSR0 register (bit 1).

The 53 byte test packet to load is as follows (all bytes in hex). The test packet only has to be loaded once; the USB controller will keep re-sending the test packet without any further intervention from the software.

Table 25-1 displays the 53 Bytes test packet content.

Table 25-1. 53 Bytes Test Packet Content

0	0	0	0	0	0	0	0
0	AA	AA	AA	AA	AA	AA	AA
AA	EE	EE	EE	EE	EE	EE	EE
EE	FE	FF	FF	FF	FF	FF	FF
FF	FF	FF	FF	FF	7F	BF	DF
EF	F7	FB	FD	FC	7E	BF	DF
EF	F7	FB	FD	7E			

This data sequence is defined in Universal Serial Bus Specification Revision 2.0 The USB controller will add the DATA0 PID to the head of the data sequence and the CRC to the end.

25.5.1.8.5 FIFO_ACCESS

The FIFO Access test mode allows you to test the operation of CPU Interface, the DMA controller (if configured), and the RAM block by loading a packet of up to 64 bytes into the Endpoint 0 FIFO and then reading it back out again. Endpoint 0 is used because it is a bidirectional endpoint that uses the same area of RAM for its Tx and Rx FIFOs.

NOTE: The core does not need to be connected to the USB bus to run this test. If it is connected, then no session should be in progress when the test is run.

The test procedure is as follows:

1. Load a packet of up to 64 bytes into the Endpoint 0 Tx FIFO.
2. Set HOST/PERI_CSR0[TXPKTRDY].
3. Write 40h to the TESTMODE register (FIFO_ACCESS = 1).
4. Unload the packet from the Endpoint Rx FIFO, again.
5. Set HOST/PERI_CSR0[SERVICEDRXPTRDY].

Writing 40h to the TESTMODE register causes the following sequence of events:

The Endpoint 0 CPU pointer (that records the number of bytes to be transmitted) is copied to the Endpoint 0 USB pointer (that records the number of bytes received).

1. The Endpoint 0 CPU pointer is reset.
2. HOST/PERI_CSR0[TXPKTRDY] is cleared.
3. HOST/PERI_CSR0[RXPTRDY] is set.
4. An Endpoint 0 interrupt is generated (if enabled).

The effect of these steps is to make the Endpoint 0 controller act as if the packet loaded into the Tx FIFO has flushed and the same packet received over the USB. The data that was loaded in the Tx FIFO can now be read out of the Rx FIFO.

25.5.1.8.6 FORCE_HOST

The Force Host test mode enables you to instruct the core to operate in Host mode, regardless of whether it is actually connected to any peripheral; that is, the state of the CID input and the LINESTATE and HOSTDISCON signals are ignored. (While in this mode, the state of the HOSTDISCON signal can be read from the BDEVICE bit in the device control register (DEVCTL)) .

This mode, which is selected by writing 80h to the TESTMODE register (FORCE_HOST = 1), allows implementation of the USB Test_Force_Enable (USB 2.0 Specification Section 7.1.20). It can also be used for debugging PHY problems in hardware.

While the FORCE_HOST bit remains set, the core enters the Host mode when the SESSION bit in DEVCTL is set to 1 and remains in the Host mode until the SESSION bit is cleared to 0 even if a connected device is disconnected during the session. The operating speed while in this mode is determined by the FORCE_HS and FORCE_FS bits in the TESTMODE register.

25.5.2 Clock Control

Two main clocks are used by the USB subsystem, the L3 clock and the UTMI/PHY clock.

The L3 Slow clock is the clock that is used to clock the controller and all other blocks of the USB Subsystem with the exception of the PHY. This clock is controlled by the PRCM. A clock rate of 60 MHz or greater must be used to guarantee core operation can deliver full USB 2.0 bandwidth (480 Mb/s). In other words, L3 Slow should not be less than 60 MHz.

The PHY clock is derived from the main device input clock. The DPLL is used to generate the required 960MHz clock frequency. The required UTMI clock is generated by the PHY from the input clock.

25.5.3 Signal Descriptions

The USB subsystem external interface signals are displayed within [Table 25-2](#).

Table 25-2. USBSS Interface Signals

Pin (x=0/1)	Type	Description
USBx_DP USBx_DM	I/O	USBx data differential pair
USBx_DRVVBUS	O	USBx VBUS Supply Enable
USBx_VBUSIN	AI	USBx VBUS Voltage Sense
USB_ID	AI	USB ID Detection
USBx_CE ⁽¹⁾	I	USBx Charge Enable

⁽¹⁾ "USBx_CE is not available on all instances of USB (for example, a pin may exist on USB0, but not USB1). Refer to the device Data Manual Terminal Functions section for details.

25.5.4 VBUS Voltage Sourcing Control

When any of the USB controllers assumes the role of a host, the USB is required to supply a +5V power source to an attached device(s) through the VBUS line. In order to achieve this task, the USB controller requires the use of an external power logic (or charge pump) capable of sourcing 5V power. The USB_DRVVBUS pin is used as a control signal to enable/disable this external power supply. The control on the USB_DRVVBUS is automatic and is handled by the USB controller. The control should be transparent to the user so long as the proper hardware connection and software initialization are in place. The USB controller drives the USB_DRVVBUS signal high when it assumes the role of a host during a valid USB session. When assuming the role of a device, the controller drives the USB_DRVVBUS signal low disabling the external charge pump; hence, no power is driven on the VBUS line by the controller. 5V VBUS is expected to be sourced by the external USB Host.

Note that when both USB Modules are self-powered and the device does not rely on the voltage on the VBUS voltage sourced by an external USB Host for controller operation when operating as a USB Device. The Voltage Level detected on the +5V VBUS is used to identify the presence of a Host and to power up the internal pull-up on the D+ line. The USB PHY continually monitors the voltage on the USB_VBUSIN and reports the status to USB controller.

25.5.5 D+/D- Pull-up/Pull-Down Resistors

Since the USB controllers are dual role controllers, the necessary required D+/D- pull-up/pull-down resistors need to be dynamically attached/detached and thus can not exist external to the device. The pull-up/pull-down resistors exist in the PHY, and are dynamically enabled and disabled based on the role the controller assumes during a USB Session.

When assuming the role of a USB Host, the data lines are pulled to USB ground by the PHY enabling internal 15K Ohms pull-down resistors. When assuming the role of a USB Device the required 1.5K ohm pull-up resistor on the D+ line is enabled automatically signifying its capability to the external USB Host as a Full Speed or High Speed Capable device. If a High Speed capable device successfully negotiates to operate at the High Speed signal rate, the internal D+ is automatically disabled by the controller.

25.5.6 Interrupts

The USB Subsystem has three interrupts that can be routed to the CPU interrupt controller.

- USB Subsystem Interrupt
- USB0 Module Interrupt
- USB1 Module Interrupt

25.5.6.1 USB Subsystem Interrupt

The following DMA interrupts are generated by the USB Subsystem DMA.

The USB Subsystem is capable of generating a single interrupt for DMA events. [Table 25-3](#) describes the DMA interrupts generated from the USB Subsystem.

Table 25-3. Subsystem Interrupts

Interrupt	CPPI DMA Packet Completion Grouping (EndPoint)	Description
rx_sop_starvation	n/a	DMA Queue Manager Start of Packet Starvation Error Interrupt
rx_mop_starvation	n/a	DMA Queue Manager Middle of Packet Starvation Error Interrupt
pd_cmp_flag	n/a	When the DMA packet is completed and the Packet Descriptor is pushed into the Queue Manager
tx_pkt_cmp_0	1, 2, ..., 15	USB0 Tx Combined DMA Packet Group completion Interrupt
rx_pkt_cmp_0	1, 2, ..., 15	USB0 Rx Combined DMA Packet Group completion Interrupt
tx_pkt_cmp_1	1, 2, ..., 15	USB1 Tx Combined DMA Packet Group completion Interrupt
rx_pkt_cmp_1	1, 2, ..., 15	USB1 Rx Combined DMA Packet Group completion Interrupt

The USBSS DMA Queue Manager outputs a total of 60 DMA packet completion interrupts. Each Packet Completion Interrupt consists of a logical combination of the data from the 15 individual Endpoint packet completion signals from the Queue Manager. If any one of the Endpoint Packet Completion signals is set then an interrupt will be generated by the USB Subsystem

The starvation interrupts occur when the DMA Queue Manager is unable to allocate a buffer for an Rx buffer. This can occur either at the start of a packet or in the middle of a series of packets.

The `pd_cmp_flag` is only set when bit 31 of the original buffer length word (word 6) of a Packet Descriptor is set and when the packet is either transmitted to the XDMA or received from the XDMA using this PD.

In order to control the frequency of the generated USB Subsystem interrupts to the CPU, interrupt pacing has been added to each of the 60 individual packet completions. Each packet completion has its own 8-bit unsigned threshold. Each threshold can range from 0 to 255 based on the `pd_cmp_flag`. If the count of the packet completion exceeds the threshold; then an interrupt will be generated. This assumes that the packet completion is enabled. The thresholds for the 60 packet completions are programmed in the USBSS `IRQ_DMA_THRESHOLD_(RX/TX)(0/1)_n` registers.

It is possible that the generation of interrupts has been reduced to an unacceptable delay due a lack of differed bits or thresholds set to too large of a number. A watch dog timer has been added which provides a secondary method of generating the interrupts. This system uses the USB start of frame pulse from the USB Controller, a counter, a threshold, and an enable. The frame sync pulse frequency is 1kHz in full-speed or low-speed mode, or 8kHz in high-speed mode.

Example 1: The DMA threshold is set to 10 and the frame threshold is set to 3 for a specific endpoint. Let's assume that the expected packet completion frequency is 5 completed packets per frame. In this example the first frame had 5 packets completed. The second frame had 5 packets completed. An interrupt is generated after the 2nd frame.

Example 2: The DMA threshold is set to 10 and the frame threshold is set to 3 for a specific endpoint. Let's assume that the expected packet completion frequency is 5 completed packets per frame. In this example the first frame had 5 packets completed. The second frame had only two packets completed and the third frame had 0 packets completed. There was some error or delay that caused the remaining packets to not complete. An interrupt is generated after the 3rd frame.

In both examples software will not be able to determine whether the interrupt was generated due to DMA threshold or frame threshold.

Each of the 60 Packet completions will have a frame counter, frame threshold, and frame enable. If the frame counter exceeds the frame threshold; then an interrupt will be generated. This assumes the frame enable counter has been enabled.

The registers for the 60 frame thresholds are stored in: `USBSS_IRQ_FRAME_THRESHOLD_ab_c`.
Where:

- (a) Tx or Rx
- (b) 0 or 1
- (c) 0, 1, 2, or 3

The 60 frame enables are stored in registers: `USBSS_IRQ_FRAME_ENABLE_0` and `USBSS_IRQ_FRAME_ENABLE_1`.

The individual frame count / packet completion count registers will be reset to zero when one of the below conditions occurs:

- Reset signal is active.
- Packet completion threshold has been exceeded.
- Packet completion count is equal to 255.
- Frame count threshold has been exceeded.
- Frame count is equal to 255.

When the low to high transition occurs for any of the four CPPI DMA Packet completions, a hardware signal is sent to the MODIRQ module. This will cause an interrupt (if enabled via software). When all packets have been removed from the queue, the pending signal is returned to a 0. Software may choose to use one of the unassigned queues if an interrupt is not wanted upon the completion of a packet.

The interrupts listed in [Table 25-3](#) can be enabled (or disabled) by setting (or clearing) the appropriate `IRQENABLE_SET` (or `IRQENABLE_CLR`) bits in the MMR registers.

To clear the interrupts it is required to write 1's to the `IRQSTAUS` registers. It is possible to manually set the interrupts by writing 1's to the `IRQSTATUS_RAW` registers.

25.5.6.2 USB Module Interrupts

Each of the USB modules generates an interrupt that can be routed to the CPU interrupt controller.

Each USB Module allows for the interrupt to be generated by one of two methods depending on the uint field of the Control Register of each USB Module

- USB Module Level Interrupts.
- USB Controller Level Interrupts.

25.5.6.2.1 USB Module Level Interrupts

There are 15 general-purpose Tx and Rx endpoints supported in addition to Endpoint 0. The Endpoint 0 Tx interrupt encapsulates both Transmit and Receive Operations.

The USB Controller will generate a corresponding EPO or TXEPn (n=1...15) interrupt when that TX endpoint successfully completes transmitting a packet onto the bus and the endpoint buffer is empty and ready to send another packet, or when the TX endpoint had an error condition. The core will generate a corresponding RXEPn (n=1...15) interrupt when that RX endpoint successfully receives a packet and all the data is ready in the RX endpoint FIFO, or when a receive error occurs.

If the USB Controller is configured to use the DMA to handle Endpoint transactions, the Tx/Rx endpoint interrupts will only generate an interrupt on error conditions, which allows software to keep the interrupt enabled for error monitoring.

Interrupts USB[0] to USB[7] are generated by the USB controller in response to certain bus conditions. Refer to the USB Controller registers for more details on these which bus conditions trigger an interrupt. Interrupt USB[8] is generated outside the USB Controller whenever the level of DRVVBUS changes. This is usually due to entering or leaving host mode, or entering or leaving power saving mode.

In addition to the 31 Tx/Rx Controller Endpoint Interrupts, the USB Module generates 16 Tx FIFO Endpoint interrupts for each endpoint. These interrupts indicate when the TXn Endpoint FIFO is ready to accept new data.

It is important to clear the USB controller interrupts by reading the respective USB controller INTRUSB Register before clearing the IRQ_ENABLE_CLR Register and setting the IRQ_EOI Register.

Table 25-4. Controller Interrupts

Interrupt	Description
TX_ENDP[15:0]	Interrupts for Transmit Endpoints 15 to 0 (TX_ENDP[0] is used for both Transmit and Receive)
RX_ENDP[15:1]	Interrupts for Receive Endpoints 15 to 1
USB[8] DRVVBUS level change	Interrupt from the USB Module when VBUSBUS logic level changes
USB[7:0]	Interrupts detected by the USB Controller for Certain Bus Conditions
TX_FIFO[15:0]	TX FIFO endpoint ready for Endpoints 15 to 0

The interrupts listed in [Table 25-4](#) can be enabled (or disabled) by setting (or clearing) the appropriate IRQENABLE_SET (or IRQENABLE_CLR) bits in the MMR registers.

The interrupt registers for all the interrupts in Table 132 are listed in both the USB0 and USB1 module memory maps. The interrupt registers for TX_ENDP[15:0], RX_ENDP[15:1], and USB[7:0] are listed in the USB Controller memory map.

25.5.6.2.2 USB Controller Level Interrupts

If the USB Controller Level interrupt mode is selected for the USB interrupts, then the USB Module interrupt sources are not valid. In this case, the USB controller interrupts will be aggregated into the module interrupt for the CPU to service. All interactions to clear and mask interrupts must be done with the USB Controller registers.

The additional USB interrupt for DRVVBUS level changes is not part of the USB controller interrupt set, and therefore is not available when using the USB Controller interrupt mode.

25.5.7 Subsystem Reset Considerations

The USB Subsystem controller can be reset by two sources: hardware reset and the soft reset.

25.5.7.1 Software Reset Considerations

When the soft reset bit in the USBSS SYSCONFIG register is set, all the USB controller registers and DMA operations are reset. The bit is cleared automatically.

A software reset on the CPU does not affect the register values and operation of the USB controller.

25.5.7.2 Hardware Reset Considerations

When a hardware reset is asserted, all the registers are set to their default values.

25.5.8 Clock, PLL, and PHY Initialization

Prior to configuring the USB Module Registers, the device USB SubSystem and PHY are required to be released from reset, provided with clocks as well as configured with appropriate settings. Not all registers related for this task are captured within this document. Please refer to the Power, Reset and Clock Manager (PRCM) for clocking and Control Module for PHY configuration registers definitions.

Note: The following initialization makes use of the software option where USB role is controlled by firmware programming USBx Mode Register.

Clock Related Configuration:

```
*0x48180B10 &= 0xFFFFF9F; // RM_DEFAULT_RSTCTRL (Release USB Module from Reset)
while ((0x48180B14 & 0x00000060)>>5)!=0x3); // Wait until Module comes out of Reset
*0x48180B14 |= 0x00000060; // RM_DEFAULT_RSTST (Clear Reset Presence)
*0x48181400 = 0x2; // CM_ALWON_L3_SLOW_CLKSTCTRL (Enable Interconnect Clock)
*0x48180558 = 0x2; // CM_DEFAULT_USB_CLKCTRL (Enable USB OCP Clock)
while(((0x48180558) & 0x70000)>>16)==0x7); // Wait until USB Module is Ready
```

USB PLL Related:

```
PLL_SUBSYS_BASE = 0x481C5000;
USB_PLL_BASE = PLL_SUBSYS_BASE + 0x260;
/*Output clock frequency from PLL (according to above function call) = ((OSC
frequency/(N+1))*M)/M2 = ((20MHz/(19+1))*960)/1 = 960MHz*/

*(0x481C5270) = 0x00010013; // USBPLL_M2NDIV
*(0x481C5274) = 0x000003C0; // USBPLL_MN2DIV

/* Load M2, N2 dividers of ADPLL */
*(0x481C526C) = 0x00000001; // USBPLL_TENABLEDIV
// Toggle to Complete Load
*(0x481C526C) = 0x00000000; // USBPLL_TENABLEDIV

/* Load M, N dividers of ADPLL */
*(0x481C5268) = 0x00000001; // USBPLL_TENABLE
// Toggle to Complete Load
*(0x481C5268) = 0x00000000; // USBPLL_TENABLE

*(0x481C5264) = ((*0x481C5264) & 0xff7fe3ff) | 0x200a080a); // USBPLL_CLKCTRL
/* Wait for phase and freq lock */
while (((0x481C5284) & 0x00000600) != 0x00000600); // USBPLL_STATUS
```

USB PHY Related

```
// Clear bits 0,1,8,9,15,16,23
*(48140620) &= ~(0x00818303); // USB_CTRL0
// Set bits 6,7,10,13,14,17,18,19,20
*(48140620) |= 0x001E64C0; // USB_CTRL0
```

Firmware is now ready to continue programming the USB Controllers.

25.6 Error Handling

When operating as an active USB Device, a control transfer may be aborted due to a protocol error on the USB, the USB Host prematurely ending the transfer, or if the USB Device software wishes to abort the transfer (for example, because it cannot process the request).

25.6.1 Error Handling as a USB Device

The USB controller automatically detects protocol errors and sends a STALL packet to the host under the following conditions:

- The USB Host sends more data during a write request than was specified in the 8 Byte Standard Request.
- The USB Host requests more data during a read request than was specified in the 8 Byte Standard Request.
- The USB Host sends more data bytes than the Maximum Packet size.
- The USB Host sends a non zero length DATA1 packet during the Status stage of a Control Transfer.

After the USB controller has sent the STALL packet to the USB Host, it automatically sets the SENTSTALL bit and generates an interrupt. When the software receives an Endpoint 0 interrupt with the SENTSTALL bit set, it should abort the current transfer, clear the SENTSTALL bit, and return to the IDLE state to await the next USB transfer from the Host.

If the host prematurely ends a transfer by entering the STATUS phase before all the data for the request has been transferred, or by sending a new SETUP packet before completing the current transfer, then the SETUPEND bit will be set and an Endpoint 0 interrupt generated. When the software receives an endpoint 0 interrupt with the SETUPEND bit set, it should abort the current transfer, set the SERV_SETUPEND bit, and return to the IDLE state. If the RXPKTRDY bit is set this indicates that the host has sent another SETUP packet and the software should then process this command.

A zero length OUT data packet is used to indicate the end of a Control transfer. In normal operation, such packets should only be received after the entire length of the device request has been transferred (i.e., after the software has set DataEnd). If, however, the host sends a zero length OUT data packet before the entire length of device request has been transferred, this signals the premature end of the transfer. In this case, the controller will automatically flush any IN token loaded by software ready for the Data phase from the FIFO and set SETUPEND bit (bit 4 of PERI_CSR0).

If the software wants to abort the current transfer, because it cannot process the command or has some other internal error, then it should set the SENDSTALL bit. The controller will then send a STALL packet to the host, set the SENTSTALL bit and generate an endpoint 0 interrupt.

25.6.2 Babble Event Detection as a USB Host

The USB2 standard defines a Babble as unexpected bus activity that persists beyond a specified point in a (micro)frame. The USB Controller, when operating as a USB Host, is able to detect a babble event. When a babble event is detected, the following steps are taken:

- Generate a babble interrupt (if enabled).
- De-assert the DRVVBUS signal which signals the VBUS charge pump to discontinue supplying 5V to VBUS.
- Go to the IDLE state, which indicates that no USB session is in progress.

Software should restart the USB controller when a babble event/interrupt is detected.

25.7 Protocol Description(s)

This section describes the functionally implementation of the USB protocol by the USB modules.

25.7.1 USB Device Operation

This section describes how the USB Controller should be as when operating as a USB Device

25.7.1.1 Control Transfers

Endpoint 0 is the main control endpoint of a USB Device. Software is required to handle all the standard USB Device Requests that may be sent or received via Endpoint 0. These are described in Universal Serial Bus Specification, Revision 2.0, Chapter 9. The protocol for these device requests involves a different number of sequences of transactions per USB Request. To accommodate this, the software needs to take a state machine approach to correctly decode and handle all Control Transactions on Endpoint 0.

The Standard USB Device Requests received by a USB Device can be divided into three categories: Zero Data Requests (in which all the information is included in the 8 byte request, Write Requests (in which the request will be followed by additional data, and Read Requests (in which the device is required to send data back to the USB Host).

This section looks at the sequence of actions that the software must perform to process these different types of device request.

25.7.1.1.1 Zero Data Requests

Zero data requests have all their information contained within the 8-byte request and require no additional data to be transferred. Examples of Zero Data standard device requests are:

- SET_FEATURE
- CLEAR_FEATURE
- SET_ADDRESS
- SET_CONFIGURATION
- SET_INTERFACE

The sequence of events will begin, as with all requests, when the software receives an Endpoint 0 interrupt. The RXPKTRDY bit of the Endpoint 0 Peripheral Control / Status Register (PERI_CSR0) will be automatically set by the controller. The 8-byte request should then be read from the Endpoint 0 FIFO, decoded and the appropriately handled. After the request is handled, the CPU should set the SERV_RXPKTRDY bit of PERI_CSR0 to indicate to the controller that the command has been read from the FIFO, and also set the DATAEND bit to indicate to the controller that no further data is expected for this request. The interval between setting SERV_RXPKTRDY bit and DATAEND bit should be very small to avoid getting a SETUPEND error condition. It is highly recommended to set both bits at the same time.

The USB Host will then transition to the status stage of the control transfer, a second Endpoint 0 interrupt will be generated to indicate that the request has successfully completed. No further action is required from the software. The second interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the CPU should write to the PERI_CSR0 register to set the SERV_RXPKTRDY bit and to set the SENDSTALL bit. When the USB Host moves to the status stage of the request, the controller will send a STALL packet telling the host that the request was not executed. A second Endpoint 0 interrupt will be generated and the SENTSTALL bit will be automatically set by the controller.

If the host sends more data after the DATAEND bit has been set, then the controller will send a STALL packet automatically. An Endpoint 0 interrupt will be generated and the SENTSTALL bit will be set.

NOTE: The DMA cannot service Endpoint 0 transactions; Endpoint 0 must always be serviced via a CPU.

25.7.1.1.2 Write Requests

Write requests involve an additional packet(s) of data being sent from the USB Host after the 8-byte USB request has been received. An example of a Write request is: SET_DESCRIPTOR.

The sequence of events will begin, as with the Zero Data Request, when the software receives an Endpoint 0 interrupt. The RXPKTRDY bit of the Endpoint 0 Peripheral Control / Status Register (PERI_CSR0) will have been automatically set by the controller. The 8-byte request should then be read from the Endpoint 0 FIFO, decoded and the appropriately handled. After the request is handled, the CPU should set the SERV_RXPKTRDY bit of PERI_CSR0 to indicate to the controller that the command has been read from the FIFO, however for write requests, the DATAEND bit should *not* be set by the user indicating that more data is expected from the USB Host.

When a second endpoint 0 interrupt is received, the PERI_CSR0 register should be read to check the endpoint status. The RXPKTRDY bit of PERI_CSR0 should be set to indicate that a data packet has been received. The COUNT0 register should then be read to determine the size of this data packet. The data packet can then be read from the endpoint 0 FIFO and stored into memory

If the length of the data associated with the request (indicated by the wLength field in the command) is greater than the maximum packet size for endpoint 0, further data packets are expected be sent. Again, PERI_CSR0 should be written to set the SERV_RXPKTRDY bit, but the DATAEND bit should not be set. When all the expected data packets have been received, the PERI_CSR0 register should be written to set the SERV_RXPKTRDY bit and to set the DATAEND bit .

The USB Host will then transition to the status stage of the control transfer, a second Endpoint 0 interrupt will be generated to indicate that the request has successfully completed. No further action is required from the software. The second interrupt is just a confirmation that the request completed successfully.

If the host sends more data after the DATAEND has been set, then the controller will automatically send a STALL. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI_CSR0 will be set.

25.7.1.1.3 Read Requests

Read requests have a packet (or packets) of data sent from the function to the host after the 8-byte command. Examples of Read Standard Device Requests are:

- GET_CONFIGURATION
- GET_INTERFACE
- GET_DESCRIPTOR
- GET_STATUS
- SYNCH_FRAME

The sequence of events will begin, as with the Zero Data Request, when the software receives an Endpoint 0 interrupt. The RXPKTRDY bit of the Endpoint 0 Peripheral Control / Status Register (PERI_CSR0) will have been automatically set by the controller. The 8-byte request should then be read from the Endpoint 0 FIFO, decoded and the appropriately handled. After the request is handled, the CPU should set the SERV_RXPKTRDY bit of PERI_CSR0 to indicate to the controller that the command has been read from the FIFO, however for read requests, the DATAEND bit should *not* be set by the user indicating that data is expected by the USB Host.

The data to be sent to the host should then be written to the endpoint 0 FIFO. If the data to be sent is greater than the maximum packet size for endpoint 0, only the maximum packet size should be written to the FIFO. The PERI_CSR0 register should then be written to set the TXPKTRDY bit to indicate to the controller that there is a packet in the FIFO to be sent. When the packet has been sent to the host, another endpoint 0 interrupt will be generated and the next data packet can be written to the FIFO.

When the last data packet has been written to the FIFO, the PERI_CSR0 register should be written to set the TXPKTRDY bit and to set the DATAEND bit indicating to the controller that no additional packets are to be send to the USB Host.

When the host moves to the status stage of the request, another endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software: the interrupt is just a confirmation that the request completed successfully.

If the host requests more data after DATAEND (bit 3) has been set, then the controller will send a STALL. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI_CSR0 will be set.

25.7.1.1.4 Endpoint 0 Interrupt Servicing

When the USB controller is operating as a peripheral device, the Endpoint 0 control needs three modes – IDLE, TX and RX – corresponding to the different phases of the control transfer and the states endpoint 0 enters for the different phases of the transfer (described in later sections).

The default mode on power-up or reset should be IDLE. RXPkTRDY bit of PERI_CSR0 becoming set when endpoint 0 is in IDLE state indicates a new device request. Once the device request is unloaded from the FIFO, the controller decodes the descriptor to find whether there is a data phase and, if so, the direction of the data phase of the control transfer (in order to set the FIFO direction). See Figure 25-2.

Depending on the direction of the data phase, endpoint 0 goes into either TX state or RX state. If there is no Data phase, endpoint 0 remains in IDLE state to accept the next device request

The actions that the CPU needs to take at the different phases of the possible transfers (for example, loading the FIFO, setting TXPKTRDY) are indicated in Figure 25-3.

Figure 25-2. CPU Actions at Transfer Phases

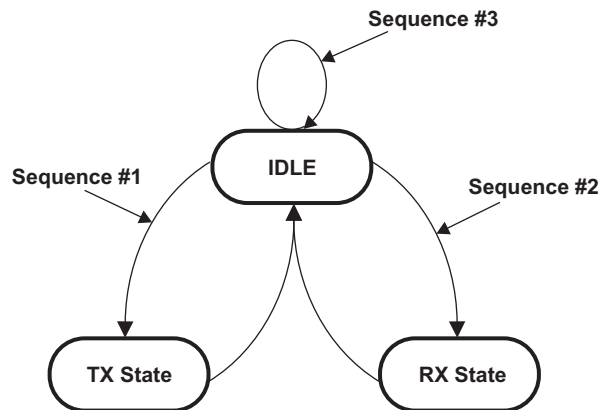

Figure 25-3. TX State

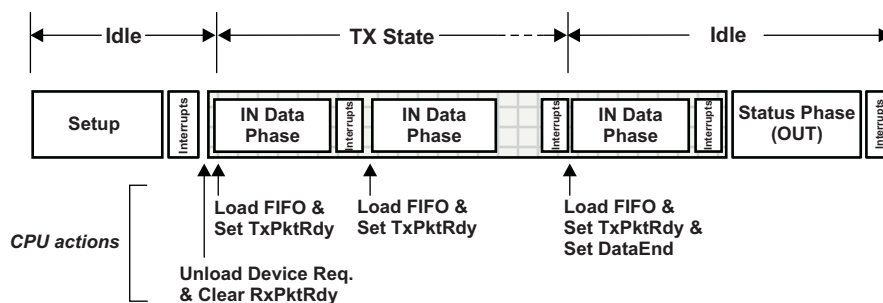

Figure 25-4. RX State

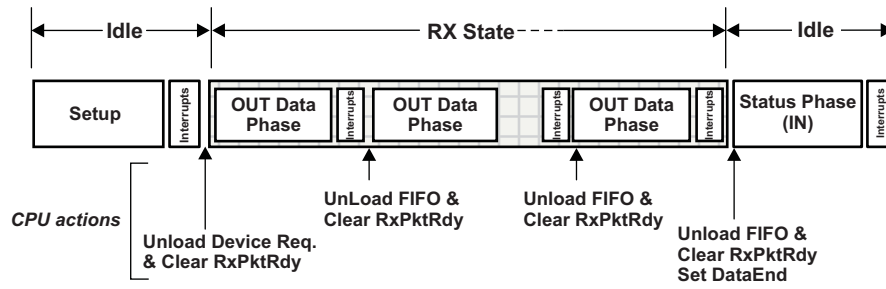

Figure 25-5. No Data Phase

25.7.1.1.4.1 Endpoint 0 Interrupt Generating Events

An Endpoint 0 interrupt is generated when any of the below events occur and Interrupt Service handler should determine the right event and launch the proper handler

The following events will cause Endpoint 0 Interrupt to be generated while the controller is operating assuming the role of a USB Device

- The controller sets the RXPKTRDY bit after a valid token has been received and data has been written to the FIFO (legal status condition).
- The controller clears the TXPKTRDY bit after the packet of data in the FIFO has been successfully transmitted to the USB host (legal status condition).
- The controller sets the SENTSTALL bit after a control transaction is ended due to a protocol violation (illegal status condition).
- The controller sets the SETUPEND bit because a control transfer has ended before DATAEND (bit 3 of PERI_CSR0) is set (illegal status condition).

In order to determine the cause of the interrupt, the detail below recommends the order of cause determination and execution.

Whenever the endpoint 0 service routine is entered, the software must first check to see if the current control transfer has been ended due to either a STALL condition or a premature end of control transfer. If the control transfer ends due to a STALL condition, the SENTSTALL bit would be set. If the control transfer ends due to a premature end of control transfer, the SETUPEND bit would be set. In either case, the software should abort processing the current control transfer and set the state to IDLE.

Once the software has determined that the interrupt was not generated by an illegal bus state, the next action taken depends on the endpoint state.

If endpoint 0 is in IDLE state, the only valid reason an interrupt can be generated is as a result of the controller receiving data from the bus. The service routine must check for this by testing the RXPKTRDY bit of PERI_CSR0 (bit 0). If this bit is set, then the controller has received a SETUP packet. This must be unloaded from the FIFO and decoded to determine the action the controller must take. Depending on the command contained within the SETUP packet, endpoint 0 will enter one of three states:

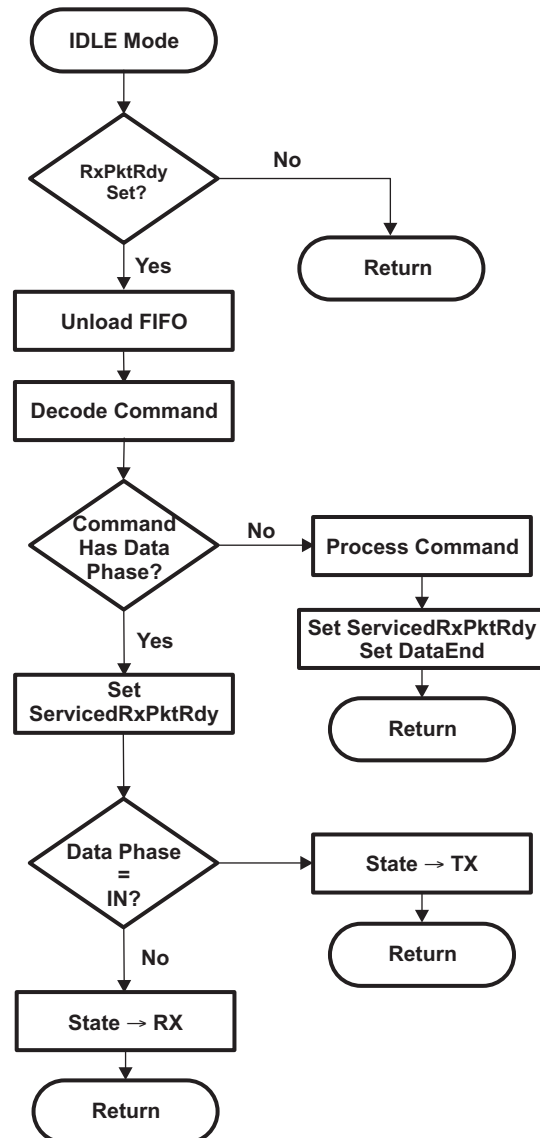

- If the command is a single packet transaction (SET_ADDRESS, SET_INTERFACE etc.) without any data phase, the endpoint will remain in IDLE state.
- If the command has an OUT data phase (SET_DESCRIPTOR etc.), the endpoint will enter RX state.
- If the command has an IN data phase (GET_DESCRIPTOR etc.), the endpoint will enter TX state.
- If the endpoint 0 is in TX state, the interrupt indicates that the core has received an IN token and data from the FIFO has been sent. The software must respond to this either by placing more data in the FIFO if the host is still expecting more data or by setting the DATAEND bit to indicate that the data phase is complete. Once the data phase of the transaction has been completed, endpoint 0 should be returned to IDLE state to await the next control transaction (status stage).
- If the endpoint is in RX state, the interrupt indicates that a data packet has been received. The software must respond by unloading the received data from the FIFO. The software must then determine whether it has received all of the expected data. If it has, the software should set the DATAEND bit and return endpoint 0 to IDLE state. If more data is expected, the firmware should set the SERV_RXPKTRDY bit of PERI_CSR0 (bit 6) to indicate that it has read the data in the FIFO and leave the endpoint in RX state.

25.7.1.1.4.2 Endpoint 0 Idle State

Idle Mode needs to be selected by the Endpoint 0 control after power-on or reset and is the mode in which the Endpoint 0 control should return when the Rx and Tx modes are terminated.

It is also the mode in which the SETUP phase of control transfer is handled (as outlined in [Figure 25-6](#)).

Figure 25-6. Flow Chart of Setup Stage of a Control Transfer in Peripheral Mode

25.7.1.1.4.3 Endpoint 0 TX State

When the endpoint is in TX state, all arriving IN tokens need to be treated as part of a data phase until the required amount of data has been sent to the host. If either a SETUP or an OUT token is received while the endpoint is in the TX state, this will cause a SETUPEND condition to occur as the core expects only IN tokens.

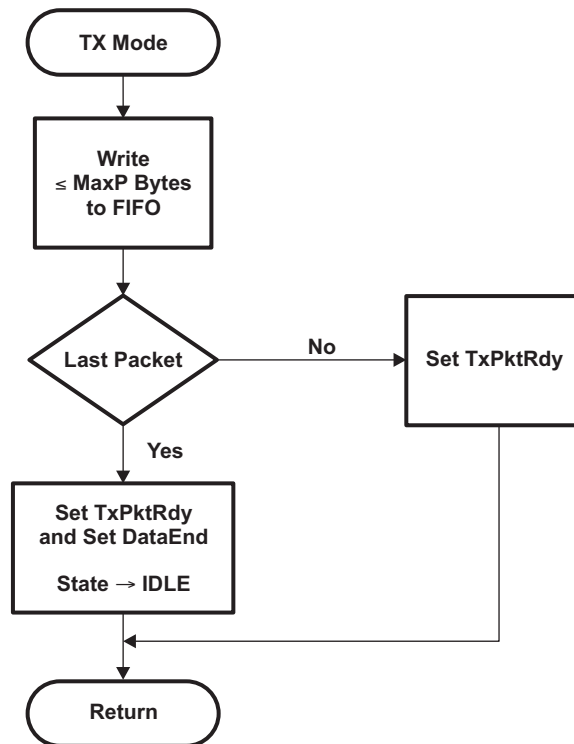

Three events can cause TX mode to be terminated before the expected amount of data has been sent as shown in Figure 25-7:

1. The host sends an invalid token causing a SETUPEND condition (bit 4 of PERI_CSR0 is set).
2. The firmware sends a packet containing less than the maximum packet size for Endpoint 0.
3. The firmware sends an empty data packet.

Until the transaction is terminated, the firmware simply needs to load the FIFO when it receives an interrupt which indicates that a packet has been sent from the FIFO. An interrupt is generated when TXPKTRDY is cleared.

When the firmware forces the termination of a transfer (by sending a short or empty data packet), it should set the DATAEND bit of PERI_CSR0 (bit 3) to indicate to the core that the data phase is complete and that the core should next receive an acknowledge packet.

Figure 25-7. Flow Chart of Transmit Data Stage of a Control Transfer in Peripheral Mode

25.7.1.1.4.4 Endpoint 0 Rx State

In RX mode, all arriving data should be treated as part of a data phase until the expected amount of data has been received. If either a SETUP or an IN token is received while the endpoint is in RX state, a SETUPEND condition will occur as the controller expects only OUT tokens.

