		4h	Update on 5 consecutive update requests
		5h	Update on 6 consecutive update requests
		6h	Update on 7 consecutive update requests
		7h	Update on 8 consecutive update requests
0	CLRz		Clears the flops, start count again, after low going pulse

7.8.3.6 VTP Initialization

VTP-controller can be used in static or dynamic update modes. For both the modes VTP- controller is required to be initialized after every power-up cycle or for recalibration. The 'READY' bit reflects the status of initialization sequence completion.

To initialize the VTP-controller a negative going CLRz pulse should be asserted for at least 4ns. Once CLRz is removed, user needs to poll for READY bit to go high to know when the impedance gets fully trained. The READY bit stays high until CLRz is asserted again to re-initialize the training sequence.

When the LOCK bit is set Dynamic update ceases and VTP controller enters static mode. In order to save power, in static mode, VTP-controller goes into power-down mode. It is to be noted that in the LOCK mode, VTP-controller cannot be cleared (CLRz is disabled).

[Table 7-83](#) shows the master connection IDs for the various initiators in the system, as seen by the DDR controllers.

7.8.3.6.1 DDR Subsystem Level Master Connection IDs

Table 7-83 shows the connection IDs of different masters in the system as seen at DDR subsystem level.

Enhanced Direct Memory Access Controller

This document describes the features and operations of the enhanced direct memory access (EDMA3) controller.

The EDMA3 is a high-performance, multichannel, multithreaded DMA controller that allows you to program a wide variety of transfer geometries and transfer sequences.

[Section 8.1](#) provides an overview of features and terminology. [Section 8.2](#) provides the details of the architecture and the common operations of the EDMA3 channel controller (EDMA3CC) and the EDMA3 transfer controller (EDMA3TC). [Section 8.3](#) contains examples and common usage scenarios. describes the memory-mapped registers that are associated with the EDMA3 controller.

8.4 EDMA Transfer Examples	1285
8.5 EDMA3 Registers	1304
8.6 Appendix A	1381
8.7 Setting Up a Transfer	1383

8.1 Overview

The enhanced direct memory access (EDMA3) controller's primary purpose is to service user-programmed data transfers between two memory-mapped slave endpoints on the device.

Typical usage includes, but is not limited to the following:

- Servicing software-driven paging transfers (for example, transfers from external memory, such as DDR2 to internal device memory, such as DSP L2 SRAM).
- Servicing event-driven peripherals, such as a serial port.
- Performing sorting or sub-frame extraction of various data structures.
- Offloading data transfers from the main device CPU(s) or DSP(s) (see the device-specific data manual for specific peripherals that are accessible via the EDMA3 controller.).

The EDMA3 controller has a different architecture from the previous EDMA2 controller on the TMS320C621x/C671x DSPs and TMS320C64x DSPs. (See the *EDMA v3.0 (EDMA3) Migration Guide for TMS320C645x DSP* ([SPRAAB9](#)) for more information on new/advanced features.)

The EDMA3 controller consists of two principal blocks:

- EDMA3 channel controller (EDMA3CC).
- EDMA3 transfer controller(s) (EDMA3TC).

The EDMA3 channel controller serves as the user interface for the EDMA3 controller. The EDMA3CC includes parameter RAM (PaRAM), channel control registers, and interrupt control registers. The EDMA3CC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TRs) to the transfer controller.

The EDMA3 transfer controllers are slaves to the EDMA3 channel controller that is responsible for data movement. The transfer controller issues read/write commands to the source and destination addresses that are programmed for a given transfer. The operation is transparent to user.

8.2 Features

The EDMA3 channel controller has following features:

- Fully orthogonal transfer description:
 - Three transfer dimensions.
 - A-synchronized transfers: one-dimension serviced per event.
 - AB-synchronized transfers: two-dimensions serviced per event.
 - Independent indexes on source and destination.
 - Chaining feature allows a 3-D transfer based on a single event.
- Flexible transfer definition:
 - Increment or FIFO transfer addressing modes.
 - Linking mechanism allows automatic PaRAM set update.
 - Chaining allows multiple transfers to execute with one event.
- Interrupt generation for the following:
 - Transfer completion.
 - Error conditions.
- Debug visibility:
 - Queue water marking/threshold.
 - Error and status recording to facilitate debug.
- 64 DMA channels:
 - Event synchronization.
 - Manual synchronization (CPU(s) write to event set register).
 - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:

- QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
- Support for programmable QDMA channel to PaRAM mapping.
- 512 PaRAM sets:
 - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Four transfer controllers/event queues. You program the system-level priority of these queues. (See the device data manual for the possible system priorities.)
- 16 event entries per event queue.
- Memory protection support:
 - Proxy memory protection for TR submission.
 - Active memory protection for accesses to PaRAM and registers.

The EDMA3 transfer controller has the following features:

- Four transfer controllers (TC).
- 128-bit wide read and write ports per TC.
- Up to four in-flight transfer requests (TRs).
- Programmable priority level.
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA3CC manages the 3rd dimension).
- Support for increment or constant addressing mode transfers.
- Interrupt and error support.
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness.

8.3 Terminology Used in This Document

The following is a brief explanation of some terms that are used in this document:

Term	Meaning
A-synchronized transfer	A transfer type where one dimension is serviced per synchronization event.
AB-synchronized transfer	A transfer type where two dimensions are serviced per synchronization event.
Chaining	A trigger mechanism in which a transfer can be initiated at the completion of another transfer or sub-transfer.
CPU(s)	The main processing engine or engines on a device. The CPU is typically a DSP or general-purpose processor (see the device-specific data manual to learn more about the CPU on your system.)
DMA channel	One of the 64 channels that external, manual, or chained events can trigger. All direct memory access (DMA) channels exist in the EDMA3CC.
Dummy set or dummy PaRAM set	A PaRAM set for which at least one of the count fields is equal to 0 and at least one of the count fields is nonzero. All of the count fields are cleared in a null PaRAM set.
Dummy transfer	A dummy set results in the EDMA3CC performing a dummy transfer. This is not an error condition. A null set results in an error condition.
EDMA3 channel controller (EDMA3CC)	The EDMA3CC is the portion of the EDMA3 that you program. The EDMA3CC contains the parameter RAM (PaRAM), event processing logic, DMA/QDMA channels, and event queues. The EDMA3CC service events (external, manual, chained, and QDMA) and is responsible for submitting transfer requests to the transfer controllers (EDMA3TC) that perform the actual transfer.
EDMA3 programmer	Any entity on the chip that has read/write access to the EDMA3 registers and can program an EDMA3 transfer.
EDMA3 transfer controller(s) (EDMA3TC)	Transfer controllers are the transfer engines for the EDMA3 controller. They perform the read/writes, as dictated by the EDMA3CC's transfer requests.
Enhanced direct memory access (EDMA3) controller	EDMA3 consists of the EDMA3 channel controller (EDMA3CC) and the EDMA3 transfer controller(s) (EDMA3TC), referred to as EDMA3 in this document.
L3	System bus infrastructure that arbitrates and decodes bus transactions from multiple masters to multiple slaves.
Link parameter set	A PaRAM set that is used for linking.

Term	Meaning
Linking	The mechanism of reloading a PaRAM set with new transfer characteristics on completion of the current transfer.
Memory-mapped slave	All on-chip memories, off-chip memories, and slave peripherals. These typically rely on the EDMA3 (or other master peripheral) to perform transfers to and from them.
Master peripherals	All peripherals that are capable of initiating read and write transfers to the system that may not solely rely on the EDMA3 for their data transfers.
Null set or null PaRAM set	A PaRAM set that has all count fields cleared (except for the link field). A dummy PaRAM set has at least one of the count fields nonzero.
Null transfer	A trigger event for a null PaRAM set results in the EDMA3CC performing a null transfer. This is an error condition. A dummy transfer is not an error condition.
Parameter RAM (PaRAM)	Programmable RAM that stores PaRAM sets that DMA channels, QDMA channels, and linking uses.
Parameter RAM (PaRAM) set	The PaRAM set is a 32-byte EDMA3 channel transfer definition. Each parameter set consists of eight words (that are four bytes each) that store the context for a DMA/QDMA/link transfer. A PaRAM set includes source address, destination address, counts, indexes, and options.
Parameter RAM (PaRAM) set entry	A PaRAM set entry is one of the eight four-byte components of the parameter set.
QDMA channel	A QDMA channel is one of the channels that you can trigger when writing to the trigger word (TRWORD) of a PaRAM set. All QDMA channels exist in the EDMA3CC.
Slave end points	Slave end points are all on-chip memories, off-chip memories, and slave peripherals. Slave end points may rely on the EDMA3 to perform transfers to and from them.
Transfer request (TR)	A command for data movement that is issued from the EDMA3CC to the EDMA3TC. A TR includes source and destination addresses, counts, indexes, and options.
Trigger event	A trigger event is an action that causes the EDMA3CC to service the channel and to submit a transfer request to the EDMA3TC. Trigger events for the DMA channels include events that are triggered manually, externally, and by chain. Trigger events for QDMA channels include events that are triggered automatically and by link.
Trigger word	For QDMA channels, the trigger word specifies the PaRAM set entry that results in a QDMA trigger event when it is written. The trigger word is programmed via the QDMA channel map register (QCHMAP) and can point to any of the PaRAM set entries.
TR synchronization (sync) event	See Trigger event.

EDMA3 Architecture

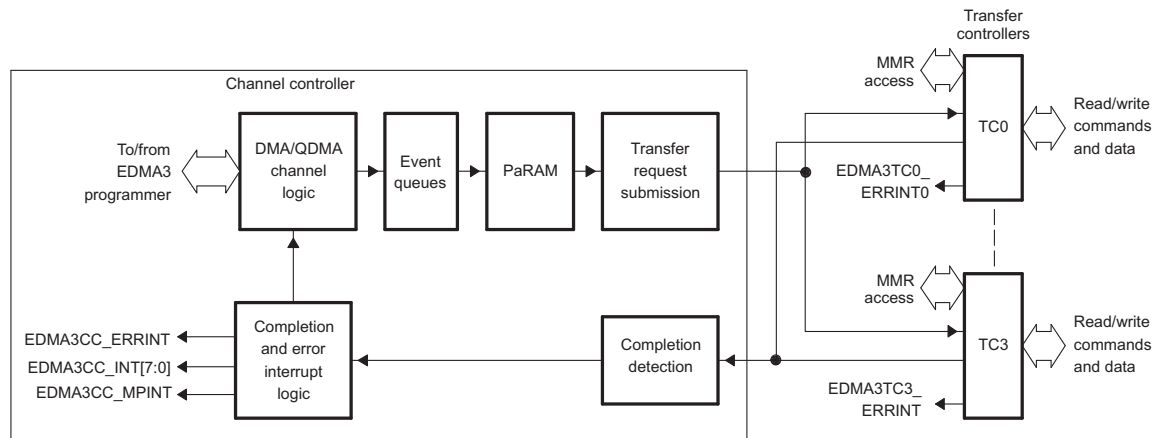

This chapter discusses the architecture of the EDMA3 controller.

8.3.1 Functional Overview

8.3.1.1 EDMA3 Controller Block Diagram

Figure 8-1 shows a block diagram for the EDMA3 controller.

Figure 8-1. EDMA3 Controller Block Diagram

8.3.1.2 EDMA3 Channel Controller (EDMA3CC)

Figure 8-2 shows a functional block diagram of the EDMA3 channel controller (EDMA3CC).

The main blocks of the EDMA3CC are as follows:

- **Parameter RAM (PaRAM):** The PaRAM maintains parameter sets for channel and reload parameter sets. You must write the PaRAM with the transfer context for the desired channels and link parameter sets. EDMA3CC processes sets based on a trigger event and submits a transfer request (TR) to the transfer controller.
- **EDMA3 event and interrupt processing registers:** Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- **Completion detection:** The completion detect block detects completion of transfers by the EDMA3TC and/or slave peripherals. You can optionally use completion of transfers to chain trigger new transfers or to assert interrupts.
- **Event queues:** Event queues form the interface between the event detection logic and the transfer request submission logic.
- **Memory protection registers:** Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

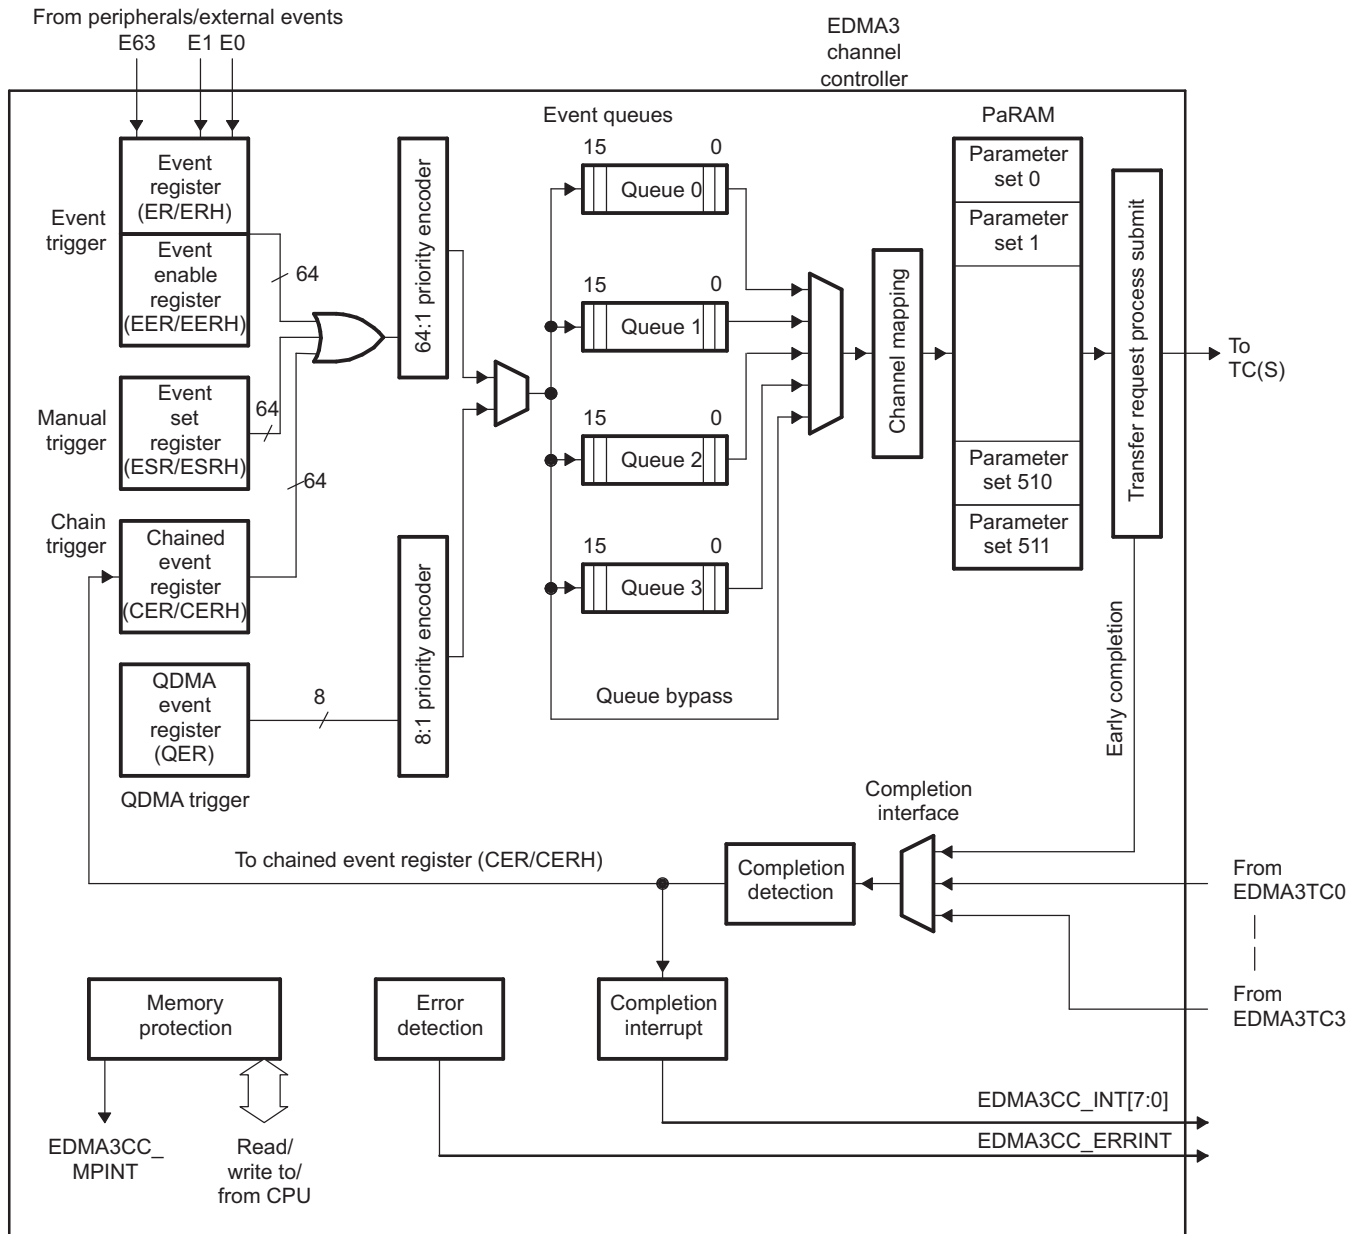

Other functions include the following:

- **Region registers:** Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA3 programmers own (for example, ARM or DSP).
- **Debug registers:** Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA3CC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main thing that differentiates a DMA channel from a QDMA channel is the method that the system uses to trigger transfers. See [Section 8.3.4](#).