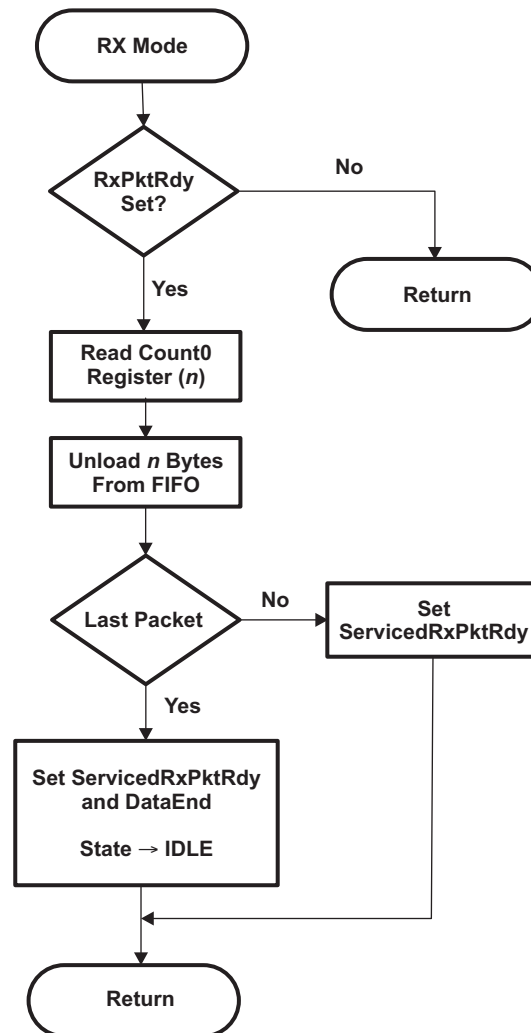

Three events can cause RX mode to be terminated before the expected amount of data has been received as shown in [Figure 25-8](#):

1. The host sends an invalid token causing a SETUPEND condition (setting bit 4 of PERI_CSR0).
2. The host sends a packet which contains less than the maximum packet size for endpoint 0.
3. The host sends an empty data packet.

Until the transaction is terminated, the software unloads the FIFO when it receives an interrupt that indicates new data has arrived (setting RXPkTRDY bit of PERI_CSR0) and to clear RXPkTRDY by setting the SERV_RXPKTRDY bit of PERI_CSR0 (bit 6).

When the software detects the termination of a transfer (by receiving either the expected amount of data or an empty data packet), it should set the DATAEND bit (bit 3 of PERI_CSR0) to indicate to the controller that the data phase is complete and that the core should receive an acknowledge packet next.

Figure 25-8. Flow Chart of Receive Data Stage of a Control Transfer in Peripheral Mode

25.7.1.2 Bulk Transfers

Bulk transactions are handled by Endpoints other than Endpoint 0. Bulk Transfers are used to handle non-periodic, large bursty communication typically used for a transfer that use any available bandwidth and can also be delayed until bandwidth is available.

The following optional features are available for use with a Tx endpoint used in peripheral mode for Bulk IN transactions:

- Double packet buffering: When enabled, up to two sequential packets can be stored in the Endpoint FIFO awaiting transmission to the host. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register
- DMA: If DMA is enabled for the Bulk Endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature allows the DMA controller to load packets into the FIFO without processor intervention

25.7.1.2.1 Bulk Transfer Setup

In configuring an Endpoint for Bulk Transfers, the firmware must properly configure the USB Controller Registers for proper operation. The Max Packet Size Register (RX/TXMAXP) register must be written with the maximum packet size (in bytes) for the Endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the Endpoint. Additionally the Control / Status Register for the respective Endpoint(s) must be appropriately configured.

For IN Transactions, Endpoint Control Status Register for Transmit Endpoint (PERI_TXCSR) should be configured for desired operation. If the DMA is to be used to service the endpoint, DMAEN and DMAMODE bit fields should be set, else left cleared [Table 25-5](#) displays the PERI_TXCSR setting when used for Bulk transfer.

When the endpoint is first configured (following a SET_CONFIGURATION or SET_INTERFACE command on Endpoint 0), the lower byte of PERI_TXCSR should be written to set the CLRDATATOG bit (bit 6). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state.

Also if there are any data packets in the FIFO, indicated by the FIFONOTEMPTY bit being set, they should be flushed by setting the FLUSHFIFO bit

NOTE: It may be necessary to set this bit twice in succession if double buffering is enabled.

Table 25-5. PERI_TXCSR Register Bit Configuration for Bulk IN Transactions

Bit Field	Bit Name	Description
Bit 15	AUTOSSET	Cleared to 0 if using DMA. For CPU Mode set to 1. if AUTOSSET bit is set, the TXPKTRDY bit will be automatically set when data of the maximum packet size is loaded into the FIFO, else set manually.
Bit 14	ISO	Cleared to 0 for Bulk Transfers.
Bit 13	MODE	Set to 1 to make sure the FIFO is enabled (only necessary if the FIFO is shared with an RX endpoint)
Bit 12	DMAEN	Set to 1 to enable DMA usage. Cleared to 0 if a CPU is being used to service the Tx Endpoint
Bit 11	FRCDATATOG	Cleared to 0 to allow normal data toggle operations.
Bit 10	DMAMODE	Set to 1 when DMA is used to service Tx FIFO.
Bit 9	Reserved	Reserved
Bit 8	Reserved	Reserved
Bit 7	Reserved	Reserved
Bit 6	ClrDataTog	This bit should be cleared to 0 by the CPU prior to Bulk Endpoint Operation
Bit 5	SentStall	This bit should be cleared to 0 by the CPU prior to Bulk Endpoint Operation
Bit 4	SendStall	This bit should be cleared to 0 by the CPU prior to Bulk Endpoint Operation
Bit 3	FlushFIFO	This bit is set when the FIFO is non-Empty.

**Table 25-5. PERI_TXCSR Register Bit Configuration for Bulk IN Transactions
(continued)**

Bit Field	Bit Name	Description
Bit 2	UnderRun	This bit should be cleared to 0 by the CPU prior to Bulk Endpoint Operation
Bit 1	FIFONotEmpty	This bit should be cleared to 0 by the CPU prior to Bulk Endpoint Operation
Bit 0	TxPktRdy	This bit should be cleared to 0 by the CPU prior to Bulk Endpoint Operation

When using DMA for OUT Endpoints, the PERI_RXCSR needs to have its DMAEN bit set and have its AUTOCLEAR and DMAMODE bits cleared. In addition, the relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint) and the PERI_RXCSR register should be set as shown in [Table 25-6](#)

Also if there are any data packets in the FIFO (indicated by the RXPkTRDY bit (bit 0 of PERI_RXCSR) being set), they should be flushed by setting the FLUSHFIFO bit (bit 4 of PERI_RXCSR).

NOTE: It may be necessary to set this bit twice in succession if double buffering is enabled.

Table 25-6. PERI_RXCSR Register Bit Configuration for Bulk OUT Transactions

Bit Field	Bit Name	Description
Bit 15	AUTOCLEAR	Cleared to 0 if using DMA. In CPU Mode of usage, if the CPU sets AUTOCLEAR bit, the RXPkTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO.
Bit 14	ISO	Cleared to 0 to enable Bulk protocol.
Bit 13	DMAEN	Set to 1 if a DMA request is required for this Rx endpoint.
Bit 12	DISNYET	Cleared to 0 to allow normal PING flow control. This will affect only high speed transactions.
Bit 11	DMAMODE	Always clear this bit to 0.

When the Rx endpoint is first configured (following a SET_CONFIGURATION or SET_INTERFACE command on Endpoint 0), the lower byte of PERI_RXCSR should be written to set the CLRDATATOG bit (bit 7). This will ensure that the data toggle (which is handled automatically by the USB controller) starts in the correct state.

25.7.1.2.2 Bulk IN Transfers

When data is to be transferred over a Bulk IN pipe, a data packet needs to be loaded into the FIFO and the PERI_TXCSR register written to set the TXPKTRDY bit. The TxPktRDY bit will remain set until the packet has been sent to the USB Host and will be automatically cleared by the USB controller. An Endpoint(n) interrupt will also be generated to signify to the firmware that the next packet can be loaded into the FIFO. If double packet buffering is enabled, then after the first packet has been loaded and the TXPKTRDY bit set, the TXPKTRDY bit will immediately be cleared by the USB controller and an interrupt generated so that a second packet can be loaded into the FIFO. The software should always load a packet into the Endpoint FIFO when it receives an interrupt, regardless of whether double packet buffering is enabled or not.

In the general case, the packet size must not exceed the size specified by the lower 11 bits of the TXMAXP register. This part of the register defines the payload (packet size) for transfers over the USB and is required by the USB Specification to be either 8, 16, 32, 64 (Full-Speed or High-Speed) or 512 bytes (High-Speed only).

The host may determine that all the data for a transfer has been sent by knowing the total amount of data that is expected. Alternatively it may infer that all the data has been sent when it receives a packet which is smaller than the maximum packet size configuration for that particular endpoint (TXMAXP[10-0]). In the latter case, if the total size of the data block is a multiple of this payload, it will be necessary for the function to send a null packet after all the data has been sent. This is done by setting TXPKTRDY when the next interrupt is received, without loading any data into the FIFO.

25.7.1.2.3 Bulk OUT Transfers

When a data packet is received by a Bulk OUT pipe, the RXPkTRDY bit is set and an interrupt is generated. The software should read the RXCOUNT register for the endpoint to determine the size of the data packet. The data packet should be read from the FIFO, and then the RXPkTRDY bit should be cleared.

The packets received should not exceed the size specified in the RXMAXP register (as this should be the value set in the wMaxPacketSize field of the endpoint descriptor sent to the host). When a block of data larger than wMaxPacketSize needs to be sent to the function, it will be sent as multiple packets. All the packets will be wMaxPacketSize in size, except the last packet which will contain the residue. The software may use an application specific method of determining the total size of the block and hence when the last packet has been received. Alternatively it may infer that the entire block has been received when it receives a packet which is less than wMaxPacketSize in size. (If the total size of the data block is a multiple of wMaxPacketSize, a null data packet will be sent after the data to signify that the transfer is complete.)

25.7.1.2.4 Error Handling of Bulk transfer

If the software wants to shut down the Bulk IN pipe, it should set the SENDSTALL bit (bit 4 of PERI_TXCSR). When the controller receives the next IN token, it will send a STALL to the host, set the SENTSTALL bit (bit 5 of PERI_TXCSR) and generate an interrupt.

When the software receives an interrupt with the SENTSTALL bit (bit 5 of PERI_TXCSR) set, it should clear the SENTSTALL bit. It should however leave the SENDSTALL bit set until it is ready to re-enable the Bulk IN pipe.

NOTE: If the host failed to receive the STALL packet for some reason, it will send another IN token, so it is advisable to leave the SENDSTALL bit set until the software is ready to re-enable the Bulk IN pipe. When a pipe is re-enabled, the data toggle sequence should be restarted by setting the CLRDATATOG bit in the PERI_TXCSR register (bit 6).

If the software wants to shut down the Bulk OUT pipe, it should set the SENDSTALL bit (bit 5 of PERI_RXCSR). When the controller receives the next packet it will send a STALL to the host, set the SENTSTALL bit (bit 6 of PERI_RXCSR) and generate an interrupt.

When the software receives an interrupt with the SENTSTALL bit (bit 6 of PERI_RXCSR) set, it should clear this bit. It should however leave the SENDSTALL bit set until it is ready to re-enable the Bulk OUT pipe.

NOTE: If the host failed to receive the STALL packet for some reason, it will send another packet, so it is advisable to leave the SENDSTALL bit set until the software is ready to re-enable the Bulk OUT pipe. When a Bulk OUT pipe is re-enabled, the data toggle sequence should be restarted by setting the CLRDATATOG bit (bit 7) in the PERI_RXCSR register.

25.7.1.3 Interrupt Transfer

An Interrupt IN transaction uses the same protocol as a Bulk IN transaction and the configuration and operation mentioned on prior sections apply to Interrupt transfer too with minor changes. Similarly, an Interrupt OUT transaction uses almost the same protocol as a Bulk OUT transaction and can be used the same way.

Tx endpoints in the USB controller have one feature for Interrupt IN transactions that they do not support in Bulk IN transactions. In Interrupt IN transactions, the endpoints support continuous toggle of the data toggle bit.

This feature is enabled by setting the FRCDATATOG bit in the PERI_TXCSR register (bit 11). When this bit is set, the controller will consider the packet as having been successfully sent and toggle the data bit for the endpoint, regardless of whether an ACK was received from the host.

Another difference is that interrupt endpoints do not support PING flow control. This means that the controller should never respond with a NYET handshake, only ACK/NAK/STALL. To ensure this, the DISNYET bit in the PERI_RXCSR register (bit 12) should be set to disable the transmission of NYET handshakes in high-speed mode.

Though DMA can be used with an interrupt OUT endpoint, it generally offers little benefit as interrupt endpoints are usually expected to transfer all their data in a single packet.

25.7.1.4 Isochronous Transfer

Isochronous transfers are used when working with isochronous data. Isochronous transfers provide periodic, continuous communication between host and device.

25.7.1.4.1 Isochronous Transfer Setup

In configuring a Tx endpoint for Isochronous IN transactions, the TXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint unless it is a high bandwidth ISO. In this case, TXMAXP should be an integer multiple of 1024. In addition, the relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint) and the PERI_TXCSR register should be set as shown in [Table 25-7](#).

Table 25-7. PERI_TXCSR Register Bit Configuration for Isochronous IN Transactions

Bit Field	Bit Name	Description
Bit 14	ISO	Set to 1 to enable Isochronous transfer protocol.
Bit 13	MODE	Set to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
Bit 12	DMAEN	Set to 1 if DMA Requests have to be enabled.
Bit 11	FRCDATATOG	Ignored in Isochronous mode.
Bit 10	DMAMODE	Set to 1 when DMA is enabled.

In configuring an Rx endpoint for Isochronous OUT transactions, the RXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint unless it is a high bandwidth ISO. In this case, RXMAXP should be an integer multiple of 1024. In addition, the relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint) and the PERI_RXCSR register should be set as shown in [Table 25-8](#).

Table 25-8. PERI_RXCSR Register Bit Configuration for Isochronous OUT Transactions

Bit Field	Bit Name	Description
Bit 15	AUTOCLEAR	Cleared to 0 if using DMA. In CPU Mode of usage, if the CPU sets AUTOCLEAR bit, the RXPKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO.
Bit 14	ISO	Set to 1 to configure endpoint usage for Isochronous transfer.
Bit 13	DMAEN	Set to 1 if a DMA request is required for this Rx endpoint.
Bit 12	DISNYET	Ignored in Isochronous Mode.
Bit 11	DMAMODE	Always clear this bit to 0.

25.7.1.4.2 Isochronous IN Transfers

The following optional features are available for use with a Tx endpoint used in Peripheral mode for Isochronous IN transactions:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the host. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).

NOTE: Double packet buffering is generally advisable for isochronous transactions in order to avoid underrun errors as described in later section.

- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature allows the DMA controller to load packets into the FIFO without processor intervention.

However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the PERI_TXCSR register needs to be accessed following every packet to check for Underrun errors.

When DMA is enabled and DMAMODE bit of PERI_TXCSR is set, endpoint interrupt will not be generated for completion of packet transfer. Endpoint interrupt will be generated only in the error conditions.

An isochronous endpoint does not support data retries, so if data underrun is to be avoided, the data to be sent to the host must be loaded into the FIFO before the IN token is received. The host will send one IN token per frame (or microframe in High-speed mode), however the timing within the frame (or microframe) can vary. If an IN token is received near the end of one frame and then at the start of the next frame, there will be little time to reload the FIFO. For this reason, double buffering of the endpoint is usually necessary.

An interrupt is generated whenever a packet is sent to the host and the software may use this interrupt to load the next packet into the FIFO and set the TXPKTRDY bit in the PERI_TXCSR register (bit 0) in the same way as for a Bulk Tx endpoint. As the interrupt could occur almost any time within a frame(/microframe), depending on when the host has scheduled the transaction, this may result in irregular timing of FIFO load requests. If the data source for the endpoint is coming from some external hardware, it may be more convenient to wait until the end of each frame(/microframe) before loading the FIFO as this will minimize the requirement for additional buffering. This can be done by using either the SOF interrupt or the external SOF_PULSE signal from the controller to trigger the loading of the next data packet. The SOF_PULSE is generated once per frame(/microframe) when a SOF packet is received. (The controller also maintains an external frame(/microframe) counter so it can still generate a SOF_PULSE when the SOF packet has been lost.) The interrupts may still be used to set the TXPKTRDY bit in PERI_TXCSR (bit 0) and to check for data overruns/underruns.

Starting up a double-buffered Isochronous IN pipe can be a source of problems. Double buffering requires that a data packet is not transmitted until the frame(/microframe) after it is loaded. There is no problem if the function loads the first data packet at least a frame(/microframe) before the host sets up the pipe (and therefore starts sending IN tokens). But if the host has already started sending IN tokens by the time the first packet is loaded, the packet may be transmitted in the same frame(/microframe) as it is loaded, depending on whether it is loaded before, or after, the IN token is received. This potential problem can be avoided by setting the ISOUPDATE bit in the POWER register (bit 7). When this bit is set, any data packet loaded into an Isochronous Tx endpoint FIFO will not be transmitted until after the next SOF packet has been received, thereby ensuring that the data packet is not sent too early.

25.7.1.4.3 Isochronous OUT Transfers

An isochronous OUT transaction is used to transfer periodic data from the host to the function controller.

Following optional features are available for use with an Rx endpoint used in Peripheral mode for Isochronous OUT transactions:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO on reception from the host. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
NOTE: Double packet buffering is generally advisable for Isochronous transactions in order to avoid overrun errors.
- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.

However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the PERI_RXCSR register needs to be accessed following every packet to check for Overrun or CRC errors.

When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

An Isochronous endpoint does not support data retries so, if a data overrun is to be avoided, there must be space in the FIFO to accept a packet when it is received. The host will send one packet per frame (or microframe in High-speed mode); however, the time within the frame can vary. If a packet is received near the end of one frame(/microframe) and another arrives at the start of the next frame, there will be little time to unload the FIFO. For this reason, double buffering of the endpoint is usually necessary.

An interrupt is generated whenever a packet is received from the host and the software may use this interrupt to unload the packet from the FIFO and clear the RXPKTRDY bit in the PERI_RXCSR register (bit 0) in the same way as for a Bulk Rx endpoint. As the interrupt could occur almost any time within a frame(/microframe), depending on when the host has scheduled the transaction, the timing of FIFO unload requests will probably be irregular. If the data sink for the endpoint is going to some external hardware, it may be better to minimize the requirement for additional buffering by waiting until the end of each frame(/microframe) before unloading the FIFO. This can be done by using either the SOF interrupt or the external SOF_PULSE signal from the controller to trigger the unloading of the data packet. The SOF_PULSE is generated once per frame(/microframe) when a SOF packet is received. (The controller also maintains an external frame(/microframe) counter so it can still generate a SOF_PULSE when the SOF packet has been lost.) The interrupts may still be used to clear the RXPKTRDY bit in PERI_RXCSR and to check for data overruns/underruns.

25.7.1.4.4 Isochronous Transfer Error Handling

If the endpoint has no data in its FIFO when an IN token is received, it will send a null data packet to the host and set the UNDERRUN bit in the PERI_TXCSR register (bit 2). This is an indication that the software is not supplying data fast enough for the host. It is up to the application to determine how this error condition is handled.

If the software is loading one packet per frame(/microframe) and it finds that the TXPKTRDY bit in the PERI_TXCSR register (bit 0) is set when it wants to load the next packet, this indicates that a data packet has not been sent (perhaps because an IN token from the host was corrupted). It is up to the application how it handles this condition: it may choose to flush the unsent packet by setting the FLUSHFIFO bit in the PERI_TXCSR register (bit 3), or it may choose to skip the current packet.

If there is no space in the FIFO to store a packet when it is received from the host, the OVERRUN bit in the PERI_RXCSR register (bit 2) will be set. This is an indication that the software is not unloading data fast enough for the host. It is up to the application to determine how this error condition is handled.

If the controller finds that a received packet has a CRC error, it will still store the packet in the FIFO and set the RXPKTRDY bit (bit 0 of PERI_RXCSR) and the DATAERROR bit (bit 3 of PERI_RXCSR). It is left up to the application to determine how this error condition is handled.

The number of USB packets sent in any microframe will depend on the amount of data to be transferred, and is indicated through the PIDs used for the individual packets. If the indicated number of packets have not been received by the end of a microframe, the INCOMPRX bit (bit 8) bit in the PERI_RXCSR register will be set to indicate that the data in the FIFO is incomplete. Equally, if a packet of the wrong data type is received, then the PID Error bit in the PERI_RXCSR register will be set. In each case, an interrupt will, however, still be generated to allow the data that has been received to be read from the FIFO.

Note: The circumstances in which a PID Error or INCOMPRX is reported depends on the precise sequence of packets received.

When the core is operating in peripheral mode, the details are in [Table 25-9](#).

Table 25-9. Isochronous OUT Error Handling: Peripheral Mode

No. Packet(s) Expected	Data Packet(s) Received	Response
1	DATA0	OK
	DATA1	PID Error set
	DATA2	PID Error set
	MDATA	PID Error set
2	DATA0	OK
	DATA1	INCOMPRX Set
	DATA2	INCOMPRX Set + PID Error set
	MDATA	INCOMPRX Set
	MDATA DATA0	PID Error Set
	MDATA DATA1	OK
	MDATA DATA2	PID Error Set
	MDATA MDATA	PID Error Set
3	DATA0	OK
	DATA1	INCOMPRX Set
	DATA2	INCOMPRX Set
	MDATA	INCOMPRX Set
	MDATA DATA0	PID Error set
	MDATA DATA1	OK
	MDATA DATA2	INCOMPRX Set
	MDATA MDATA	INCOMPRX Set
	MDATA MDATA DATA0	PID Error set
	MDATA MDATA DATA1	PID Error set
	MDATA MDATA DATA2	OK
	MDATA MDATA MDATA	PID Error set

25.7.2 USB Host Operation

This section describes how the USB Controller should be as when operating as a USB Host

25.7.2.1 Control Transfers

Host control transactions are conducted through Endpoint 0. Firmware is required to handle all the Standard USB Device Requests that may be sent or received via Endpoint 0. Endpoint 0 cannot be serviced by the DMA.

There are three categories of Standard Device Requests to be handled: Zero Data Requests (in which all the information is included in the request); Write Requests (in which the request will be followed by additional data); and Read Requests (in which the device is required to send data back to the host).

1. Zero Data Requests comprise a SETUP Token packet followed by an IN Status Stage.
2. Write Requests comprise a SETUP Token packet followed by an OUT Data Phase which is in turn followed by an IN Status Phase.
3. Read Requests comprise a SETUP Token packet, followed by an IN Data Phase which is in turn followed by an OUT Status Phase.

A timeout may be set to limit the length of time for which the host controller will retry a transaction that is continually NAKed by the device. This limit can be between 2 and 2.15 (micro)frames and is set through the NAKLIMIT0 register.

The following sections describe the actions that the CPU needs to take in issuing these different types of request through looking at the steps to take in the different phases of a control transaction.

25.7.2.1.1 Setup Stage of Control Transfer

For the SETUP stage of a control transaction ([Figure 25-9](#)), the software driving the USB host device needs to:

1. Load the Address of the USB Device into the FADDR Register
2. Load the 8 bytes of the required USB Standard Device Request into the Endpoint 0 FIFO
3. Set SETUPPKT and TXPKTRDY (bits 3 and 1 of HOST_CSR0, respectively).
NOTE: These bits must be set together.
 The controller then proceeds to send a SETUP token followed by the 8-byte request to Endpoint 0 of the addressed device, retrying as necessary. *Note:* On errors, the controller retries the transaction three times.
4. At the end of the attempt to send the 8-byte request data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK_TIMEOUT bit (bit 7) has been set.
 If RXSTALL is set, it indicates that the target did not accept the command (for example, because it is not supported by the target device) and so has issued a STALL response. If ERROR is set, it means that the controller has tried to send the SETUP Packet and the following data packet three times without getting any response from the device.
 If NAK_TIMEOUT is set, it means that the controller has received a NAK response to each attempt to send the SETUP packet, for longer than the time set in HOST_NAKLIMIT0. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.
5. If neither of the RXSTALL, ERROR or NAK_TIMEOUT bits is set, the SETUP Stage has been correctly ACKed by the device and the firmware should proceed to following IN Data Phase, OUT Data Phase or Status Phase as specified for the particular Standard Device Request.

Figure 25-9. Flow Chart of Setup Stage of a Control Transfer in Host Mode

25.7.2.1.2 Data Stage of a Control Transfer

The Data Stage is an optional stage of a Control Transfer depending on the USB Request. The Data Stage can be either an IN Data Stage or an OUT Data Stage. The following sections show how to handle a Data Stage for both an IN and OUT directions.

25.7.2.1.2.1 Data Stage of a Control Transfer

For the IN Data Stage of a control transfer (Figure 25-10), the software driving the USB host device needs to

1. Set REQPKT bit of HOST_CSR0 (bit 5)
2. Wait while the controller sends the IN token and receives the required data back.
3. When the controller generates the Endpoint 0 interrupt, read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4), the NAK_TIMEOUT bit (bit 7) or RXPKTRDY bit (bit 0) has been set.
If RXSTALL is set, it indicates that the target has issued a STALL response.
If ERROR is set, it means that the controller has tried to send the required IN token three times without getting any response. If NAK_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in HOST_NAKLIMIT0. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by clearing REQPKT before clearing the NAK_TIMEOUT bit
4. If RXPKTRDY has been set, the software should read the data from the Endpoint 0 FIFO, then clear RXPKTRDY.
5. If further data is expected, the software should repeat Steps 1-4.

When all the data has been successfully received, the CPU should proceed to the OUT Status Phase of the Control Transfer.

Figure 25-10. Flow Chart of Data Stage (IN Data Phase) of a Control Transfer in Host Mode

25.7.2.1.2.2 OUT Data Stage of a Control Transfer

For the OUT Data Stage of a control transfer (Figure 25-11), the software driving the USB host device needs to:

1. Load the data to be sent into the endpoint 0 FIFO.
2. Set the TXPKTRDY bit of HOST_CSR0 (bit 1). The controller then proceeds to send an OUT token followed by the data from the FIFO to Endpoint 0 of the addressed device, retrying as necessary.
3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK_TIMEOUT bit (bit 7) has been set.
If RXSTALL bit is set, it indicates that the target has issued a STALL response.
If ERROR bit is set, it means that the controller has tried to send the OUT token and the following data packet three times without getting any response. If NAK_TIMEOUT is set, it means that the controller has received a NAK response to each attempt to send the OUT token, for longer than the time set in the HOST_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.
If none of RXSTALL, ERROR or NAKLIMIT is set, the OUT data has been correctly ACKed.
4. If further data needs to be sent, the software should repeat Steps 1-3.
When all the data has been successfully sent, the software should proceed to the IN Status Phase of the Control Transfer.

Figure 25-11. Flow Chart of Data Stage (OUT Data Phase) of a Control Transfer in Host Mode

25.7.2.1.3 Status Stage

The directionality of the Status Stage of a USB Control Transfer will depend on the previous directionality of the Setup (or Data) Stage

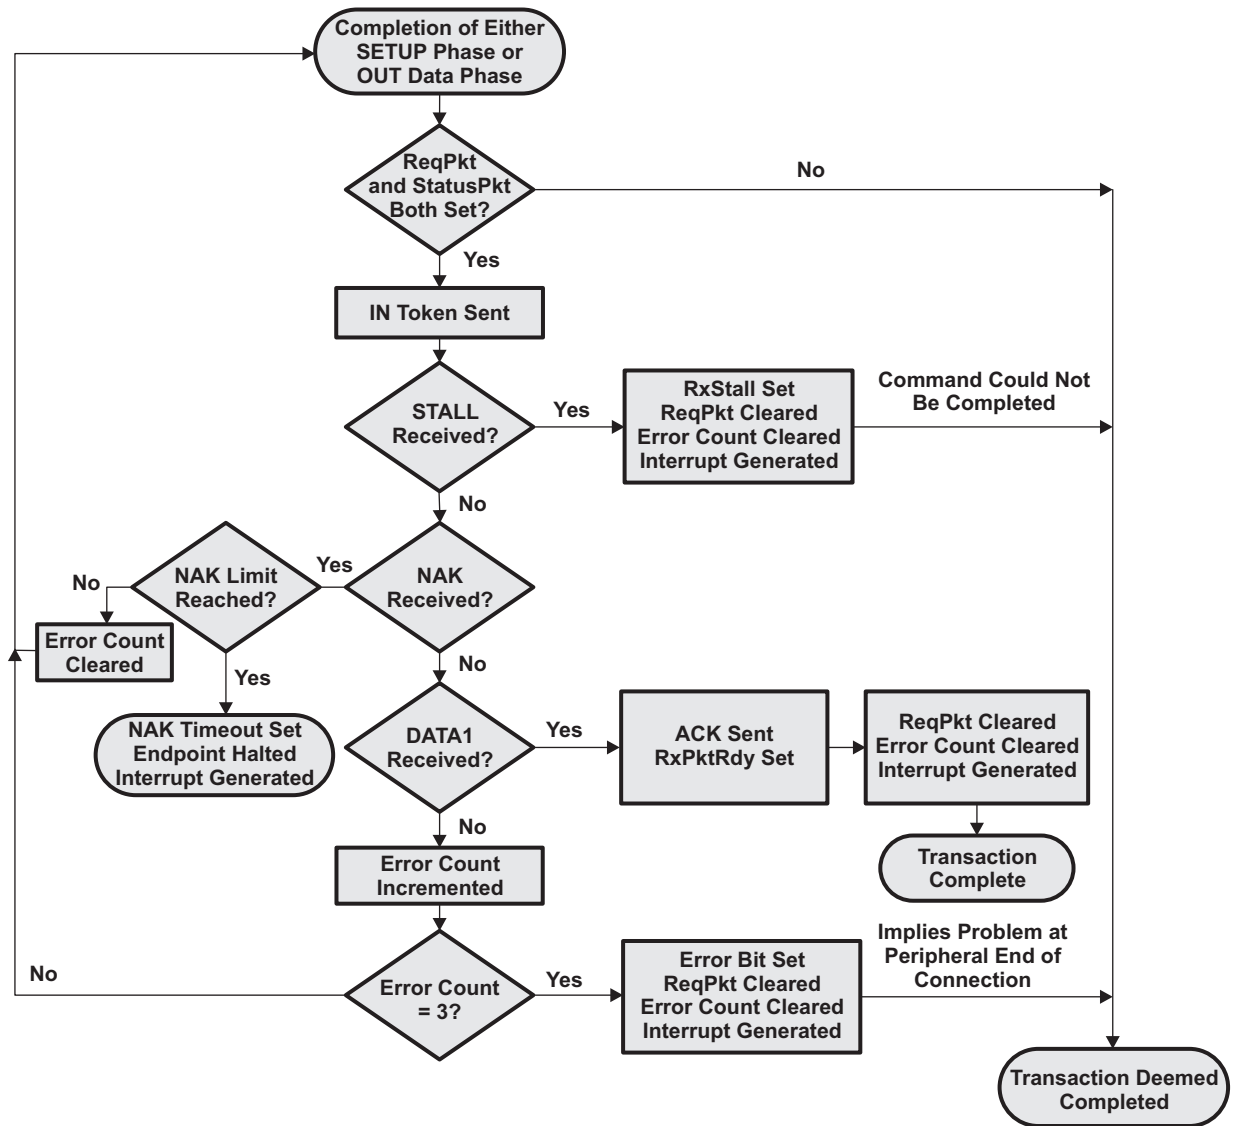

25.7.2.1.3.1 IN Status Stage of a Control Transfer

IN Status Phase of a control transfer exists for a Zero Data Request or for a Write Request of a control transfer. The IN Status Phase follows the Setup Stage, if no Data Stage of a control transfer exists, or OUT Data Phase of a Data Stage of a control transfer.

For the IN Status Stage of a control transaction ([Figure 25-12](#)), the software driving the USB Host device needs to:

1. Set the STATUSPKT and REQPKT bits of HOST_CSR0 (bit 6 and bit 5, respectively).
2. Wait while the controller sends an IN token and receives a response from the USB peripheral device.
3. When the controller generates the Endpoint 0 interrupt, read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4), the NAK_TIMEOUT bit (bit 7) or RXPkTRDY bit (bit 0) has been set.
If RXSTALL bit is set, it indicates that the target could not complete the command and so has issued a STALL response.
If ERROR bit is set, it means that the controller has tried to send the required IN token three times without getting any response.
If NAK_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the HOST_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by clearing REQPKT bit and STATUSPKT bit before clearing the NAK_TIMEOUT bit.
4. The CPU should clear the STATUSPPKT bit of HOST_CSR0 together with (i.e., in the same write operation as) RxPktRdy if this has been set.

Figure 25-12. Flow Chart of Status Stage of Zero Data Request or Write Request of a Control Transfer in Host Mode

25.7.2.1.3.2 OUT Status Stage of a Control Transfer

OUT Status Stage of a control transfer exist for a Read Request or a control transfer where data was received by the host controller. The OUT Status phase follows the IN Data Stage of a control transfer.

For the OUT Status Stage of a control transaction ([Figure 25-13](#)), the CPU driving the host device needs to:

1. Set STATUSPKT and TXPKTRDY bits of HOST_CSR0 (bit 6 and bit 1, respectively).
NOTE: These bits need to be set together
2. Wait while the controller sends the OUT token and a zero-length DATA1 packet.
3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK_TIMEOUT bit (bit 7) has been set.
If RXSTALL bit is set, it indicates that the target could not complete the command and so has issued a STALL response.
If ERROR bit is set, it means that the controller has tried to send the STATUS Packet and the following data packet three times without getting any response.
If NAK_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the HOST_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.
4. If none of RXSTALL, ERROR or NAK_TIMEOUT bits is set, the STATUS Phase has been correctly ACKed.

Figure 25-13. Chart of Status Stage of a Read Request of a Control Transfer in Host Mode

25.7.2.2 Bulk Transfer

Bulk transfers are handled by endpoints other than endpoint 0. They are used to handle non-periodic, large bursty communication typically used for a transfer that uses any available bandwidth and can also be delayed until bandwidth is available.

25.7.2.2.1 Bulk IN Transfers:

A Bulk IN transfer may be used to transfer non-periodic data from the external USB peripheral to the host.

The following optional features are available for use with an Rx endpoint used in host mode to receive the data:

- **Double packet buffering:** When enabled, up to two packets can be stored in the FIFO on reception from the host. This allows that one packet can be received while another is being read. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
- **DMA:** If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.

When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions. For more information see section on CPPI DMA

25.7.2.2.1.1 Bulk IN Setup

Before initiating any Bulk IN Transactions in Host mode:

- The HOST_RXTYPE register for the endpoint that is to be used needs to be programmed as:
 - Operating speed in the SPEED bit field (bits 7 and 6).
 - Set 10 (binary value) in the PROT field for bulk transfer.
 - Endpoint Number of the target device in RENDPN field. This is the endpoint number contained in the Rx endpoint descriptor returned by the target device during enumeration.
- The RXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_RXINTERVAL register needs to be written with the required value for the NAK limit (2-215 frames/microframes), or set to zero if the NAK timeout feature is not required.
- The relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint).

Note: Whether interrupt is handled from PDR level or Core level, interrupt is required to be enabled at the core level. See details on Core Interrupt registers, CTRLR register, and sections on Interrupt Handling

- The AUTOREQ bit field should be used only when servicing transfers using CPU mode and must be cleared when using DMA Mode. For DMA Mode, dedicated registers USB0/1 Req Registers exist and the HOST_RXCSR[AUTOREQ] should be cleared.

When DMA is enabled, the following bits of HOST_RXCSR register should be set as:

- Clear AUTOCLEAR.
- Set DMAEN (bit 13) to 1 if a DMA request is required for this endpoint.
- Clear DSINYET (bit 12) to 0 to allow normal PING flow control. This will affect only High Speed transactions.
- Clear DMAMODE (bit 11) to 0.

Note: If DMA is enabled, the USB0/1 Auto Req register can be set for generating IN tokens automatically after receiving the data. Set the bit field RXn_AUTOREQ (where n is the endpoint number) with binary value 01 or 11.

When the endpoint is first configured, the endpoint data toggle should be cleared to 0 either by using the DATATOGWREN and DATATOG bits of HOST_RXCSR (bit 10 and bit 9) to toggle the current setting or by setting the CLRDATATOG bit of HOST_RXCSR (bit 7). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state. Also if there are any data packets in the FIFO (indicated by the RXPBKTRDY bit (bit 0 of HOST_RXCSR) being set), they should be flushed by setting the FLUSHFIFO bit of HOST_RXCSR (bit 4).

NOTE: It may be necessary to set this bit twice in succession if double buffering is enabled.

25.7.2.2.1.2 Bulk IN Operation

When Bulk data is required from the USB peripheral device, the software should set the REQPKT bit in the corresponding HOST_RXCSR register (bit 5). The controller will then send an IN token to the selected peripheral endpoint and waits for data to be returned.

If data is correctly received, RXPBKTRDY bit of HOST_RXCSR (bit 0) is set. If the USB peripheral device responds with a STALL, RXSTALL bit (bit 6 of HOST_RXCSR) is set. If a NAK is received, the controller tries again and continues to try until either the transaction is successful or the POLINTVL_NAKLIMIT set in the HOST_RXINTERVAL register is reached. If no response at all is received, two further attempts are made before the controller reports an error by setting the ERROR bit of HOST_RXCSR (bit 2).

The controller then generates the appropriate endpoint interrupt, whereupon the software should read the corresponding HOST_RXCSR register to determine whether the RXPBKTRDY, RXSTALL, ERROR or DATAERR_NAKTIMEOUT bit is set and act accordingly. If the DATAERR_NAKTIMEOUT bit is set, the controller can be directed either to continue trying this transaction (until it times out again) by clearing the DATAERR_NAKTIMEOUT bit or to abort the transaction by clearing REQPKT bit before clearing the DATAERR_NAKTIMEOUT bit.

The packets received should not exceed the size specified in the RXMAXP register (as this should be the value set in the wMaxPacketSize field of the endpoint descriptor sent to the host).

In the general case, the application software (if CPU is servicing the endpoint) will need to read each packet from the FIFO individually. If large blocks of data are being transferred, the overhead of calling an interrupt service routine to unload each packet can be avoided by using DMA.

Note: When using DMA, see CPPI DMA section for the proper configuration of the core register, HOST_RXCSR.

25.7.2.2.1.3 Bulk IN Error Handling

If the target wants to shut down the Bulk IN pipe, it will send a STALL response to the IN token. This will result in the RXSTALL bit of HOST_RXCSR (bit 6) being set.

25.7.2.2.2 Bulk OUT Transfers

A Bulk OUT transaction may be used to transfer non-periodic data from the host to the USB peripheral.

Following optional features are available for use with a Tx endpoint used in Host mode to transmit this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the peripheral device. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature can be used to allow the DMA controller to load packets into the FIFO without processor intervention. For more information on using DMA, consult the section discussing CPPI DMA.
When DMA is enabled and DMAMODE bit in HOST_TXCSR register is set, an endpoint interrupt will not be generated for completion of packet reception. An endpoint interrupt will be generated only in the error conditions.