Figure 8-2. EDMA3 Channel Controller (EDMA3CC) Block Diagram

A trigger event is needed to initiate a transfer. A trigger event may be due to an external event, manual write to the event set register, or chained event for DMA channels. QDMA channels auto-trigger when a write to the trigger word that you program occurs on the associated PaRAM set. All such trigger events are logged into appropriate registers upon recognition.

Once a trigger event is recognized, the appropriate event gets queued in the EDMA3CC event queue. The assignment of each DMA/QDMA channel to an event queue is programmable. Each queue is 16 events deep; therefore, you can queue up to 16 events (on a single queue) in the EDMA3CC at a time. Additional pending events that are mapped to a full queue are queued when the event queue space becomes available. See [Section 8.3.11](#).

If events on different channels are detected simultaneously, the events are queued based on a fixed priority arbitration scheme with the DMA channels being higher priority events than the QDMA channels. Among the two groups of channels, the lowest-numbered channel is the highest priority.

Each event in the event queue is processed in FIFO order. When the head of the queue is reached, the PaRAM associated with that channel is read to determine the transfer details. The TR submission logic evaluates the validity of the TR and is responsible for submitting a valid transfer request (TR) to the appropriate EDMA3TC (based on the event queue to the EDMA3TC association, Q0 goes to TC0, Q1 goes to TC1, Q2 goes to TC2, and Q3 goes to TC3). For more information, refer to [Section 8.3.3](#).

The EDMA3TC receives the request and is responsible for data movement, as specified in the transfer request packet (TRP), other necessary tasks like buffering, and ensuring transfers are carried out in an optimal fashion wherever possible. For more information on EDMA3TC, refer to [Section 8.3.1.3](#).

If you have decided to receive an interrupt or to chain to another channel on completion of the current transfer, the EDMA3TC signals completion to the EDMA3CC completion detection logic when the transfer is complete. You can alternately choose to trigger completion when a TR leaves the EDMA3CC boundary, rather than wait for all of the data transfers to complete. Based on the setting of the EDMA3CC interrupt registers, the completion interrupt generation logic is responsible for generating EDMA3CC completion interrupts to the CPU. For more information, refer to [Section 8.3.5](#).

Additionally, the EDMA3CC also has an error detection logic that causes an error interrupt generation on various error conditions (like missed events, exceeding event queue thresholds, etc.). For more information on error interrupts, refer to [Section 8.3.9.4](#).

8.3.1.3 EDMA3 Transfer Controller (EDMA3TC)

[Section 8.3.9.4](#) shows a functional block diagram of the EDMA3 transfer controller (EDMA3TC).

Figure 8-3. EDMA3 Transfer Controller (EDMA3TC) Block Diagram

The main blocks of the EDMA3TC are:

- **DMA program register set:** The DMA program register set stores the transfer requests received from the EDMA3 channel controller (EDMA3CC).
- **DMA source active register set:** The DMA source active register set stores the context for the DMA transfer request currently in progress in the read controller.
- **Read controller:** The read controller issues read commands to the source address.
- **Destination FIFO register set:** The destination (DST) FIFO register set stores the context for the DMA transfer request(s) currently in progress in the write controller.
- **Write controller:** The write controller issues write commands/write data to the destination slave.
- **Data FIFO:** The data FIFO exists for holding temporary in-flight data.
- **Completion interface:** The completion interface sends completion codes to the EDMA3CC when a transfer completes, and generates interrupts and chained events (also, see [Section 8.3.1.2](#) for more information on transfer completion reporting).

When the EDMA3TC is idle and receives its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA3CC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands governed by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization. For more information on command fragmentation and optimization, refer to [Section 8.3.12.1.1](#).

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

8.3.2 Types of EDMA3 Transfers

An EDMA3 transfer is always defined in terms of three dimensions. [Figure 8-4](#) shows the three dimensions used by EDMA3 transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using SRCBIDX or DSTBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the 3rd dimension is separated from the previous by an index programmed using SRCCIDX or DSTCIDX.

Note that the reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (SYNCDIM bit in OPT). Of the three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

Figure 8-4. Definition of ACNT, BCNT, and CCNT

8.3.2.1 A-Synchronized Transfers

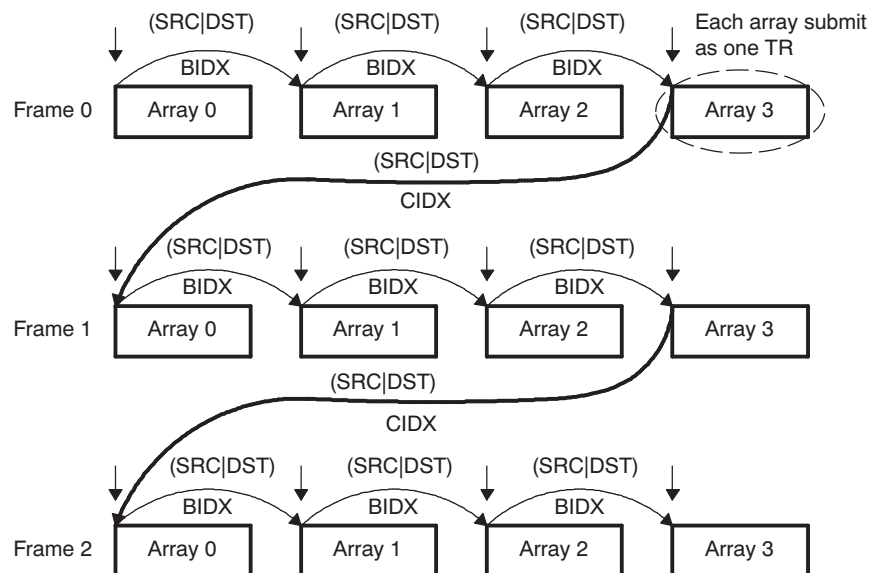

In an A-synchronized transfer, each EDMA3 sync event initiates the transfer of the 1st dimension of ACNT bytes, or one array of ACNT bytes. In other words, each event/TR packet conveys the transfer information for one array only. Thus, $BCNT \times CCNT$ events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX, as shown in [Figure 8-5](#), where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) BIDX.

Frames are always separated by SRCCIDX and DSTCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in [Figure 8-5](#), SRCCIDX/DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

[Figure 8-5](#) shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events ($BCNT \times CCNT$) exhaust a PaRAM set. See [Section 8.3.3.6](#) for details on parameter set updates.

Figure 8-5. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

8.3.2.2 AB-Synchronized Transfers

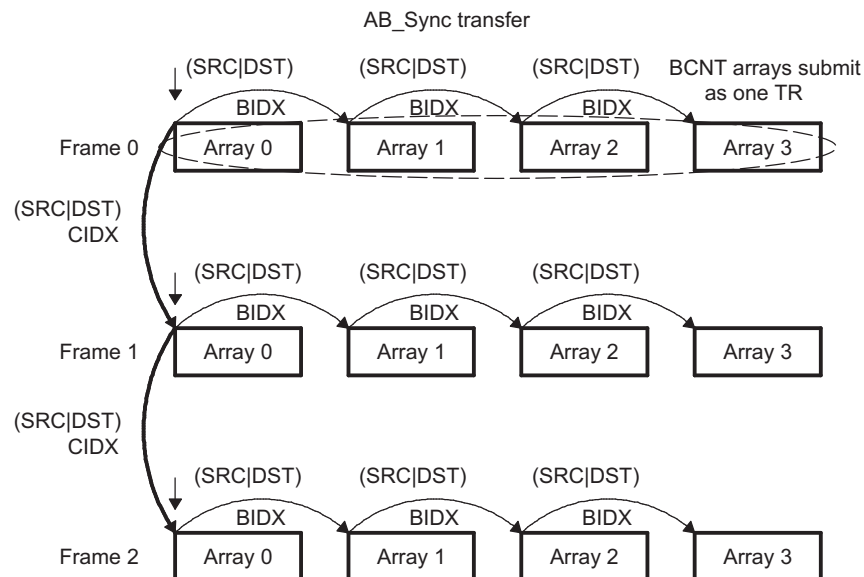

In a AB-synchronized transfer, each EDMA3 sync event initiates the transfer of 2 dimensions or one frame. In other words, each event/TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Thus, CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX as shown in Figure 8-6. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add SRCCIDX/DSTCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 8.3.3.6 for details on parameter set updates.