25.7.2.2.2.1 Bulk OUT Setup

Before initiating any bulk OUT transactions:

- The target function address needs to be set in the TXFUNCADDR register for the selected controller endpoint. (TXFUNCADDR register is available for all endpoints from EP0 to EP15.)
- The HOST_TXTYPE register for the endpoint that is to be used needs to be programmed as:
 - Operating speed in the SPEED bit field (bits 7 and 6).
 - Set PROT field to 10b for bulk transfer.
 - Enter Endpoint Number of the target device in TENDPN field. This is the endpoint number contained in the OUT(Tx) endpoint descriptor returned by the target device during enumeration.
- The TXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_TXINTERVAL register needs to be written with the required value for the NAK limit (2-215 frames/microframes), or set to zero if the NAK timeout feature is not required.
- The relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST_TXCSR register should be set as:
 - Set the MODE bit (bit 13) to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
 - Clear the FRCDATATOG bit (bit 11) to 0 to allow normal data toggle operations.
 - Clear/Set AUTOSET bit (bit 15). The setting of this bit depends on the desire of the user/application in automatically setting the TXPKTRDY bit when servicing transactions using CPU.

Note: If DMA is needed to be used in place of the CPU, the following table displays the setting of the core register HOST_TXCSR register in Host mode. For the CPPI DMA registers settings consult the section on CPPI DMA within this document.

Bit Field	Bit Name	Description
Bit 15	AUTOSET	Cleared to 0 if using DMA. For CPU Mode use, if AUTOSET bit is set, the TXPKTRDY bit will be automatically set when data of the maximum packet size is loaded into the FIFO.
Bit 14	ISO	Cleared to 0 for bulk mode operation.
Bit 13	MODE	Set to 1 to make sure the FIFO is enabled (only necessary if the FIFO is shared with an RX endpoint)
Bit 12	DMAEN	Set to 1 to enable DMA usage; not needed if CPU is being used to service the Tx Endpoint
Bit 11	FRCDATATOG	Cleared to 0 to allow normal data toggle operations.
Bit 10	DMAMODE	Set to 1 when DMA is used to service Tx FIFO.

When the endpoint is first configured, the endpoint data toggle should be cleared to 0 either by using the DATATOGWREN bit and DATATOG bit of HOST_TXCSR (bit 9 and bit 8) to toggle the current setting or by setting the CLRDATATOG bit of HOST_TXCSR (bit 6). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state. Also, if there are any data packets in the FIFO (indicated by the FIFONOTEMPTY bit of HOST_TXCSR register (bit 1) being set), they should be flushed by setting the FLUSHFIFO bit (bit 3 of HOST_TXCSR).

NOTE: It may be necessary to set this bit twice in succession if double buffering is enabled.

25.7.2.2.2 Bulk OUT Operation

When Bulk data is required to be sent to the USB peripheral device, the software should write the first packet of the data to the FIFO (or two packets if double-buffered) and set the TXPKTRDY bit in the corresponding HOST_TXCSR register (bit 0). The controller will then send an OUT token to the selected peripheral endpoint, followed by the first data packet from the FIFO.

If data is correctly received by the peripheral device, an ACK should be received whereupon the controller will clear TXPKTRDY bit of HOST_TXCSR (bit 0). If the USB peripheral device responds with a STALL, the RXSTALL bit (bit 5) of HOST_TXCSR is set. If a NAK is received, the controller tries again and continues to try until either the transaction is successful or the NAK limit set in the HOST_TXINTERVAL register is reached. If no response at all is received, two further attempts are made before the controller reports an error by setting ERROR bit in HOST_TXCSR (bit 2).

The controller then generates the appropriate endpoint interrupt, whereupon the software should read the corresponding HOST_TXCSR register to determine whether the RXSTALL (bit 5), ERROR (bit 2) or NAK_TIMEOUT (bit 7) bit is set and act accordingly. If the NAK_TIMEOUT bit is set, the controller can be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.

If large blocks of data are being transferred, then the overhead of calling an interrupt service routine to load each packet can be avoided by using DMA.

25.7.2.2.3 Bulk OUT Error Handling

If the target wants to shut down the Bulk OUT pipe, it will send a STALL response. This is indicated by the RXSTALL bit of HOST_TXCSR register (bit 5) being set.

25.7.2.3 Interrupt Transfer

When the controller is operating as the host, interactions with an Interrupt endpoint on the USB peripheral device are handled in very much the same way as the equivalent Bulk transactions (described in previous sections).

The principal difference as far as operational steps are concerned is that the PROT field of HOST_RXTYPE and HOST_TXTYPE (bits 5-4) need to be set (binary value) to represent an Interrupt transaction. The required polling interval also needs to be set in the HOST_RXINTERVAL and HOST_TXINTERVAL registers.

25.7.2.4 Isochronous Transfer

Isochronous transfers are used when working with isochronous data. Isochronous transfers provide periodic, continuous communication between host and device.

An Isochronous IN transaction is used to transfer periodic data from the USB peripheral to the host.

25.7.2.4.1 Isochronous IN Transfers

The following optional features are available for use with an Rx endpoint used in Host mode to receive this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. This allows that one packet can be received while another is being read. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
- AutoRequest: When the AutoRequest feature is enabled, the REQPKT bit of HOST_RXCSR (bit 5) will be automatically set when the RXPKTRDY bit is cleared. This only applies when the CPU is being used to service the endpoint. When using DMA, this bit field needs to be cleared to Zero. CPPI DMA has its own configuration registers that renders a similar task, USB0/1 Auto Req registers, that needs to be used to have a similar effect. For more information, see section on CPPI DMA.
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention. However, this feature is not particularly useful with isochronous endpoints because the packets transferred are often not maximum packet size.

- When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

25.7.2.4.1.1 Isochronous IN Transfer Setup

Before initiating an Isochronous IN Transactions in Host mode:

- The target function address needs to be set in the RXFUNCADDR register for the selected controller endpoint (RXFUNCADDR register is available for all endpoints from EP0 to EP4).
- The HOST_RXTYPE register for the endpoint that is to be used needs to be programmed as:
 - Operating speed in the SPEED bit field (bits 7 and 6).
 - Set 01 (binary value) in the PROT field for isochronous transfer.
 - Endpoint Number of the target device in RENDPN field. This is the endpoint number contained in the Rx endpoint descriptor returned by the target device during enumeration.
- The RXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_RXINTERVAL register needs to be written with the required transaction interval (usually one transaction per frame/microframe).
- The relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST_RXCSR register should be set as:
 - Clear AUTOCLEAR
 - Set the DMAEN bit (bit 13) to 1 if a DMA request is required for this endpoint.
 - Clear the DISNYET it (bit 12) to 0 to allow normal PING flow control. This will only affect High Speed transactions.
 - Clear DMAMODE bit (bit 11) to 0.
- If DMA is enabled, AUTOREQ register can be set for generating IN tokens automatically after receiving the data. Set the bit field RXn_AUTOREQ (where n is the endpoint number) with binary value 01 or 11. For detailed information on using CPPI DMA, consult related section within this document.

25.7.2.4.1.2 Isochronous IN Operation

The operation starts with the software setting REQPKT bit of HOST_RXCSR (bit 5). This causes the controller to send an IN token to the target.

When a packet is received, an interrupt is generated which the software may use to unload the packet from the FIFO and clear the RXPKTRDY bit in the HOST_RXCSR register (bit 0) in the same way as for a Bulk Rx endpoint. As the interrupt could occur almost any time within a frame(/microframe), the timing of FIFO unload requests will probably be irregular. If the data sink for the endpoint is going to some external hardware, it may be better to minimize the requirement for additional buffering by waiting until the end of each frame before unloading the FIFO. This can be done by using the SOF_PULSE signal from the controller to trigger the unloading of the data packet. The SOF_PULSE is generated once per frame(/microframe). The interrupts may still be used to clear the RXPKTRDY bit in HOST_RXCSR.

25.7.2.4.1.3 Isochronous IN Error Handling

If a CRC or bit-stuff error occurs during the reception of a packet, the packet will still be stored in the FIFO but the DATAERR_NAKTIMEOUT bit of HOST_RXCSR (bit 3) is set to indicate that the data may be corrupt.

Note: The number of USB packets sent in any microframe will depend on the amount of data to be transferred, and is indicated through the PIDs used for the individual packets. If the indicated numbers of packets have not been received by the end of a microframe, the INCOMPRX bit in the HOST_RXCSR register will be set to indicate that the data in the FIFO is incomplete. Equally, if a packet of the wrong data type is received, then the PID Error bit in the HOST_RXCSR register will be set. In each case, an interrupt will, however, still be generated to allow the data that has been received to be read from the FIFO.

25.7.2.4.2 Isochronous OUT Transfers

An Isochronous OUT transaction may be used to transfer periodic data from the host to the USB peripheral.

Following optional features are available for use with a Tx endpoint used in Host mode to transmit this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the peripheral device. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).

DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature can be used to allow the DMA controller to load packets into the FIFO without processor intervention.

However, this feature is not particularly useful with isochronous endpoints because the packets transferred are often not maximum packet size.

When DMA is enabled and endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

25.7.2.4.2.1 Isochronous OUT Transfer Setup

Before initiating any Isochronous OUT transactions:

- The target function address needs to be set in the TXFUNCADDR register for the selected controller endpoint (TXFUNCADDR register is available for all endpoints from EP0 to EP4).
- The HOST_TXTYPE register for the endpoint that is to be used needs to be programmed as:
 - Operating speed in the SPEED bit field (bits 7 and 6).
 - Set 01 (binary value) in the PROT field for isochronous transfer.
 - Endpoint Number of the target device in TENDPN field. This is the endpoint number contained in the OUT(Tx) endpoint descriptor returned by the target device during enumeration.
- The TXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_TXINTERVAL register needs to be written with the required transaction interval (usually one transaction per frame/microframe).
- The relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST_TXCSR register should be set as:
 - Set the MODE bit (bit 13) to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
 - Set the DMAEN bit (bit 12) to 1 if a DMA request is required for this endpoint
 - The FRCDATATOG bit (bit 11) is ignored for isochronous transactions.
 - Set the DMAMODE bit (bit 10) to 1 when DMA is enabled.For more details in using DMA, consult CPPI DMA section within this document.

25.7.2.4.2.2 Isochronous OUT Transfer Operation

The operation starts when the software writes to the FIFO and sets TXPKTRDY bit of HOST_TXCSR (bit 0). This triggers the controller to send an OUT token followed by the first data packet from the FIFO.

An interrupt is generated whenever a packet is sent and the software may use this interrupt to load the next packet into the FIFO and set the TXPKTRDY bit in the HOST_TXCSR register (bit 0) in the same way as for a Bulk Tx endpoint. As the interrupt could occur almost any time within a frame, depending on when the host has scheduled the transaction, this may result in irregular timing of FIFO load requests. If the data source for the endpoint is coming from some external hardware, it may be more convenient to wait until the end of each frame before loading the FIFO as this will minimize the requirement for additional buffering. This can be done by using the SOF_PULSE signal from the controller to trigger the loading of the next data packet. The SOF_PULSE is generated once per frame(/microframe). The interrupts may still be used to set the TXPKTRDY bit in HOST_TXCSR.

25.8 DMA

The Communications Port Programming Interface (CPPI) Version 4.1 DMA module supports the transmission and reception of USB packets. The DMA is designed to facilitate the segmentation and reassembly of packets to/from smaller data blocks that are natively compatible with the specific requirements of each networking port. The DMA controller maintains state information for each of the ports which allows packet segmentation and reassembly operations to be time division multiplexed between USB Endpoints in order to share the underlying DMA hardware. A DMA scheduler is used to control the ordering and rate at which this multiplexing occurs.

The CPPI DMA controller sub-module is a common 15 port DMA controller. It supports 15 Tx and 15 Rx ports attaches to the associated endpoint in the USB controller. Port 1 maps to endpoint 1 and Port 2 maps to endpoint 2 and so on with Port 15 mapped to endpoint 15 of USB0. Port 16 is mapped to USB1 EP1 and so on with Port 30 mapped to USB1 EP15

25.8.1 CPPI Terminology

Host/CPU— The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port interrupts.

Main Memory — The area of data storage managed by the CPU. The CPPI DMA (CDMA) reads and writes DMA packets from and to main memory. This memory can exist internal or external from the device.

CPPI FIFO — The CPPI FIFO provides FIFO interfaces (for each of the 15 transmit and 15 receive endpoints) between the USB Controllers and Main Memory.

CPPI DMA (CDMA) — The CDMA is responsible for transferring data between the CPPI FIFO and Main Memory.

Transfer DMA (XDMA) — The XDMA receives DMA requests from the USB Controller and initiates DMAs to the CPPI FIFO.

Packet Queue — A packet queue is hardware managed list of valid (i.e. populated) packet descriptors that is used for forwarding a packet from one entity to another for any number of purposes.

NOTE: All descriptors (regardless of type) must be allocated at addresses that are naturally aligned to the smallest power of 2 that is equal to or greater than the descriptor size.

Queue Manager (QM) — The QM is responsible for accelerating management of a variety of Packet Queues and Free Descriptor / Buffer Queues.

Data Buffer — A data buffer is a single data structure that contains payload information for transmission to or reception from a port. A data buffer is a byte aligned contiguous block of memory used to store packet payload data. A data buffer may hold any portion of a packet and may be linked together (via descriptors) with other buffers to form DMA packets. Data buffers may be allocated anywhere within the 32-bit memory space. The Buffer Length field of the packet descriptor indicates the number of valid data bytes in the buffer. There may be from 1 to 4M-1 valid data bytes in each buffer.

Buffer Descriptor — A buffer descriptor is a single data structure that contains information about one or more data buffers. This type of descriptor is required when more than one descriptor is needed to define an entire packet, i.e., it either defines the middle of a packet or end of a packet.

Packet Descriptor — A packet descriptor is another name for the first buffer descriptor within a packet. Some fields within a data buffer descriptor are only valid when it is a packet descriptor including the tags, packet length, packet type, and flags. This type of descriptor is always used to define a packet since it provides packet level information that is useful to both the ports and the Host in order to properly process the packet. It is the only descriptor used when single descriptor solely defines a packet. When multiple descriptors are needed to define a packet, the packet descriptor is the first descriptor used to define a packet.

Teardown Descriptor — Teardown Descriptor is a special structure which is not used to describe either a packet or a buffer but is instead used to describe the completion of a channel halt and teardown event. Channel teardown is an important function because it ensures that when a connection is no longer needed that the hardware can be reliably halted and any remaining packets which had not yet been transmitted can be reclaimed by the Host without the possibility of losing buffer or descriptor references (which results in a memory leak).

Free Descriptor/Buffer Queue — A free descriptor/buffer queue is a hardware managed list of available descriptors with pre-linked empty buffers that are to be used by the receive ports for host type descriptors. Free Descriptor/Buffer Queues are implemented by the Queue Manager.

CDMA Scheduler (CDMAS) — The CDMAS is responsible for scheduling CDMA transmit and receive operations. It uses Queue Indicators from the QM and the CDMA to determine the types of operations to schedule.

Endpoint FIFOs — The Endpoint FIFOs are the USB packet storage elements used by the USB Controller for packet transmission or reception. The XDMA transfers data between the CPPI FIFO and the Endpoint FIFOs for transmit operations and between the Endpoint FIFOs and the CPPI FIFO for receive operations.

Port — A port is the communications module (peripheral hardware) that contains the control logic for Direct Memory Access for a single transmit/receive interface or set of interfaces. A port is usually subdivided into transmit and receive pairs which are independent of each other. Each endpoint, excluding endpoint 0, has its own dedicated port.

25.8.2 Data Structures

Two data structures are mainly used to identify data buffers used by packet and buffer descriptors. A third Descriptor, Teardown Descriptor, exists. The purpose of this Descriptor is a channel halt and teardown event. Each of these Descriptor layouts as well as bit fields are shown below.

25.8.2.1 Packet Descriptor

Packet Descriptors are designed to be used when USB like application requires support for true, unlimited fragment count scatter/gather type operations. The DMA Packet Descriptor is synonymous with the first Buffer Descriptor in a sequence of linked Buffer Descriptors. The Packet Descriptor is the first Buffer Descriptor on multiple descriptors DMA Packet or the only Buffer Descriptor in a single descriptor DMA Packet. The Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a packet descriptor (always 10h)
- Source and destination tags (reserved)
- Packet type
- Packet length
- Protocol specific region size
- Protocol specific control/status bits
- Pointer to the first valid byte in the SOP data buffer
- Length of the SOP data buffer
- Pointer to the next buffer descriptor in the packet

Packet descriptors can vary in size by design of their defined fields from 32 bytes up to 104 bytes. Within this range, packet descriptors always contain at least 32 bytes of required information and may also contain an additional 8 bytes of software specific tagging information and up to 64 bytes (indicated in 4 byte increments) of protocol specific information. How much protocol specific information (and therefore the allocated size of the descriptors) is application dependent. Port will make use of the first 32 bytes only.

From a general USB use perspective, a 32-byte descriptor size is sufficient and the use of this size is expected for a normal USB usage.

The packet descriptor layout is shown in [Figure 25-14](#) and described within [Table 25-10](#) through [Table 25-17](#).

Figure 25-14. Packet Descriptor Layout

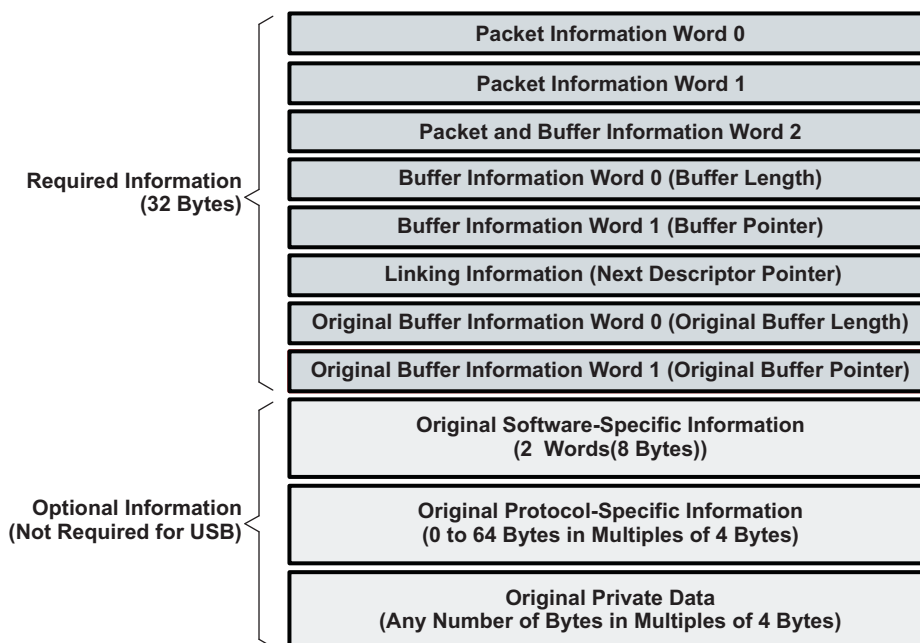

Table 25-10. Packet Descriptor Word 0 (PD0) Bit Field Descriptions

Bits	Field Name	Description
31-27	Descriptor type	The host packet descriptor type is 16 decimal (10h). The CPU initializes this field.
26-22	Protocol-specific valid word count	This field indicates the valid number of 32-bit words in the protocol-specific region. The CPU initializes this field. This is encoded in increments of 4 bytes as: 0 = 0 byte 1 = 4 bytes ... 16 = 64 bytes 17-31 = Reserved
21-0	Packet length	The length of the packet in bytes. If the packet length is less than the sum of the buffer lengths, then the packet data will be truncated. A packet length greater than the sum of the buffers is an error. The valid range for the packet length is 0 to (4M - 1) bytes. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

Table 25-11. Packet Descriptor Word 1 (PD1) Bit Field Descriptions

Bits	Field Name	Description
31-27	Source Tag; Port #	This field indicates the port number (0-31) from which the packet originated. The DMA overwrites this field on packet reception. This is the RX Endpoint number from which the packet originated.
26-21	Source Tag; Channel #	This field indicates the channel number within the port from which the packet originated. The DMA overwrites this field on packet reception. This field is always 0-67.
20-16	Source Tag; Sub-channel #	This field indicates the sub-channel number (0-31) within the channel from which the packet originated. The DMA overwrites this field on packet reception. This field is always 0.
15-0	Destination Tag	This field is application-specific. This field is always 0.

Table 25-12. Packet Descriptor Word 2 (PD2) Bit Field Descriptions

Bits	Field Name	Description
31	Packet error	This bit indicates if an error occurred during reception of this packet (0 = no error occurred; 1 = error occurred). The DMA overwrites this field on packet reception. Additional information about different errors may be encoded in the protocol specific fields in the descriptor.
30-26	Packet type	This field indicates the type of this packet. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. This field is encoded as: 5 = USB 8-31 = Reserved
25-20	Reserved	Reserved
19	Zero-length packet indicator	If a zero-length USB packet is received, the XDMA will send the CDMA a data block with a byte count of 0 and this bit is set. The CDMA will then perform normal EOP termination of the packet without transferring data. For transmit, if a packet has this bit set, the XDMA will ignore the CPPI packet size and send a zero-length packet to the USB controller.
18-16	Protocol-specific	This field contains protocol-specific flags/information that can be assigned based on the packet type. Not used for USB.

Table 25-12. Packet Descriptor Word 2 (PD2) Bit Field Descriptions (continued)

Bits	Field Name	Description
15	Return policy	This field indicates the return policy for this packet. The CPU initializes this field. 0 = Entire packet (still linked together) should be returned to the queue specified in bits 13-0. 1 = Each buffer should be returned to the queue specified in bits 13-0 of Word 2 in their respective descriptors. The Tx DMA will return each buffer in sequence.
14	On-chip	This field indicates whether or not this descriptor is in a region which is in on-chip memory space (1) or in external memory (0).
31-12	Packet return queue mgr #	This field indicates which queue manager in the system the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU. There is only one queue manager in the USB HS/FS device controller. This field must always be 0.
11-0	Packet return queue #	This field indicates the queue number within the selected queue manager that the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU.

Table 25-13. Packet Descriptor Word 3 (PD3) Bit Field Descriptions

Bits	Field Name	Description
31-22	Reserved	Reserved
21-0	Buffer 0 length	The buffer length field indicates how many valid data bytes are in the buffer. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

Table 25-14. Packet Descriptor Word 4 (PD4) Bit Field Descriptions

Bits	Field Name	Description
31-0	Buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

Table 25-15. Packet Descriptor Word 5 (PD5) Bit Field Descriptions

Bits	Field Name	Description
31-0	Next descriptor pointer	The 32-bit word aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is zero, then the current buffer is the last buffer in the packet. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

Table 25-16. Packet Descriptor Word 6 (PD6) Bit Field Descriptions

Bits	Field Name	Description
31-22	Reserved	Reserved
21-0	Original buffer 0 length	The buffer length field indicates the original size of the buffer in bytes. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the CPU at initialization. Since the buffer length in Word 3 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.

Table 25-17. Packet Descriptor Word 7 (PD7) Bit Field Descriptions

Bits	Field Name	Description
31-22	Reserved	Reserved
21-0	Original buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer location as allocated by the CPU at initialization. Since the buffer pointer in Word 4 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information.

25.8.2.2 Buffer Descriptor (BD)

The Buffer Descriptor is identical in size and organization to a Packet Descriptor but does not include valid information in the packet level fields and does not include a populated region for protocol specific information. The packet level fields are not needed since the Packet Descriptor already contains this information and additional copy of this data is not needed/necessary.

Buffer descriptors are designed to be linked onto a Packet Descriptor or another buffer descriptor to provide support for unlimited scatter / gather type operations. Buffer descriptors provide information about a single corresponding data buffer. Every buffer descriptor stores the following information:

- Pointer to the first valid byte in the data
- Length of the data buffer
- Pointer to the next buffer descriptor in the packet

Buffer descriptors always contain 32 bytes of required information. Since it is a requirement that it is possible to convert a descriptor between a Buffer Descriptor and a Packet Descriptor (by filling in the appropriate fields) in practice, Buffer Descriptors will be allocated using the same sizes as Packet Descriptors. In addition, since the 5 LSBs of the Descriptor Pointers are used in CPPI 4.1 for the purpose of indicating the length of the descriptor, the minimum size of a descriptor is always 32 bytes

The buffer descriptor layout is shown in [Figure 25-15](#) and described within [Table 25-18](#) through [Table 25-25](#).

Figure 25-15. Buffer Descriptor (BD) Layout

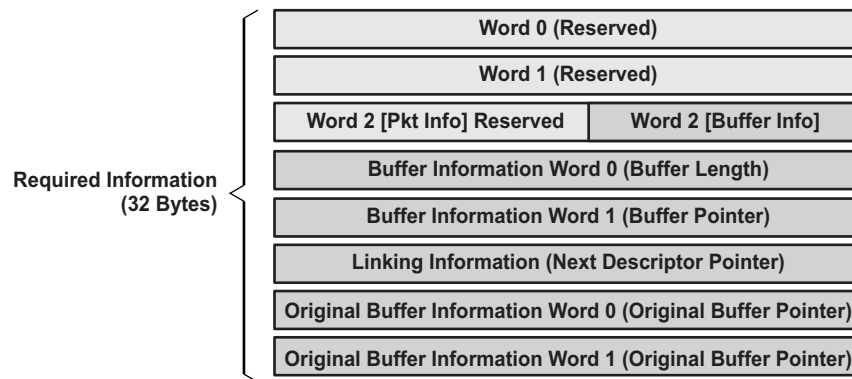

Table 25-18. Buffer Descriptor Word 0 (BD0) Bit Field Descriptions

Bits	Field Name	Description
31-0	Reserved	Reserved

Table 25-19. Buffer Descriptor Word 1 (BD1) Bit Field Descriptions

Bits	Field Name	Description
31-0	Reserved	Reserved

Table 25-20. Buffer Descriptor Word 2 (BD2) Bit Field Descriptions

Bits	Field Name	Description
31-15	Reserved	Reserved
14	On-chip	This field indicates whether or not this descriptor is in a region which is on-chip memory space (1) or in external memory (0).

Table 25-20. Buffer Descriptor Word 2 (BD2) Bit Field Descriptions (continued)

Bits	Field Name	Description
13-12	Packet return queue mgr #	This field indicates which queue manager in the system the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU. There is only 1 queue manager in the USB HS/FS device controller. This field must always be 0.
11-0	Packet return queue #	This field indicates the queue number within the selected queue manager that the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU.

Table 25-21. Buffer Descriptor Word 3 (BD3) Bit Field Descriptions

Bits	Field Name	Description
31-22	Reserved	Reserved
21-0	Buffer 0 length	The buffer length field indicates how many valid data bytes are in the buffer. The CPU initializes this field for transmitted packets. The DMA overwrites this field upon packet reception.

Table 25-22. Buffer Descriptor Word 4 (BD4) Bit Field Descriptions

Bits	Field Name	Description
31-0	Buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. The CPU initializes this field for transmitted packets. The DMA overwrites this field upon packet reception.

Table 25-23. Buffer Descriptor Word 5 (BD5) Bit Field Descriptions

Bits	Field Name	Description
31-0	Next description pointer	The 32-bit word aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is zero, then the current descriptor is the last descriptor in the packet. The CPU initializes this field for transmitted packets. The DMA overwrites this field upon packet reception.

Table 25-24. Buffer Descriptor Word 6 (BD6) Bit Field Descriptions

Bits	Field Name	Description
31-22	Reserved	Reserved
21-0	Original buffer 0 length	The buffer length field indicates the original size of the buffer in bytes. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the CPU at initialization. Since the buffer length in Word 3 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.

Table 25-25. Buffer Descriptor Word 7 (BD7) Bit Field Descriptions

Bits	Field Name	Description
31-0	Original buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer location as allocated by the CPU at initialization. Since the buffer pointer in Word 4 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information.

25.8.2.3 Teardown Descriptor

The Teardown Descriptor is used to describe a channel halt and teardown event. Channel teardown ensures that when a connection is no longer needed that the hardware can be reliably halted and any remaining packets which had not yet been transmitted can be reclaimed by the CPU without the possibility of losing buffer or descriptor references (which results in a memory leak).

The Teardown descriptor is always 32 bytes long and is comprised of 4 bytes of actual teardown information and 28 bytes of pad. The teardown descriptor layout and associated bit field descriptions are shown in the Figure below and Tables that follows. Since the 5 LSBs of the descriptor pointers are used in CPPI 4.1 for the purpose of indicating the length of the descriptor, the minimum size of a descriptor is 32 bytes.

The teardown descriptor contains the following information:

- Indicator which identifies the descriptor as a teardown packet descriptor
- DMA controller number where teardown
- Channel number within DMA where teardown occurred
- Indicator of whether this teardown was for the Tx or Rx channel

Figure 25-16. Teardown Descriptor Layout

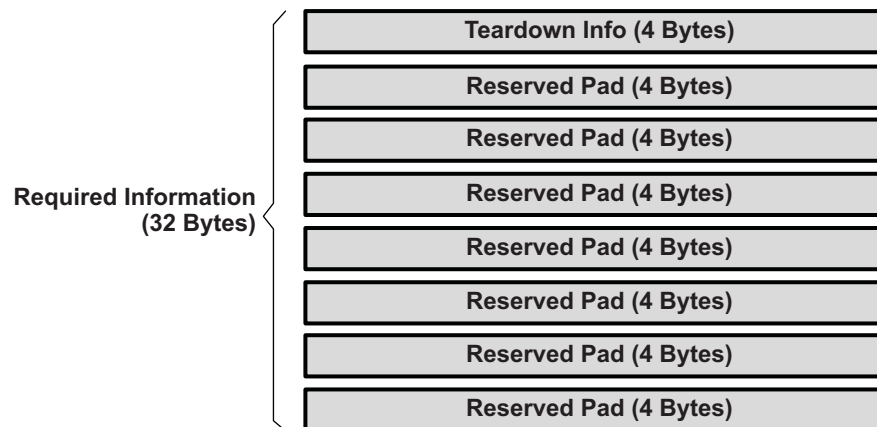

Table 25-26. Teardown Descriptor Word 0 Bit Field Descriptions

Bits	Field Name	Description
31-27	Descriptor type	The teardown descriptor type is 19 decimal (13h)
26-17	Reserved	Reserved
16	TX_RX	Indicates whether teardown is a TX (0) or RX (1).
15-10	DMA number	Indicates the DMA number for this teardown.
9-6	Reserved	Reserved
5-0	Channel number	Indicates the channel number within the DMA that was torn down.

Table 25-27. Teardown Descriptor Words 1 to 7 Bit Field Descriptions

Bits	Field Name	Description
31-0	Reserved	Reserved

Teardown operation of an endpoint requires three operations. The teardown register in the CPPI DMA must be written, the corresponding endpoint bit in TEARDOWN of the USB module must be set, and the FlushFIFO bit in the USB controller Tx/RxCSR register must be set.

The following is the Transmit teardown procedure highlighting the steps required to be followed:

1. Set the TX_TEARDOWN bit in the CPPI DMA TX channel n global configuration register (TXGCRn).
2. Set the appropriate TX_TDOWN bit in the USBOTG controller's USB teardown register (TEARDOWN). Write Tx Endpoint Number to teardown to TEARDOWN[TX_TDOWN] field.
3. Check if the teardown descriptor has been received on the teardown queue: The Completion Queue (see Queue Assignment table) is usually used as the Teardown queue when the Teardown descriptor has been received, the descriptor address will be loaded onto CTRLD[Completion Queue #] register:
 - (a) If not, go to step 2
 - (b) If so, go to step 4
4. Set the appropriate TX_TDOWN bit in the USBOTG controller's USB teardown register (TEARDOWN). Set the bit corresponding to the Channel Number within TEARDOWN[TX_TDOWN] field.
5. Flush the TX FIFO in the USB Controller: Set PERI_TXCSR[FLUSHFIFO] for the corresponding Endpoint.
6. Re-enable the Tx DMA channel.
 - (a) Clear TXGCRn[TX_TEARDOWN and TX_ENABLE] bit.
 - (b) Set TXGCRn[TX_ENABLE] bit.

25.8.3 Queue Manager

The Queue Manager (QM) is a hardware module that is responsible for accelerating management of the queues, i.e. queues are maintained within a queue manager module. Packets are added to a queue by writing the 32-bit descriptor address to a particular memory mapped location in the queue manager module. Packets are de-queued by reading the same location for that particular queue. A single queue manager exists within the subsystem and handles all available 156 queues.

Descriptors are queued (pushed) onto a logical queue by writing the descriptor pointer to the Queue[n] Register D. When the Queue[n] Register D is written, this kicks off the queue manager causing it to add the descriptor to the tail of queue.

The Queue Manager keeps track of the order of the descriptors pushed within a queue and the linking status of the descriptors. To accomplish this linking status, the Queue Manager will first resolve the 32-bit descriptor pointer into a 16-bit index which is used for linking a queue pointer purposes. Once the address to index computation is performed, i.e., the physical index information is determined, the Queue Manager will link that descriptor onto the descriptor chain that is maintained for that logical queue by writing the linking information out to a linking RAM which is external to the queue manager. More on linking RAM discussion will follow in latter sections. The Queue Manager will also update the queue tail pointers appropriately. Since logical queues within the queue manager are maintained using linked lists, queues cannot become full and no check for fullness is required before queuing a packet descriptor.

25.8.3.1 Queue Types

Several types of queues exist (a total of 156 queues) within the CPPI 4.1 DMA. Regardless of the type of queue, queues are used to hold pointers to Packet or Buffer Descriptors while they are being passed between the CPU and / or any of the ports in the USB subsystem.

The following types of Queues exist:

- Transmit Submit Queue
- Transmit Completion Queue
- Receive Submit Queue
- Receive Completion Queue

[Table 25-28](#) displays queue-endpoint assignments.

25.8.3.1.1 Transmit Submission Queue

Transmit ports use transmit submit queues to store the Packet Descriptors that are waiting to be transmitted. Each transmit endpoint has dedicated queues (2 queues per port) that are reserved exclusively for a use by a single endpoint. Multiple queues per port are allocated to facilitate quality of service (QoS) for applications that require QoS.

25.8.3.1.2 Transmit Completion Queue

Transmit ports use transmit Completion Queues to return Packet Descriptor to the CPU after the payload associated with the Packet Descriptors have been transmitted.

Transmit Completion Queues are also used to return Packet Descriptors when performing a Transmit channel teardown operation.

25.8.3.1.3 Receive Submission Queue (Free Descriptor Queue)

Receive endpoints use receive submit queues (also known as free descriptor queues) to forward received packets to the CPU. The entries on the free descriptor queues have pre-attached empty buffers whose size and location are described in the descriptor. The host is required to allocate both the descriptor and buffer and pre-link them prior to adding (submitting) a descriptor to one of the available free descriptor queue.

25.8.3.1.4 Receive Completion Queue

Receive ports use receive Completion Queues to return packet descriptors to the port after DMA packets have been received by the CPU and the payload has been unloaded.

Receive channel teardown is not necessary for receive transactions and no channel teardown information nor resource is available

The Queues Assignment within the USB Subsystem are split between Transmit and Receive operations.

- Each USB Endpoint has dedicated transmit queues that are used for DMA Packet Submission and Completion
- Each USB Endpoint has 15 dedicated Receive queues that are used for DMA Packet Completion. An additional pool of 32 queues are allocated to be used as DMA Packet Submission Queues across both USB Modules. Any one of the 32 Receive Submit queues can be used to service any receive endpoint within the USB Subsystem

Table 25-28. Queue-Endpoint Mapping

Queue Start Number	Queue Count	Queue-Endpoint Association
0	32	USB0/1 Endpoint[n] Submission Queues (Free Descriptor Queues), where n = 1,2,3...15
32	2	USB0 Endpoint 1 Transmit Submission Queues

25.8.4 Memory Regions and Linking RAM

To accomplish the linking of submitted descriptors, the queue manager will first resolve a 32-bit descriptor pointer into a 16-bit index which is used for linking and queue pointer purposes. Once the physical index information is determined, the queue manager will link that descriptor onto the descriptor chain that is maintained for that logical queue by writing the linking information out to a linking RAM which is external to the queue manager. The queue manager will also update the queue tail pointer appropriately. Since logical queues within the queue manager are maintained using linked lists, queues cannot become full and no check for fullness is required before queuing a packet descriptor.

In addition to allocating memory for Descriptors and associated buffers, the CPU is responsible for allocating additional memory for exclusive use of the CPPI DMA Queue Manager to be used as a scratch pad RAM. The queue manager uses this memory to manage states of descriptors submitted within the submit queues. The allocated memory can be a single contiguous block of memory or two separate blocks of memory. These blocks of memory are referred to as a Linking RAM Regions and should not be confused with memory regions that are used to store descriptors. That is, the use of the term *region* should be used in the context of its use.

The actual physical size of the Linking RAM region(s) to be allocated depends on the total number of descriptors defined within all memory regions. A minimum of four bytes of memory needs to be allocated for each Descriptor defined within all 16 memory regions.

The queue manager has the capability of managing up to 16 memory regions. These memory regions are used to store descriptors of variable sizes. The total number of descriptors that can be managed by the queue manager should not exceed 64K. Each memory region has descriptors of one configurable size. Descriptors with different sizes cannot be housed within a single memory region. These 64K descriptors are internally referenced in the queue manager using a 16-bit quantity index.

The information about the Linking RAM regions and the size that are allocated is communicated to the CPPI DMA via three registers dedicated for this purpose. Two of the three registers are used to store the 32-bit aligned start addresses of the Linking RAM regions. The remaining one register is used to store the size of the first Linking RAM. The linking RAM size value stored here is the number of descriptors that is to be managed by the queue manager within a particular Linking RAM region not the physical size of the buffer, which is four times the number of descriptors.

Note that application is not required to use both linking RAM regions, if the size of the Linking RAM for the first region is large enough to accommodate all descriptors defined. No linking RAM size register for linking RAM region 1 exists. The size of the second linking RAM, when used, is indirectly computed from the total number of descriptors defined less the number of descriptors managed by the first linking RAM

[Figure 25-17](#) displays the relationship between several memory regions and linking RAM.

Figure 25-17. Relationship Between Memory Regions and Linking RAM

25.8.5 Zero Length Packets

A special case is the handling of null packets with the DMA controller. Upon receiving a zero length USB packet, the XFER DMA will send a data block to the DMA controller with byte count of zero and the zero byte packet bit of INFO Word 2 set. The DMA controller will then perform normal End of Packet termination of the packet, without transferring data.

If a zero-length USB packet is received, the XDMA will send the CDMA a data block with a byte count of 0 and this bit set. The CDMA will then perform normal EOP termination of the packet without transferring data. For transmit, if a packet has this bit set, the XDMA will ignore the CPPI packet size and send a zero-length packet to the USB controller.

25.8.6 CPPI DMA Scheduler

The CPPI DMA scheduler is responsible for controlling the rate and order between the different Tx and Rx threads/transfers that are provided in the CPPI DMA controller. The scheduler table RAM exists within the scheduler.

The DMA controller maintains state information for each of the endpoints which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. A DMA scheduler is used to control the ordering and rate at which this multiplexing occurs.