Figure 8-6 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

Figure 8-6. AB-Synchronized Transfers (ACNT = n , BCNT = 4, CCNT = 3)

NOTE: ABC-synchronized transfers are not directly supported. But can be logically achieved by chaining between multiple AB-synchronized transfers.

8.3.3 Parameter RAM (PaRAM)

The EDMA3 controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table within EDMA3CC, referred to as PaRAM. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 512 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels
- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0. These should be remapped before use. For more information, see [Section 8.5.1.1.3](#) (DCHMAP registers) and [Section 8.5.1.1.4](#) (QCHMAP registers).

Table 8-1. EDMA3 Parameter RAM Contents

PaRAM Set Number	Address ⁽¹⁾	Parameters ⁽²⁾
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
:	:	:
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
:	:	:
510	EDMA Base Address + 7FC0h to EDMA Base Address + 7FDFh	PaRAM set 510
511	EDMA Base Address + 7FE0h to EDMA Base Address + 7FFFh	PaRAM set 511

⁽¹⁾ The EDMA base address can be obtained from the device-specific data manual. See EDMA TPCC Registers.

⁽²⁾ The device has 8 QDMA channels that can be mapped to any parameter set number from 0 to 511.

8.3.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in [Figure 8-7](#) and described in [Table 8-2](#). Each PaRAM set consists of 16-bit and 32-bit parameters.

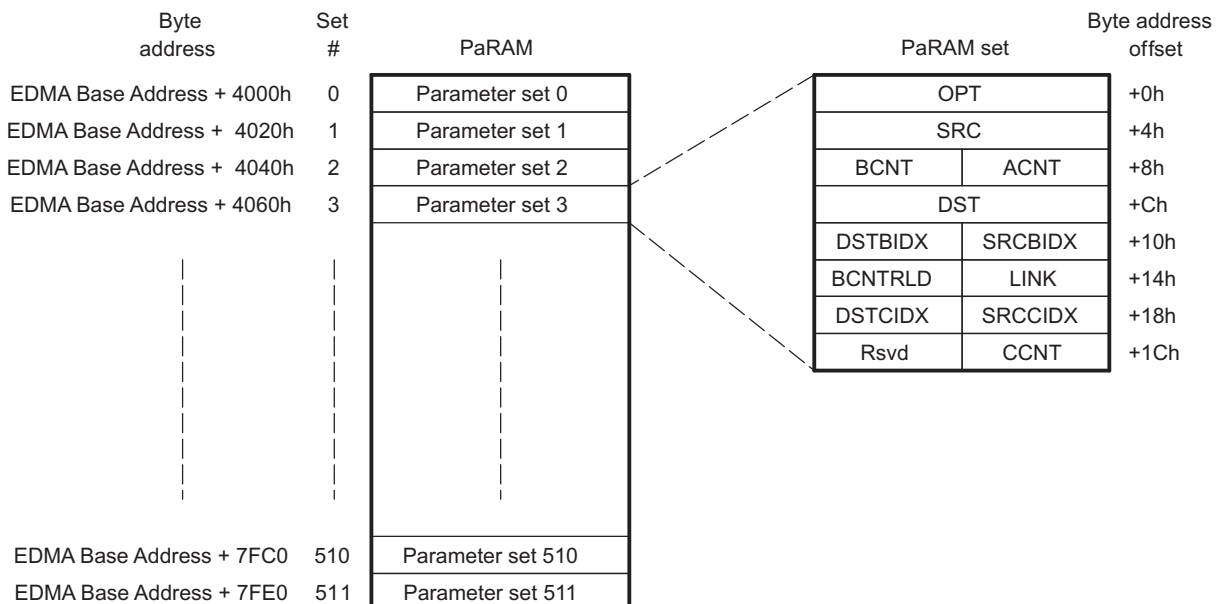

Figure 8-7. PaRAM Set

Table 8-2. EDMA3 Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options	Transfer configuration options
4h	SRC	Channel Source Address	The byte address from which data is transferred
8h ⁽¹⁾	ACNT	Count for 1st Dimension	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address	The byte address to which data is transferred
10h ⁽¹⁾	SRCBIDX	Source BCNT Index	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DSTBIDX	Destination BCNT Index	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h ⁽¹⁾	LINK	Link Address	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h ⁽¹⁾	SRCCIDX	Source CCNT Index	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DSTCIDX	Destination CCNT index	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	RSVD	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

- (1) If OPT, SRC, or DST is the trigger word for a QDMA transfer then it is required to do a 32-bit access to that field. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor will swap addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

8.3.3.2 EDMA3 Channel PaRAM Set Entry Fields

8.3.3.2.1 Channel Options Parameter (OPT)

The channel options parameter (OPT) is shown in [Figure 8-8](#) and described in [Table 8-3](#).

Figure 8-8. Channel Options Parameter (OPT)

31	30	28	27	24	23	22	21	20	19	18	17	16

Table 8-3. Channel Options Parameters (OPT) Field Descriptions

Bit	Field	Value	Description
31	PRIV	0 1	Privilege level (supervisor versus user) for the host/CPU/DMA that programmed this PaRAM set. This value is set with the EDMA3 master's privilege value when any part of the PaRAM set is written. User level privilege. Supervisor level privilege.
30-28	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
27-24	PRIVID	0-Fh	Privilege identification for the external host/CPU/DMA that programmed this PaRAM set. This value is set with the EDMA3 master's privilege identification value when any part of the PaRAM set is written.
23	ITCCHEN	0 1	Intermediate transfer completion chaining enable. 0 Intermediate transfer complete chaining is disabled. 1 Intermediate transfer complete chaining is enabled. When enabled, the chained event register (CER/CERH) bit is set on every intermediate chained transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in CER or CERH is the TCC value specified.
22	TCCHEN	0 1	Transfer complete chaining enable. 0 Transfer complete chaining is disabled. 1 Transfer complete chaining is enabled. When enabled, the chained event register (CER/CERH) bit is set on final chained transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in CER or CERH is the TCC value specified.
21	ITCINTEN	0 1	Intermediate transfer completion interrupt enable. 0 Intermediate transfer complete interrupt is disabled. 1 Intermediate transfer complete interrupt is enabled. When enabled, the interrupt pending register (IPR / IPRH) bit is set on every intermediate transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in IPR or IPRH is the TCC value specified. To generate a completion interrupt to the CPU, the corresponding IER [TCC] / IERH [TCC] bit must be set.
20	TCINTEN	0 1	Transfer complete interrupt enable. 0 Transfer complete interrupt is disabled. 1 Transfer complete interrupt is enabled. When enabled, the interrupt pending register (IPR / IPRH) bit is set on transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in IPR or IPRH is the TCC value specified. To generate a completion interrupt to the CPU, the corresponding IER [TCC] / IERH [TCC] bit must be set.
19-18	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

Table 8-3. Channel Options Parameters (OPT) Field Descriptions (continued)

Bit	Field	Value	Description
17-12	TCC	0-3Fh	Transfer complete code. This 6-bit code sets the relevant bit in the chaining enable register (CER [TCC] / CERH [TCC]) for chaining or in the interrupt pending register (IPR [TCC] / IPRH [TCC]) for interrupts.
11	TCCMODE	0 1	Transfer complete code mode. Indicates the point at which a transfer is considered completed for chaining and interrupt generation. 0 Normal completion: A transfer is considered completed after the data has been transferred. 1 Early completion: A transfer is considered completed after the EDMA3CC submits a TR to the EDMA3TC. TC may still be transferring data when the interrupt/chain is triggered.
10-8	FWID	0-7h 0 1h 2h 3h 4h 5h 6h-7h	FIFO Width. Applies if either SAM or DAM is set to constant addressing mode. 0 FIFO width is 8-bit. 1h FIFO width is 16-bit. 2h FIFO width is 32-bit. 3h FIFO width is 64-bit. 4h FIFO width is 128-bit. 5h FIFO width is 256-bit. 6h-7h Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	STATIC	0 1	Static set. 0 Set is not static. The PaRAM set is updated or linked after a TR is submitted. A value of 0 should be used for DMA channels and for non-final transfers in a linked list of QDMA transfers. 1 Set is static. The PaRAM set is not updated or linked after a TR is submitted. A value of 1 should be used for isolated QDMA transfers or for the final transfer in a linked list of QDMA transfers.
2	SYNCDIM	0 1	Transfer synchronization dimension. 0 A-synchronized. Each event triggers the transfer of a single array of ACNT bytes. 1 AB-synchronized. Each event triggers the transfer of BCNT arrays of ACNT bytes.
1	DAM	0 1	Destination address mode. 0 Increment (INCR) mode. Destination addressing within an array increments. Destination is not a FIFO. 1 Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM	0 1	Source address mode. 0 Increment (INCR) mode. Source addressing within an array increments. Source is not a FIFO. 1 Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

8.3.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA3. For SAM in constant addressing mode, you must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See [Section 8.3.12.3](#) for additional details.