25.8.6.1 CPPI DMA Scheduler Operation

Once the scheduler is enabled it will begin processing the entries in the table. When appropriate the scheduler will pass credits to the DMA controller to perform a Tx or Rx operation. The operation of the DMA controller is as follows:

1. After the DMA scheduler is enabled it begins with the table index set to 0.
2. The scheduler reads the entry pointed by the index and checks to see if the channel in question is currently in a state where a DMA operation can be accepted.
 - (a) The DMA channel must be enabled AND
 - (b) The CPPI FIFO that the channel talks to has free space on TX (FIFO full signal is not asserted) or a valid block on Rx (FIFO empty signal is not asserted)
3. If the DMA channel is capable of processing a credit to transfer a block, the DMA scheduler will issue that credit via the DMA scheduling interface which is a point to point connection between the DMA

Scheduler and the DMA Controller.

- (a) The DMA controller may not be ready to accept the credit immediately and is provided a `sched_ready` signal which is used to stall the scheduler until it can accept the credit. The DMA controller only asserts the `sched_ready` signal when it is in the IDLE state.
 - (b) Once a credit has been accepted (indicated by `sched_req` and `sched_ready` both asserted), the scheduler will increment the index to the next entry and will start again at step 2.
4. If the channel in question is not currently capable of processing a credit, the scheduler will increment the index in the scheduler table to the next entry and will start at step 2.
 5. Note that when the scheduler attempts to increment its index, to the value programmed in the table size register, the index will be reset to 0.

25.8.6.1.1 CPPI DMA Scheduler Initialization

Before the scheduler can be used, the host is required to initialize and enable the block. This initialization is performed as follows:

1. The Host initializes entries within an internal memory array in the scheduler. This array contains up to 256 entries (4 entries per table word n where $n=0-63$) and each entry consists of a DMA channel number and a bit indicating if this is a Tx or Rx opportunity. These entries represent both the order and frequency that various Tx and Rx channels will be processed. A table size of 256 entries allows channel bandwidth to be allocated with a maximum precision of 1/256th of the total DMA bandwidth. The more entries that are present for a given channel, the bigger the slice of the bandwidth that channel will be given. Larger tables can be accommodated to allow for more precision. This array can only be written by the Host, it cannot be read.
2. If the application does not need to use the entire 256 entries, firmware can initialize the portion of the 256 entries and indicate the size of the entries used by writing onto an internal register in the scheduler which sets the actual size of the array (it can be less than 256 entries).
3. The host writes an internal register bit to enable the scheduler. The scheduler is not required to be disabled in order to change the scheduler array contents.

25.8.6.1.2 CPPI DMA Scheduler Programming Examples

Consider a three endpoints use on a system with the following configurations: EP1-Tx, EP2-Rx, and EP2-Tx. Two assumptions are considered:

Case 1: Assume that you would like to service each enabled endpoints (EP1-Tx, EP2-Rx, and EP2-Tx) with equal priority.

The scheduler handles the rate at which an endpoint is serviced by the number of credits programmed (entries) for that particular endpoint within the scheduler Table Words. The scheduler has up to 256 credits that it can grant and for this example the user can configure the number of entries/credits to be anywhere from 3 to 256 with a set of 3 entries.

However, the optimum and direct programming for this scenario would be programming only the first three entries of the scheduler via scheduler Table WORD[0]. Since this case expects the Scheduler to use only the first three entries, you communicate that by programming `DMA_SCHED_CTRL.LAST_ENTRY` with 2 (that is, 3 -1). The Enabled Endpoint numbers and the data transfer direction is then communicated by programming the first three entries of WORD[0] (`ENTRY0_CHANNEL = 1: ENTRY0_RXTX = 0;` `ENTRY1_CHANNEL = 2: ENTRY1_RXTX = 1;` `ENTRY2_CHANNEL = 2: ENTRY2_RXTX = 0`). With this programming, the Scheduler will only service the first three entries in a round-robin fashion, checking each credited endpoint for transfer one after the other, and servicing the endpoint that has data to transfer.

Case 2: Enabled endpoint EP1-Tx is serviced at twice the rate as the other enabled endpoints (EP2-Rx and EP2-Tx).

The number of entries/credit that has to be awarded to EP1-Tx has to be twice as much of the others. Four entries/credits would suffice to satisfy our requirement with two credits for EP1-Tx, one credit for EP2-Rx, and one credit for EP2-Tx. This requirement is satisfied by allocating any two of the four entries to EP1-Tx endpoint. Again for this example, scheduler Table WORD[0] would suffice since it can handle the first 4 entries. Even though several scenarios exist to programming the order of service for this case, one scenario would be to allow servicing EP1-Tx to back-to-back followed by the other enabled endpoints. Program DMA_SCHED_CTRL.LAST_ENTRY with 3 (that is, 4 -1). Program WORD[0] (ENTRY0_CHANNEL = 1: ENTRY0_RXTX = 0; ENTRY1_CHANNEL = 1: ENTRY1_RXTX = 0; ENTRY2_CHANNEL = 2: ENTRY2_RXTX = 1; ENTRY3_CHANNEL = 2: ENTRY3_RXTX = 0).

25.8.7 CPPI DMA State Registers

The port must store and maintain state information for each transmit and receive port/channel. The state information is referred to as the Tx DMA State and Rx DMA State.

25.8.7.1 Transmit DMA State Registers

The Tx DMA State is a combination of control fields and protocol specific port scratchpad space used to manipulate data structures and transmit packets. Each transmit Endpoint has two queues. Each queue has a one head descriptor pointer and one completion pointer. There are thirty Tx DMA State registers; one for each port.

The following information is stored in the Tx DMA State:

- Tx Queue Head Descriptor Pointer(s)
- Tx Completion Pointer(s)
- Protocol specific control/status (port scratchpad)

25.8.7.2 Receive DMA State Registers

The Rx DMA State is a combination of control fields and protocol specific port scratchpad space used to manipulate data structures in order to receive packets. Each receive channel has only one queue. Each channel queue has one head descriptor pointer and one completion pointer. There are thirty Rx DMA State registers; one for each port/channel.

The following information is stored in the Rx DMA State:

- Rx Queue Head Descriptor Pointer
- Rx Queue Completion Pointer
- Rx Buffer Offset

25.8.8 CPPI DMA Protocols Supported

Four different type of DMA transfers protocols are supported by the DMA; Transparent, RNDIS, Generic RNDIS, and Linux CDC. The following sections will outline the details on these DMA transfer types.

25.8.8.1 Transparent DMA Transfer

Transparent Mode DMA operation is the default DMA mode where DMA interrupt is generated whenever a DMA packet is transferred. In the transparent mode, DMA packet size cannot be greater than USB MaxPktSize for the endpoint. This transfer type is ideal for transfer (not packet) sizes that are less than a max packet size.

25.8.8.1.1 Transparent DMA Transfer Setup

The following will configure all 30 ports for Transparent DMA Transfer type.

Make sure that RNDIS Mode is disabled globally. This allows the application to configure the CPPI DMA protocol in use to be configured per endpoint need. To disable RNDIS operation, clear RNDIS bit in the USB Control Registers corresponding to the USB Module (default setting), that is, CTRL0[RNDIS] = 0 and CTRL1[RNDIS] = 0.

Configure the USB0/1 Tx/Rx DMA Mode Registers (USB0/1 TX(RX)MODE0/1) for the Endpoint field in use is programmed for Transparent Mode, that is, TXMODE0/1[TXn_MODE] = 00b and RXMODE0/1[RXn_MODE] = 00b.

25.8.8.2 RNDIS DMA Transfer

RNDIS mode DMA is used for large transfers (that is, total data size to be transferred is greater than USB MaxPktSize where the MaxPktSize is a multiple of 64 bytes) that requires multiple USB packets. This is accomplished by breaking the larger packet into smaller packets, where each packet size being USB MaxPktSize except the last packet where its size is less than USB MaxPktSize, including zero bytes. This implies that multiple USB packets of MaxPktSize will be received and transferred together as a single large DMA transfer and the DMA interrupt is generated only at the end of the complete reception of DMA transfer. The protocol defines the end of the complete transfer by receiving a short USB packet (smaller than USB MaxPktSize as mentioned in USB specification 2.0). If the DMA packet size is an exact multiple of USB MaxPktSize, the DMA controller waits for a zero byte packet at the end of complete transfer to signify the completion of the transfer.

NOTE: RNDIS Mode DMA is supported only when USB MaxPktSize is an integral multiple of 64 bytes.

25.8.8.2.1 RNDIS DMA Transfer Setup

If all endpoints in use are desired to operate in RNDIS mode, it is only suffix to configure RNDIS DMA operation in RNDIS mode at the global level and application can ignore individual endpoint DMA mode configuration. This is achieved by programming CTRLR0/1[RNDIS] with a '1.'

However if DMA mode is required to be configured at the endpoint level, it is required to disable the use of RNDIS at the global level, this is achieved by clearing RNDIS bit field (CTRLR0/1[RNDIS] = 0), since global configuration over-rides endpoint configuration.

To configure RNDIS DMA mode use, configure the field that correspond to the USB module endpoint using the corresponding USB0/1 TX(RX) Mode Register, that is, TXMODE0/1[TXn_MODE] = 01b and RXMODE0/1[RXn_MODE] = 01b

25.8.8.3 Generic RNDIS DMA Transfer

Generic RNDIS DMA transfer mode is identical to the normal RNDIS mode in nearly all respects, except for the exception case where the last packet of the transfer can either be a short packet or the MaxPktSize. When the last packet size is equal to the MaxPktSize then no additional zero-byte packet is sent when using Generic RNDIS transfer. Generic RNDIS transfer makes use of a USB0/1 GENERIC RNDIS EPn Size register that must be programmed with the transfer size (in bytes) of the transfer for the USB Module (USB0 or USB1) prior to posting a transfer transaction. If the transfer size is an integer multiple of USB MaxPktSize then no additional zero-byte packet is sent when using Generic RNDIS transfer. However, if the a short packet has been sent prior to programmed size count, the transfer would end in a similar fashion an RNDIS transfer would behave. For example, if the USB MaxPktSize (Tx/RxMaxP) is programmed with a value of 64, the Generic RNDIS EP Size register for that endpoint must be programmed with a value that is an integer multiple of 64 (for example, 64, 128, 192, 256, etc.) for it behave differently than RNDIS transfer. In other words, when using Generic RNDIS mode and the DMA is tasked to transfer data transfer size that is less than or equal to the size value programmed within the USB0/1 GENERIC RNDIS EPn Size register.

This means that Generic RNDIS mode will perform data transfer in the same manner as RNDIS mode, closing the CPPI packet if a USB packet with a size less than the USB MaxPktSize size value is received. Otherwise, the packet will be closed when the value in the Generic RNDIS EP Size register is reached.

Using USB0/1 GENERIC RNDIS EPn Size register, a packet of up to 64K bytes (65536 bytes) can be transferred. This is to allow the host software to program the USB module to transfer data that is an exact multiple of the USB MaxPktSize (Tx/RxMaxP programmed value) without having to send an additional short packet to terminate.

NOTE: As in RNDIS mode, the USB max packet size (Tx/RxMaxp programmed value) of any Generic RNDIS mode enabled endpoints must be a multiple of 64 bytes. Generic RNDIS acceleration should not be enabled for endpoints where the max packet size is not a multiple of 64 bytes. Only transparent mode should be used for such endpoints.

25.8.8.3.1 Generic RNDIS DMA Transfer Setup

Disable the use of RNDIS at the global level, this is achieved by clearing RNDIS bit field (CTRLR0/1[RNDIS]=0), since global configuration over-rides endpoint configuration.

Configure the field that correspond to the USB module endpoint using the corresponding USB0/1 TX(RX) Mode Register, that is, TXMODE0/1[TXn_MODE] = 11b and RXMODE0/1[RXn_MODE] = 11b.

25.8.8.4 Linux CDC DMA Transfer

Linux CDC DMA transfer mode acts in the same manner as RNDIS packets, except for the case where the last data matches the max USB packet size requiring additional zero-byte packet transfer in RNDIS mode. If the last data packet of a transfer is a short packet where the data size is greater than zero and less the USB MaxPktSize, then the behavior of the Linux CDC DMA transfer type is identical with the RNDIS DMA transfer type. The only exception is when the short packet length terminating the transfer is a Null Packet. In this case, instead of transferring the Null Packet, it will transfer a data packet of size 1 byte with the data value of 00h.

In transmit operation, if an endpoint is configured or CDC Linux mode, upon receiving a Null Packet from the CPPI DMA, the XFER DMA will then generate a packet containing 1 byte of data, whose value is 00h, indicating the end of the transfer. During receive operation, the XFER DMA will recognize the one byte zero packet as a termination of the data transfer, and sends a block of data with the EOP indicator set and a byte count of one to the CPPI DMA controller. The CPPI DMA realizing the end of the transfer termination will not update/increase the packet size count of the Host Packet Descriptor.

25.8.8.4.1 Linux CDC DMA Transfer Setup

Disable the use of RNDIS at the global level, this is achieved by clearing RNDIS bit field (CTRLR0/1[RNDIS]=0), since global configuration over-rides endpoint configuration.

Configure the field that correspond to the USB module endpoint using the corresponding USB0/1 TX(RX) Mode Register, that is, TXMODE0/1[TXn_MODE] = 10b and RXMODE0/1[RXn_MODE] = 10b.

25.8.9 USB Data Flow Using DMA

The necessary steps required to perform a USB data transfer using the CPPI 4.1 DMA is expressed using an example for both transmit and receive cases. Assume USB0 is ready to perform a USB data transfer of size 608 bytes (see [Figure 25-18](#)).

The 608 bytes data to be transferred is described using three buffer descriptors with a buffer size of 256 bytes.

The following nomenclature is Defined:

PD — Host Packet Descriptor

PPD — Pointer to Host Packet Descriptor

BD — Buffer Descriptor or Host Buffer Descriptor

PBD — Pointer to Host Buffer Descriptor

DB — Data Buffer Size of 256 Bytes

TXSQ — Transmit Submit Queue

TXCQ — Transmit Completion Queue

RXCQ — Receive Completion Queue

RXSQ — Receive Submit Queue (Receive Free/Buffer Descriptor Queue)

Figure 25-18. High-level Transmit and Receive Data Transfer Example

Example assumptions:

- The CPPI data buffers are 256 bytes in length.
- USB0 module is to be used to perform this transfer. Note that the steps required is similar for USB1 use.
- The USB0 endpoint 1 Tx and Rx endpoint 1 size are programmed to handle max USB packet size of 512 bytes.
- A single transfer length is 608 bytes.
- The SOP offset is 0.

The above translates to the following multi-descriptor setup:

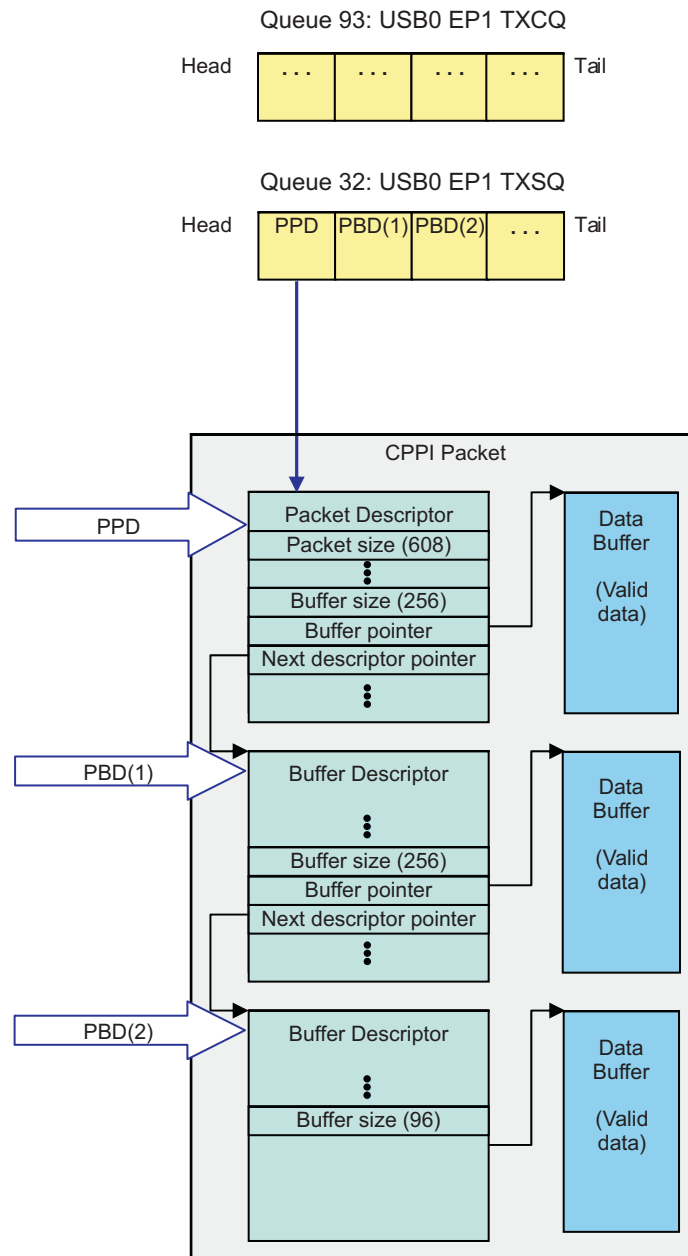

25.8.9.1 Transmit USB Data Flow Using DMA

The transmit descriptors and queue status configuration prior to the transfer taking place is shown in Figure 25-19.

Transmit Case

- One packet descriptor with DMA packet length field of 608 bytes and a data Buffer of size 256 Bytes linked to the 1st buffer descriptor.
- One buffer descriptor with buffer size of 256 bytes.
- One buffer descriptor with a data buffer size of 96 bytes.

Figure 25-19. Transmit Descriptors and Queue Status Configuration

25.8.9.1.1 Transmit Initialization (Step 1)

The CPU performs the following steps for transmit initialization:

1. Initializes Memory Region 0 base address and Memory Region 0 size, Link RAM0 Base address, Link RAM0 data size, and Link RAM1 Base address.
2. Creates Packet Descriptors, Buffer Descriptors, and data buffers in main memory and link as indicated in [Figure 25-20](#).
3. Initializes and configures the Queue Manager, Channel Setup, DMA Scheduler, and the USB Controller.
4. Adds (pushes) the Pointer to the Packet Descriptor and the two Pointers to the Buffer Descriptors to the Transmit Submit Queue by writing the Packet Descriptor address to the Transmit Submit Queue Control D Register.

[Figure 25-20](#) captures the Buffer Descriptor/Data Buffer pair in main memory and later submitted within the Transmit Submit Queue.

Figure 25-20. Transmit USB Data Flow Example (Initialization)

25.8.9.1.2 CDMA and XDMA Transfer Packet Data Into Endpoint FIFO (Step 2)

The steps for CDMA and XDMA to transfer packet data into endpoint FIFO are as follows:

1. The Queue Manager informs the CDMA Scheduler that the Transmit Submit Queue is not empty.
2. CDMA Scheduler checks that the CPPI FIFO FIFO_full is not asserted, then issues a credit to the CDMA.
3. CDMA reads the Packet Descriptor pointer (PPD) and descriptor size from the queue manager
4. For each 64-byte block of data in the DMA Packet Descriptor payload
 - (a) The CDMA transfers a max burst of 64-byte block from the data to be transferred in main memory to the CPPI FIFO
 - (b) The XDMA sees FIFO_empty not asserted and transfers 64-byte block from CPPI FIFO to USB Controller Endpoint FIFO.
5. The CDMA reads the first Buffer Descriptor Pointer.
6. For each 64-byte block of data in the Buffer Descriptor payload:
 - (a) The CDMA transfers a max burst of 64-byte block from the data to be transferred in main memory to the CPPI FIFO.
 - (b) The XDMA sees FIFO_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.

7. The CDMA reads the second Buffer Descriptor Pointer
8. For each 64-byte block of data in the Buffer Descriptor Payload:
 - (a) The CDMA transfers a max burst of 64-byte block from the data to be transferred in main memory to the CPPI FIFO.
 - (b) The XDMA sees FIFO_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.
 - (c) The CDMA transfers the last remaining 32-byte from the data to be transferred in main memory to the CPPI FIFO.
 - (d) The XDMA sees FIFO_empty not asserted and transfers 32-byte block from CPPI FIFO to Endpoint FIFO.

25.8.9.1.3 USB 2.0 Core Transmits USB Packets for Tx (Step 3)

1. Once the XDMA has transferred enough 64-byte blocks of burst of data from the CPPI FIFO to fill the Endpoint FIFO (accumulated 512 bytes), it signals the USB 2.0 Controller that a TX packet is ready (sets the endpoint's TxPktRdy bit).
2. The USB 2.0 Controller will transmit the packet from the Endpoint FIFO out on the USB BUS when it receives a corresponding IN request from the attached USB Host.
3. After the USB packet is transferred, the USB 2.0 Controller issues a TX DMA_req to the XDMA.
4. This process is repeated until (the above steps '1', '2', and '3') the entire packet has been transmitted. The XDMA will also generate the required termination packet depending on the termination mode configured for the endpoint.

25.8.9.1.4 Return Packet to Completion Queue and Interrupt CPU for Tx (Step 4)

1. After all data for the packet has been transmitted (as specified by the packet size field), the CDMA will write the pointer of the Packet Descriptor only to the TX Completion Queue specified in the return queue manager / queue number fields of the packet descriptor.
2. The Queue Manager then indicates the status of the TXSQ (empty) to the CDMAS and the TXCQ to the CPU via an interrupt.

25.8.9.2 Receive USB Data Flow Using DMA

The receive buffer descriptors and queue status configuration prior to the transfer taking place is shown in [Figure 25-21](#).

Receive Case

- Two buffer descriptors with a 256 byte data buffer
- One buffer descriptor with a 96 byte data buffer

For this example since each data buffer size is 256 bytes, we would require a minimum of three descriptors that would define data buffer size of 608 bytes. The receive setup is as follows:

Figure 25-21. Receive Buffer Descriptors and Queue Status Configuration

25.8.9.2.1 Receive Initialization (Step 1)

1. The CPU initializes Queue Manager with the Memory Region 0 base address and Memory Region 0 size, Link RAM0 Base address, Link RAM0 data size, and Link RAM1 Base address.
2. The CPU creates Buffer Descriptors, and data buffers in main memory and link them.
3. CPU then initializes the Receive Completion Queue and configures the Queue Manager, Channel Setup, and DMA Scheduler.
4. The CPU then adds (pushes) the pointers of three Buffer Descriptors into the Receive Submit Queue by writing onto CTRL D register.

Figure 25-22 displays receive operation Initialization.

Figure 25-22. Receive USB Data Flow Example (Initialization)

25.8.9.2.2 USB 2.0 Core Receives a Packet, XDMA Starts Data Transfer for Receive (Step 2)

1. The USB 2.0 Controller receives a USB packet from the USB Host and stores it in the Controller Endpoint FIFO.
2. It then asserts a DMA_req to the XDMA informing it that data is available in the Endpoint FIFO.
3. The XDMA verifies the corresponding CPPI FIFO is not full via the FIFO_full signal, then starts transferring 64-byte data blocks from the Endpoint FIFO into the CPPI FIFO.

25.8.9.2.3 CDMA Transfers Data from SSRAM / PPU to Main Memory for Receive (Step 3)

1. The CDMA Scheduler see FIFO_empty de-asserted (there is RX data in the FIFO) and issues a transaction credit to the CDMA.
2. The CDMA begins packet reception by fetching the first Pointer to the Packet Descriptor from the Queue Manager using the Receive Submit Queue index that was initialized in the RX port DMA state for that channel.
3. The CDMA will then begin writing the 64-byte block of packet data into this Data Buffer.
4. The CDMA will continue filling the buffer with additional 64-byte blocks of data from the CPPI FIFO and will fetch additional pointers to Buffer Descriptors as needed using the Receive Submit Queue 1, 2, and 3 indexes for the 2nd, 3rd, and remaining buffers in the packet. After each buffer is filled, the CDMA writes the buffer descriptor to main memory.

25.8.9.2.4 CDMA Completes the Packet Transfer for Receive (Step 4)

1. After the entire DMA packet has been received, the CDMA writes the packet descriptor to main memory.
2. The CDMA then writes the packet descriptor to the Receive Completion Queue specified in the Queue Manager / Queue Number fields in the RX Global Configuration Register.
3. The Queue Manager then indicates the status of the Receive Completion Queue to the CPU via an interrupt.
4. The CPU can then process the received packet by popping the received packet information from the Receive Submit Queue and accessing the packet's data from main memory.

25.9 Registers

The USB20OTG_REGS submodule contains the MMRs that are used in the submodules within the USB controller. The complete list of registers is listed in the following sections.

The registers required to access and control the USBSS are partitioned in blocks based on their functions. [Table 25-29](#) lists the starting base offset and size of the USBSS and its submodules.

The USBSS base address is 4740 0000h.

Table 25-29. USBSS Submodule Base Addresses and Size

Submodule Name	Submodule Base Address Offset	Size (Kbytes)
USBSS registers	0000 0000h	1000h
USB0 controller registers	0000 1000h	800h
USB1 controller registers	0000 1800h	800h
CPPI DMA controller registers	0000 2000h	1000h
CPPI DMA scheduler registers	0000 3000h	1000h
CPI DMA Queue Manager registers	0000 4000h	4000h

25.9.1 USBSS Registers

The USBSS registers contain the registers that are used to control at the global level and applies to all submodules. [Table 25-30](#) lists the registers for the USBSS submodule.

Table 25-30. USBSS Registers

Address Offset	Acronym	USBSS Register
0h	REVREG	USBSS REVISION
10h	SYSCONFIG	USBSS SYSCONFIG
20h	EOI	USBSS IRQ_EOI
24h	IRQSTATRAW	USBSS IRQ_STATUS_RAW
28h	IRQSTAT	USBSS IRQ_STATUS
2Ch	IRQENABLER	USBSS IRQ_ENABLE_SET
30h	IRQCLEARR	USBSS IRQ_ENABLE_CLR
100h	IRQDMATHOLDTX00	USBSS IRQ_DMA_THRESHOLD_TX0_0
104h	IRQDMATHOLDTX01	USBSS IRQ_DMA_THRESHOLD_TX0_1
108h	IRQDMATHOLDTX02	USBSS IRQ_DMA_THRESHOLD_TX0_2
10Ch	IRQDMATHOLDTX03	USBSS IRQ_DMA_THRESHOLD_TX0_3

244h	IRQFRAMEENABLE1	USBSS_IRQ_FRAME_ENABLE_1

25.9.1.1 USBSS Revision Register (REVREG)

The revision register contains the major and minor revisions for the USB subsystem module. The USBSS revision register is shown in [Figure 25-23](#) and described in [Table 25-31](#).

Figure 25-23. USBSS Revision Register (REVREG)

LEGEND: R = Read only; -n = value after reset

Table 25-31. USBSS Revision Register (REVREG) Field Description

Bits	Field	Value	Description
31-30	Scheme	1	Used to distinguish between old scheme and current. Highlander 0.8
29-28	Reserved	0	Reserved
27-16	func	EA2h	Function indicates a software compatible module family.
15-11	R_rtl	1	RTL revision. Will vary depending on release.
10-8	X_major	0	Major revision.
7-6	Custom	0	Custom revision
5-0	Y_minor	Bh	Minor revision.

25.9.1.2 USBSS SYSCONFIG Register (SYSCONFIG)

The SYSCONFIG register is the clock management configuration register for the USBSS.

The clock enable bits 8 to 11 should only be configured/modified during the firmware initialization stage of the USBSS. In other words, these bits should not be modified while the system is running or after enabling the clock. These bits control the clock generation modules. Dynamically setting these bits can disable the power management logic. The USBSS SYSCONFIG register is shown in shown in [Figure 25-24](#) and described in [Table 25-32](#).

Figure 25-24. USBSS SYSCONFIG Register (SYSCONFIG)

31	Reserved				18	17	16

Table 25-32. USBSS SYSCONFIG Register (SYSCONFIG) Field Descriptions (continued)

Bits	Field	Value	Description
0	Soft reset		Software reset of USBSS, USB0, and USB1 modules
		Write 0	No action
		Write 1	Initiate software reset
		Read 0	Reset done, no action
		Read 1	Reset ongoing

25.9.1.3 USBSS End of Interrupt Register (EOI)

The USBSS end of interrupt register (EOI) allows the CPU to acknowledge completion of an interrupt by writing 0, zero, to the EOI_VECTOR field. An eoi_write signal will be generated and another interrupt will be triggered if interrupt sources remain.

This register will be reset one cycle after it has been written to. The USBSS end of interrupt register is shown in [Figure 25-25](#) and described in [Table 25-33](#).

Figure 25-25. USBSS End of Interrupt Register (EOI)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-33. USBSS End of Interrupt Register (EOI) Field Descriptions

Bits	Field	Description
31-1	Reserved	Always read as 0. Writes have no effect.
0	EOI_VECTOR	EOI for USBSS interrupt

25.9.1.4 USBSS IRQ_STATUS_RAW (IRQSTATRAW)

The USBSS IRQSTATRAW register allows the USBSS interrupt sources to be manually triggered when writing a 1 to a specific bit. A read from this register returns the USBSS interrupt event pending value. This register is shown in [Figure 25-26](#) and described in [Table 25-34](#).

General actions per bit:

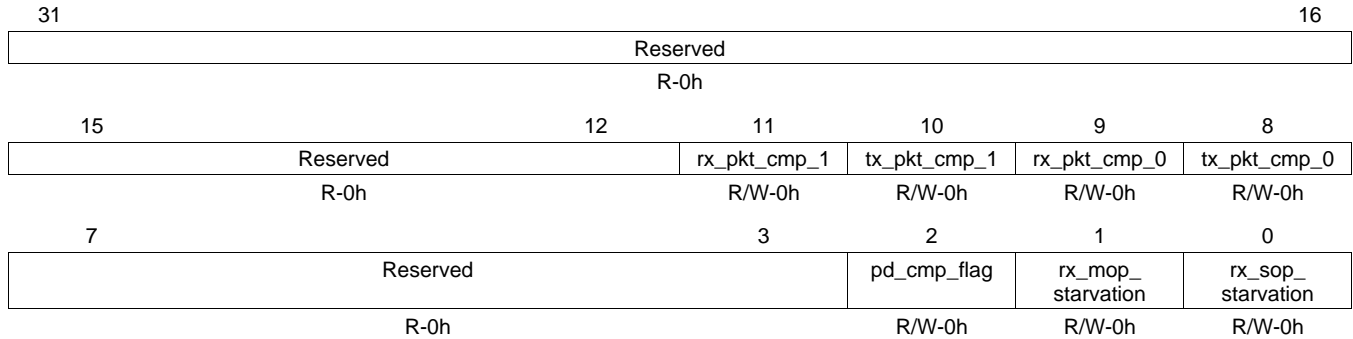

Write 0: No action

Write 1: Set event

Read 0: No event pending

Read 1: Event pending

Figure 25-26. USBSS IRQ_STATUS_RAW (IRQSTATRAW)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-34. USBSS IRQ_STATUS_RAW (IRQSTATRAW) Field Descriptions

Bits	Field	Description
31-12	Reserved	Always read as 0. Writes have no effect.
11	rx_pkt_cmp_1	Interrupt status for USB1 Rx CPPI DMA packet completion status
10	tx_pkt_cmp_1	Interrupt status for USB1 Tx CPPI DMA packet completion status
9	rx_pkt_cmp_0	Interrupt status for USB0 Rx CPPI DMA packet completion status
8	tx_pkt_cmp_0	Interrupt status for USB0 Tx CPPI DMA packet completion status
7-3	Reserved	Always read as 0. Writes have no effect.
2	pd_cmp_flag	Interrupt status when the packet is completed and the Packet Descriptor is pushed into the queue manager
1	rx_mop_starvation	Interrupt status when queue manager cannot allocate an Rx buffer in the middle of a packet.
0	rx_sop_starvation	Interrupt status when queue manager cannot allocate an Rx buffer at the start of a packet.

25.9.1.5 USBSS IRQ_STATUS Register (IRQSTAT)

The USBSS IRQSTAT register contains the interrupt sources status of the enabled interrupt. IRQSTAT register is a subset of IRQSTATRAW register. Writing a '1' to a bit field will clear a pending interrupt event. This register is shown in [Figure 25-27](#) and described in [Table 25-35](#).

General actions per bit:

Write 0: No action

Write 1: Clear event

Read 0: No event pending

Read 1: Event pending

Figure 25-27. USBSS IRQ_STATUS (IRQSTAT)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-35. USBSS IRQ_STATUS (IRQSTAT) Field Descriptions

Bits	Field	Description
31-12	Reserved	Always read as 0. Writes have no effect.
11	rx_pkt_cmp_1	Interrupt status for USB1 Rx CPPI DMA packet completion status
10	tx_pkt_cmp_1	Interrupt status for USB1 Tx CPPI DMA packet completion status
9	rx_pkt_cmp_0	Interrupt status for USB0 Rx CPPI DMA packet completion status
8	tx_pkt_cmp_0	Interrupt status for USB0 Tx CPPI DMA packet completion status
7-3	Reserved	Always read as 0. Writes have no effect.
2	pd_cmp_flag	Interrupt status when the packet is completed and the Packet Descriptor is pushed into the queue manager.
1	rx_mop_starvation	Interrupt status when queue manager cannot allocate an Rx buffer in the middle of a packet.
0	rx_sop_starvation	Interrupt status when queue manager cannot allocate an Rx buffer at the start of a packet.

25.9.1.6 USBSS IRQ_ENABLE_SET Register (IRQENABLER)

The USB interrupt mask set register (IRQENABLER) allows the USB interrupts to be enabled (unmasked). A read from this register returns the USB interrupts enabled.

The USBSS IRQ_ENABLE_SET register is shown in [Figure 25-28](#) and described in [Table 25-36](#).

General actions per bit:

Write 0: No action

Write 1: Interrupt enabled

Read 0: Interrupt disabled

Read 1: Interrupt enabled

Figure 25-28. USBSS IRQ_ENABLE_SET Register (IRQENABLER)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-36. USBSS IRQ_ENABLE_SET Register (IRQENABLER) Field Descriptions

Bits	Field	Description
31-12	Reserved	Always read as 0. Writes have no effect.
11	rx_pkt_cmp_1	Interrupt enable for USB1 Rx CPPI DMA packet completion status
10	tx_pkt_cmp_1	Interrupt enable for USB1 Tx CPPI DMA packet completion status
9	rx_pkt_cmp_0	Interrupt enable for USB0 Rx CPPI DMA packet completion status
8	tx_pkt_cmp_0	Interrupt enable for USB0 Tx CPPI DMA packet completion status
7-3	Reserved	Always read as 0. Writes have no effect.
2	pd_cmp_flag	Interrupt enable when the packet is completed and the Packet Descriptor is pushed into the queue manager.
1	rx_mop_starvation	Interrupt enable when queue manager cannot allocate an Rx buffer in the middle of a packet.
0	rx_sop_starvation	Interrupt enable when queue manager cannot allocate an Rx buffer at the start of a packet.

25.9.1.7 USBSS IRQ_ENABLE_CLR Register (IRQCLEARR)

The USBSS IRQCLEARR register allows the USBSS interrupt sources to be masked when writing a 1 to a specific bit. A read of this register returns the USBSS interrupt enabled value.

The USBSS IRQ_ENABLE_CLR register is shown in [Figure 25-29](#) and described in [Table 25-37](#).

General actions per bit:

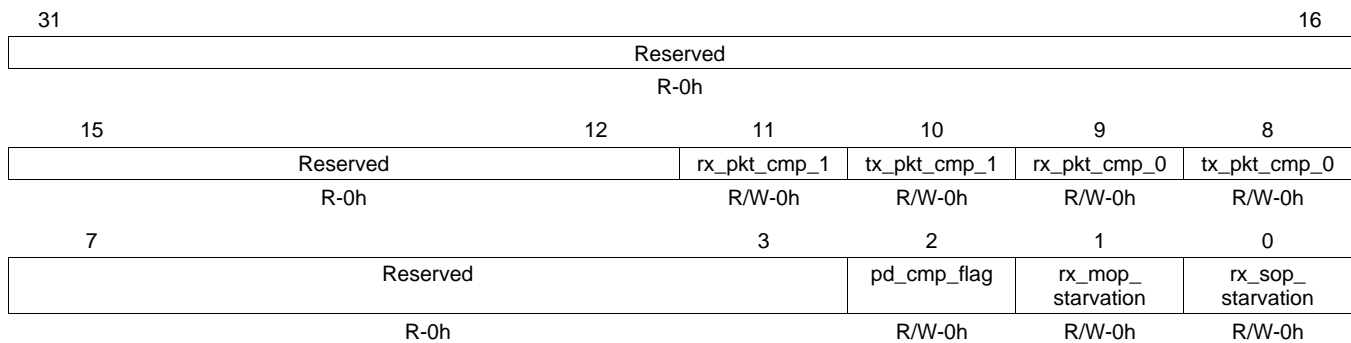

Write 0: No action

Write 1: Disable interrupt

Read 0: Interrupt disabled

Read 1: Interrupt enabled

Figure 25-29. USBSS IRQ_ENABLE_CLR Register (IRQCLEARR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-37. USBSS IRQ_ENABLE_CLR Register (IRQCLEARR) Field Descriptions

Bits	Field	Description
31-12	Reserved	Always read as 0. Writes have no effect.
11	rx_pkt_cmp_1	Interrupt enable for USB1 Rx CPPI DMA packet completion status
10	tx_pkt_cmp_1	Interrupt enable for USB1 Tx CPPI DMA packet completion status
9	rx_pkt_cmp_0	Interrupt enable for USB0 Rx CPPI DMA packet completion status
8	tx_pkt_cmp_0	Interrupt enable for USB0 Tx CPPI DMA packet completion status
7-3	Reserved	Always read as 0. Writes have no effect.
2	pd_cmp_flag	Interrupt enable when the packet is completed and the Packet Descriptor is pushed into the queue manager.
1	rx_mop_starvation	Interrupt enable when queue manager cannot allocate an Rx buffer in the middle of a packet.
0	rx_sop_starvation	Interrupt enable when queue manager cannot allocate an Rx buffer at the start of a packet.

25.9.1.8 USBSS IRQ_DMA_THRESHOLD_TX0_0 Register (IRQDMATHOLDTX00)

The USBSS IRQDMATHOLDTX00 register defines the size of the four DMA thresholds for interrupt pacing for USB0. Each threshold contains an 8-bit unsigned number and can range from 0 to 255. A possible interrupt can be triggered if the count for that specific endpoint has exceeded the value of the threshold. The counter for the compared value is also an 8-bit unsigned number; therefore, setting the threshold to 255 prevents the possibility of a trigger.

The USBSS IRQ_DMA_THRESHOLD_TX0_0 register is shown in [Figure 25-30](#) and described in [Table 25-38](#).