8.3.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA3. For DAM in constant addressing mode, you must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See [Section 8.3.12.3](#) for additional details.

8.3.3.2.4 Count for 1st Dimension (ACNT)

ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA3TC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

See [Section 8.3.3.5](#) and [Section 8.3.5.3](#) for details on dummy/null completion conditions.

8.3.3.2.5 Count for 2nd Dimension (BCNT)

BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

See [Section 8.3.3.5](#) and [Section 8.3.5.3](#) for details on dummy/null completion conditions.

8.3.3.2.6 Count for 3rd Dimension (CCNT)

CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

A CCNT value of 0 is considered either a null or dummy transfer. See [Section 8.3.3.5](#) and [Section 8.3.5.3](#) for details on dummy/null completion conditions.

8.3.3.2.7 BCNT Reload (BCNTRLD)

BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA3CC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA3CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA3CC submits the BCNT in the TR and the EDMA3TC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

8.3.3.2.8 Source B Index (SRCBIDX)

SRCBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for SRCBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- SRCBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- SRCBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- SRCBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

8.3.3.2.9 Destination B Index (DSTBIDX)

DSTBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for DSTBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. See SRCBIDX for examples.

8.3.3.2.10 Source C Index (SRCCIDX)

SRCCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for SRCCIDX are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when SRCCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 8-5), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 8-6).

8.3.3.2.11 Destination C Index (DSTCIDX)

DSTCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when DSTCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 8-5), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 8-6).

8.3.3.2.12 Link Address (LINK)

The EDMA3CC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the EDMA3CC loads/reloads the next PaRAM set during linking.

You must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA3CC ignores the upper 2 bits of the LINK entry, allowing the programmer the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if you make use of the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

You should make sure to program the LINK field correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

A LINK value of FFFFh is referred to as a NULL link that should cause the EDMA3CC to perform an internal write of 0 to all entries of the current PaRAM set, except for the LINK field that is set to FFFFh. Also, see Section 8.3.5 for details on terminating a transfer.

8.3.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (ACNT, BCNT, and CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA3CC, the bit corresponding to the channel is set in the associated event missed register (EMR, EMRH, or QEMR). This bit remains set in the associated secondary event register (SER, SERH, or QSER). *This implies that any future events on the same channel are ignored by the EDMA3CC and you are required to clear the bit in SER, SERH, or QSER for the channel.* This is considered an error condition, since events are not expected on a channel that is configured as a null transfer. See Section 8.5.1.6.8 and Section 8.5.1.2.1 for more information on the SER and EMR registers, respectively.

8.3.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (ACNT, BCNT, or CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA3CC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EMR, EMRH, or QEMR) and the secondary event register (SER, SERH, or QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes. See Section 8.5.1.6.8 and Section 8.5.1.2.1 for more information on the SER and EMR registers, respectively.

8.3.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA3CC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E_n) in EMR to get set and the E_n bit in SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

[Table 8-4](#) summarizes the conditions and effects of null and dummy transfer requests.

Table 8-4. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EMR/EMRH/QEMR is set	Yes	No
SER/SERH/QSER remains set	Yes	No
Link update (STATIC = 0 in OPT)	Yes	Yes
QER is set	Yes	Yes
IPR/IPRH CER/CERH is set using early completion	Yes	Yes

8.3.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA3CC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of CCNT after submission of every transfer request.

See [Table 8-5](#) for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in [Section 8.3.3.7](#).

After the TR is read from the PaRAM (and is in process of being submitted to EDMA3TC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: ACNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK.
- AB-synchronized: ACNT, BCNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK.

Note that PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA3TC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in [Section 8.3.12](#). For A-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes (BCNT = 1 and CCNT = 1). For AB-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes of BCNT arrays (CCNT = 1). The EDMA3TC is responsible for updating source and destination addresses within the array based on ACNT and FWID (in OPT). For AB-synchronized transfers, the EDMA3TC is also responsible to update source and destination addresses between arrays based on SRCBIDX and DSTBIDX.

[Table 8-5](#) shows the details of parameter updates that occur within EDMA3CC for A-synchronized and AB-synchronized transfers.

Table 8-5. Parameter Updates in EDMA3CC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	CCNT > 1	CCNT == 1
SRC	+= SRCBIDX	+= SRCCIDX	= Link.SRC	in EDMA3TC	+= SRCCIDX	= Link.SRC
DST	+= DSTBIDX	+= DSTCIDX	= Link.DST	in EDMA3TC	+= DSTCIDX	= Link.DST
ACNT	None	None	= Link.ACNT	None	None	= Link.ACNT
BCNT	-= 1	= BCNTRLD	= Link.BCNT	in EDMA3TC	N/A	= Link.BCNT
CCNT	None	-= 1	= Link.CCNT	in EDMA3TC	-= 1	= Link.CCNT
SRCBIDX	None	None	= Link.SRCBIDX	in EDMA3TC	None	= Link.SRCBIDX
DSTBIDX	None	None	= Link.DSTBIDX	None	None	= Link.DSTBIDX
SRCCIDX	None	None	= Link.SRCBIDX	in EDMA3TC	None	= Link.SRCBIDX
DSTCIDX	None	None	= Link.DSTBIDX	None	None	= Link.DSTBIDX
LINK	None	None	= Link.LINK	None	None	= Link.LINK
BCNTRLD	None	None	= Link.BCNTRLD	None	None	= Link.BCNTRLD
OPT ⁽¹⁾	None	None	= LINK.OPT	None	None	= LINK.OPT

⁽¹⁾ In all cases, no updates occur if OPT.STATIC == 1 for the current PaRAM set.

NOTE: The EDMA3CC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. You should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

8.3.3.7 Linking Transfers

The EDMA3CC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed that the 16-bit link address field of the current parameter set points to. Linking only occurs when the STATIC bit in OPT is cleared.

NOTE: You should always link a transfer (EDMA3 or QDMA) to another useful transfer. If you must terminate a transfer, then you should link the transfer to a NULL parameter set. See [Section 8.3.3.3](#).

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA3 channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the STATIC bit in OPT and the LINK field. In both cases (null or dummy), if the value of LINK is FFFFh, then a null PaRAM set (with all 0s and LINK set to FFFFh) is written to the current PaRAM set. Similarly, if LINK is set to a value other than FFFFh, then the appropriate PaRAM location that LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA3CC reads the entire set (eight words) from the PaRAM set specified by LINK and writes all eight words to the PaRAM set that is associated with the current channel. [Figure 8-9](#) shows an example of a linked transfer.

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (see [Section 8.3.6](#)) should only be used for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by QCHMAP n), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in QER because a write to the trigger word was performed. You can use this feature to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. See [Section 8.3.4.2](#).

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA3 channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. [Figure 8-10](#) shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

NOTE: If the STATIC bit in OPT is set for a PaRAM set, then link updates are not performed.

8.3.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either SAM or DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding BIDX should be an even multiple of 32 bytes (256 bits). The EDMA3CC does not recognize errors here, but the EDMA3TC asserts an error if this is not true. See [Section 8.3.12.3](#).

NOTE: The constant addressing (CONST) mode has limited applicability. The EDMA3 should be configured for the constant addressing mode (SAM/DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. See the device-specific data manual and/or peripheral user's guide to verify if the constant addressing mode is supported. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (SAM/DAM = 0) by appropriately programming the count and indices values.

8.3.3.9 Element Size

The EDMA3 controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: ACNT, BCNT, and CCNT. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that need to be transferred. For example, if you have 16-bit audio data and 256 audio samples that must be transferred to a serial port, you can only do this by programming the ACNT = 2 (2 bytes) and BCNT = 256.

Figure 8-9. Linked Transfer

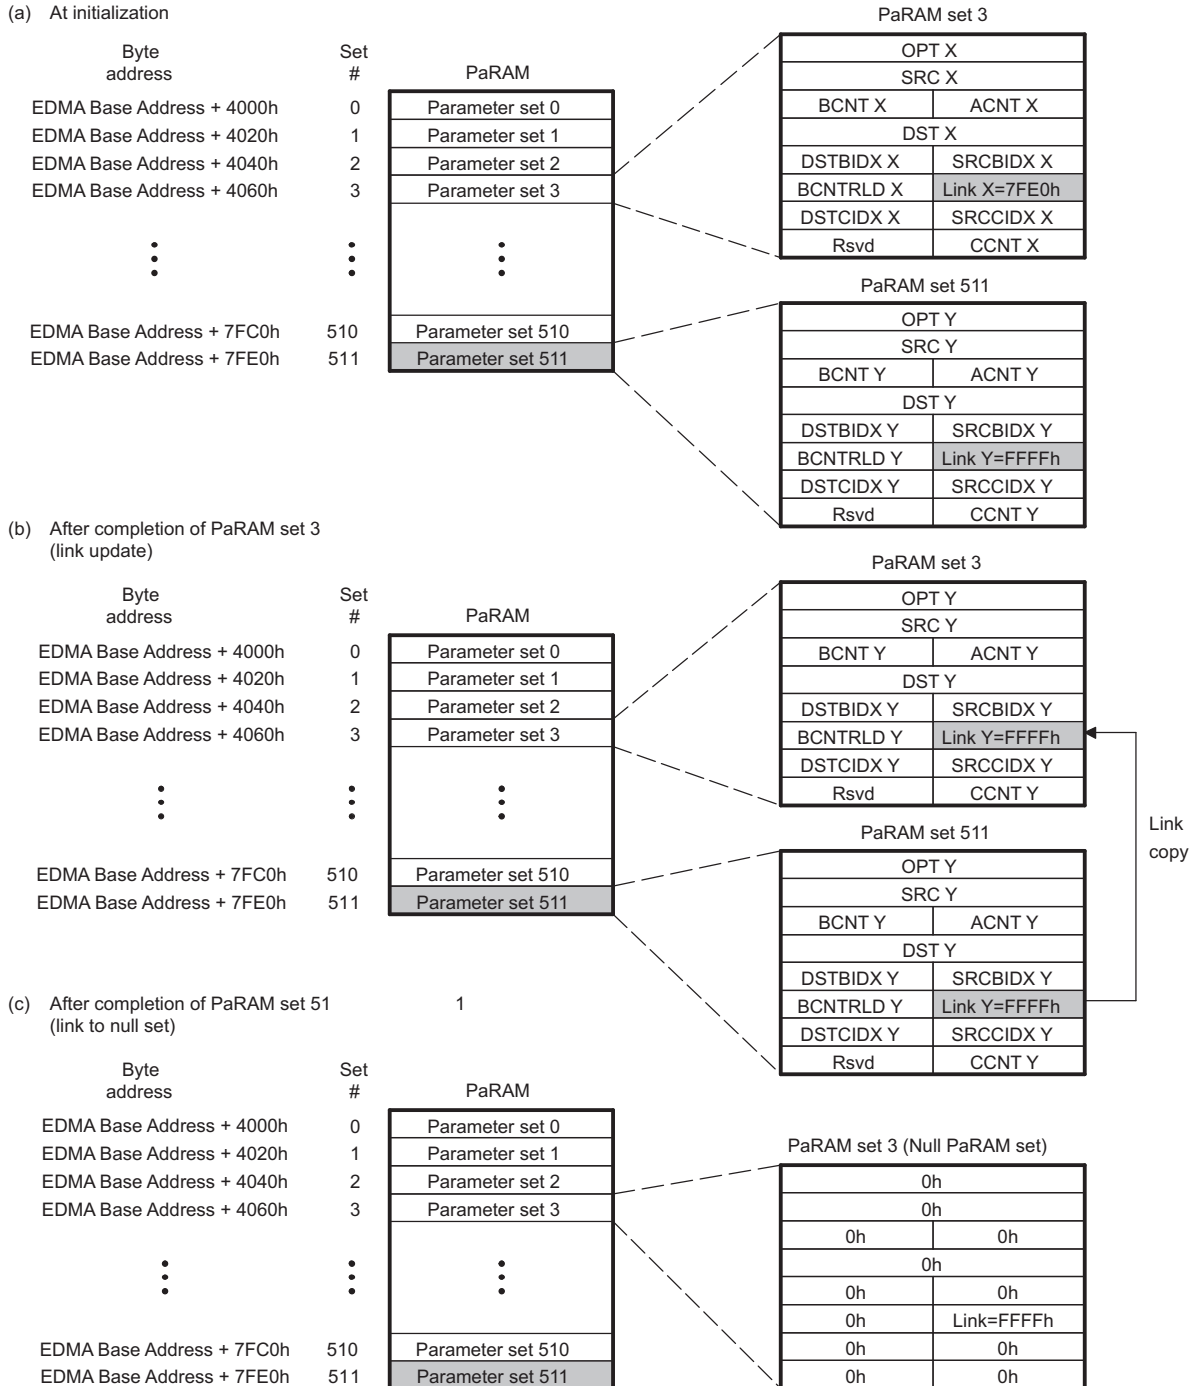

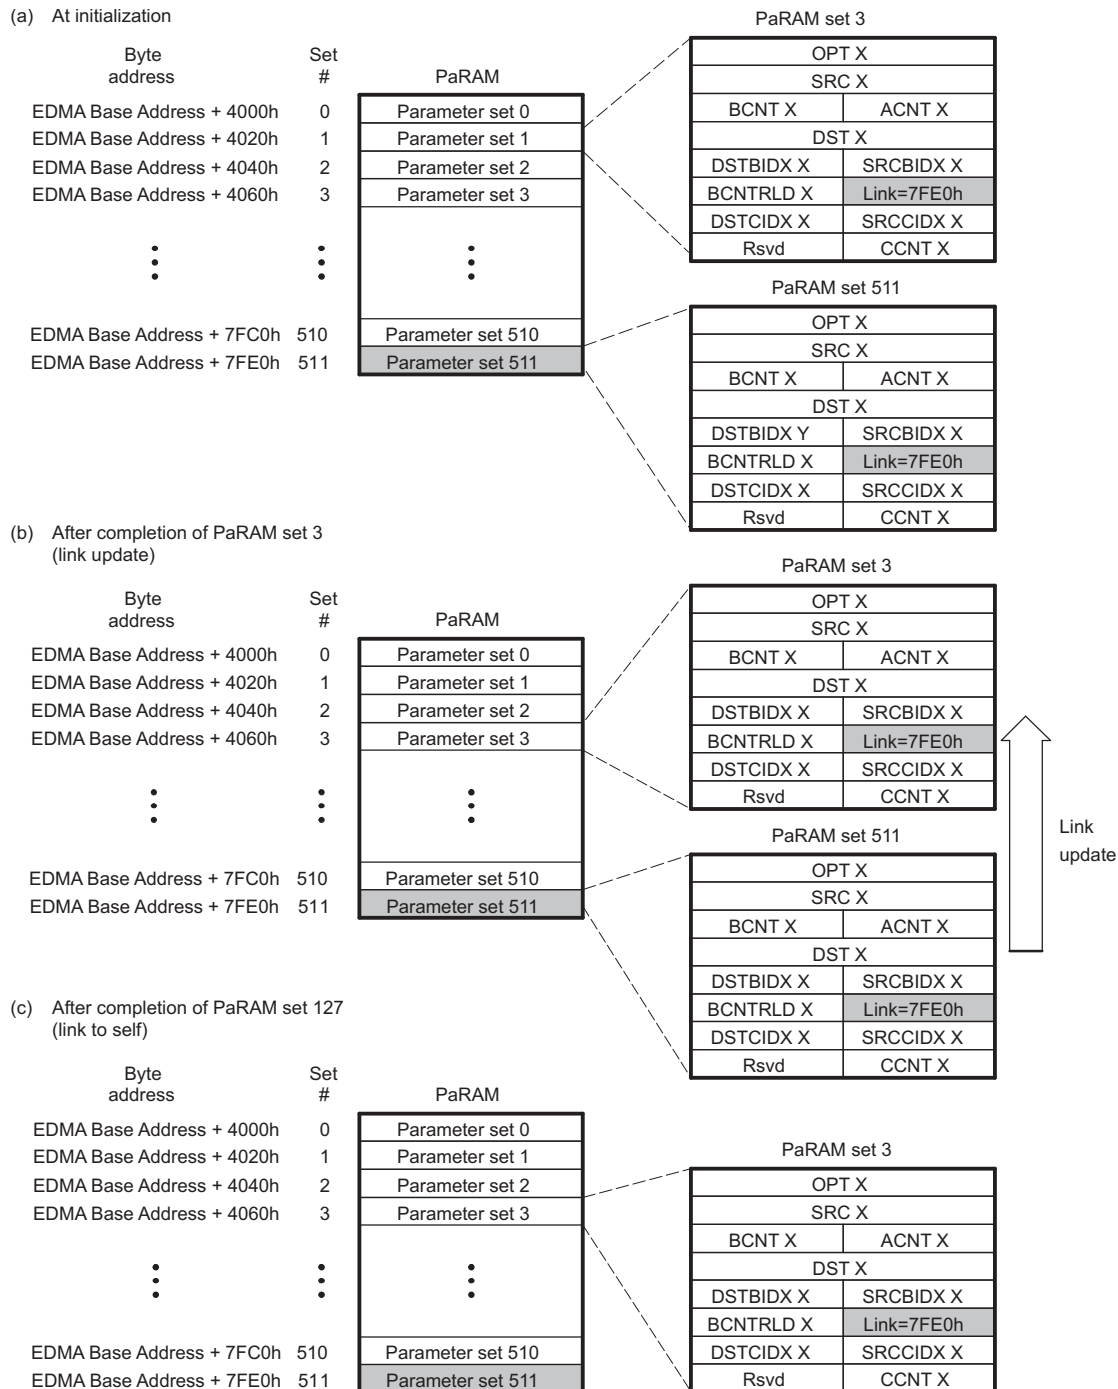

Figure 8-10. Link-to-Self Transfer

8.3.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA3 channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the more typical usage of EDMA3): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:** The CPU manually triggers a transfer by writing a 1 to the

corresponding bit in the event set register (ESR/ESRH).

- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

8.3.4.1 DMA Channel

8.3.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register ($ER.En = 1$). For peripheral event to DMA event mapping, see the device-specific data manual. If the corresponding event in the event enable register (EER) is enabled ($EER.En = 1$), then the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaPARAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA3TC and the En bit in ER is cleared. At this point, a new event can be safely received by the EDMA3CC.

If the PaPARAM set associated with the channel is a NULL set (see [Section 8.3.3.3](#)), then no transfer request (TR) is submitted and the corresponding En bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register ($EMR.En = 1$) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set ($ER.En = 1$), regardless of the state of $EER.En$. If the event is disabled when an external event is received ($ER.En = 1$ and $EER.En = 0$), the $ER.En$ bit remains set. If the event is subsequently enabled ($EER.En = 1$), then the pending event is processed by the EDMA3CC and the TR is processed/submitted, after which the $ER.En$ bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared ($ER.En \neq 0$), then the second event is registered as a missed event in the corresponding bit of the event missed register ($EMR.En = 1$).

The EDMA section in the device-specific data manual gives the table of the synchronization events associated with each of the programmable DMA channels in the device. It also provides the mapping of events to the EDMA event crossbar. See the device-specific data manual to determine the event to channel mapping.

8.3.4.1.2 Manually-Triggered Transfer Request

The CPU or any EDMA programmer initiates a DMA transfer by writing to the event set register (ESR). Writing a 1 to an event bit in the ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the $EER.En$ bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaPARAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaPARAM set associated with the channel is a NULL set (see [Section 8.3.3.3](#)), then no transfer request (TR) is submitted and the corresponding En bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register ($EMR.En = 1$) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register ($ESR.En = 1$) prior to the original being cleared ($ESR.En = 0$), then the second event is registered as a missed event in the corresponding bit of the event missed register ($EMR.En = 1$).

8.3.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code (TCC[5:0] in OPT of the PaRAM set associated with the channel), it results in the corresponding bit in the chained event register (CER) to be set (CER.E[TCC] = 1).

Once a bit is set in CER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 8.3.3.3](#)), then no transfer request (TR) is submitted and the corresponding En bit in CER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR. En = 1) to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared by you before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared (CER. En != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register (EMR. En = 1).

NOTE: Chained event registers, event registers, and event set registers operate independently. An event (En) can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

8.3.4.2 QDMA Channels

8.3.4.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register (QER. En = 1). A bit corresponding to a QDMA channel is set in the QDMA event register (QER) when the following occurs:

- A CPU (or any EDMA3 programmer) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register (QCHMAP n)) for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register (QEER. En = 1).
- EDMA3CC performs a link update on a PaRAM set address that is configured as a QDMA channel (matches QCHMAP n settings) and the corresponding channel is enabled via the QDMA event enable register (QEER. En = 1).

Once a bit is set in QER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If a bit is already set in QER (QER. En = 1) and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register (QEMR. En = 1).

8.3.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization. QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other EDMA3 programmer) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA3CC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered). Note that for CPU triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register (ESR) to kick-off the transfer.

QDMA channels are typically for cases where a single event will accomplish a complete transfer since the CPU (or EDMA3 programmer) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. In other words, QDMA transfers are programmed with BCNT = CCNT = 1 for A-synchronized transfers, and CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if STATIC = 0 in OPT) for QDMA transfers, it allows you to initiate a linked list of QDMAs, so when EDMA3CC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel will automatically be recognized as a valid QDMA event and initiate another set of transfers as specified by the linked set.

8.3.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in [Table 8-6](#) for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (BCNT and/or CCNT) are this value, the next TR results in a:

- Final chaining or interrupt codes to be sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 8-6. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	BCNT == 1 && CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	CCNT == 1

You must program the PaRAM OPT field with a specific transfer completion code (TCC) along with the other OPT fields (TCCHEN, TCINTEN, ITCCHEN, and ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register (CER[TCC]) and/or interrupt pending register (IPR[TCC]) is set.

You can also selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set (TCCHEN or TCINTEN), for all but the final transfer request (TR) of a parameter set (ITCCHEN or ITCINTEN), or for all TRs of a parameter set (both). See [Section 8.3.8](#) for details on chaining (intermediate/final chaining) and [Section 8.3.9](#) for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA3 channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value should point to another predefined PaRAM set. Alternatively, a non-repetitive transfer should set the link address value to the null link value. The null link value is defined as FFFFh. See [Section 8.3.3.7](#) for more details.

NOTE: Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition should be cleared before the corresponding channel is used again. See [Section 8.3.3.5](#).

There are three ways the EDMA3CC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

8.3.5.1 Normal Completion

In normal completion mode (TCCMODE = 0 in OPT), the transfer or sub-transfer is considered to be complete when the EDMA3 channel controller receives the completion codes from the EDMA3 transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

8.3.5.2 Early Completion

In early completion mode (TCCMODE = 1 in OPT), the transfer is considered to be complete when the EDMA3 channel controller submits the transfer request (TR) to the EDMA3 transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

8.3.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set ([Section 8.3.3.4](#)) or null set ([Section 8.3.3.3](#)). In both cases, the EDMA3 channel controller does not submit the associated transfer request to the EDMA3 transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it will set the appropriate bits in the interrupt pending registers (IPR/IPRH) or chained event register (CER/CERH). The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA3CC generates the completion code).

8.3.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the EDMA_EVT[3:0] pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (ACNT, BCNT, CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

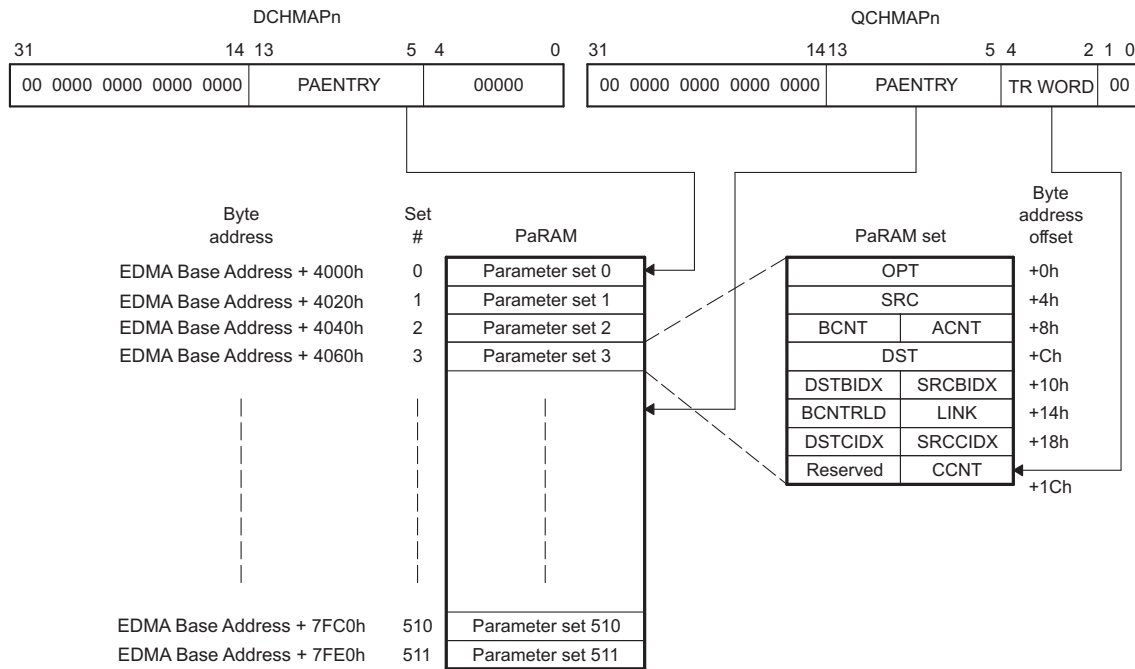

The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it. At the SoC level, the EDMA event crossbar can be used to select which SoC level events (of which there are more than 64) are mapped to the 64 input events to the EDMA Channel Controller. The default mapping and event crossbar mapping are defined in section *EDMA Channel Synchronization Events* of the *Chip Level Resources* chapter. The event crossbar mapping is controlled by the EDMA3CC_EVTMUX_m_n registers (refer to Control Module chapter for their description).