25.9.1.24 USBSS IRQ_DMA_ENABLE_0 Register (IRQDMAENABLE0)

The USBSS IRQDMAENABLE0 contains 32 enables. Sixteen enables are assigned to the 16 endpoints associated with the tx_pkt_cmp_0 interrupt and 16 enables are assigned to the 16 endpoints associated with the rx_pkt_cmp_0 interrupt. Endpoint 0 for both the tx and rx does not exist; but it is included for completeness of this register.

If the enable is set; then that specific endpoint can generate an interrupt if the event pending count has exceeded the threshold.

If the enable is cleared; then that specific endpoint cannot generate an interrupt regardless if the event pending count has exceeded the threshold or not.

The USBSS IRQ_DMA_ENABLE_0 Register is shown in [Figure 25-46](#) and described in [Table 25-54](#).

25.9.1.26 USBSS IRQ_FRAME_THRESHOLD_TX0_0 Register (IRQFRAMETHOLDTX00)

The USBSS IRQFRAMETHOLDTX00 register defines the size of the four FRAME thresholds for interrupt pacing for USB0. Each threshold contains is an 8-bit unsigned number and can range from 0 to 255. A possible interrupt can be triggered if the count for that specific endpoint has exceeded the value of the threshold. The counter for the compared value is also an 8-bit unsigned number; therefore, setting the threshold to 255 prevents the possibility of a trigger.

The USBSS IRQ_FRAME_THRESHOLD_TX0_0 register is shown in [Figure 25-48](#) and described in [Table 25-56](#).

Figure 25-48. USBSS IRQ_FRAME_THRESHOLD_TX0_0 Register (IRQFRAMETHOLDTX00)

25.9.1.34 USBSS IRQ_FRAME_THRESHOLD_TX1_0 Register (IRQFRAMETHOLDTX10)

The USBSS IRQFRAMETHOLDTX10 register defines the size of the four FRAME thresholds for interrupt pacing for USB1. Each threshold contains is an 8-bit unsigned number and can range from 0 to 255. A possible interrupt can be triggered if the count for that specific endpoint has exceeded the value of the threshold. The counter for the compared value is also an 8-bit unsigned number; therefore, setting the threshold to 255 prevents the possibility of a trigger.

The USBSS IRQ_FRAME_THRESHOLD_TX1_0 register is shown in [Figure 25-56](#) and described in [Table 25-64](#).

15-8	frame_thres_rx1_13	FRAME threshold value for rx_pkt_cmp_0 for USB1 Endpoint 13
7-0	frame_thres_rx1_12	FRAME threshold value for rx_pkt_cmp_0 for USB1 Endpoint 12

25.9.1.42 USBSS IRQ_FRAME_ENABLE_0 Register (IRQFRAMEENABLE0)

The USBSS IRQFRAMEENABLE0 register contains 32 enables for USB0. Sixteen enables are assigned to the 16 endpoints associated with the tx_pkt_cmp_0 interrupt and 16 enables are assigned to the 16 endpoints associated with the rx_pkt_cmp_0 interrupt. Endpoint 0 for both the tx and rx does not exist; but it is included for completeness of this register.

If the enable is set; then that specific endpoint can generate an interrupt if the frame count has exceeded the threshold. If the enable is not set; then no hardware interrupt will be generated for that specific endpoint. It is still possible to generate the interrupt via software.

If the enable is cleared; then that specific endpoint cannot generate an interrupt regardless if the frame count has exceeded the threshold or not.

The USBSS IRQ_FRAME_ENABLE_0 register is shown in [Figure 25-64](#) and described in [Table 25-72](#).

0	Reserved	Always read as 0. Writes have no effect.

25.9.2 USB0 and USB1 Controller Registers

The USB0 and USB1 register descriptions are included in this section.

25.9.2.1 USB0 Controller Registers

Table 25-74 lists the registers for the USB0 Controller submodule.

Table 25-74. USB0 Controller Registers

Address Offset	Acronym	USB0 Controller Register
1000h	USB0REV	USB0 REVISION
1014h	USB0CTRL	USB0 Control Register
1018h	USB0STAT	USB0 Status Register
1020h	USB0IRQMSTAT	USB0 IRQ_MERGED_STATUS
1024h	USB0IRQEOI	USB0 IRQ_EOI
1028h	USB0IRQSTATRAW0	USB0 IRQ_STATUS_RAW_0
102Ch	USB0IRQSTATRAW1	USB0 IRQ_STATUS_RAW_1
1030h	USB0IRQSTAT0	USB0 IRQ_STATUS_0
1034h	USB0IRQSTAT1	USB0 IRQ_STATUS_1
1038h	USB0IRQENABLESET0	USB0 IRQ_ENABLE_SET_0
103Ch	USB0IRQENABLESET1	USB0 IRQ_ENABLE_SET_1
1040h	USB0IRQENABLECLR0	USB0 IRQ_ENABLE_CLR_0
1044h	USB0IRQENABLECLR1	USB0 IRQ_ENABLE_CLR_1
1070h	USB0TXMODE	USB0 Tx Mode Register
1074h	USB0RXMODE	USB0 Rx Mode Register
1080h	USB0GENRNDISEP1	USB0 Generic RNDIS Size EP1
1084h	USB0GENRNDISEP2	USB0 Generic RNDIS Size EP2
1088h	USB0GENRNDISEP3	USB0 Generic RNDIS Size EP3
108Ch	USB0GENRNDISEP4	USB0 Generic RNDIS Size EP4
1090h	USB0GENRNDISEP5	USB0 Generic RNDIS Size EP5
1094h	USB0GENRNDISEP6	USB0 Generic RNDIS Size EP6
1098h	USB0GENRNDISEP7	USB0 Generic RNDIS Size EP7
109Ch	USB0GENRNDISEP8	USB0 Generic RNDIS Size EP8
10A0h	USB0GENRNDISEP9	USB0 Generic RNDIS Size EP9
10A4h	USB0GENRNDISEP10	USB0 Generic RNDIS Size EP10
10A8h	USB0GENRNDISEP11	USB0 Generic RNDIS Size EP11
10ACh	USB0GENRNDISEP12	USB0 Generic RNDIS Size EP12
10B0h	USB0GENRNDISEP13	USB0 Generic RNDIS Size EP13
10B4h	USB0GENRNDISEP14	USB0 Generic RNDIS Size EP14
10B8h	USB0GENRNDISEP15	USB0 Generic RNDIS Size EP15
10D0h	USB0AUTOREQ	USB0 Auto Req Register
10D4h	USB0SRPFXITIME	USB0 SRP Fix Time
10D8h	USB0TDOWN	USB0 Teardown Register
10DCh		USB0 Threshold XDMA Idle Register
10E0h	USB0UTMI	USB0 PHY UTMI Register
10E4h	USB0UTMILB	USB0 MGC UTMI Loopback Register
10E8h	USB0MODE	USB0 Mode Register
1400h–1468Ch	-	USB0 Mentor Core Registers/FIFOs
146Ch	USB0HWVVERS	USB0 Mentor Core HWVVERS Register (see Section 25.9.7.2.6)
0x1470 – 0x159C	-	USB0 Mentor Core Registers/FIFOs

25.9.2.1.1 USB0 Revision Register (USB0REV)

The USB0 revision register (USB0REV) register contains the major and minor revisions for the USB0 module. The USB0 revision register is shown in [Figure 25-66](#) and described in [Table 25-75](#).

Figure 25-66. USB0 Revision Register (USB0REV)

31	30	29	28	27											
Scheme		Reserved		func											
R-1		R-0		R-EA2h											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R_rtl				X_major			Custom			Y_minor					
R-1				R-0			R-0			R-0					

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-75. USB0 Revision Register (USB0REV) Field Descriptions

Bits	Field	Value	Description
31-30	Scheme	1	Used to distinguish between old scheme and current Highlander 0.8
29-28	Reserved	0	Reserved
27-16	func	EA2h	Function indicates a software compatible module family.
15-11	R_rtl	1h	RTL revision. Will vary depending on release.
10-8	X_major	0h	Major revision
7-6	Custom	0h	Custom revision
5-0	Y_minor	0h	Minor revision

25.9.2.1.2 USB0 Control Register (USB0CTRL)

The USB0 control register (USB0CTRL) allows the CPU to control various aspects of the module. If uint is set high, then the Mentor controller generic interrupt for USB[9] will be generated (if enabled). This requires software to read the Mentor controller's registers to determine which interrupt USB[0] to USB[7] occurred. If uint is set low, then the usb20otg_f module will automatically read the Mentor controller's registers and set the appropriate interrupt USB[0] to USB[7] (if enabled). The generic interrupt for USB[9] will not be generated.

The USB0 control register is shown in [Figure 25-67](#) and described in [Table 25-76](#).

Figure 25-67. USB0 Control Register (USB0CTRL)

31	30	29					16

R-0h	R/W-0h	R/W-0h	R/W-0h	R-0h	R/W-0h	R/W1-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-76. USB0 Control Register (USB0CTRL) Field Descriptions

Bits	Field	Value	Description
31	dis_deb		Disable the VBUS debouncer circuit fix
30	dis_srp		Disable the OTG Session Request Protocol (SRP) AVALID circuit fix. When enabled (=0) this allows additional time for the VBUS signal to be measured against the VBUS thresholds. The time is specified in the USB0 SRP Fix Time Register.
29-6	Reserved		Always read as 0. Writes have no effect.
5	soft reset isolation		Soft reset isolation. When high this bit forces all USB0 signals that connect to the USBSS to zeros during a soft reset via bit 0 of this register. This bit should be set high prior to setting bit 0 and cleared after bit 0 is cleared.
4	rndis		Global RNDIS mode enable for all endpoints
3	uint	1 0	USB non-Highlander interrupt enable Non-Highlander Highlander
2	Reserved		Always read as 0. Writes have no effect.
1	clkfack		Clock stop fast ack enable
0	soft reset	Write 0 Write 1 Read 0 Read 1	Software reset of USB0 No action Initiate software reset Reset done, no action Reset ongoing

25.9.2.1.3 USB0 Status Register (USB0STAT)

The USB0 status register (USB0STAT) allows the CPU to check the voltage state level of USB0_DRVVBUS pin. The USB0 status register is shown in [Figure 25-68](#) and described in [Table 25-77](#).

Figure 25-68. USB0 Status Register (USB0STAT)

31	Reserved	1	0
		R-0h	drvbus R-0h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-77. USB0 Status Register (USB0STAT) Field Descriptions

Bits	Field	Description
31-1	Reserved	Always read as 0. Writes have no effect.
0	drvbus	Current USB0_DRVVBUS value

25.9.2.1.4 USB0 IRQ_MERGED_STATUS Register (USB0IRQMSTAT)

The USB0 IRQ_MERGED_STATUS register (USB0IRQMSTAT) register contains a merged status for all the events for USB0. This register optimizes software accesses in a module where a large number of events are associated to one IRQ line. The merged status is read-only, and does not need to be actively cleared like the IRQ status. It will clear automatically.

The USB0 IRQ_MERGED_STATUS register is shown in [Figure 25-69](#) and described in [Table 25-78](#).

Figure 25-69. USB0 IRQ_MERGED_STATUS Register (USB0IRQMSTAT)

31	Reserved	2	1	0
		R-0h	Bank1 R-0h	Bank1 R-0h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-78. USB0 IRQ_MERGED_STATUS Register (USB0IRQMSTAT) Field Descriptions

Bits	Field	Unit	Description
31-2	Reserved		Always read as 0. Writes have no effect.
1	Bank1	0	No events pending from IRQ_STATUS_1
		1	At least one event is pending from IRQ_STATUS_1
0	Bank0	0	No events pending from IRQ_STATUS_0
		1	At least one event is pending from IRQ_STATUS_0

25.9.2.1.5 USB0 IRQ_EOI Register (USB0IRQEOI)

The USB0 IRQ_EOI register (USB0IRQEOI) allows the CPU to acknowledge completion of an interrupt by writing to the EOI. An eoi_write signal will be generated and another interrupt will be triggered if interrupt sources remain.

This register will be reset one cycle after it has been written to.

The USB0 IRQ_EOI register is shown in [Figure 25-70](#) and described in [Table 25-79](#).

Figure 25-70. USB0 IRQ_EOI Register (USB0IRQEOI)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-79. USB0 IRQ_EOI Register (USB0IRQEOI) Field Descriptions

Bits	Field	Description
31-1	Reserved	Always read as 0. Writes have no effect.
0	EOI for USB0	EOI for USB0 interrupt

25.9.2.1.6 USB0_IRQ_STATUS_RAW_0 Register (USB0IRQSTATRAW0)

The USB0_IRQ_STATUS_RAW_0 register (USB0IRQSTATRAW0) allows the USB0 interrupt sources to be manually triggered when writing a 1 to a specific bit. A read of this register returns the USB0 interrupt event pending value.

General actions per bit:

Write 0: No action

Write 1: Set event

Read 0: No event pending

Read 1: Event pending

The USB0_IRQ_STATUS_RAW_0 register is shown in [Figure 25-71](#) and described in [Table 25-80](#).

25.9.2.1.10 USB0_IRQ_ENABLE_SET_0 Register (USB0IRQENABLESET0)

The USB0_IRQ_ENABLE_SET_0 register (USB0IRQENABLESET0) allows the USB0 interrupt sources to be manually enabled when writing a 1 to a specific bit. A read of this register returns the USB0 interrupt enabled value. General actions per bit:

Write 0: No action

Write 1: Interrupt enabled

Read 0: Interrupt disabled

Read 1: Interrupt enabled

The USB0_IRQ_ENABLE_SET_0 register is shown in [Figure 25-75](#) and described in [Table 25-84](#).

25.9.2.1.16 USB0 Generic RNDIS EPn Size Register (USB0GENRNDISEPn)

The USB0 generic RNDIS EPn size register (USB0GENRNDISEPn) is programmed with a RNDIS packet size in bytes. When EP(n) is in Generic RNDIS mode, the received USB packets will be collected into a single CPPI packet that is completed when the number of bytes equal to the value of this register has been received, or a "short" packet is received. Note that this register must be programmed with a value that is an integer multiple of the endpoint size. The maximum value this register can be programmed with is 0x10000, or 65536. N can range from 1 to 15.

The USB0 generic RNDIS EPn size register is shown in [Figure 25-81](#) and described in [Table 25-90](#).

Figure 25-81. USB0 Generic RNDIS EPn Size Register (USB0GENRNDISEPn)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-90. USB0 Generic RNDIS EPn Size Register (USB0GENRNDISEPn) Field Descriptions

Bits	Field	Description
31-17	Reserved	Always read as 0. Writes have no effect.
16-0	Ep(n)_size	Generic RNDIS packet size. n=1-15

25.9.2.1.17 USB0 Auto Req Register (USB0AUTOREQ)

The USB0 auto req register (USB0AUTOREQ) allows the CPU to enable an automatic IN token request generation for host mode RX operation per each RX endpoint. This feature has the DMA set the ReqPkt bit in the RXCSR when it clears the RxPktRdy bit after reading out a packet. The ReqPkt bit is used by the core to generate an IN token to receive data. By using this feature, the host can automatically generate an IN token after the DMA finishes receiving data and empties an endpoint buffer, thus receiving the next data packet as soon as possible from the connected device. Without this feature, the CPU will have to manually set the ReqPkt bit for every USB packet.

There are two modes that Auto Req can function: always or all except an EOP. The always mode will set the ReqPkt bit after every USB packet the DMA receives thus generating a new IN token after each USB packet. The EOP mode will set the ReqPkt bit after every USB packet that isn't an EOP (end of packet) in the CPPI descriptor. For RNDIS, CDC, and Generic RNDIS modes the auto req will stop when the EOP is received (either via a short packet for RNDIS, CDC, and Generic RNDIS or the count is reached for Generic RNDIS), making it useful for starting a large RNDIS packet and having it auto generate IN tokens until the end of the RNDIS packet. For transparent mode every USB packet is an EOP CPPI packet so the auto req never functions and acts like auto req is disabled.

The USB0 auto req register is shown in [Figure 25-82](#) and described in [Table 25-91](#).

Figure 25-82. USB0 Auto Req Register (USB0AUTOREQ)

25.9.2.1.18 USB0 SRP Fix Time Register (USB0SRPFIXTIME)

The USB0 SRP fix time register (USB0SRPFIXTIME) allows the CPU to configure the maximum amount of time the SRP fix logic blocks the AVAID from the PHY to the OTG core. This time allows the VBUS signal the ability to get below the thresholds and therefore remove the chance of voltage bounces which could give false threshold measurements.

The USB0 SRP fix time register is shown in [Figure 25-83](#) and described in [Table 25-92](#).

Figure 25-83. USB0 SRP Fix Time Register (USB0SRPFIXTIME)

Table 25-92. USB0 SRP Fix Time Register (USB0SRPFIXTIME) Field Descriptions

Bits	Field	Description
31-0	srpfixtime	SRP Fix maximum time in 60 MHz cycles. Default is 700 ms.

25.9.2.1.19 USB0 Teardown Register (USB0TDOWN)

The USB0 teardown register (USB0TDOWN) controls the tearing down of rx and tx fifos in the USB controller. When a '1' is written to a valid bit in this register, the CPPI FIFO pointers for that endpoint are cleared, and the register automatically clears itself after 1 clock cycle. This register must be used in conjunction with the CPPI DMA Teardown mechanism. The host should also write the FlushFIFO bits in the TXCSR and RXCSR Mentor USB Controller registers to ensure a complete teardown of the endpoint. See the Mentor specification for details.

The USB0 teardown register is shown in [Figure 25-84](#) and described in [Table 25-93](#).

16	Reserved	Always read as 0. Writes have no effect.
15-1	rx_tdown	RX Endpoint Teardown. Write '1' to corresponding bit to set. Read as '0'. Bit 15 = Endpoint 15 ... Bit 1 = Endpoint 1
0	Reserved	Always read as 0. Writes have no effect.

25.9.2.1.20 USB0 Threshold XDMA Idle Register

The USB0 Threshold XDMA Idle register provides a cycle threshold number that is programmable. This cycle threshold and cycle count is used by the XDMA state machine when the EP_STATE machine is in the IDLE mode. When the threshold is reached, the XDMA leaves the G_IDLE state and reads the TXCSR registers within the Mentor controller and possibly generates an interrupt for TX_FIFO[15:0].

See the XDMA section in the Integration Specification for more details about the various state machines.

The USB0 threshold XDMA idle register is shown in [Figure 25-85](#) and described in [Table 25-94](#).

25.9.2.1.21 USB0 PHY UTMI Register (USB0UTMI)

The USB0 PHY UTMI register (USB0UTMI) controls various PHY UTMI signals. The UTMI interface is located between the PHY module and the Mentor Graphics Controller. These signals are inputs to the PHY but are not outputs from the Mentor Graphics Controller.

The USB0 PHY UTMI register is shown in [Figure 25-86](#) and described in [Table 25-95](#).

Figure 25-86. USB0 PHY UTMI Register (USB0UTMI)

25.9.2.1.22 USB0 MGC UTMI Loopback Register (USB0UTMILB)

The USB0 MGC UTMI loopback register (USB0UTMILB) contains most of the input and output UTMI signals for the Mentor Graphics Controller. The UTMI interface is located between the PHY module and the Mentor Graphics Controller.

In the loopback mode test register bits 11 to 0 control various UTMI signals that are input to the Mentor Graphics Controller.

In the loopback mode test register bits 28 to 16 observe various UTMI signals that are output from the Mentor Graphics Controller.

The USB0 MGC UTMI loopback register is shown in [Figure 25-87](#) and described in [Table 25-96](#).

3-2	linestate	Loopback test value for linestate
1-0	Reserved	Always read as 0. Writes have no effect.

25.9.2.1.23 USB0 Mode Register (USB0MODE)

The USB mode (USB0MODE) register allows the user a flexibility of controlling the role that the controller assumes. Via the setting of the USB0MODE, the user has the capability of allowing the control to be coming from a register field (USB0MODE[Bit8=iddig]) or from the USB_ID pin which is indirectly controlled by the cable end. if USB0MODE=0, the state of the USB_ID pin controls the role the controller assumes.

The loopback bit enables the loopback test. This test allows MGC0 to be connected to MGC1. It is important to set both loopback bits in both USB0/1 Mode registers. The USB0 MGC UTMI loopback register contains the various UTMI signals to be controlled and observed during loopback test.

The phy_test bit enables the phy_test mode. This test mode is intended to allow additional control of the UTMI inputs to the PHY. Currently, these inputs are drvbus, dppulldown, dmpulldown, and idpullup. When phy_test is high, then the pin inputs for these signals control the inputs to the PHY instead of the Mentor controller outputs. The phy_test mode is not active with loopback mode is active.

When phy_test is active than the PHY inputs datainh is equal to datain. And txvalidh is equal to txvalid.

The USB0 mode register is shown in [Figure 25-88](#) and described in [Table 25-97](#).

Figure 25-88. USB0 Mode Register (USB0MODE)

0	loopback	0 1	Loopback test mode Normal mode Loopback test mode

25.9.2.1.24 USB0 Mentor Core Registers

A description of the Mentor core registers is available in [Section 25.9.6](#). Two instantiations of the USB core exists, USB0 and USB1. These registers reside back to back within USB0 space. The core registers that are used by USB0 subsystem are defined within offsets 1400h-159Ch, while the core registers that are used by USB1 subsystem are defined within offset 1C00h-1D9Ch.

25.9.2.2 USB1 Controller Registers

Table 25-98 lists the registers for the USB1 controller submodule.

Table 25-98. USB1 Controller Registers

25.9.2.2.1 USB1 Revision Register (USB1REV)

The USB1 revision register (USB1REV) contains the major and minor revisions for the USB1 module.

The USB1 revision register is shown in [Figure 25-89](#) and described in [Table 25-99](#).

Figure 25-89. USB1 Revision Register (USB1REV)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-99. USB1 Revision Register (USB1REV) Field Descriptions

Bits	Field	Values	Description
31-30	Scheme	1	Used to distinguish between old scheme and current. Highlander 0.8
29-28	Reserved	0	Reserved
27-16	func	EA2h	Function indicates a software compatible module family.
15-11	R_rtl	1h	RTL revision. Will vary depending on release.
10-8	X_major	0h	Major revision.
7-6	Custom	0h	Custom revision
5-0	Y_minor	0h	Minor revision.

25.9.2.2.2 USB1 Control Register (USB1CTRL)

The USB1 control register (USB1CTRL) allows the CPU to control various aspects of the module. If uint is set high, then the Mentor controller generic interrupt for USB[9] will be generated (if enabled). This requires software to read the Mentor controller's registers to determine which interrupt USB[0] to USB[7] occurred. If uint is set low, then the usb20otg_f module will automatically read the Mentor controller's registers and set the appropriate interrupt USB[0] to USB[7] (if enabled). The generic interrupt for USB[9] will not be generated.

The USB1 control register is shown in [Figure 25-90](#) and described in [Table 25-100](#).

Figure 25-90. USB1 Control Register (USB1CTRL)

31	30	29					16

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-100. USB1 Control Register (USB1CTRL) Field Descriptions

Bits	Field	Value	Description
31	dis_deb		Disable the VBUS debouncer circuit fix
30	dis_srp		Disable the OTG Session Request Protocol (SRP) AVALID circuit fix. When enabled (=0) this allows additional time for the VBUS signal to be measured against the VBUS thresholds. The time is specified in the USB1 SRP Fix Time Register.
29-06	Reserved	0	Always read as 0. Writes have no effect.
5	soft reset isolation		Soft reset isolation. When high this bit forces all USB1 signals that connect to the USBSS to zeros during a soft reset via bit 0 of this register. This bit should be set high prior to setting bit 0 and cleared after bit 0 is cleared.
4	rndis		Global RNDIS mode enable for all endpoints.
3	uint	0 1	USB non-highlander interrupt enable Highlander Non-highlander
2	Reserved	0	Always read as 0. Writes have no effect.
1	clkfack		Clock stop fast ack enable.
0	soft reset	Write 0 Write 1 Read 0 Read 1	Software reset of USB1. Write 0 = no action Write 1 = Initiate software reset Read 0 = Reset done, no action Read 1 = Reset ongoing

If uint is set high, then the Mentor controller generic interrupt for USB[9] will be generated (if enabled). This requires software to read the Mentor controller's registers to determine which interrupt USB[0] to USB[7] occurred.

If uint is set low, then the usb20otg_f module will automatically read the Mentor controller's registers and set the appropriate interrupt USB[0] to USB[7] (if enabled). The generic interrupt for USB[9] will not be generated.

25.9.2.2.3 USB1 Status Register (USB1STAT)

The USB1 status register (USB1STAT) allows the CPU to check the voltage state level of USB1_DRVVBUS pin.

This USB1 status register is shown in [Figure 25-91](#) and described in [Table 25-101](#).

Figure 25-91. USB1 Status Register (USB1STAT)

31	Reserved	1	0
	R-0h	drvbus	R-0h

Table 25-101. USB1 Status Register (USB1STAT) Field Descriptions

Bits	Field	Description
31-1	Reserved	Always read as 0. Writes have no effect.
0	drvbus	Current USB1_DRVVBUS value

25.9.2.2.4 USB1 IRQ_MERGED_STATUS Register (USB1IRQMSTAT)

The USB1 IRQ_MERGED_STATUS register (USB1IRQMSTAT) contains a merged status for all the events for USB1. This register optimizes software accesses in a module where a large number of events are associated to one IRQ line. The merged status is read-only, and does not need to be actively cleared like the IRQ status. It will clear automatically.

The USB1 IRQ_MERGED_STATUS register is shown in [Figure 25-92](#) and described in [Table 25-102](#).

Figure 25-92. USB1 IRQ_MERGED_STATUS Register (USB1IRQMSTAT)

31	Reserved	2	1	0
	R-0h	Bank1	Bank0	R-0h R-0h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-102. USB1 IRQ_MERGED_STATUS Register (USB1IRQMSTAT) Field Descriptions

Bits	Field	Value	Description
31-2	Reserved	0	Always read as 0. Writes have no effect.
1	Bank1	0	No events pending from IRQ_STATUS_1
		1	At least one event is pending from IRQ_STATUS_1
0	Bank0	0	No events pending from IRQ_STATUS_0
		1	At least one event is pending from IRQ_STATUS_0

25.9.2.2.5 USB1 IRQ_EOI Register (USB1IRQEOI)

The USB1 IRQ_EOI register (USB1IRQEOI) allows the CPU to acknowledge completion of an interrupt by writing to the end of interrupt (EOI). An eoi_write signal will be generated and another interrupt will be triggered if interrupt sources remain. This register will be reset one cycle after it has been written to.

The USB1 IRQ_EOI register is shown in [Figure 25-93](#) and described in [Table 25-103](#).

Figure 25-93. USB1 IRQ_EOI Register (USB1IRQEOI)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-103. USB1 IRQ_EOI Register (USB1IRQEOI) Field Descriptions

Bits	Field	Description
31-1	Reserved	Always read as 0. Writes have no effect.
0	EOI for USB1	EOI for USB1 interrupt

25.9.2.2.6 USB1_IRQ_STATUS_RAW_0 Register (USB1IRQSTATRAW0)

The USB1_IRQ_STATUS_RAW_0 register (USB1IRQSTATRAW0) allows the USB1 interrupt sources to be manually triggered when writing a 1 to a specific bit. A read of this register returns the USB1 interrupt event pending value.

General actions per bit:

Write 0: No action

Write 1: Set event

Read 0: No event pending

Read 1: Event pending

The USB1_IRQ_STATUS_RAW_0 register is shown in [Figure 25-94](#) and described in [Table 25-104](#).

25.9.2.2.12 USB1_IRQ_ENABLE_CLR_0 Register (USB1IRQENABLECLR0)

The USB1_IRQ_ENABLE_CLR_0 register (USB1IRQENABLECLR0) allows the USB1 interrupt sources to be manually disabled when writing a 1 to a specific bit. A read of this register returns the USB1 interrupt enabled value.

General actions per bit:

Write 0: No action

Write 1: Disable interrupt

Read 0: Interrupt disabled

Read 1: Interrupt enabled

The USB1_IRQ_ENABLE_CLR_0 register is shown in [Figure 25-100](#) and described in [Table 25-110](#).

25.9.2.2.16 USB1 Generic RNDIS EP N Size Register (USB1GENRNDISEPn)

The USB1 generic RNDIS EP N size register (USB1GENRNDISEPn) is programmed with a RNDIS packet size in bytes. When EP(N) is in Generic RNDIS mode, the received USB packets will be collected into a single CPPI packet that is completed when the number of bytes equal to the value of this register has been received, or a “short” packet is received. Note that this register must be programmed with a value that is an integer multiple of the endpoint size. The maximum value this register can be programmed with is 10000h, or 65536. N can range from 1 to 15.

The USB1 generic RNDIS EP N size register is shown in [Figure 25-104](#) and described in [USB1 Generic RNDIS EP N Size Register \(USB1GENRNDISEPn\) Field Descriptions](#).

Figure 25-104. USB1 Generic RNDIS EP N Size Register (USB1GENRNDISEPn)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

USB1 Generic RNDIS EP N Size Register (USB1GENRNDISEPn) Field Descriptions

Bits	Field	Description
31-17	Reserved	Always read as 0. Writes have no effect.
16-0	Ep(N)_size	Generic RNDIS packet size.

25.9.2.2.17 USB1 Auto Req Register (USB1AUTOREQ)

The USB1 auto req register (USB1AUTOREQ) allows the CPU to enable an automatic IN token request generation for host mode RX operation per each RX endpoint. This feature has the DMA set the ReqPkt bit in the RXCSR when it clears the RxPktRdy bit after reading out a packet. The ReqPkt bit is used by the core to generate an IN token to receive data. By using this feature, the host can automatically generate an IN token after the DMA finishes receiving data and empties an endpoint buffer, thus receiving the next data packet as soon as possible from the connected device. Without this feature, the CPU will have to manually set the ReqPkt bit for every USB packet.

There are two modes that Auto Req can function: always or all except an EOP. The always mode will set the ReqPkt bit after every USB packet the DMA receives thus generating a new IN token after each USB packet. The EOP mode will set the ReqPkt bit after every USB packet that isn't an EOP (end of packet) in the CPPI descriptor. For RNDIS, CDC, and Generic RNDIS modes the auto req will stop when the EOP is received (either via a short packet for RNDIS, CDC, and Generic RNDIS or the count is reached for Generic RNDIS), making it useful for starting a large RNDIS packet and having it auto generate IN tokens until the end of the RNDIS packet. For transparent mode, every USB packet is an EOP CPPI packet, so the auto req never functions and acts like auto req is disabled.

The USB1 auto req register is shown in [Figure 25-105](#) and described in [Table 25-114](#).

25.9.2.2.18 USB1 SRP Fix Time Register (USB1SRPFIXTIME)

The USB1 SRP fix time register (USB1SRPFIXTIME) allows the CPU to configure the maximum amount of time the SRP fix logic blocks the AVAID from the PHY to the OTG core. This time allows the VBUS signal the ability to get below the thresholds and therefore remove the chance of voltage bounces which could give false threshold measurements.

The USB1 SRP fix time register is shown in [Figure 25-106](#) and described in [Table 25-115](#).

Figure 25-106. USB1 SRP Fix Time Register (USB1SRPFIXTIME)

R/W-0280de80h		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-115. USB1 SRP Fix Time Register (USB1SRPFIXTIME) Field Descriptions

Bits	Field	Description
31-0	srpfixtime	SRP Fix maximum time in 60 MHz cycles. Default is 700 ms.

25.9.2.2.19 USB1 Teardown Register (USB1TDOWN)

The USB1 teardown register (USB1TDOWN) controls the tearing down of rx and tx fifos in the USB controller. When a '1' is written to a valid bit in this register, the CPPI FIFO pointers for that endpoint are cleared, and the register automatically clears itself after 1 clock cycle. This register must be used in conjunction with the CPPI DMA Teardown mechanism. The Host should also write the FlushFIFO bits in the TXCSR and RXCSR Mentor USB Controller registers to ensure a complete teardown of the endpoint. See the Mentor specification for details.

The USB1 teardown register is shown in [Figure 25-107](#) and described in [Table 25-116](#).

Figure 25-107. USB1 Teardown Register (USB1TDOWN)

31	17	16	15	0

Bits	Field	Description
31-17	tx_tdown	Tx Endpoint Teardown. Write '1' to corresponding bit to set. Read as '0'. Bit 31 = Endpoint 15 ... Bit 17 = Endpoint 1
16	Reserved	Always read as 0. Writes have no effect.
15-1	rx_tdown	RX Endpoint Teardown. Write '1' to corresponding bit to set. Read as '0'. Bit 15 = Endpoint 15 ... Bit 1 = Endpoint 1
0	Reserved	Always read as 0. Writes have no effect.

25.9.2.2.20 USB1 Threshold XDMA Idle Register

The USB1 Threshold XDMA Idle register provides a cycle threshold number that is programmable. This cycle threshold and cycle count is used by the XDMA state machine when the EP_STATE machine is in the IDLE mode. When the threshold is reached, the XDMA leaves the G_IDLE state and reads the TXCSR registers within the Mentor controller and possibly generates an interrupt for TX_FIFO[15:0].

See the XDMA section in the Integration Specification for more details about the various state machines.

The USB1 threshold XDMA idle register is shown in [Figure 25-108](#) and described in [Table 25-117](#).

Figure 25-108. USB1 Threshold XDMA Idle Register

7-0	thres_xdma_idle	Threshold XDMA Idle cycle parameter. Valid values are 0 to 255. Default is 24 cycles.

25.9.2.2.21 USB1 PHY UTMI Register (USB1UTMI)

The USB1 PHY UTMI register (USB1UTMI) controls various PHY UTMI signals. The UTMI interface is located between the PHY module and the Mentor Graphics Controller. These signals are inputs to the PHY but are not outputs from the Mentor Graphics Controller.

The USB1 PHY UTMI register is shown in [Figure 25-109](#) and described in [Table 25-118](#).

Figure 25-109. USB1 PHY UTMI Register (USB1UTMI)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-118. USB1 PHY UTMI Register (USB1UTMI) Field Descriptions

1	Reserved	Reserved, this bit has no function.
0	Reserved	Reserved, this bit has no function.

25.9.2.2.22 USB1 MGC UTMI Loopback Register (USB1UTMILB)

The USB1 MGC UTMI loopback register (USB1UTMILB) contains most of the input and output UTMI signals for the Mentor Graphics Controller. The UTMI interface is located between the PHY module and the Mentor Graphics Controller.

In the loopback mode test register bits 11 to 0 control various UTMI signals that are input to the Mentor Graphics Controller.

In the loopback mode test register bits 28 to 16 observe various UTMI signals that are output from the Mentor Graphics Controller.

The USB1 MGC UTMI loopback register is shown in [Figure 25-110](#) and described in [Table 25-119](#).

Figure 25-110. USB1 MGC UTMI Loopback Register (USB1UTMILB)

9	sessend	Loopback test value for sessend
8	avalid	Loopback test value for avalid
7	vbusvalid	Loopback test value for vbusvalid
6	rxerror	Loopback test value for rxerror
5-4	Reserved	Always read as 0. Writes have no effect.
3-2	linestate	Loopback test value for linestate
1-0	Reserved	Always read as 0. Writes have no effect.

25.9.2.2.23 USB1 Mode Register (USB1MODE)

The USB1 mode register (USB1MODE) allows the user a flexibility of controlling the role that the controller assumes. Via the setting of the USB1MODE, the user has the capability of allowing the control to be coming from a register field (USB1MODE[Bit8=iddig]) or from the USB_ID pin which is indirectly controlled by the cable end. if USB1MODE=0, the state of the USB_ID pin controls the role the controller assumes.

The loopback bit enables the loopback test. This test allows MGC1 to be connected to MGC0. It is important to set both loopback bits in both USB0/1 Mode registers. The USB0 MGC UTMI Loopback Register contains the various UTMI signals to be controlled and observed during loopback test.

The phy_test bit enables the phy_test mode. This test mode is intended to allow additional control of the UTMI inputs to the PHY. Currently, these inputs are drvbus, dppulldown, dmpulldown, and idpullup. When phy_test is high, then the pin inputs for these signals control the inputs to the PHY instead of the Mentor controller outputs. The phy_test mode is not active with loopback mode is active.

When phy_test is active then the PHY inputs datainh is equal to datain and txvalidh is equal to txvalid.

The USB1 mode register is shown in [Figure 25-111](#) and described in [Table 25-120](#).

Figure 25-111. USB1 Mode Register (USB1MODE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Bits	Field	Value	Description
31-9	Reserved		Always read as 0. Writes have no effect.
8	iddig	0 1	MGC input value for iddig A type B type
7-2	Reserved		Always read as 0. Writes have no effect.
1	phy_test	0 1	PHY test Normal mode PHY test mode
0	loopback	0 1	Loopback test mode Normal mode Loopback test mode

25.9.2.2.24 USB1 Mentor Core Registers

A description of the mentor core registers is available in [Section 25.9.6](#). Two instantiations of the USB core exists, USB0 and USB1. These registers reside back to back within USB0 space. The core registers that are used by USB0 subsystem are defined within offsets 1400h-159Ch, while the core registers that are used by USB1 subsystem are defined within offsets 1C00h-1D9Ch.

25.9.3 CPPI DMA Controller Registers

Table 25-121 lists the registers for the CPPI DMA Controller submodule.

Table 25-121. CPPI DMA Controller Registers

Address Offset	Acronym	CPPI DMA Controller Register
2000h	DMAREVID	Revision Register
2004h	TDFDQ	Teardown Free Descriptor Queue Control Register
2008h	DMAEMU	Emulation Control Register
2800h	TXGCR0	Tx Channel 0 Global Configuration Register
2808h	RXGCR0	Rx Channel 0 Global Configuration Register
280Ch	RXHPCRA0	Rx Channel 0 Host Packet Configuration Register A
2810h	RXHPCRB0	Rx Channel 0 Host Packet Configuration Register B
2820h	TXGCR1	Tx Channel 1 Global Configuration Register
2828h	RXGCR1	Rx Channel 1 Global Configuration Register
282Ch	RXHPCRA1	Rx Channel 1 Host Packet Configuration Register A
2830h	RXHPCRB1	Rx Channel 1 Host Packet Configuration Register B

2BB0h	RXHPCRB29	Rx Channel 29 Host Packet Configuration Register B

25.9.3.1 CPPI DMA Revision Register (DMAREVID)

The CPPI DMA revision register (DMAREVID) contains the major and minor revisions for the module. The CPPI DMA revision register is shown in [Figure 25-112](#) and described in [Table 25-122](#).

Figure 25-112. CPPI DMA Revision Register (DMAREVID)

31	30	29					16	15			11	10	8	7	0
Rsvd			modID					revrtl		revmaj		revmin

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-122. CPPI DMA Revision Register (DMAREVID) Field Descriptions

Bits	Field	Description
31-30	Reserved	Always read as 0. Writes have no effect.
29-16	modID	Module ID field
15-11	revrtl	RTL revision. Will vary depending on release.
10-8	revmaj	Major revision.
7-0	revmin	Minor revision.

25.9.3.2 CPPI DMA Teardown Free Descriptor Queue Control Register (TDFDQ)

The CPPI DMA teardown free descriptor queue control register (TDFDQ) is used to inform the DMA of the location in memory or descriptor array which is to be used for signaling of a teardown complete for each Tx and Rx channel. The CPPI DMA teardown free descriptor queue control register is shown in [Figure 25-113](#) and described in [Table 25-123](#).

Figure 25-113. CPPI DMA Teardown Free Descriptor Queue Control Register (TDFDQ)

Table 25-123. CPPI DMA Teardown Free Descriptor Queue Control Register (TDFDQ) Field Descriptions

Bits	Field	Description
31-14	Reserved	Reserved
13-12	td_desc_qmgr	This field controls which of the four Queue Managers the DMA will access in order to allocate a channel teardown descriptor from the teardown descriptor queue.
11-0	td_desc_qnum	This field controls which of the 2K queues in the indicated queue manager should be read in order to allocate channel teardown descriptors.

25.9.3.3 CPPI DMA Emulation Control Register (DMAEMU)

The CPPI DMA emulation control register (DMAEMU) is used to control the behavior of the DMA when the emususp input is asserted. The CPPI DMA emulation control register is shown in [Figure 25-114](#) and described in [Table 25-124](#).

Figure 25-114. CPPI DMA Emulation Control Register (DMAEMU)

31	Reserved	2	1	0
R-0h			soft	free
			R/W-0h	R/W-0h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-124. CPPI DMA Emulation Control Register (DMAEMU) Field Descriptions

Bits	Field	Value	Description
31-2	Reserved	0	Always read as 0. Writes have no effect.
1	soft	0	Control for emulation pause request Forces emu_pause_req low
		1	Does not force emu_pause_req low
0	free	0	Enable for emulation suspend Emulation halt disabled
		1	Emulation halt enabled

25.9.3.4 Tx Channel N Global Configuration Register (TXGCRn)

The Tx channel N global configuration register (TXGCRn) are used to initialize the behavior of each of the Tx CPPI DMA channels. N,n ranges from 0 to 14. The Tx channel N global configuration register is shown in [Figure 25-115](#) and described in [Table 25-125](#).

Figure 25-115. Tx Channel N Global Configuration Register (TXGCRn)

R/W-0h	R/W-0h	R/W-0h	R-0h	
15	14	13	12	11
Reserved		tx_default_qmgr	tx_default_qnum	
R-0h		W-0h	W-0h	

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

Table 25-125. Tx Channel N Global Configuration Register (TXGCRn) Field Descriptions

Bits	Field Name		Description
31	tx_enable	0	This field enables or disables the channel Channel is disabled
		1	Channel is enabled This field will be cleared after a channel teardown is complete.
30	tx_teardown	0 - 1	Setting this bit will request the channel to be torn down. This field will remain set after a channel teardown is complete.
29	tx_pause	0 - 1	Setting this bit causes the CPPI DMA to be suspended for tx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
28-14	Reserved	0	Reserved
13-12	tx_default_qmgr	0 - 3	This field controls the default queue manager number that will be used to queue teardown descriptors back to the host.

Table 25-125. Tx Channel N Global Configuration Register (TXGCRn) Field Descriptions (continued)

Bits	Field Name		Description
11-0	tx_default_qnum	0 - FFFh	This field controls the default queue number within the selected queue manager onto which teardown descriptors will be queued back to the host.

25.9.3.5 Rx Channel N Global Configuration Register (RXGCRn)

The Rx channel global configuration registers are used to initialize the global (non descriptor type specific) behavior of each of the Rx CPPI DMA channels. If the enable bit is being set, the Rx Channel Global Configuration Register should only be written after all of the other Rx Configuration Registers have been initialized. N,n ranges from 0 to 14.

The Rx channel N global configuration register is shown in [Figure 25-116](#) and described in [Table 25-126](#)

Figure 25-116. Rx Channel N Global Configuration Register (RXGCRn)

31	30	29	28	26	25	24

7						0
rx_default_rq_qnum						
W-0h						

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

Table 25-126. Rx Channel N Global Configuration Register (RXGCRn) Field Descriptions

Bits	Field Name	Value	Description
31	rx_enable	0	Channel is disabled
		1	Channel is enabled
		This field will be cleared after a channel teardown is complete.	
30	rx_teardown	0 - 1	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	rx_pause	0 - 1	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
28-26	rx_max_buffer_cnt	0	This bit is used to control an optional Rx mode of operation where packets are delimited based on an integer number of buffers in addition to the EOP bit in the CPPI FIFO information word 0.
		1h	Mode is disabled – the DMA will delimit Rx packets only using the SOP and EOP fields in the info word 0.
		2h	The DMA ignores the SOP bit and closes up a packet after two buffers have been filled OR if the EOP field is set in the info word 0.
		3h	The DMA ignores the SOP bit and closes up a packet after three buffers have been filled OR if the EOP field is set in the info word 0.
		4h	The DMA ignores the SOP bit and closes up a packet after four buffers have been filled OR if the EOP field is set in the info word 0.

Table 25-126. Rx Channel N Global Configuration Register (RXGCRn) Field Descriptions (continued)

Bits	Field Name	Value	Description
		5h-7h	Reserved
25	Reserved	0	Reserved
24	rx_error_handling	0 1	<p>This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs):</p> <p>0 Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to</p> <p>1 Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added.</p> <p>Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when</p>
23-16	rx_sop_offset	0 - FFh	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 – 255 bytes.
15-14	rx_default_desc_type	0 1h 2h-3h	<p>This field indicates the default descriptor type to use:</p> <p>0 Reserved</p> <p>1h Host</p> <p>2h-3h Reserved</p> <p>The actual descriptor type that will be used for reception can be overridden by information provided in the CPPI FIFO data block.</p>
13-12	rx_default_rq_qmgr	0 - 3h	This field indicates the default receive queue manager that this channel should use. The actual receive queue manager index can be overridden by information provided in the CPPI FIFO data block.
11-0	rx_default_rq_qnum	0 - FFFh	This field indicates the default receive queue that this channel should use. The actual receive queue that will be used for reception can be overridden by information provided in the CPPI FIFO data block.

25.9.3.6 Rx Channel N Host Packet Configuration Register A (RXHPCRAN)

The Rx channel host packet configuration A registers are used to initialize the behavior of each of the Rx CPPI DMA channels for reception of host type packets. N,n ranges from 0 to 14.

The Rx channel host packet configuration A registers are shown in [Figure 25-117](#) and described in [Table 25-127](#)

Figure 25-117. Rx Channel N Host Packet Configuration Register A (RXHPCRAN)

Table 25-130. CPPI DMA Scheduler Control Register (DMA_SCHED_CTRL) Field Descriptions

Bits	Field Name	Value	Description
31	enable	0 1	This is the enable bit for the scheduler and is encoded as follows: Scheduler is disabled and will no longer fetch entries from the scheduler table or pass credits to the DMA controller. Scheduler is enabled. This bit should only be set after the table has been initialized.
30-8	Reserved	0	Reserved
7-0	last_entry	0 1 ... 254 255	This field indicates the last valid entry in the scheduler table. There are 64 words in the table and there are 4 entries in each word. The table can be programmed with any integer number of entries from 1 to 256. The corresponding encoding for this field is as follows: 1 entry 2 entries ... 255 entries 256 entries

25.9.4.2 CPPI DMA Scheduler Table Word N (WORDn)

The CPPI DMA scheduler table word N (WORDn) registers are used to initialize the behavior of each of the Tx DMA channels. N ranges from 0 to 63.

The CPPI DMA scheduler table word N (WORDn) registers are shown in [Figure 25-120](#) and described in [Table 25-131](#).

Figure 25-120. CPPI DMA Scheduler Table Word N (WORDn)

Table 25-131. CPPI DMA Scheduler Table Word N (WORDn) Field Descriptions

Bits	Field Name	Value	Description
31	entry3_rxtx	0 1	This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: Tx Channel Rx Channel
30-29	Reserved	0	Reserved
28-24	entry3_channel	0 - 1Fh	This field indicates the channel number that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
23	entry2_rxtx	0 1	This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: Tx Channel Rx Channel
22-21	Reserved	0	Reserved
20-16	entry2_channel	0 - 1Fh	This field indicates the channel number that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
15	entry1_rxtx	0 1	This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: Tx Channel Rx Channel
14-13	Reserved	0	

Table 25-131. CPPI DMA Scheduler Table Word N (WORDn) Field Descriptions (continued)

Bits	Field Name	Value	Description
12-8	entry1_channel	0 - 1Fh	This field indicates the channel number that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
7	entry0_rxtx	0 1	This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: 0 Tx Channel 1 Rx Channel
6-5	Reserved	0	Reserved
4-0	entry0_channel	0 - 1Fh	This field indicates the channel number that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.

25.9.5 CPPI DMA Queue Manager Registers

Table 25-132 lists the registers for the CPPI DMA Queue Manager submodule.

Table 25-132. CPPI DMA Queue Manager Registers

Address Offset	Queue Manager Register
4000h	Qmgr Revision Register
4008h	Qmgr Queue Diversion Register

7008h + 16 x N	Queue N Status Register C

25.9.5.1 Queue Manager Revision Register (QMGRREVID)

The queue manager revision register contains the major and minor revisions for the module. It does not support byte accesses.

The revision register is shown in [Figure 25-121](#) and described in [Table 25-133](#).

Figure 25-121. Queue Manager Revision Register (QMGRREVID)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-133. Queue Manager Revision Register (QMGRREVID) Field Descriptions

Bits	Field Name	Description
31-30	scheme	Scheme that this register is compliant with
29-28	Reserved	Reserved
27-16	function	Function
15-11	revrtl	RTL revision
10-8	revmaj	Major revision
7-6	revcustom	Custom revision
5-0	revmin	Minor revision

25.9.5.2 Queue Manager Queue Diversion Register (DIVERSION)

The queue manager queue diversion register is used to transfer the contents of one queue onto another queue. It does not support byte accesses.

The queue manager queue diversion register is shown in [Figure 25-122](#) and described in [Table 25-134](#).

Figure 25-122. Queue Manager Queue Diversion Register (DIVERSION)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-134. Queue Manager Queue Diversion Register (DIVERSION) Field Descriptions

Bits	Field Name	Description
31	head_tail	Indicates whether queue contents should be merged on to head or tail of destination queue. Clear this field for head and set for tail.
30	Reserved	Reserved
29-16	dest_qnum	Destination Queue Number
15-14	Reserved	Reserved
13-0	source_qnum	Source Queue Number

25.9.5.3 Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (FDBSC0)

The free descriptor/buffer queue starvation count register 0 provides statistics about how many starvation events are occurring on the Rx free descriptor/buffer queues 0-3. It does not support byte accesses.

The free descriptor/buffer queue starvation count register 0 is shown in [Figure 25-123](#) and described in [Table 25-135](#).

Figure 25-123. Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (FDBSC0)

Bits	Field Name	Description
31-24	fdbq3_starve_cnt	This field increments each time the Free Descriptor/Buffer Queue 3 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
23-16	fdbq2_starve_cnt	This field increments each time the Free Descriptor/Buffer Queue 2 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
15-8	fdbq1_starve_cnt	This field increments each time the Free Descriptor/Buffer Queue 1 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
7-0	fdbq0_starve_cnt	This field increments each time the Free Descriptor/Buffer Queue 0 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.

25.9.5.4 Queue Manager Free Descriptor/Buffer Starvation Count Register 1 (FDBSC1)

The free descriptor/buffer queue starvation count register 1 provides statistics about how many starvation events are occurring on the Rx free descriptor/buffer queues 4-7. It does not support byte accesses.

The free descriptor/buffer queue starvation count register 1 is shown in [Figure 25-124](#) and described in [Table 25-136](#).

Figure 25-124. Queue Manager Free Descriptor/Buffer Starvation Count Register 1 (FDBSC1)

23-16	fdbq6_starve_cnt	This field increments each time the Free Descriptor/Buffer Queue 6 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
15-8	fdbq5_starve_cnt	This field increments each time the Free Descriptor/Buffer Queue 5 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
7-0	fdbq4_starve_cnt	This field increments each time the Free Descriptor/Buffer Queue 4 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.

25.9.5.5 Queue Manager Free Descriptor/Buffer Starvation Count Register 2 (FDBSC2)

The free descriptor/buffer queue starvation count register 2 provides statistics about how many starvation events are occurring on the Rx free descriptor/buffer queues 8-11. It does not support byte accesses.

The free descriptor/buffer queue starvation count register 2 is shown in [Figure 25-125](#) and described in [Table 25-137](#).

23-16	fdbq30_starve_cnt	This field increments each time the Free Descriptor/Buffer Queue 30 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
15-8	fdbq29_starve_cnt	This field increments each time the Free Descriptor/Buffer Queue 29 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
7:0	fdbq28_starve_cnt	This field increments each time the Free Descriptor/Buffer Queue 28 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.

25.9.5.11 Queue Manager Linking RAM Region 0 Base Address Register (LRAM0BASE)

The Linking RAM region 0 base address register is used to set the base address for the first portion of the Linking RAM. This address must be 32-bit aligned. It is used by the Queue Manager to calculate the 32-bit linking address for a given descriptor index. It does not support byte accesses.

The Linking RAM region 0 base address register is shown in [Figure 25-131](#) and described in [Table 25-143](#).

Figure 25-131. Queue Manager Linking RAM Region 0 Base Address Register (LRAM0BASE)

31	2 1 0
region0_base	Rsvd
R/W-0h	R-0h

LEGEND: R/W = Read/Write; R = Read only; RC = Read Clear; -n = value after reset

Table 25-143. Queue Manager Linking RAM Region 0 Base Address Register (LRAM0BASE) Field Descriptions

Bits	Field Name	Description
31-2	region0_base	This field stores the base address for the first region of the linking RAM. This may be anywhere in 32-bit address space but would be typically located in on-chip memory.
1-0	Reserved	Reserved. All data accesses must be words.

25.9.5.12 Queue Manager Linking RAM Region 0 Size Register (LRAM0SIZE)

The Linking RAM region 0 size register is used to set the size of the array of linking pointers that are located in Region 0 of Linking RAM. The size specified the number of descriptors for which linking information is stored in this region. It does not support byte accesses.

The Linking RAM region 0 size register is shown in [Figure 25-132](#) and described in [Table 25-144](#).

Figure 25-132. Queue Manager Linking RAM Region 0 Size Register (LRAM0SIZE)

31	14 13	0
Reserved	region0_size	
R-0h	R/W-0h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-144. Queue Manager Linking RAM Region 0 Size Register (LRAM0SIZE) Field Descriptions

Bits	Field Name	Description
31-14	Reserved	Reserved
13-0	region0_size	This field indicates the number of entries that are contained in the linking RAM region 0. A descriptor with index less than region0_size value has its linking location in region 0. A descriptor with index greater than region0_size has its linking location in region 1. The queue manager will add the index (left shifted by 2 bits) to the appropriate regionX_base_addr to get the absolute 32-bit address to the linking location for a descriptor.

25.9.5.13 Queue Manager Linking RAM Region 1 Base Address Register (LRAM1BASE)

The Linking RAM region 1 base address register is used to set the base address for the second portion of the Linking RAM. This base address is used by the Queue Manager to calculate the 32-bit linking address from the descriptor index. All descriptors with index higher than that given in Linking RAM 0 Size register have linking information stored in linking RAM region 1. It does not support byte accesses.

The Linking RAM region 1 base address register is shown in [Figure 25-133](#) and described in [Table 25-145](#).

Figure 25-133. Queue Manager Linking RAM Region 1 Base Address Register (LRAM1BASE)

	R/W-0h	Rsvd R-0h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-145. Queue Manager Linking RAM Region 1 Base Address Register (LRAM1BASE) Field Descriptions

Bits	Field Name	Description
31-2	region1_base	This field stores the base address for the second region of the linking RAM. This may be anywhere in 32-bit address space but would be typically located in off-chip memory.
1-0	Reserved	Reserved

25.9.5.14 Queue Manager Queue Pending Register 0 (PEND0)

The queue pending register 0 can be read to find the pending status for queues 31 to 0. It does not support byte accesses.

The queue pending register 0 is shown in [Figure 25-134](#) and described in [Table 25-146](#).

Figure 25-134. Queue Manager Queue Pending Register 0 (PEND0)

Bits	Field Name	Description
31-0	qpend0	This field indicates the queue pending status for queues[31:0].

25.9.5.15 Queue Manager Queue Pending Register 1 (PEND1)

The queue pending register 1 can be read to find the pending status for queues 63 to 32. It does not support byte accesses.

The queue pending register 1 is shown in [Figure 25-135](#) and described in [Table 25-147](#).

Figure 25-135. Queue Manager Queue Pending Register 1 (PEND1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-147. Queue Manager Queue Pending Register 1 (PEND1) Field Descriptions

Bits	Field Name	Description
31-0	qpend1	This field indicates the queue pending status for queues[63:32]

25.9.5.16 Queue Manager Queue Pending Register 2 (PEND2)

The queue pending register 2 can be read to find the pending status for queues 95 to 64. It does not support byte accesses.

The queue pending register 2 is shown in [Figure 25-136](#) and described in [Table 25-148](#).

Figure 25-136. Queue Manager Queue Pending Register 2 (PEND2)

Bits	Field Name	Description
31-0	qpend4	This field indicates the queue pending status for queues[159:128]

25.9.5.19 Queue Manager Memory Region R Base Address Register (QMEMRBASER)

The memory region R base address register is written by the host to set the base address of memory region R. This memory region will store a number of descriptors of a particular size as determined by the Memory Region R Control Register. It does not support byte accesses. R ranges from 0 to 15.

The memory region R base address register is shown in [Figure 25-139](#) and described in [Table 25-151](#).

Figure 25-139. Queue Manager Memory Region R Base Address Register (QMEMRBASER)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-151. Queue Manager Memory Region R Base Address Register (QMEMRBASER) Field Descriptions

Bits	Field Name	Description
31-5	reg	This field contains the base address of the memory region R.
4-0	Reserved	Reserved

25.9.5.20 Queue Manager Memory Region R Control Register (QMEMRCTRLr)

The memory region R control register is written by the host to configure various parameters of this memory region. It does not support byte accesses. R ranges from 0 to 15.

The memory region R control register is shown in [Figure 25-140](#) and described in [Table 25-152](#).

Figure 25-140. Queue Manager Memory Region R Control Register (QMEMRCTRLr)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-152. Queue Manager Memory Region R Control Register (QMEMRCTRLr) Field Descriptions

Bits	Field Name	Description	Type	Reset Value
31-30	Reserved	Reserved	R	0h
29-16	start_index	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.	R/W	0h
15-12	Reserved	Reserved	R	0h
11:08	desc_size	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as $2^{(5+desc_size)}$ number of bytes. The settings of desc_size from 9-15 are reserved.	R/W	0h
7-3	Reserved	Reserved	R	0h
2-0	reg_size	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as $2^{(5+reg_size)}$ number of descriptors.	R/W	0h

25.9.5.21 Queue Manager Queue N Register A (CTRLAn)

The queue N register A is an optional register that is only implemented for a queue if the queue supports entry/byte count feature. The entry count feature provides a count of the number of entries that are currently valid in the queue. It does not support byte accesses. N ranges from 0 to 155.

The queue N register A is shown in [Figure 25-141](#) and described in [Table 25-153](#).

Figure 25-141. Queue Manager Queue N Register A (CTRLAn)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-153. Queue Manager Queue N Register A (CTRLAn) Field Descriptions

Bits	Field Name	Description
31-14	Reserved	Reserved
13-0	queue_entry_count	This field indicates how many packets are currently queued on the queue. This count is incremented by 1 whenever a packet is added to the queue. This count is decremented by 1 whenever a packet is popped from the queue.

25.9.5.22 Queue Manager Queue N Register B (CTRLBn)

The Queue N Register B is an optional register that is only implemented for a queue if the queue supports a total byte count feature. The total byte count feature provides a count of the total number of bytes in all of the packets that are currently valid in the queue. This register must be read prior to reading Queue N register D during packet pop operation if the total size information is desired. It does not support byte accesses. N ranges from 0 to 155.

The queue N register B is shown in [Figure 25-142](#) and described in [Table 25-154](#).

Figure 25-142. Queue Manager Queue N Register B (CTRLBn)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-154. Queue Manager Queue N Register B (CTRLBn) Field Descriptions

Bits	Field Name	Description
31-28	Reserved	Reserved
27-0	queue_byte_count	This field indicates how many bytes total are contained in all of the packets which are currently queued on this queue.

25.9.5.23 Queue Manager Queue N Register C (CTRLCn)

The Queue N Register C is used to provide additional information about the packet that is being pushed or popped from the queue. This register provides an option for the packet to be pushed onto either the tail of the queue (default) or the head of the queue (override). This register must be written prior to writing the Queue N register D during packet write operations. This register must be read prior to reading Queue N register D during pop operations if the packet size information is desired. It does not support byte accesses. N ranges from 0 to 155.

The queue N register C is shown in [Figure 25-143](#) and described in [Table 25-155](#).

Figure 25-143. Queue Manager Queue N Register C (CTRLCn)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-155. Queue Manager Queue N Register C (CTRLCn) Field Descriptions

Bits	Field Name	Description
31	head_tail	Head/Tail Push Control. Set to 0 in order to push packet onto tail of queue and set to 1 in order to push packet onto head of queue.
30-14	Reserved	Reserved
13-0	packet_size	This field indicates packet size of the head element of a queue. This field indicates packet size for packet pop operation.

25.9.5.24 Queue Manager Queue N Register D (CTRLDn)

The queue N register D is written to add a packet to the queue and read to pop a packets off a queue. The packet is only pushed or popped to/from the queue when the queue register D is written. It does not support byte accesses. N ranges from 0 to 155.

The queue N register D is shown in [Figure 25-144](#) and described in [Table 25-156](#).

Figure 25-144. Queue Manager Queue N Register D (CTRLDn)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-156. Queue Manager Queue N Register D (CTRLDn) Field Descriptions

Bits	Field Name	Description
31-5	desc_ptr	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	desc_size	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read.

25.9.5.25 Queue Manager Queue N Status Register A (QSTATAn)

The Queue N Status Register A is an optional register that is only implemented for a queue if the queue supports entry/byte count feature. The entry count feature provides a count of the number of entries that are currently valid in the queue. It does not support byte accesses. N ranges from 0 to 155.

The queue N status register A is shown in [Figure 25-145](#) and described in [Table 25-157](#).

Figure 25-145. Queue Manager Queue N Register A (QSTATAn)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-157. Queue Manager Queue N Status Register A (QSTATAn) Field Descriptions

Bits	Field Name	Description
31-14	Reserved	Reserved
13-0	queue_entry_count	This field indicates how many packets are currently queued on the queue.

25.9.5.26 Queue Manager Queue N Status Register B (QSTATBn)

The Queue N Status Register B is an optional register that is only implemented for a queue if the queue supports a total byte count feature. The total byte count feature provides a count of the total number of bytes in all of the packets that are currently valid in the queue. It does not support byte accesses. N ranges from 0 to 155.

The queue N status register B is shown in [Figure 25-146](#) and described in [Table 25-158](#).

Figure 25-146. Queue Manager Queue N Status Register B (QSTATBn)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-158. Queue Manager Queue N Status Register B (QSTATBn) Field Descriptions

Bits	Field Name	Description
31-28	Reserved	Reserved
27-0	queue_byte_count	This field indicates how many bytes total are contained in all of the packets which are currently queued on this queue.

25.9.5.27 Queue Manager Queue N Status Register C (QSTATCn)

The Queue N Status Register C specifies the packet size for the head element of a queue. It does not support byte accesses. N ranges from 0 to 155.

The queue N status register C is shown in [Figure 25-147](#) and described in [Table 25-159](#).

Figure 25-147. Queue Manager Queue N Status Register C (QSTATCn)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-159. Queue Manager Queue N Status Register C (QSTATCn) Field Descriptions

Bits	Field Name	Description
31-14	Reserved	Reserved
13-0	packet_size	This field indicates packet size of the head element of a queue.

25.9.6 USB Mentor Core Registers

The Mentor Control register map is divided into the following sections:

- **Common USB registers (0h–Fh)** – These registers provide control and status for the complete core.
- **Indexed Endpoint Control/Status registers (10h–1Fh)** – These registers provide control and status for the currently selected endpoint. The registers mapped into this section depend on whether the core is in Peripheral mode or in Host mode and on the value of the Index register.
- **FIFOs (20h–5Fh)** – This address range provides access to the endpoint FIFOs.
- **Additional Control and Configuration registers (60h–7Fh)** – These registers provide additional device status and control.
- **Target Endpoint Control Registers (80h–FFh)** – These registers provide target function and hub address details for each of the endpoints.
- **Non-Indexed Endpoint Control/Status registers (100h and above)** – The registers available at 10h–1Fh, accessible independently of the setting of the Index register. 100h–10Fh, EP0 registers; 110h–11Fh, EP1 registers; 120h–12Fh, EP2; and so on.

Two instances of the Mentor Core registers exist within USB0 space. Since both USB modules operate independent of each other, each USB core has its own set of registers. USB0 Mentor Base Address is 0x4740_1400 while USB1 Mentor Core Registers Base address is 0x4740_1C00. Below offset of the core registers The absolute address is computed by summing the CORE_OFFSET with USBn_OFFSET.

25.9.6.1 Common USB Registers

These registers provide control and status for the complete core. [Table 25-160](#) lists the registers.

Table 25-160. Common USB Registers

Core Address Offset	Common USB Registers
0h	Function Address Register
1h	Power Management Register
2h	Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 15
4h	Interrupt Register for Receive Endpoints 1 to 15
6h	Interrupt Enable Register for INTRTX
8h	Interrupt Enable Register for INTRRX
Ah	Interrupt Register for Common USB Interrupts
Bh	Interrupt Enable Register for INTRUSB
Ch	Frame Number Register
Eh	Index Register for Selecting the Endpoint Status and Control Registers
Fh	Register to Enable the USB 2.0 Test Modes

25.9.6.1.1 Function Address Register (USBn_FADDR)

The function address register (USBn_FADDR) is an 8-bit register that should be written with the 7-bit address of the peripheral part of the transaction.

Since USB cores are configured with multipoint support, this register only applies to operations carried out when the controller is in peripheral mode. In Host mode, this register is ignored.

The function address register is shown in [Figure 25-148](#) and described in [Table 25-161](#).

Figure 25-148. Function Address Register (USBn_FADDR)

7	6	0
Reserved	FUNCADDR	
R-0h	W-0-7Fh	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-161. Function Address Register (USBn_FADDR) Field Descriptions

Bits	Field Name	Description
7	Reserved	Reserved
6-0	FUNCADDR	7-bit address of the peripheral part of the transaction. When used in peripheral mode, this register should be written with the address received through a SET_ADDRESS command, which is then used for decoding the function address in subsequent token packets.

25.9.6.1.2 Power Management Register (USBn_POWER)

The power management register (USBn_POWER) is an 8-bit register that is used for controlling suspend and resume signaling, and some basic operational aspects of the USB core. This register is shown in [Figure 25-149](#) and described in [Table 25-162](#).

Figure 25-149. Power Management Register (USBn_POWER)

7	6	5	4	3	2	1	0
ISOUPDATE	SOFTCONN	HSEN	HSMODE	RESET	RESUME	SUSPENDM	ENSUSPM
R/W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-162. Power Management Register (USBn_POWER) Field Descriptions

Bits	Field Name	Description
7	ISOUPDATE	When set, the USB controller will wait for an SOF token from the time TxPktRdy is set before sending the packet. If an IN token is received before an SOF token, then a zero length data packet will be sent. Note: this is only valid in Peripheral Mode. This bit only affects endpoints performing Isochronous transfers.
6	SOFTCONN	If Soft Connect/Disconnect feature is enabled, then the USB D+/D-lines are enabled when this bit is set and tri-stated when this bit is cleared. Note: This is only valid in Peripheral Mode.
5	HSEN	When set, the USB controller negotiates for high-speed mode when the device is reset by the hub. If not set, the device will only operate in full-speed mode.
4	HSMODE	This bit is set when the USB controller has successfully negotiated for high-speed mode.
3	RESET	This bit is set when reset signaling is present on the bus. Note: this bit is Read/Write in Host Mode, but read-only in peripheral mode.
2	RESUME	Set to generate resume signaling when the controller is in suspend mode. The bit should be cleared after 10 ms (a maximum of 15 ms) to end resume signaling. In Host mode, this bit is also automatically set when resume signaling from the target is detected while the USB controller is suspended.
1	SUSPENDM	In Host mode, this bit should be set to enter suspend mode. In peripheral mode, this bit is set on entry into suspend mode. It is cleared when the interrupt register is read, or the RESUME bit is set.
0	ENSUSPM	Set to enable the SUSPENDM output.

25.9.6.1.3 Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 15 (USBn_INTRTX)

The interrupt register for endpoint 0 plus transmit endpoints 1 to 15 (USBn_INTRTX) is a 16-bit read-only register that indicates which interrupts are currently active for endpoint 0 and the TX endpoints 1–15. Note also that all active interrupts are cleared when this register is read.

The interrupt register for endpoint 0 plus transmit endpoints 1 to 15 is shown in [Figure 25-150](#) and described in [Table 25-163](#).

Figure 25-150. Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 15 (USBn_INTRTX)

0	EP0	Endpoint 0 (transmit or receive) interrupt active

25.9.6.1.4 Interrupt Register for Receive Endpoints 1 to 15 (INTRRX)

The interrupt register for receive endpoints 1 to 15 (INTRRX) is a 16-bit read-only register that indicates which of the interrupts for Rx Endpoints 1 – 15 are currently active. Note also that all active interrupts are cleared when this register is read.

The interrupt register for receive endpoints 1 to 15 is shown in [Figure 25-151](#) and described in [Table 25-164](#).

Figure 25-151. Interrupt Register for Receive Endpoints 1 to 15 (INTRRX)

25.9.6.1.5 Interrupt Enable Register for INTRTX (INTRTXE)

The interrupt enable register for INTRTX (INTRTXE) is a 16-bit register that provides interrupt enable bits for the interrupts in InrTx. On reset, the bits corresponding to endpoint 0 and the TX endpoints are set to 1. This register is shown in [Figure 25-152](#) and described in [Table 25-165](#).

Figure 25-152. Interrupt Enable Register for INTRTX (INTRTXE)

25.9.6.1.6 Interrupt Enable Register for INTRRX (INTRRXE)

The interrupt enable register for INTRRX (INTRRXE) is a 16-bit register that provides interrupt enable bits for the interrupts in USBn_INTRRX. On reset, the bits corresponding to the Rx endpoints are set to 1. This register is shown in [Figure 25-153](#) and described in [Table 25-166](#).

25.9.6.1.7 Interrupt Register for Common USB Interrupts (USBn_INTRUSB)

The interrupt register for common USB interrupts (USBn_INTRUSB) is an 8-bit read-only register that indicates which USB interrupts are currently active. All active interrupts will be cleared when this register is read. This register is shown in [Figure 25-154](#) and described in [Table 25-167](#).

Figure 25-154. Interrupt Register for Common USB Interrupts (USBn_INTRUSB)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-167. Interrupt Register for Common USB Interrupts (USBn_INTRUSB) Field Descriptions

Bits	Field Name	Description
7	VBUSERR	Set when VBus drops below the VBus valid threshold during a session. Only valid when the USB controller is 'A' device. All active interrupts will be cleared when this register is read.
6	SESSREQ	Set when session request signaling has been detected. Only valid when USB controller is 'A' device.
5	DISCON	Set in host mode when a device disconnect is detected. Set in peripheral mode when a session ends.
4	CONN	Set when a device connection is detected. Only valid in host mode.
3	SOF	Set when a new frame starts.
2	RESET_BABBLE	Set in peripheral mode when reset signaling is detected on the bus set in host mode when babble is detected.
1	RESUME	Set when resume signaling is detected on the bus while the USB controller is in suspend mode.
0	SUSPEND	Set when suspend signaling is detected on the bus only valid in peripheral mode.

25.9.6.1.8 Interrupt Enable Register for INTRUSB (USBn_INTRUSBE)

The interrupt enable register for INTRUSB (USBn_INTRUSBE) is an 8-bit register that provides interrupt enable bits for each of the interrupts in USBn_INTRUSB. This register is shown in [Figure 25-155](#) and described in [Table 25-168](#).

Figure 25-155. Interrupt Enable Register for INTRUSB (USBn_INTRUSBE)

4	CONN	Connect interrupt enable
3	SOF	Start of frame interrupt enable
2	RESET_BABBLE	Reset interrupt enable
1	RESUME	Resume interrupt enable
0	SUSPEND	Suspend interrupt enable

25.9.6.1.9 Frame Number Register (USBn_FRAME)

The frame number register (USBn_FRAME) is a 16-bit read-only register that holds the last received frame number. This register is shown in [Figure 25-156](#) and described in [Table 25-169](#).

Figure 25-156. Frame Number Register (USBn_FRAME)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-169. Frame Number Register (USBn_FRAME) Field Descriptions

Bits	Field Name	Description
15-11	Reserved	Reserved
10-0	FRAMENUMBER	Last received frame number

25.9.6.1.10 Index Register for Selecting the Endpoint Status and Control Registers (USBn_INDEX)

Each TX endpoint and each Rx endpoint have their own set of control/status registers located between Core_Offset 0x0100 – 0x01FF. In addition one set of TX control/status and one set of Rx control/status registers appear at Core_Offset 0x0010 – 0x0019. This block of memory can be used as a proxy to access endpoint configuration registers. Index is a 4-bit register that determines which endpoint control/status registers are accessed.

Before accessing an endpoint's control/status registers at Core_Offset 0x0010 – 0x0019, the endpoint number should be written to the Index register to ensure that the correct control/status registers appear in the memory map.

The index register for selecting the endpoint status and control registers is shown in [Figure 25-157](#) and described in [Table 25-170](#).

Figure 25-157. Index Register for Selecting the Endpoint Status and Control Registers (USBn_INDEX)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-170. Index Register for Selecting the Endpoint Status and Control Registers (USBn_INDEX) Field Descriptions

Bits	Field Name	Description
7-4	Reserved	Reserved
3-0	EPSEL	Each transmit endpoint and each receive endpoint have their own set of control/status registers. EPSEL determines which endpoint control/status registers are accessed. Before accessing an endpoint's control/status registers, the endpoint number should be written to the Index register to ensure that the correct control/status registers appear in the memory-map.

25.9.6.1.11 Register to Enable the USB 2.0 Test Modes (USBn_TESTMODE)

The register to enable the USB 2.0 test modes (USBn_TESTMODE) is an 8-bit register that is primarily used to put the USB controller into one of the four test modes for high-speed operation described in the USB 2.0 specification – in response to a SET FEATURE: TESTMODE command. It is not used in normal operation.

The register to enable the USB 2.0 test modes is shown in [Figure 25-158](#) and described in [Table 25-171](#).

Figure 25-158. Register to Enable the USB 2.0 Test Modes (USBn_TESTMODE)

7	6	5	4	3	2	1	0
FORCE_HOST	FIFO_ACCESS	FORCE_FS	FORCE_HS	TEST_PACKET	TEST_K	TEST_J	TEST_SE0_NAK
R/W-0-1h	W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-171. Register to Enable the USB 2.0 Test Modes (USBn_TESTMODE) Field Descriptions

Bits	Field Name	Description
7	FORCE_HOST	Set this bit to forcibly put the USB controller into Host mode when SESSION bit is set, regardless of whether it is connected to any peripheral. The controller remains in Host mode until the session bit is cleared, even if a device is disconnected. And if the FORCE_HOST bit remains set, it re-enters Host mode next time the SESSION bit is set. The operating speed is determined using the FORCE_HS and FORCE_FS bits.
6	FIFO_ACCESS	Set this bit to transfer the packet in EP0 Tx FIFO to EP0 Receive FIFO. It is cleared automatically.
5	FORCE_FS	Set this bit to force the USB controller into full-speed mode when it receives a USB reset.
4	FORCE_HS	Set this bit to force the USB controller into high-speed mode when it receives a USB reset.
3	TEST_PACKET	Set this bit to enter the Test_Packet test mode. In this mode, the USB controller repetitively transmits a 53-byte test packet on the bus, the form of which is defined in the Universal Serial Bus Specification Revision 2.0. Note: The test packet has a fixed format and must be loaded into the endpoint 0 FIFO before the test mode is entered.
2	TEST_K	Set this bit to enter the Test_K test mode. In this mode, the USB controller transmits a continuous K on the bus.
1	TEST_J	Set this bit to enter the Test_J test mode. In this mode, the USB controller transmits a continuous J on the bus.
0	TEST_SE0_NAK	Set this bit to enter the Test_SE0_NAK test mode. In this mode, the USB controller remains in high-speed mode, but responds to any valid IN token with a NAK.

25.9.6.2 Indexed Register Space

This is a block of the core register space that is used as a proxy to access the configuration and status registers of an endpoint. Mapping is done by programming the INDEX register with the endpoint number. [Table 25-172](#) lists the registers.

Table 25-172. Indexed Region Registers

Core Address Offset	Indexed Region Registers
10h	Maximum Packet Size for Peripheral/Host Transmit Endpoint
12h	Control Status Register for Endpoint 0 in Peripheral Mode
12h	Control Status Register for Endpoint 0 in Host Mode
12h	Control Status Register for Peripheral Transmit Endpoint
12h	Control Status Register for Host Transmit Endpoint
14h	Maximum Packet Size for Peripheral/Host Receive Endpoint
16h	Control Status Register for Peripheral Receive Endpoint
16h	Control Status Register for Host Receive Endpoint
18h	Count 0 Register
18h	Receive Count Register
1Ah	Type Register (Host mode only)
1Ah	Transmit Type Register (Host mode only)
1Bh	NAKLimit0 Register (Host mode only)
1Bh	Transmit Interval Register (Host mode only)
1Ch	Receive Type Register (Host mode only)
1Dh	Receive Interval Register (Host mode only)
1Fh	Configuration Data Register

25.9.6.2.1 Maximum Packet Size for Peripheral/Host Transmit Endpoint Register (USBn_TXMAXP)

The maximum packet size for peripheral/host transmit endpoint register (USBn_TXMAXP) defines the maximum amount of data that can be transferred through the selected Tx endpoint in a single operation. There is a TxMaxP register for each Tx endpoint (except Endpoint 0). Endpoint 0 resource is hardened in design and max packet size is set to 64 bytes and no user configuration is required or does not exist.

The maximum packet size for peripheral/host transmit endpoint register is shown in [Figure 25-159](#) and described in [Table 25-173](#).

Figure 25-159. Maximum Packet Size for Peripheral/Host Transmit Endpoint Register (USBn_TXMAXP)

15	11	10	0
Reserved	MAXPAYLOAD		
R-0h	R/W-0-400h		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-173. Maximum Packet Size for Peripheral/Host Transmit Endpoint (USBn_TXMAXP) Field Descriptions

Bits	Field Name	Description
15-11	Reserved	Reserved
10-0	MAXPAYLOAD	The maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes, but is subject to the constraints placed by the USB specification on packet sizes for bulk, interrupt, and isochronous transfers in full-speed and high-speed operations. The value written to this register should match the wMaxPacketSize field of the standard endpoint descriptor for the associated endpoint. A mismatch could cause unexpected results.

25.9.6.2.2 Control Status Register for Endpoint 0 in Peripheral Mode (USBn_PERI_CSR0)

The control status register for endpoint 0 in peripheral mode (USBn_PERI_CSR0) is a 16-bit register that provides control and status bits for endpoint 0 when USB controller assumes the role of a peripheral. This register is shown in [Figure 25-160](#) and described in [Table 25-174](#).

Figure 25-160. Control Status Register for Endpoint 0 in Peripheral Mode (USBn_PERI_CSR0)

Reserved								9	8

7	6	5	4	3	2	1	0		
SERV_ SETUPEND	SERV_ RXPKTRDY	SENDSTALL	SETUPEND	DATAEND	SENTSTALL	TXPKTRDY	RXPKTRDY		
W-0-1h	W-0-1h	W-0-1h	R-0-1h	W-0-1h	R/W-0-1h	R/W-0-1h	R-0h		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-174. Control Status Register for Endpoint 0 in Peripheral Mode (USBn_PERI_CSR0) Field Descriptions

Bits	Field Name	Description
15-9	Reserved	Reserved
8	FLUSHFIFO	Set this bit to flush the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXPKTRDY/RXPKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless TXPKTRDY/RXPKTRDY is set.
7	SERV_SETUPEND	Set this bit to clear the SETUPEND bit. It is cleared automatically.
6	SERV_RXPKTRDY	Set this bit to clear the RXPKTRDY bit. It is cleared automatically.
5	SENDSTALL	Set this bit to terminate the current transaction. The STALL handshake will be transmitted and then this bit will be cleared automatically.
4	SETUPEND	This bit will be set when a control transaction ends before the DATAEND bit has been set. An interrupt is generated, and the FIFO will be flushed at this time. The bit is cleared by the writing a 1 to the SERV_SETUPEND bit.
3	DATAEND	Set this bit to 1: a. When setting TXPKTRDY for the last data packet. b. When clearing RXPKTRDY after unloading the last data packet. c. When setting TXPKTRDY for a zero length data packet. It is cleared automatically.
2	SENTSTALL	This bit is set when a STALL handshake is transmitted. This bit should be cleared.
1	TXPKTRDY	Set this bit after loading a data packet into the FIFO. It is cleared automatically when the data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.
0	RXPKTRDY	This bit is set when a data packet has been received. An interrupt is generated when this bit is set. This bit is cleared by setting the SERV_RXPKTRDY bit.

25.9.6.2.3 Control Status Register for Endpoint 0 in Host Mode (USBn_HOST_CSR0)

The control status register for endpoint 0 in host mode (USBn_HOST_CSR0) is a 16-bit register that provides control and status bits for endpoint 0 when USB controller assumes the role of a host. This register is shown in [Figure 25-161](#) and described in [Table 25-175](#).

Figure 25-161. Control Status Register for Endpoint 0 in Host Mode (USBn_HOST_CSR0)

Reserved				DSPING	DATATOGWREN	DATATOG	FLUSHFIFO

NAK_TIMEOUT	STATUSPKT	REQPKT	ERROR	SETUPPKT	RXSTALL	TXPKTRDY	RXPKTRDY
W-0-1h	R/W-0-1h	R/W-0-1h	W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h	R/W-0-1h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 25-175. Control Status Register for Endpoint 0 in Host Mode (USBn_HOST_CSR0)
Field Descriptions**

Bits	Field Name	Description
15-12	Reserved	Reserved
11	DSPING	The CPU writes a 1 to the DSPING bit to instruct the core not to issue PING tokens in the data and status phases of a high-speed control transfer (for use with devices that do not respond to PING).
10	DATATOGWREN	Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
9	DATATOG	When read, this bit indicates the current state of the EP0 data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
8	FLUSHFIFO	Write 1 to this bit to flush the next packet to be transmitted/read from the Endpoint 0 FIFO. The FIFO pointer is reset and the TXPKTRDY/RXPKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless TXPKTRDY/RXPKTRDY is set.
7	NAK_TIMEOUT	This bit will be set when endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the NAKLIMIT0 register. This bit should be cleared to allow the endpoint to continue.
6	STATUSPKT	Set this bit at the same time as the TXPKTRDY or REQPKT bit is set, to perform a status stage transaction. Setting this bit ensures that the data toggle is set so that a DATA1 packet is used for the Status Stage transaction.
5	REQPKT	Set this bit to request an IN transaction. It is cleared when RXPKTRDY is set.
4	ERROR	This bit is set when three attempts have been made to perform a transaction with no response from the peripheral. You should clear this bit. An interrupt is generated when this bit is set.
3	SETUPPKT	Set this bit, at the same time as the TXPKTRDY bit is set, to send a SETUP token instead of an OUT token for the transaction.
2	RXSTALL	This bit is set when a STALL handshake is received. You should clear this bit.
1	TXPKTRDY	Set this bit after loading a data packet into the FIFO. It is cleared automatically when the data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.
0	RXPKTRDY	This bit is set when a data packet has been received. An interrupt is generated when this bit is set. Clear this bit by setting the SERV_RXPKTRDY bit.

25.9.6.2.4 Control Status Register for Peripheral Transmit Endpoint (USB_n_PERI_TXCSR)

The control status register for peripheral transmit endpoint (USB_n_PERI_TXCSR) is a 16-bit register that provides control and status bits for transfers through the currently-selected Tx endpoint when controller assumes the role of a peripheral. There is a TXCSR register for each configured Tx endpoint (not including Endpoint 0).

The control status register for peripheral transmit endpoint is shown in [Figure 25-162](#) and described in [Table 25-176](#).

Figure 25-162. Control Status Register for Peripheral Transmit Endpoint (USB_n_PERI_TXCSR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-176. Control Status Register for Peripheral Transmit Endpoint (USB_n_PERI_TXCSR) Field Descriptions

Bits	Field Name	Description
15	AUTOSET	DMA Mode: The CPU needs to set the AUTOSET bit prior to enabling the Tx DMA. CPU Mode: If the CPU sets the AUTOSET bit, the TXPKTRDY bit will be automatically set when data of the maximum packet size (value in TXMAXP) is loaded into the Tx FIFO. If a packet of less than the maximum packet size is loaded, then the TXPKTRDY bit will have to be set manually.
14	ISO	Set this bit to enable the Tx endpoint for Isochronous transfers, and clear it to enable the Tx endpoint for Bulk or Interrupt transfers.
13	MODE	Set this bit to enable the endpoint direction as Tx, and clear the bit to enable it as Rx. Note: This bit has any effect only where the same endpoint FIFO is used for both Transmit and Receive transactions.
12	DMAEN	Set this bit to enable the DMA request for the Tx endpoint.
11	FRCDATATOG	Set this bit to force the endpoint data toggle to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This can be used by Interrupt Tx endpoints that are used to communicate rate feedback for Isochronous endpoints.
10	DMAMODE	This bit should always be set to 1 when the DMA is enabled.
9-7	Reserved	Reserved
6	CLRDATATOG	Write a 1 to this bit to reset the endpoint data toggle to 0.
5	SENTSTALL	This bit is set automatically when a STALL handshake is transmitted. The FIFO is flushed and the TXPKTRDY bit is cleared. You should clear this bit.
4	SENDSTALL	Write a 1 to this bit to issue a STALL handshake to an IN token. Clear this bit to terminate the stall condition. Note: This bit has no effect where the endpoint is being used for Isochronous transfers.
3	FLUSHFIFO	Write a 1 to this bit to flush the next packet to be transmitted from the endpoint Tx FIFO. The FIFO pointer is reset and the TXPKTRDY bit is cleared. Note: FlushFIFO has no effect unless the TXPKTRDY bit is set. Also note that, if the FIFO is double-buffered, FlushFIFO may need to be set twice to completely clear the FIFO.
2	UNDERRUN	This bit is set automatically if an IN token is received when TXPKTRDY is not set. You should clear this bit.
1	FIFONOTEMPTY	This bit is set when there is at least 1 packet in the Tx FIFO. You should clear this bit.
0	TXPKTRDY	Set this bit after loading a data packet into the FIFO. It is cleared automatically when a data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.

25.9.6.2.5 Control Status Register for Host Transmit Endpoint (USBn_HOST_TXCSR)

The control status register for host transmit endpoint (USBn_HOST_TXCSR) is a 16-bit register that provides control and status bits for transfers through the currently-selected Tx endpoint when controller assumes the role of a host. There is a TXCSR register for each configured Tx endpoint (not including Endpoint 0).

The control status register for host transmit endpoint is shown in [Figure 25-163](#) and described in [Figure 25-163](#).

Figure 25-163. Control Status Register for Host Transmit Endpoint (USBn_HOST_TXCSR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-177. Control Status Register for Host Transmit Endpoint (USBn_HOST_TXCSR) Field Descriptions

Bits	Field Name	Description
15	AUTOSET	DMA Mode: The CPU needs to set the AUTOSET bit prior to enabling the Tx DMA. CPU Mode: If the CPU sets the AUTOSET bit, the TXPKTRDY bit will be automatically set when data of the maximum packet size (value in TXMAXP) is loaded into the Tx FIFO. If a packet of less than the maximum packet size is loaded, then the TXPKTRDY bit will have to be set manually.
14	Reserved	Reserved
13	MODE	Set this bit to enable the endpoint direction as Tx, and clear the bit to enable it as Rx. Note: This bit has any effect only where the same endpoint FIFO is used for both Transmit and Receive transactions.
12	DMAEN	Set this bit to enable the DMA request for the Tx endpoint.
11	FRCDATATOG	Set this bit to force the endpoint data toggle to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This can be used by Interrupt Tx endpoints that are used to communicate rate feedback for Isochronous endpoints.
10	DMAMODE	This bit should always be set to 1 when the DMA is enabled.
9	DATATOGWREN	Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
8	DATATOG	When read, this bit indicates the current state of the Tx EP data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
7	NAK_TIMEOUT	This bit will be set when the Tx endpoint is halted following the receipt of NAK responses for longer than the time set as the NAKLIMIT by the TXINTERVAL register. It should be cleared to allow the endpoint to continue. Note: This is valid only for Bulk endpoints.
6	CLRDATATOG	Write a 1 to this bit to reset the endpoint data toggle to 0.
5	RXSTALL	This bit is set when a STALL handshake is received. The FIFO is flushed and the TXPKTRDY bit is cleared (see below). You should clear this bit.
4	SETUPPKT	Set this bit at the same time as TXPKTRDY is set, to send a SETUP token instead of an OUT token for the transaction. Note: Setting this bit also clears the DATATOG bit.
3	FLUSHFIFO	Write a 1 to this bit to flush the next packet to be transmitted from the endpoint Tx FIFO. The FIFO pointer is reset and the TXPKTRDY bit (below) is cleared. Note: FlushFIFO has no effect unless the TXPKTRDY bit is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.
2	ERROR	The USB controller sets this bit when 3 attempts have been made to send a packet and no handshake packet has been received. You should clear this bit. An interrupt is generated when the bit is set. This is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONOTEMPTY	The USB controller sets this bit when there is at least 1 packet in the Tx FIFO.
0	TXPKTRDY	Set this bit after loading a data packet into the FIFO. It is cleared automatically when a data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.

25.9.6.2.6 Maximum Packet Size for Peripheral/Host Receive Endpoint Register (USB_n_RXMAXP)

The maximum packet size for peripheral/host receive endpoint register (USB_n_RXMAXP) defines the maximum amount of data that can be transferred through the selected Rx endpoint in a single operation. There is a RxMaxP register for each Rx endpoint (except Endpoint 0). Endpoint 0 resource is hardened in design and max packet size is set to 64 bytes and no user configuration is required or does not exist.

The maximum packet size for peripheral/host receive endpoint register is shown in [Figure 25-164](#) and described in [Table 25-178](#).

Figure 25-164. Maximum Packet Size for Peripheral/Host Receive Endpoint Register (USB_n_RXMAXP)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-178. Maximum Packet Size for Peripheral Host Receive Endpoint (USB_n_RXMAXP) Field Descriptions

Bit	Field	Description
15-11	Reserved	Reserved
10-0	MAXPAYLOAD	Defines the maximum amount of data that can be transferred through the selected Receive endpoint in a single frame/microframe (high-speed transfers). The value set can be up to 1024 bytes, but is subject to the constraints placed by the USB specification on packet sizes for bulk, interrupt, and isochronous transfers in full-speed and high-speed operations. The value written to this register should match the wMaxPacketSize field of the standard endpoint descriptor for the associated endpoint. A mismatch could cause unexpected results.

25.9.6.2.7 Control Status Register for Peripheral Receive Endpoint (USB_n_PERI_RXCSR)

The control status register for peripheral receive endpoint (USB_n_PERI_RXCSR) is a 16-bit register that provides control and status bits for transfers through the currently-selected Tx endpoint when controller assumes the role of a peripheral. There is a RXCSR register for each configured Rx endpoint (not including endpoint 0).

The control status register for peripheral receive endpoint is shown in [Figure 25-165](#) and described in [Table 25-179](#).

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-179. Control Status Register for Peripheral Receive Endpoint (USB_n_PERI_RXCSR) Field Descriptions

Bit	Field	Description
15	AUTOCLEAR	DMA Mode: The CPU sets the AUTOCLEAR bit prior to enabling the Rx DMA. CPU Mode: If the CPU sets the AUTOCLEAR bit, then the RXPKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO. When packets of less than the maximum packet size are unloaded, RXPKTRDY will have to be cleared manually.
14	ISO	Set this bit to enable the Receive endpoint for Isochronous transfers, and clear it to enable the Receive endpoint for bulk/interrupt transfers.
13	DMAEN	Set this bit to enable the DMA request for the Receive endpoints.
12	DISNYET	DISNYET: Applies only for bulk/interrupt transactions: The CPU sets this bit to disable the sending of NYET handshakes. When set, all successfully received Rx packets are ACK'd including at the point at which the FIFO becomes full. Note: This bit only has any effect in high-speed mode, in which mode it should be set for all Interrupt endpoints. PID_ERROR: Applies only for ISO Transactions: The core sets this bit to indicate a PID error in the received packet.
11	DMAMODE	Always clear this bit to 0.
10	DATATOGWREN	Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
9	DATATOG	When read, this bit indicates the current state of the Receive EP data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
8	Reserved	Reserved
7	CLRDATATOG	Write a 1 to this bit to reset the endpoint data toggle to 0.
6	SENTSTALL	This bit is set when a STALL handshake is transmitted. The FIFO is flushed and the TXPKTRDY bit is cleared. You should clear this bit.
5	SENDSTALL	Write a 1 to this bit to issue a STALL handshake. Clear this bit to terminate the stall condition. Note: This bit has no effect where the endpoint is being used for Isochronous transfers.
4	FLUSHFIFO	Write a 1 to this bit to flush the next packet to be read from the endpoint Receive FIFO. The FIFO pointer is reset and the RXPKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless RXPKTRDY is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.

Table 25-179. Control Status Register for Peripheral Receive Endpoint (USBn_PERI_RXCSR)
Field Descriptions (continued)

Bit	Field	Description
3	DATAERROR	This bit is set when RXPKTRDY is set if the data packet has a CRC or bit-stuff error. It is cleared when RXPKTRDY is cleared. Note: This bit is only valid when the endpoint is operating in ISO mode. In Bulk mode, it always returns zero.
2	OVERRUN	This bit is set if an OUT packet cannot be loaded into the Receive FIFO. You should clear this bit. Note: This bit is only valid when the endpoint is operating in ISO mode. In bulk mode, it always returns zero.
1	FIFOFULL	This bit is set when no more packets can be loaded into the Receive FIFO.
0	RXPKTRDY	This bit is set when a data packet has been received. You should clear this bit when the packet has been unloaded from the Receive FIFO. An interrupt is generated when the bit is set.

25.9.6.2.8 Control Status Register for Host Receive Endpoint (USBn_HOST_RXCSR)

The control status register for host receive endpoint (USBn_HOST_RXCSR) is a 16-bit register that provides control and status bits for transfers through the currently-selected Rx endpoint when controller assumes the role of a host. There is a TXCSR register for each configured Rx endpoint (not including endpoint 0).

The control status register for host receive endpoint is shown in [Figure 25-166](#) and described in [Table 25-180](#).

**Table 25-180. Control Status Register for Host Receive Endpoint (USBn_HOST_RXCSR)
Field Descriptions**

Bit	Field	Description
15	AUTOCLEAR	DMA Mode: The CPU sets the AUTOCLEAR bit prior to enabling the Rx DMA. CPU Mode: If the CPU sets the AUTOCLEAR bit, then the RXPKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO. When packets of less than the maximum packet size are unloaded, RXPKTRDY will have to be cleared manually.
14	AUTOREQ	If the CPU sets the AUTOREQ bit, then the REQPKT bit will be automatically set when the RXPKTRDY bit is cleared. Note: This bit is automatically cleared when a short packet is received.
13	DMAEN	Set this bit to enable the DMA request for the Receive endpoints.
12	DISNYET	Set this bit to disable the sending of NYET handshakes. When set, all successfully received Receive packets are ACKED including at the point at which the FIFO becomes full. Note: This bit only has any effect in high-speed mode, in which mode it should be set for all Interrupt endpoints.
11	DMAMODE	Always clear this bit to 0.
10	DATATOGWREN	Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
9	DATATOG	When read, this bit indicates the current state of the Receive EP data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
8	Reserved	Reserved
7	CLRDATATOG	Write a 1 to this bit to reset the endpoint data toggle to 0.
6	RXSTALL	When a STALL handshake is received, this bit is set and an interrupt is generated. You should clear this bit.
5	REQPKT	Write a 1 to this bit to request an IN transaction. It is cleared when RXPKTRDY is set.
4	FLUSHFIFO	Write a 1 to this bit to flush the next packet to be read from the endpoint Receive FIFO. The FIFO pointer is reset and the RXPKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless RXPKTRDY is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.

Table 25-180. Control Status Register for Host Receive Endpoint (USBn_HOST_RXCSR)
Field Descriptions (continued)

Bit	Field	Description
3	DATAERR_NAKTIME OUT	When operating in ISO mode, this bit is set when RXPKTRDY is set if the data packet has a CRC or bit-stuff error and cleared when RXPKTRDY is cleared. In Bulk mode, this bit will be set when the Receive endpoint is halted following the receipt of NAK responses for longer than the time set as the NAK Limit by the RXINTERVAL register. You should clear this bit to allow the endpoint to continue.
2	ERROR	The USB controller sets this bit when three attempts have been made to receive a packet and no data packet has been received. You should clear this bit. An interrupt is generated when the bit is set. Note: This bit is only valid when the transmit endpoint is operating in Bulk or Interrupt mode. In ISO mode, it always returns zero.
1	FIFOFULL	This bit is set when no more packets can be loaded into the Receive FIFO.
0	RXPKTRDY	This bit is set when a data packet has been received. You should clear this bit when the packet has been unloaded from the Receive FIFO. An interrupt is generated when the bit is set.

25.9.6.2.9 Count 0 Register (USBn_COUNT0)

The count 0 register (USBn_COUNT0) is a 7-bit read-only register that indicates the number of received data bytes in the Endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while RxPktRdy (bit 0) is set. This register is shown in [Figure 25-167](#) and described in [Table 25-181](#).

Figure 25-167. Count 0 Register (USBn_COUNT0)

15	7	6	0
Reserved R-0h		EP0RXCOUNT R-0-7h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-181. Count 0 Register (USBn_COUNT0) Field Descriptions

Bit	Field	Description
15-7	Reserved	Reserved
6-0	EP0RXCOUNT	Indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while RXPKTRDY of USBn_PERI_CSR0 or USBn_HOST_CSR0 is set.

25.9.6.2.10 Receive Count Register (USBn_RXCOUNT)

The receive count register (USBn_RXCOUNT) is a 13-bit read-only register that holds the number of received data bytes in the packet currently in line to be read from the Rx FIFO for endpoints other than endpoint 0.

Note: The value returned changes as the FIFO is unloaded and is only valid while RxPktRdy (bit 0) is set.

The receive count register is shown in [Figure 25-168](#) and described in [Table 25-182](#).

Figure 25-168. Receive Count Register (USBn_RXCOUNT)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-182. Receive Count Register (USBn_RXCOUNT) Field Descriptions

Bit	Field	Description
15-13	Reserved	Reserved
12-0	EPRXCOUNT	Holds the number of received data bytes in the packet in the Receive FIFO. The value returned changes as the contents of the FIFO change and is only valid while RXPkTRDY of PERI_RXCSR or HOST_RXCSR is set.

25.9.6.2.11 Type Register (Host Mode Only) (USBn_HOST_TYPE0)

The type register (Host mode only) (USBn_HOST_TYPE0) is an 8-bit register, meaningful only when controller assumes the role of a host, of which only bits 6 and 7 are implemented. These bits should be written with the operating speed of the targeted device. This register is shown in [Figure 25-169](#) and described in [Table 25-183](#).

Figure 25-169. Type Register (Host Mode Only) (USBn_HOST_TYPE0)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-183. Type Register (Host Mode Only) (USBn_HOST_TYPE0) Field Descriptions

Bit	Field	Value	Description
7-6	SPEED		Operating Speed of Target Device
		0h	Illegal
		1h	High
		2h	Full
		3h	Low
5-0	Reserved	0	Reserved

25.9.6.2.12 Transmit Type Register (Host Mode Only) (USBn_HOST_TXTYPE)

The transmit type register (Host mode only) (USBn_HOST_TXTYPE) is an 8-bit register that should be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently-selected Tx endpoint, and its operating speed. There is a TxType register for each configured Tx endpoint (except Endpoint 0).

The transmit type register is shown in [Figure 25-170](#) and described in [Table 25-184](#).

Figure 25-170. Transmit Type Register (Host Mode Only) (USBn_HOST_TXTYPE)

7	6	5	4	3	0

		3h	Low
5-4	PROT	0h	Control
		1h	Isochronous
		2h	Bulk
		3h	Interrupt
3-0	TENDPN		Set this value to the endpoint number contained in the transmit endpoint descriptor returned to the USB controller during device enumeration.

25.9.6.2.13 NAKLimit0 Register (Host Mode Only) (USBn_HOST_NAKLIMIT0)

The NAKLimit0 register (Host mode only) (USBn_HOST_NAKLIMIT0) is a 5-bit register that sets the number of frames/microframes (high-speed transfers) after which endpoint 0 should timeout on receiving a stream of NAK responses. (Equivalent settings for other endpoints can be made through their TxInterval and RxInterval registers.) The number of frames/microframes selected is $2^{(m-1)}$ (where m is the value set in the register, valid values 2 – 16). If the host receives NAK responses from the target for more frames than the number represented by the Limit set in this register, the endpoint will be halted. Note: A value of 0 or 1 disables the NAK timeout function.

The NAKLimit0 register is shown in [Figure 25-171](#) and described in [Table 25-185](#).

Figure 25-171. NAKLimit0 Register (Host Mode Only) (USBn_HOST_NAKLIMIT0)

LEGEND: R/W = Read/Write; R = Read only; - n = value after reset

Table 25-185. NAKLimit0 Register (Host Mode Only) (USBn_HOST_NAKLIMIT0) Field Descriptions

Bit	Field	Description
7-5	Reserved	Reserved
4-0	EP0NAKLIMIT	Sets the number of frames/microframes (high-speed transfers) after which endpoint 0 should time out on receiving a stream of NAK responses. The number of frames/microframes selected is $2^{(m-1)}$ (where m is the value set in the register, valid values 2-16). If the host receives NAK responses from the target for more frames than the number represented by the Limit set in this register, the endpoint will be halted. Note: A value of 0 or 1 disables the NAK timeout function.

25.9.6.2.14 Transmit Interval Register (Host Mode Only) (USBn_HOST_TXINTERVAL)

The transmit interval register (Host mode only) (USBn_HOST_TXINTERVAL) is an 8-bit register (meaningful only when controller assumes the role of a host) that, for interrupt and isochronous transfers, defines the polling interval for the currently-selected Tx endpoint. For bulk endpoints, this register sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses. There is a TxInterval register for each configured Tx endpoint (except endpoint 0).

The transmit interval register is shown in [Figure 25-172](#) and described in [Table 25-186](#).

Figure 25-172. Transmit Interval Register (Host Mode Only) (USBn_HOST_TXINTERVAL)

7	POLINTVL_NAKLIMIT	0
R/W-0-FFh		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 25-186. Transmit Interval Register (Host Mode Only) (USBn_HOST_TXINTERVAL)
Field Descriptions**

Bit	Field	Description			
7-0	POLINTVL_NAKLIMIT	For interrupt and isochronous transfers, defines the polling interval for the currently-selected transmit endpoint. For bulk endpoints, sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses. There is a transmit interval register for each configured transmit endpoint (except endpoint 0). In each case, the value that is set defines a number of frames/microframes (high-speed transfers), as follows:			
		Transfer Type	Speed	Valid values (m)	Interpretation
		Interrupt	Low Speed or Full Speed	1-255	Polling interval is m frames
		Isochronous	Full Speed or High Speed	1-16	Polling interval is 2 ⁽⁻¹⁾ microframes
		Bulk	Full Speed or High Speed	2-16	NAK Limit is 2 ⁽⁻¹⁾ frames/microframes
Note: A value of 0 or 1 disables the NAK timeout function.					

25.9.6.2.15 Receive Type Register (Host Mode Only) (USBn_HOST_RXTYPE)

The receive type register (Host mode only) (USBn_HOST_RXTYPE) is an 8-bit register that should be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently-selected Rx endpoint, and its operating speed. There is a RxType register for each configured Rx endpoint (except endpoint 0).

The receive type register is shown in [Figure 25-173](#) and described in [Table 25-187](#).

Figure 25-173. Receive Type Register (Host Mode Only) (USBn_HOST_RXTYPE)

3-0	RENDPN		Set this value to the endpoint number contained in the Receive endpoint descriptor returned to the USB controller during device enumeration

25.9.6.2.16 Receive Interval Register (Host Mode Only) (USBn_HOST_RXINTERVAL)

The receive interval register (Host mode only) (USBn_HOST_RXINTERVAL) is an 8-bit register (only meaningful in host mode only) that, for Interrupt and Isochronous transfers, defines the polling interval for the currently-selected Rx endpoint. For bulk endpoints, this register sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses. There is a RxInterval register for each configured Rx endpoint (except endpoint 0).

The receive interval register is shown in [Figure 25-174](#) and described in [Table 25-188](#).

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 25-188. Transmit Interval Register (Host Mode Only) (USBn_HOST_RXINTERVAL)
Field Descriptions**

Bit	Field	Description			
7-0	POLINTVL_NAKLIMIT	For interrupt and isochronous transfers, defines the polling interval for the currently-selected transmit endpoint. For bulk endpoints, sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses. There is a transmit interval register for each configured transmit endpoint (except endpoint 0). In each case, the value that is set defines a number of frames/microframes (high-speed transfers), as follows:			
		Transfer Type	Speed	Valid values (m)	Interpretation
		Interrupt	Low Speed or Full Speed	1-255	Polling interval is m frames
			High Speed	1-16	Polling interval is 2 ⁽⁻¹⁾ microframes
		Isochronous	Full Speed or High Speed	1-16	Polling interval is 2 ⁽⁻¹⁾ frames/microframes
	Bulk	Full Speed or High Speed	2-16	NAK Limit is 2 ⁽⁻¹⁾ frames/microframes	
Note: A value of 0 or 1 disables the NAK timeout function.					

25.9.6.2.17 Configuration Data Register (USBn_CONFIGDATA)

The configuration data register (USBn_CONFIGDATA) is an 8-bit read-only register that returns information about the selected core configuration. This register information can only be accessed from Indexed Region and INDEX has to be programmed, with zero, selecting endpoint 0. This register is shown in [Figure 25-175](#) and described in [Table 25-189](#).

Figure 25-175. Configuration Data Register (USBn_CONFIGDATA)

Table 25-189. Configuration Data Register (USBn_CONFIGDATA) Field Descriptions

Bit	Field	Value	Description
7	MPRXE	0	Indicates automatic amalgamation of bulk packets. (INDEX register needs to be set to zero.) Automatic amalgamation of bulk packets is not selected.
		1	Automatic amalgamation of bulk packets is selected.
6	MPTXE	0	Indicates automatic splitting of bulk packets. (INDEX register needs to be set to zero.) Automatic splitting of bulk packets is not selected.
		1	Automatic splitting of bulk packets is selected.
5	BIGENDIAN	0	Indicates endian ordering. (INDEX register needs to be set to zero.) Little-endian ordering is selected.
		1	Big-endian ordering is selected.
4	HBRXE	0	Indicates high-bandwidth Rx ISO endpoint support. (INDEX register needs to be set to zero.) High-bandwidth Rx ISO endpoint support is not selected.
		1	High-bandwidth Rx ISO endpoint support is selected.
3	HBTXE	0	Indicates high-bandwidth Tx ISO endpoint support. (INDEX register needs to be set to zero.) High-bandwidth Tx ISO endpoint support is not selected.
		1	High-bandwidth Tx ISO endpoint support is selected.
2	DYNFIFO	0	Indicates dynamic FIFO sizing. (INDEX register needs to be set to zero.) Dynamic FIFO sizing option is not selected.
		1	Dynamic FIFO sizing option is selected.
1	SOFTCONE	0	Indicates soft connect/disconnect. (INDEX register needs to be set to zero.) Soft connect/disconnect option is not selected.
		1	Soft connect/disconnect option is selected.
0	UTMIDATAWIDTH	0	Indicates selected UTMI data width. (INDEX register needs to be set to zero.) 8 bits
		1	16 bits

25.9.7 FIFOs

This address range provides access to the endpoint FIFOs. Register offset addresses for this block is 20h to 5Fh.

25.9.7.1 Transmit and Receive FIFO Register for Endpoint 0 - 15 (USBn_FIFO0 – USBn_FIFO15)

This address range provides 16 addresses for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the TxFIFO for the corresponding endpoint. Reading from these addresses unloads data from the RxFIFO for the corresponding endpoint. The address range is 20h – 5Fh and the FIFOs are located on 32-bit double-word boundaries (endpoint 0 at 20h, endpoint 1 at 24h ... Endpoint 15 at 5Ch).

Note 1: Transfers to and from FIFOs may be 8-bit, 16-bit or 32-bit as required, and any combination of access is allowed provided the data accessed is contiguous. However, all the transfers associated with one packet must be of the same width so that the data is consistently byte-, word- or double-word-aligned. The last transfer may however contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

Note 2: Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or doublepacket buffering. However, burst writing of multiple packets is not supported as flags need to be set after each packet is written.

Note 3: Following a STALL response or a Tx strike out error on endpoint 1 – 15, the associated FIFO is completely flushed.

The transmit and receive FIFO register for endpoint 0 - 15 (USBn_FIFO0 – USBn_FIFO15) is shown in [Figure 25-176](#) and described in [Table 25-190](#).

Figure 25-176. Transmit and Receive FIFO Register for Endpoint 0 - 15 (USBn_FIFO0 – USBn_FIFO15)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-190. FIFOs: Transmit and Receive FIFO Register for Endpoint 0 - 15 (USBn_FIFO0 – USBn_FIFO15) Field Descriptions

Bit	Field	Description
31-0	DATA	Writing to these addresses loads data into the Transmit FIFO for the corresponding endpoint. Reading from these addresses unloads data from the Receive FIFO for the corresponding endpoint.

25.9.7.2 Additional Control and Configuration Registers

Table 25-191 lists the additional Control and Configuration registers.

Table 25-191. Additional Control and Configuration Registers

Core Address Offset	Control and Configuration Registers
60h	Device Control Register
62h	Transmit Endpoint FIFO Size Register
63h	Receive Endpoint FIFO Size Register
64h	Transmit Endpoint FIFO Address Register
66h	Receive Endpoint FIFO Address Register
6Ch	Hardware Version Register

25.9.7.2.1 Device Control Register (USB_n_DEVCTL)

The device control register (USB_n_DEVCTL) is an 8-bit register that is used to select whether the USB controller is operating in peripheral mode or in host mode, and for controlling and monitoring the USB VBus line. If the PHY is suspended no PHY clock is received and the VBus is not sampled. This register is shown in Figure 25-177 and described in Table 25-192.

Figure 25-177. Device Control Register (USB_n_DEVCTL)

7	6	5	4	3	2	1	0
BDEVICE	FSDEV	LSDEV	VBUS		HOSTMODE	HOSTREQ	SESSION

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-192. Device Control Register (USB_n_DEVCTL) Field Descriptions

Bit	Field	Value	Description
7	BDEVICE	0 1	This read-only bit indicates whether the USB controller is operating as the 'A' device or the 'B' device. A device B device
6	FSDEV		This read-only bit is set when a full-speed or high-speed device has been detected being connected to the port (high-speed devices are distinguished from full-speed by checking for high-speed chirps when the device is reset). Only valid in Host mode.
5	LSDEV		This read-only bit is set when a low-speed device has been detected being connected to the port. Only valid in Host mode.
4-3	VBUS	0h 1h 2h 3h	These read-only bits encode the current VBus level as follows: Below session end Above session dnd, below AValid Above AValid, below VBusValid Above VBusValid
2	HOSTMODE		This read-only bit is set when the USB controller is acting as a Host.
1	HOSTREQ		When set, the USB controller initiates the Host negotiation when suspend mode is entered. It is cleared when Host negotiation is completed. ('B' device only)
0	SESSION		When operating as an 'A' device, you must set or clear this bit start or end a session. When operating as a 'B' device, this bit is set/cleared by the USB controller when a session starts/ends. You must also set this bit to initiate the session request protocol. When the USB controller is in suspend mode, you may clear the bit to perform a software disconnect. A special software routine is required to perform SRP. Details will be made available in a later document version.

25.9.7.2.2 Transmit Endpoint FIFO Size Register (USBn_TXFIFOSZ)

The allocation of FIFO space to the different endpoints requires the specification for each Tx endpoint:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required

The transmit endpoint FIFO size register (USBn_TXFIFOSZ) defines the amount of space that needs to be allocated to the FIFO in either single or double buffering context.

For more information, see the *Dynamic FIFO Allocation* section.

The transmit endpoint FIFO size register is shown in [Figure 25-178](#) and described in [Table 25-193](#).

Figure 25-178. Transmit Endpoint FIFO Size Register (USBn_TXFIFOSZ)

7	6	5	4	3	0
Reserved			DPB	SZ	
R-0h			R-0-1h	R-0-Fh	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-193. Transmit Endpoint FIFO Size Register (USBn_TXFIFOSZ) Field Descriptions

Bit	Field	Value	Description
7-5	Reserved		Reserved
4	DPB	0	Double packet buffering enable. Single packet buffering is supported.
		1	Double packet buffering is enabled
3-0	SZ		Maximum packet size to be allowed (before any splitting within the FIFO of Bulk packets prior to transmission). If m = SZ, the FIFO size is calculated as 2(m+3) for single packet buffering and 2(m+4) for dual packet buffering.

25.9.7.2.3 Receive Endpoint FIFO Size Register (USBn_RXFIFOSZ)

The allocation of FIFO space to the different endpoints requires the specification for each Rx endpoint

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required

The receive endpoint FIFO size register (USBn_RXFIFOSZ) defines the amount of space that needs to be allocated to the FIFO in either single or double buffering context.

For more information, see the *Dynamic FIFO Allocation* section.

The receive endpoint FIFO size register is shown in [Figure 25-179](#) and described in [Table 25-194](#).

Figure 25-179. Receive Endpoint FIFO Size Register (USBn_RXFIFOSZ)

7	6	5	4	3	0
Reserved			DPB	SZ	
0h			0-1h	0-Fh	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-194. Receive Endpoint FIFO Size Register (USBn_RXFIFOSZ) Field Descriptions

Bit	Field	Value	Description
7-5	Reserved		Reserved
4	DPB	0	Double packet buffering enable. Single packet buffering is supported.
		1	Double packet buffering is enabled
3-0	SZ		Maximum packet size to be allowed (before any splitting within the FIFO of Bulk packets prior to transmission). If m = SZ, the FIFO size is calculated as 2(m+3) for single packet buffering and 2(m+4) for dual packet buffering.

25.9.7.2.4 Transmit Endpoint FIFO Address Register (USBn_TXFIFOADDR)

The allocation of FIFO space to the different endpoints requires the specification for each Tx endpoint:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required

The transmit endpoint FIFO address register (USBn_TXFIFOADDR) the coding for the start address of the FIFO. Note that the 1st 64 bytes of the FIFO RAM is reserved for the use of endpoint 0. Allocation of FIFO should exclude this reserved location.

The transmit endpoint FIFO address register is shown in [Figure 25-180](#) and described in [Table 25-195](#).

Figure 25-180. Transmit Endpoint FIFO Address Register (USBn_TXFIFOADDR)

15	13	12	0
Reserved		ADDR	
0h		0-1FFFh	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Bit	Field	Description
15-13	Reserved	Reserved
12-0	ADDR	Start address of endpoint FIFO in units of 8 bytes If m = ADDR, then the start address is 8 x m

25.9.7.2.5 Receive Endpoint FIFO Address Register (USBn_RXFIFOADDR)

The allocation of FIFO space to the different endpoints requires the specification for each Rx endpoint:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required

The receive endpoint FIFO address register (USBn_RXFIFOADDR) the coding for the start address of the FIFO. Note that the 1st 64 bytes of the FIFO RAM is reserved for the use of endpoint 0. Allocation of FIFO should exclude this reserved location.

The receive endpoint FIFO address register is shown in [Figure 25-181](#) and described in [Table 25-196](#).

Table 25-196. Receive Endpoint FIFO Address Register (USBn_RXFIFOADDR) Field Descriptions

Bit	Field	Description
15-13	Reserved	Reserved
12-0	ADDR	Start address of endpoint FIFO in units of 8 bytes. If m = ADDR, then the start address is 8 x m.

25.9.7.2.6 Hardware Version Register (USBn_HWVERS)

The hardware version register (USBn_HWVERS) is a 16-bit read-only register that returns information about the version of the RTL from which the core hardware was generated, in particular the RTL version number (REVMAJ.REVMIN). This register is shown in [Figure 25-182](#) and described in [Table 25-197](#).

Figure 25-182. Hardware Version Register (USBn_HWVERS)

15	14	10	9	0
RC	REVMAJ		REVMIN	
0-1h	0-1Fh		0-3E7h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-197. Hardware Version Register (USBn_HWVERS) Field Descriptions

Bit	Field	Description
15	RC	Set to 1 if RTL is used from a Release Candidate, rather than from a full release of the core.
14-10	REVMAJ	Major version of RTL. Range is 0-31.
9-0	REVMIN	Minor version of RTL. Range is 0-999.

25.9.7.3 Target Endpoint Control Registers

Table 25-198 lists the target endpoint control registers. These registers provide target function and hub address details for each of the endpoints. Register addresses consumed by this block is 0x0080 to 0x00FF.

Table 25-198. Target Endpoint Control Registers

Core Address Offset	Target Endpoint Control Registers
80h	Transmit Function Address Register
82h	Transmit Hub Address Register
83h	Transmit Hub Port Register
84h	Receive Function Address Register
86h	Receive Hub Address Register
87h	Receive Hub Port Register

25.9.7.3.1 Transmit Function Address Register (USBn_TXFUNCADDRm)

The transmit function address register (USBn_TXFUNCADDRm) is a 7-bit read/write register (meaningful in host mode operation only) that records the address of the target function that is to be accessed through the associated endpoint (EPn). USBn_TXFUNCADDR needs to be defined for each Tx endpoint that is used.

Note: USBn_TXFUNCADDRm needs to be defined for endpoint 0. This register, together with the USBn_TXHUBADDRm and USBn_TXHUBPORTm registers described below, allow the allocation of multiple devices to the USB controller endpoints.

The transmit function address register is shown in Figure 25-183 and described in Table 25-199.

Figure 25-183. Transmit Function Address Register (USBn_TXFUNCADDRm)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-199. Transmit Function Address (USBn_TXFUNCADDRm) Field Descriptions

Bit	Field	Description
7	Reserved	Reserved
6-0	FUNCADDR	Address of target function

25.9.7.3.2 Transmit Hub Address Register (USBn_TXHUBADDRm)

The transmit hub address register (USBn_TXHUBADDRm) is an 8-bit read/write register which, like USBn_TXHUBPORTm, only need to be written where a full- or low-speed device is connected to Tx endpoint EPn via a high-speed USB 2.0 hub that carries out the necessary transaction translation to convert between high-speed transmission and full-/low-speed transmission. In such circumstances:

- The lower 7 bits should record the address of this USB 2.0 hub
- The top bit should record whether the hub has multiple transaction translators (set to '0' if single transaction translator; set to '1' if multiple transaction translators).

Note: If endpoint 0 is connected to a hub, then USBn_TXHUBADDRm need to be defined for this endpoint.

The transmit hub address register is shown in [Figure 25-184](#) and described in [Table 25-200](#).

Figure 25-184. Transmit Hub Address Register (USBn_TXHUBADDRm)

7	6	0
Reserved	FUNCADDR	
0h	0-7Fh

6-0	HUBADDR	Address of hub

25.9.7.3.3 Transmit Hub Port Register (USBn_TXHUBPORTm)

The transmit hub port register (USBn_TXHUBPORTm) (meaningful in host mode operation only) only needs to be written where a full- or low-speed device is connected to Tx Endpoint EPn via a high-speed USB 2.0 hub which carries out the necessary transaction translation. In such circumstances, these 7-bit read/write registers need to be used to record the port of that USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: If Endpoint 0 is connected to a hub, then USBn_TXHUBPORT needs to be defined for this endpoint.

The transmit hub port register is shown in [Figure 25-185](#) and described in [Table 25-201](#).

Figure 25-185. Transmit Hub Port Register (USBn_TXHUBPORTm)

7	6	0
Reserved	FUNCADDR	
0h	0-7Fh

6-0	HUBPORT	Port number of the hub

25.9.7.3.4 Receive Function Address Register (USBn_RXFUNCADDRm)

The receive function address register (USBn_RXFUNCADDRm) is a 7-bit read/write register (meaningful in host mode operation only) that record the address of the target function that is to be accessed through the associated endpoint (EPn). USBn_RXFUNCADDR needs to be defined for each Rx endpoint that is used.

Note: USBn_RXFUNCADDRm need to be defined for Endpoint 0. This register (together with the USBn_RXHUBADDRm and USBn_RXHUBPORTm registers described below) allow the allocation of multiple devices to the USB controller endpoints.

The receive function address register is shown in [Figure 25-186](#) and described in [Table 25-202](#).

Figure 25-186. Receive Function Address Register (USBn_RXFUNCADDRm)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-202. Receive Function Address Register (USBn_RXFUNCADDRm) Field Descriptions

Bit	Field	Description
7	Reserved	Reserved
6-0	FUNCADDR	Address of target function.

25.9.7.3.5 Receive Hub Address Register (USBn_RXHUBADDRm)

The receive hub address register (USBn_RXHUBADDRm) is an 8-bit read/write register (meaningful in host mode operation only) which, like USBn_RXHUBPORTm, only needs to be written where a full- or low-speed device is connected to Rx Endpoint EPn via a high-speed USB 2.0 hub which carries out the necessary transaction translation to convert between high-speed transmission and full-/low-speed transmission. In such circumstances:

- The lower 7 bits should record the address of this USB 2.0 hub
- The top bit should record whether the hub has multiple transaction translators (set to '0' if single transaction translator; set to '1' if multiple transaction translators).

Note: If Endpoint 0 is connected to a hub, then USBn_RXHUBADDRm need to be defined for this endpoint.

The receive hub address register is shown in [Figure 25-187](#) and described in [Table 25-203](#).

Figure 25-187. Receive Hub Address Register (USBn_RXHUBADDRm)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-203. Receive Hub Address Register (USBn_RXHUBADDRm) Field Descriptions

Bit	Field	Description
7	MULT_TRANS	Set to 1 if hub has multiple transaction translators. Cleared to 0 if only single transaction translator is available.
6-0	HUBADDR	Address of HUB.

25.9.7.3.6 Receive Hub Port Register (USBn_RXHUBPORTm)

The receive hub port register (USBn_RXHUBPORTm) (meaningful in host mode operation only) only needs to be written where a full- or low-speed device is connected to Rx Endpoint EPn via a high-speed USB 2.0 hub which carries out the necessary transaction translation. In such circumstances, these 7-bit read/write registers need to be used to record the port of that USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: If Endpoint 0 is connected to a hub, then USBn_RXHUBPORT needs to be defined for this endpoint.

The receive hub port register is shown in [Figure 25-188](#) and described in [Table 25-204](#).

Figure 25-188. Receive Hub Port Register (USBn_RXHUBPORTm)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 25-204. Receive Hub Port Register (USBn_RXHUBPORTm) Field Descriptions

Bit	Field	Description
7	Reserved	Reserved
6-0	HUBPORT	Port number of HUB.

25.9.7.4 Non-Indexed Endpoint Control/Status Registers

The registers available at indexed region, offset 10h–1Fh, are accessible independently of the setting of the Index register. The Non-Indexed region has dedicated block of register space for each endpoint with memory block between 100h–10Fh are reserved for endpoint 0 registers; memory block between 110h–11Fh are reserved for endpoint 1 registers; memory block between 120h–12Fh are reserved for endpoint 2 registers; and so on.

[Table 25-205](#) and [Table 25-206](#) display the set of endpoint registers that are accessible from their dedicated block of memory in both peripheral and host mode, respectively. Note that the definitions of these register is discussed in detail in [Section 25.9.6.2](#).

Table 25-205. Peripheral Mode Configuration and Status Register Mapping where n=0,1 (USB0 or USB1) and m=1-15 (endpoint number)

Watchdog Timer

This chapter describes the watchdog timer.

Topic	Page
26.1 Introduction	2921
26.2 Architecture	2922
26.3 Low-Level Programming Model	2928
26.4 Watchdog Timer Registers	2930

26.1 Introduction

26.1.1 Overview

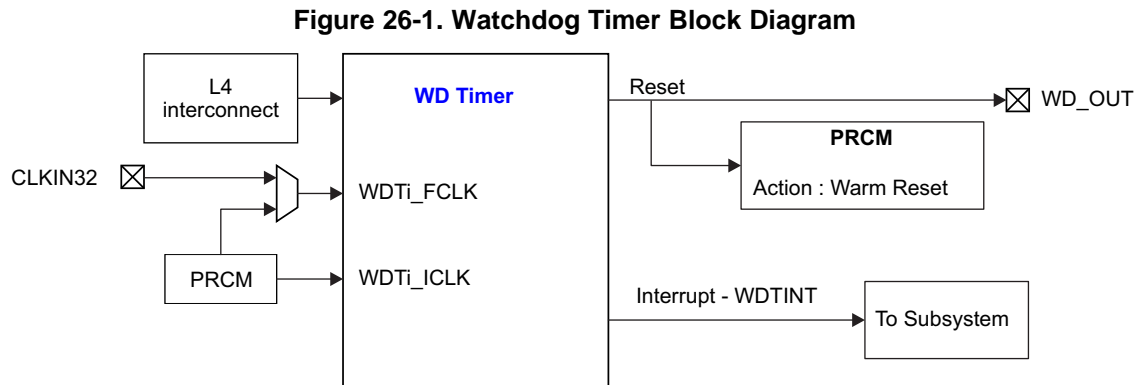

The watchdog timer is an upward counter capable of generating a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The watchdog timer serves resets to the PRCM module and serves watchdog interrupts to the host subsystem. The reset of the PRCM module causes warm reset of the device.

The watchdog timer can be accessed, loaded, and cleared by registers through the L4 interface. The watchdog timer has the 32-kHz clock for its timer clock input.

The watchdog timer connects to a single target agent port on the L4 interconnect. The default state of the watchdog timer is enabled and not running.

26.1.2 Functional Block Diagram

Figure 26-1 shows a block diagram of the watchdog timer.

26.1.3 Features

The main features of the watchdog timer controllers are:

- L4 slave interface support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 11-bit address bus width
 - Burst mode not supported
 - Write nonposted transaction mode only
- Free-running 32-bit upward counter
- Programmable divider clock source (2^n where $n = 0-7$)
- On-the-fly read/write register (while counting)
- Subset programming model of the timer
- The watchdog timers are reset either on power-on or after a warm reset before they start counting.
- Reset or interrupt actions when a timer overflow condition occurs
- The watchdog timer generates a reset or an interrupt in its hardware integration.

26.1.4 Watchdog Timer Environment

The watchdog timers are accessible through the L4 interface.

26.2 Architecture

26.2.1 Power Management

There are two clock domains in the watchdog timers:

- Functional clock domain: WDTi_FCLK is a 32 kHz watchdog timer functional clock. It is used to clock the watchdog timer internal logic.
- Interface clock domain: WDTi_ICLK is a 125 MHz watchdog timer interface clock. It is used to synchronize the watchdog timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDTi_ICLK.

In this device, the watchdog timer clocks are always On. The clocks cannot be turned off, if the watchdog timer is not being used.

26.2.2 Interrupts

Table 26-1 list the event flags, and their masks, that cause module interrupts.

Table 26-1. Watchdog Timer Events

Event Flag	Event Mask	Mapping	Comments
WDT_WIRQSTAT[0] EVENT_OVF	WDT_WIRQENSET/WDT_WIRQENCLR[0] OVF_IT_ENA	WDTINT	Watchdog timer overflow
WDT_WIRQSTAT[1] EVENT_DLY	WDT_WIRQENSET/WDT_WIRQENCLR[1] DLY_IT_ENA	WDTINT	Watchdog delay value reached

26.2.3 General Watchdog Timer Operation

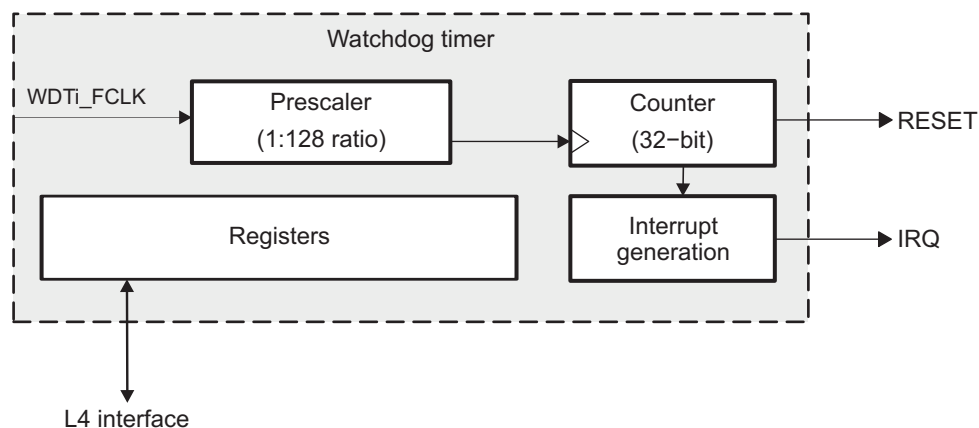

The watchdog timers are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. Figure 26-2 is a functional block diagram of the watchdog timer.

The interrupt generation mechanism is controlled through the WDT_WIRQENSET/WDT_WIRQENCLR and WDT_WIRQSTAT registers.

The prescaler ratio can be set from 1 to 128 by accessing the WDT_WCLR[4:2] PTV bit field and the WDT_WCLR[5] PRE bit of the watchdog control register (WDT_WCLR).

The current timer value can be accessed on-the-fly by reading the watchdog timer counter register (WDT_WCRR), can be modified by accessing the watchdog timer load register (WDT_WLDR) (no on-the-fly update), or can be reloaded by following a specific reload sequence on the watchdog timer trigger register (WDT_WTGR). A start/stop sequence applied to the watchdog timer start/stop register (WDT_WSPR) can start and stop the watchdog timers.

Figure 26-2. 32-Bit Watchdog Timer Functional Block Diagram

26.2.4 Reset Context

The watchdog timers are enabled after reset. Table 26-2 lists the default reset values of the two watchdog timer load registers (the WDT_WLDR) and prescaler ratios (the WDT_WCLR[4:2] PTV bit field). To get these values, software must read the corresponding WDT_WCLR[4:2] PTV bit field and the 32-bit register to retrieve the static configuration of the module.

Table 26-2. Count and Prescaler Default Reset Values

Timer	WDT_WLDR Reset Value	PTV Reset Value
WDT	FFFF FFBEh	0

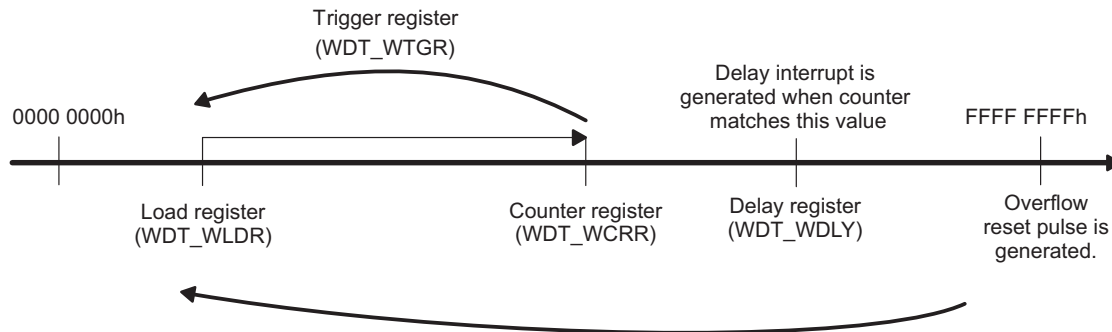

26.2.5 Overflow/Reset Generation

When the watchdog timer counter register (WDT_WCRR) overflows, an active-low reset pulse is generated to the PRCM module. This RESET pulse causes the PRCM module to generate global WARM reset of the device. It is also driven out of the device through the WD_OUT pin. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register (WDT_WLDR) and the prescaler is reset (the prescaler ratio remains unchanged). When the reset pulse output is generated, the timer counter begins incrementing again.

Figure 26-3 shows a general functional view of the watchdog timers.

Figure 26-3. Watchdog Timers General Functional View

26.2.6 Prescaler Value/Timer Reset Frequency

Each watchdog timer is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WDT_WCLR[5] PRE bit and the WDT_WCLR[4:2] PTV bit field)
- Value loaded into the timer load register (WDT_WLDR)

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WDT_WCLR[4:2] PTV bit field) and is enabled with the WDT_WCLR[5] PRE bit.

Table 26-3 lists the prescaler clock ratio values.

Table 26-3. Prescaler Clock Ratio Values

WDT_WCLR[5] PRE	WDT_WCLR[4:2] PTV	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

Thus the watchdog timer overflow rate is expressed as:

$$OVF_Rate = (FFFF\ FFFFh - WDT_WLDR + 1) \times (wd\text{-functional clock period}) \times PS$$

where $wd\text{-functional clock period} = 1/(wd\text{-functional clock frequency})$ and $PS = 2^{(PTV)}$

CAUTION

Internal resynchronization causes some latency in any software write to WDT_WSPR before WDT_WSPR is updated with the programmed value:

$1.5 \times \text{functional clock cycles} \leq \text{write_WDT_WSPR_latency} \leq 2.5 \times \text{functional clock cycles}$

Remember to consider this latency whenever the watchdog timer must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 1 (clock divided by 2) and WDT_WCLR[5] PRE = 1 (clock divider enabled), the reset period is as listed in [Table 26-4](#).

Table 26-4. Reset Period Examples

WDT_WLDR Value	Reset Period
0000 0000h	74 h 56 min
FFFF 0000h	4 s
FFFF FFF0h	1 ms
FFFF FFFFh	62.5 us

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a watchdog timer is enabled, software must periodically trigger a reload before the counter overflows. Hence, the value of the WDT_WLDR[31:0] bit field must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, WDT_WLDR[31:0] = FFFF FFFFh is a special case, although such a value of WDT_WLDR is meaningless. When WDT_WLDR is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the watchdog timer is stopped.

Table 26-5 lists the default reset periods for the watchdog timers.

Table 26-5. Default Watchdog Timer Reset Periods

Watchdog Timers	Clock Source	Default Reset Period
WDT	32 kHz	2 s

26.2.7 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the watchdog timer trigger register (WDT_WTGR) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WDT_WTGR register differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without the generation of a reset pulse.

The timer counter is loaded with the value of the watchdog timer load register (the WDT_WLDR[31:0] TIMER_LOAD bit field), and the prescaler is reset.

26.2.8 Start/Stop Sequence for Watchdog Timers (Using the WDT_WSPR Register)

To start and stop a watchdog timer, access must be made through the start/stop register (WDT_WSPR) using a specific sequence.

To disable the timer, follow this sequence:

1. Write XXXX AAAAh in WDT_WSPR.
2. Write XXXX 5555h in WDT_WSPR.

To enable the timer, follow this sequence:

1. Write XXXX BBBBh in WDT_WSPR.
2. Write XXXX 4444h in WDT_WSPR.

All other write sequences on the WDT_WSPR register have no effect on the start/stop feature of the module.

26.2.9 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (the WDT_WCRR register), prescaler ratio (the WDT_WCLR[4:2] PTV bit field), delay configuration value (the WDT_WDLR[31:0] DLY_VALUE bit field), or the load value (the WDT_WLDR[31:0] TIMER_LOAD bit field), the watchdog timer must be disabled by using the start/stop sequence (the WDT_WSPR register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (the WDT_WTGR register).

26.2.10 Watchdog Counter Register Access Restriction (WDT_WCRR Register)

A 32-bit shadow register is implemented to read a coherent value of the WDT_WCRR register because the WDT_WCRR register is directly related to the timer counter value and is updated on the timer clock (WDT_FCLK). The shadow register is updated by a 16-bit LSB read command.

NOTE: Although the L4 clock (WDT_ICLK) is completely asynchronous with the timer clock (WDT_FCLK), some synchronization is performed to ensure that the value of the WDT_WCRR register is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is performed directly from the accessed register.

To ensure that a coherent value is read inside WDT_WCRR, the first read access is to the lower 16 bits (offset = 8h), followed by read access to the upper 16 bits (offset = Ah).

26.2.11 Watchdog Timer Interrupt Generation

When an interrupt source occurs, the interrupt status bit (the WDT_WIRQSTAT[0] EVENT_OVF or WDT_WIRQSTAT[1] EVENT_DLY bit) is set to 1. The output interrupt line (WDTi_IRQ) is asserted (active low) when status (the EVENT_xxx bit) and enable (the xxx_IT_ENA bit) flags are set to 1; the order is not relevant. Writing 1 to the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status next). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WDT_WIRQSTAT register. Reading the WDT_WIRQSTAT register and writing the value back allows a fast interrupt acknowledge process.

The watchdog timer issues an overflow interrupt if this interrupt is enabled in the watchdog interrupt enable register (WDT_WIRQENSET[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WDT_WIRQSTAT[0] EVENT_OVF bit) is set to 1. The output interrupt line (WDT_IRQ) is asserted (active low) when status (EVENT_OVF) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. This interrupt can be disabled by setting the WDT_WIRQENCLR[0] OVF_IT_ENA bit to 1.

The watchdog can issue the delay interrupt if this interrupt is enabled in the interrupt enable register (WDT_WIRQENSET[1] DLY_IT_ENA = 1). When the counter is running and the counter value matches the value stored in the delay configuration register (WDT_WDLY), the corresponding interrupt status bit is set in the watchdog status register (WDT_WIRQSTAT) and the output interrupt line is asserted (active low) when the flag (EVENT_DLY) and enable (DLY_IT_ENA) bits are 1 in the WDT_WIRQSTAT and WDT_WIRQENSET registers, respectively; the order (normally enable, then flag), is not relevant. This interrupt can be disabled by setting the WDT_WIRQENCLR[1] DLY_IT_ENA bit to 1.

NOTE: Writing 0 to the WDT_WIRQSTAT[0] EVENT_OVF bit or the WDT_WIRQSTAT[1] EVENT_DLY bit has no effect.

The two clock domains are resynchronized because the interrupt event is generated on the functional clock domain (WDTi_FCLK) during the updating of the interrupt status register (WDT_WIRQSTAT).

The WDT_WDLY register is used to specify the value of the delay configuration register. The delay time to interrupt is the difference between the reload value stored in the counter load register (WDT_WLDR) and the programmed value in this register (WDT_WDLY).

Use the following formula to estimate the delay time:

$$\text{Delay time period} = (\text{WDT_WDLY} - \text{WDT_WLDR} + 1) \times \text{Timer clock period} \times \text{Clock divider}$$

Where:

- Timer clock period = 1/(Timer clock frequency)
- Clock divider = 2PTV

If the counter value (WDT_WCRR) reaches the programmed value (WDT_WDLY), the status bit (EVENT_DLY) gets set in the interrupt status register (WDT_WIRQSTAT), and an interrupt occurs if the corresponding enable bit is set in the interrupt enable register (WDT_WIRQENSET).

CAUTION

If the reload event occurs (after a triggering sequence or after a reset sequence) before reaching the programmed value (WDT_WDLY[31:0] WDLY_VALUE), no interrupt is generated.

Also, no interrupt is generated if the value programmed in the delay configuration register (WDT_WDLY) is less than the value stored in the counter load register (WDT_WLDR).

26.2.12 Watchdog Timers Under Emulation

During emulation mode, the watchdog timer can/cannot continue running, according to the value of the WDT_WDSC[5] EMUFREE bit of the system configuration register (WDT_WDSC).

- When EMUFREE is 1, watchdog timer execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

26.2.13 Accessing Watchdog Timer Registers

Posted/nonposted selection applies only to functional registers that require synchronization on/from the timer functional clock domain (WDTi_FCLK). For write/read operation, the following registers are affected:

- WDT_WCLR
- WDT_WCRR
- WDT_WLDR
- WDT_WTGR
- WDT_WDLY
- WDT_WSPR

The timer interface clock domain synchronous registers are not affected by the posted/nonposted selection; the write/read operation is effective and acknowledged (command accepted) after one WDT_ICLK cycle from the command assertion. The timer interface clock domain synchronous registers are:

- WDT_WIDR
- WDT_WDSC
- WDT_WDST
- WDT_WIRQSTATRAW
- WDT_WIRQSTAT
- WDT_WIRQENSET
- WDT_WIRQENCLR
- WDT_WWPS

NOTE: Accesses to WDT2 and WDT3 are posted.

26.3 Low-Level Programming Model

This section covers the low-level hardware programming sequences for configuration and use of the module.

26.3.1 Global Initialization

26.3.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the watchdog timer is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the watchdog timer (see [Table 26-6](#)).

Table 26-6. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled.
Control module	Module-specific pad multiplexing must be set in the control module.
GP Device	Enable WDT in the GP device. See the Control Module Register: CONTROL_SEC_CTRL in the <i>Control Module</i> chapter.
MPU INTC	The MPU INTC configuration must be performed to enable the interrupts from the watchdog timer.

26.3.1.2 Main Sequence – Watchdog Timer Module Global Initialization

[Table 26-7](#) lists the steps for initializing the watchdog timer module when the module is to be used for the first time.

Table 26-7. Watchdog Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	WDT_WDSC[1] SOFTRESET	1
Wait until reset release?	WDT_WDSC[1] SOFTRESET	0
Enable delay interrupt.	WDT_WIRQENSET[1] ENABLE_DLY	1
Enable overflow interrupt.	WDT_WIRQENSET[0] ENABLE_OVF	1

26.3.2 Operational Mode Configuration

26.3.2.1 Main Sequence – Watchdog Timer Basic Configuration

[Table 26-8](#) lists the steps for the basic configuration of the watchdog timer.

Table 26-8. Watchdog Timer Basic Configuration

Step	Register/Bit Field/Programming Model	Value
Disable the watchdog timer.	See Section 26.3.2.2 .	
Set prescaler value.	WDT_WCLR[4:2] PTV	xxx
Enable prescaler.	WDT_WCLR[5] PRE	1
Load delay configuration value.	WDT_WDLY	xxx
Load timer counter value.	WDT_WCRR	xxx
Enable the watchdog timer.	See Section 26.3.2.3 .	

26.3.2.2 Subsequence – Disable the Watchdog Timer

[Table 26-9](#) lists the steps to disable the watchdog timer.

Table 26-9. Disable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write disable sequence Data1.	WDT_WSPR	XXXX AAAAh
Write disable sequence Data2.	WDT_WSPR	XXXX 5555h

26.3.2.3 Subsequence – Enable the Watchdog Timer

[Table 26-10](#) lists the steps to enable the watchdog timer.

Table 26-10. Enable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write enable sequence Data1.	WDT_WSPR	XXXX BBBBh
Write enable sequence Data2.	WDT_WSPR	XXXX 4444h

26.4 Watchdog Timer Registers

The watchdog timer registers are listed in [Table 26-11](#).

CAUTION

The watchdog timers registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

NOTE:

- The WDT_WISR and WDT_WIRQSTATRAW registers have the same functionality. The WDT_WISR register is used for software backward compatibility.
- The WDT_WIER and WDT_WIRQENSET/WDT_WIRQENCLR registers have the same functionality. The WDT_WIER register is used for software backward compatibility.
- The WDT_WIRQSTATRAW and WDT_WIRQSTAT registers give the same information when read. The WDT_WIRQSTATRAW register is used for debug.

Table 26-11. Watchdog Timer Registers

Offset	Acronym	Register Name	Section
0h	WDT_WIDR	WDT_WIDR	Section 26.4.1
10h	WDT_WDSC	WDT_WDSC	Section 26.4.2
14h	WDT_WDST	WDT_WDST	Section 26.4.3

60h	WDT_WIRQENCLR	WDT_WIRQENCLR	Section 26.4.16

26.4.1 WDT_WIDR Register

The WDT_WIDR register is shown and described in the figure and table below.

Figure 26-4. WDT_WIDR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-12. WDT_WIDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	REVISION	R	0	IP Revision

26.4.2 WDT_WDSC Register

The WDT_WDSC register is shown and described in the figure and table below.

This register controls the various parameters of the L4 interface.

Figure 26-5. WDT_WDSC Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-13. WDT_WDSC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	Reserved	R	0	Write 0s for future compatibility. Reads return 0.
5	EMUFREE	R/W	0	Emulation mode 0 = Timer counter frozen in emulation 1 = Timer counter free-running in emulation
4-2	Reserved	R	0	Write 0s for future compatibility. Reads return 0.
1	SOFTRESET	R/W	0	Software reset. (Optional) Read 0 = Reset done, no pending action Write 0 = No action Write 1 = Initiate software reset. Read 1 = Reset (software or other) ongoing
0	Reserved	R	0	Write 0s for future compatibility. Reads return 0.

26.4.3 WDT_WDST Register

The WDT_WDST register provides status information about the module. It is shown and described in the figure and table below.

Figure 26-6. WDT_WDST Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-14. WDT_WDST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0	Reads return 0.
0	RESETDONE	R	1	Internal module reset monitoring Read 0 = Internal module reset is ongoing. Read 1 = Reset completed

26.4.4 WDT_WISR Register

This register shows which interrupt events are pending inside the module. It is shown and described in the figure and table below.

Figure 26-7. WDT_WISR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-15. WDT_WISR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	Reserved	R	0	Reads return 0.
1	DLY_IT_FLAG	R/W	0	Pending delay interrupt status. Read 0 = No delay interrupt pending Write 0 = Status unchanged Write 1 = Status bit cleared Read 1 = Delay interrupt pending
0	OVF_IT_FLAG	R/W	0	Pending overflow interrupt status. Read 0 = No overflow interrupt pending Write 0 = Status unchanged Write 1 = Status bit cleared Read 1 = Overflow interrupt pending

26.4.5 WDT_WIER Register

The WDT_WIERs register controls (enable/disable) the interrupt events.
It is shown and described in the figure and table below.

Figure 26-8. WDT_WIER Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-16. WDT_WIER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	Reserved	R	0	Reads return 0.
1	DLY_IT_ENA	R/W	0	Delay interrupt enable/disable 0 = Disable delay interrupt. 1 = Enable delay interrupt.
0	OVF_IT_ENA	R/W	0	Overflow interrupt enable/disable 0 = Disable overflow interrupt. 1 = Enable overflow interrupt.

26.4.6 WDT_WCLR Register

The WDT_WCLR register controls the prescaler stage of the counter.
It is shown and described in the figure and table below.

Figure 26-9. WDT_WCLR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-17. WDT_WCLR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	Reserved	R	0	Reads return 0.
5	PRE	R/W	1	Prescaler enable/disable configuration 0 = Prescaler disabled 1 = Prescaler enabled
4-2	PTV	R/W	0	Prescaler value The timer counter is prescaled with the value: 2**PTV. Example: PTV = 3 then counter increases value if started after 8 functional clock periods. On reset, it is loaded from PI_PTV_RESET_VALUE input port.
1-0	Reserved	R	0	Write 0s for future compatibility. Reads return 0.

26.4.7 WDT_WCRR Register

The WDT_WCRR register holds the value of the internal counter.

It is shown and described in the figure and table below.

Figure 26-10. WDT_WCRR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-18. WDT_WCRR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TIMER_COUNTER	R/W	0	Value of the timer counter register

26.4.8 WDT_WLDR Register

The WDT_WLDR register holds the timer load value.

It is shown and described in the figure and table below.

Figure 26-11. WDT_WLDR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-19. WDT_WLDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TIMER_LOAD	R/W	0	Value of the timer load register

26.4.9 WDT_WTGR Register

Writing a different value than the one already written in this register does a watchdog counter reload.

Figure 26-12. WDT_WTGR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-20. WDT_WTGR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TTGR_VALUE	R/W	0	Value of the trigger register

26.4.10 WDT_WWPS Register

This register contains the write posting bits for all writeable functional registers.

Figure 26-13. WDT_WWPS Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-21. WDT_WWPS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	Reserved	R	0	Write 0s for future compatibility. Reads return 0.
5	W_PEND_WDLY	R	0	Write pending for register WDLY Read 0 = No register write pending Read 1 = Register write pending
4	W_PEND_WSPR	R	0	Write pending for register WSPR Read 0 = No register write pending Read 1 = Register write pending
3	W_PEND_WTGR	R	0	Write pending for register WTGR Read 0 = No register write pending Read 1 = Register write pending
2	W_PEND_WLDR	R	0	Write pending for register WLDR Read 0 = No register write pending Read 1 = Register write pending
1	W_PEND_WCRR	R	0	Write pending for register WCRR Read 0 = No register write pending Read 1 = Register write pending
0	W_PEND_WCLR	R	0	Write pending for register WCLR Read 0 = No register write pending Read 1 = Register write pending

26.4.11 WDT_WDLY Register

The WDT_WDLY register holds the delay value that controls the internal pre-overflow event detection.

Figure 26-14. WDT_WDLY

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-22. WDT_WDLY Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	WDLY_VALUE	R/W	0	Value of the delay register

26.4.12 WDT_WSPR Register

The WDT_WSPR register holds the start-stop value that controls the internal start-stop FSM.

Figure 26-15. WDT_WSPR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-23. WDT_WSPR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	WSPR_VALUE	R/W	0	Value of the start-stop register

26.4.13 WDT_WIRQSTATRAW Register

IRQ unmasked status, status set per-event raw interrupt status vector, line 0. Raw status is set even if event is not enabled. Write 1 to set the (raw) status, mostly for debug.

Figure 26-16. WDT_WIRQSTATRAW Register

31	2	1	0
Reserved	EVENT_DLY	EVENT_OVF	
R-0	R/W1S-0	R/W1S-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-24. WDT_WIRQSTATRAW Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	Reserved	R	0	Write 0s for future compatibility. Reads return 0.
1	EVENT_DLY	R/W1S	0	Settable raw status for delay event Read 0 = No event pending Write 0 = No action Write 1 = Set event (debug) Read 1 = Event pending
0	EVENT_OVF	R/W1S	0	Settable raw status for overflow event Read 0 = No event pending Write 0 = No action Write 1 = Set event (debug) Read 1 = Event pending

26.4.14 WDT_WIRQSTAT Register

IRQ masked status, status clear per-event enabled interrupt status vector, line 0. Enabled status is not set unless event is enabled. Write 1 to clear the status after interrupt has been serviced (raw status gets cleared, that is, even if not enabled).

Figure 26-17. WDT_WIRQSTAT Register

31	2	1	0
Reserved	EVENT_DLY	EVENT_OVF	
R-0	R/W1C-0	R/W1C-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-25. WDT_WIRQSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	Reserved	R	0	Write 0s for future compatibility. Reads return 0.
1	EVENT_DLY	R/W1C	0	Clearable, enabled status for delay event Read 0 = No (enabled) event pending Write 0 = No action Write 1 = Clear (raw) event Read 1 = Event pending
0	EVENT_OVF	R/W1C	0	Clearable, enabled status for overflow event Read 0 = No (enabled) event pending Write 0 = No action Write 1 = Clear (raw) event Read 1 = Event pending

26.4.15 WDT_WIRQENSET Register

IRQ enable set per-event interrupt enable bit vector, line 0. Write 1 to set (enable interrupt). Readout equal to corresponding _CLR register.

Figure 26-18. WDT_WIRQENSET Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-26. WDT_WIRQENSET Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	Reserved	R	0	Write 0s for future compatibility. Reads return 0.
1	ENABLE_DLY	R/W1S	0	Enable for delay event Read 0 = Interrupt disabled (masked) Write 0 = No action Write 1 = Enable interrupt. Read 1 = Interrupt enabled
0	ENABLE_OVF	R/W1S	0	Enable for overflow event Read 0 = Interrupt disabled (masked) Write 0 = No action Write 1 = Enable interrupt. Read 1 = Interrupt enabled

26.4.16 WDT_WIRQENCLR Register

IRQ enable clear per-event interrupt enable bit vector, line 0. Write 1 to clear (disable interrupt). Readout equal to corresponding _SET register.

Figure 26-19. WDT_WIRQENCLR Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 26-27. WDT_WIRQENCLR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	Reserved	R	0	Write 0s for future compatibility. Reads return 0.
1	ENABLE_DLY	R/W1C	0	Enable for delay event Read 0 = Interrupt disabled (masked) Write 0 = No action Write 1 = Disable interrupt. Read 1 = Interrupt enabled
0	ENABLE_OVF	R/W1C	0	Enable for overflow event Read 0 = Interrupt disabled (masked) Write 0 = No action Write 1 = Disable interrupt. Read 1 = Interrupt enabled

Revision History

Changes from October 14, 2013 to July 4, 2015 (from D Revision (October 2013) to E Revision)	Page
• Chapter 1: Chip Level Resources	130
• Updated Dual Cortex-M3 MPU Subsystem Overview section.....	133
• Removed DSP Interrupt Map and NMI Interrupt section.	156
• Added Arteris and Sonics trademark notes.	259
• Updated image.....	270
• Chapter 2: PRCM	397
• Updated Audio Clock Structure image.....	419
• Changed MCBSP_CLKSEL Mux Source 3 from Reserved to CLK5.	421
• Added DEEPSLEEP control register not supported in this SoC.	460
• Removed SSC from MPUPLL_CLKCTRL register.....	466
• Removed SSC from DSPPLL_CLKCTRL register.	480
• Updated DSPPLL_FRACDIV register description.	486
• Removed SSC from SGXPLL_CLKCTRL register.	492
• Updated SGXPLL_FRACDIV register description.	498
• Removed SSC from HDVICPPLL_CLKCTRL register.	504
• Updated HDVICPPLL_FRACDIV register description.	510
• Removed SSC from L3PLL_CLKCTRL register.	516
• Updated L3PLL_FRACDIV register description.	522
• Removed SSC from ISPPLL_CLKCTRL register.	528
• Updated ISPPLL_FRACDIV register description.	534
• Removed SSC from DSSPLL_CLKCTRL register.	540
• Updated DSSPLL_FRACDIV register description.	546
• Removed SSC from VIDEO0PLL_CLKCTRL register.	552
• Updated VIDEO0PLL_FRACDIV register description.	558
• Removed SSC from VIDEO1PLL_CLKCTRL register.	564
• Updated VIDEO1PLL_FRACDIV register description.	570
• Removed SSC from HDMIPPLL_CLKCTRL register.	576
• Updated HDMIPPLL_FRACDIV register description.	582
• Removed SSC from AUDIOPLL_CLKCTRL register.	588
• Updated AUDIOPLL_FRACDIV register description.	594
• Removed SSC from USBPLL_CLKCTRL register.	600
• Updated USBPLL_FRACDIV register description.	606
• Removed SSC from DDRPLL_CLKCTRL register.	612
• Updated DDRPLL_FRACDIV register description.	618
• Changed SYSCLK16 to SYSCLK18 in CM_SYSCLK18_CLKSEL register description.....	662
• Chapter 4: ROM Code Memory and Peripheral Booting	952
• Updated MMC/SD Detection Procedure image.	983
• Chapter 6: DMM/TILER	1087
• Figure 6-1: Deleted frequencies	1088
• Figure 6-1: Connected DMM to EMIF and DDR Bank	1088
• Changed DMM_PEG_PRI01 to DMM_PEG_PRI07.	1091
• Changed DMM_PEG_PRI0_0-DMM_PEG_PRI0_1 register to DMM_PEG_PRI0_0-DMM_PEG_PRI0_7.	1160
• Chapter 7: DDR2 and DDR3 Memory Controller	1161
• Updated Programmable Slew-rate Settings table.	1182
• Changed DDR_TERM in SDRRCR Configuration table from 50 to 75 Ohms.	1186
• Updated DDR_TERM recommendation in SDRAM Configuration register from 50 to 75 Ohms.....	1198
• Changed Bits 23-21 in SDRAM Timing 3 register from Reserved to T_CKESR.	1208
• Updated Audio Video Bridging section, added Hardware Example Usage section.	1402
• Chapter 11: GPMC	1565

-
- Updated GPMC Connection to an External NOR Flash Memory figure. 1667
 - Changed value ECCTOPSECTOR bit field in GPMC_ECC_CONFIG register from 512Kb to 512bytes. 1703
-

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