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

8.3.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see Table 8-1). The DMA channel mapping registers (DCHMAPn) in the EDMA3CC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 8-11 illustrates the use of DCHMAP. There is one DCHMAP register per channel.

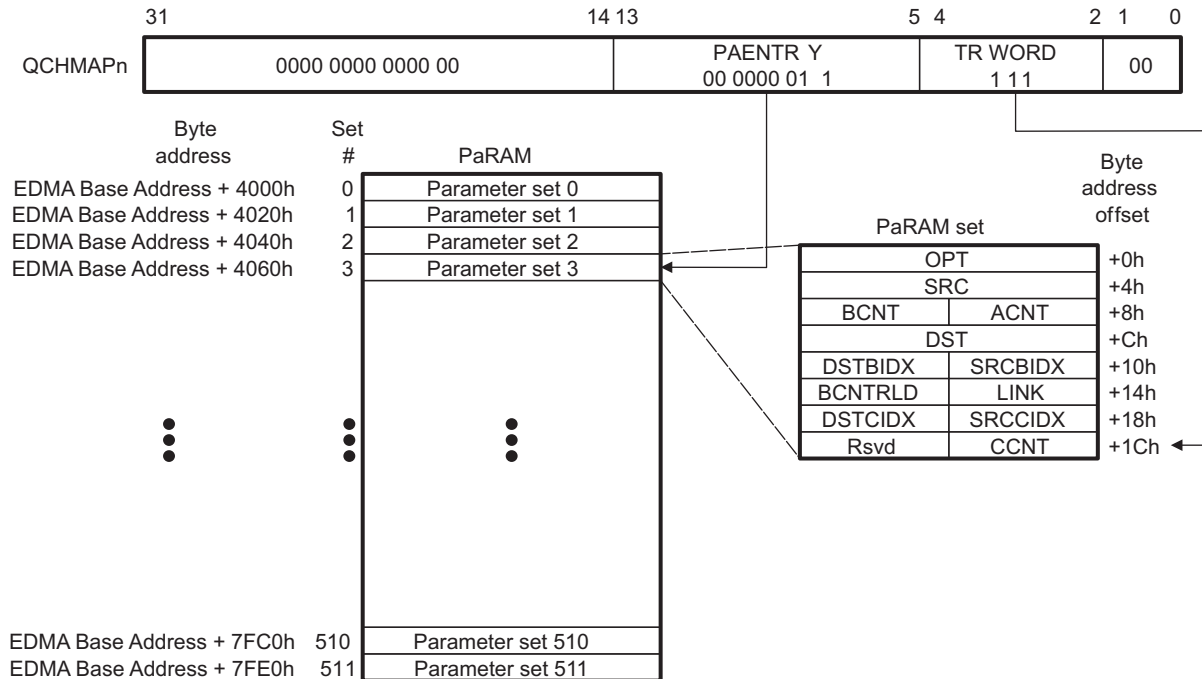

Figure 8-11. DMA Channel and QDMA Channel to PaRAM Mapping

8.3.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register (QCHMAP) in the EDMA3CC allows you to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 8-12 illustrates the use of QCHMAP.

Additionally, QCHMAP allows you to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA3CC is a write to the trigger word in the PaRAM set pointed to by QCHMAP for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0. You must appropriately re-map PaRAM set 0 before you use it.

Figure 8-12. QDMA Channel to PaRAM Mapping

8.3.7 EDMA3 Channel Controller Regions

The EDMA3 channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific EDMA programmer.

You can design the application software to use regions or to ignore them altogether. You can use active memory protection in conjunction with regions so that only a specific EDMA programmer (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA programmer only modifies the state of the assigned resources. Memory protection is described in [Section 8.3.10](#).

8.3.7.1 Region Overview

The EDMA3 channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA3CC memory map. These registers control EDMA3 resource mapping and provide debug visibility and error tracking information. See the device-specific data manual for the EDMA3CC memory map.

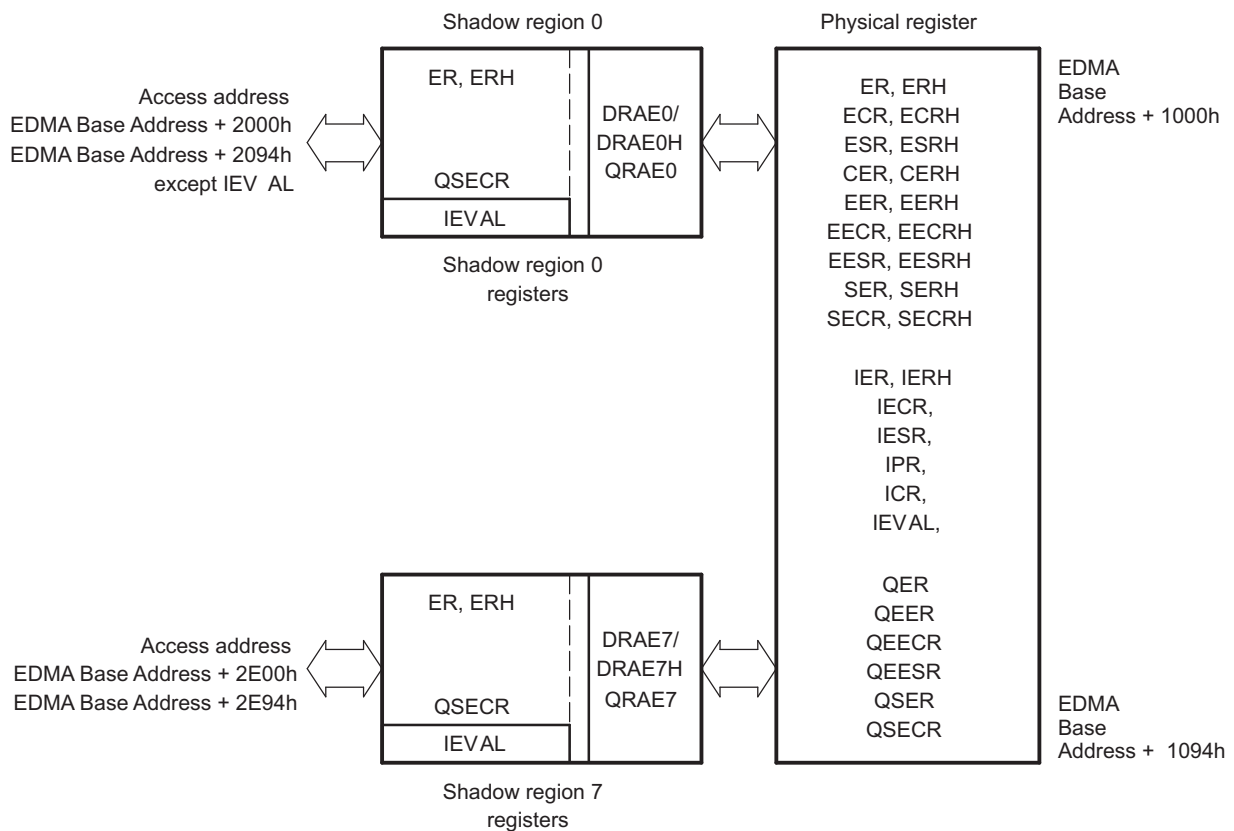

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow n channel region address range(s). For example, the event enable register (EER) is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, ... EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers (DRAEm) and the QDMA region access enable registers (QRAEn) control the underlying control register bits that are accessible via the shadow region address space (except for IEVALn). [Table 8-7](#) lists the registers in the shadow region memory map. See the EDMA3CC memory map ([Table 8-19](#)) for the complete global and shadow region memory maps. [Figure 8-13](#) illustrates the conceptual view of the regions.

Table 8-7. Shadow Region Registers

DRAE _m	DRAEH _m	QRAE _n

Register not affected by DRAE\DRAEH		
IEVAL		

Figure 8-13. Shadow Region Registers

8.3.7.2 Channel Controller Regions

There are eight EDMA3 shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- **DRAE m and DRAEH m :** One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAE/DRAEH pair. A value of 1 in the corresponding DRAE(H) bit implies that the corresponding DMA/interrupt channel is accessible; a value of 0 in the corresponding DRAE(H) bit forces writes to be discarded and returns a value of 0 for reads.
- **QRAE n :** One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 QEER, the respective bit in QRAE must be set or writing into QEESR will not have the desired effect.
- **MPPA n and MPPAG:** One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows for restricted access to EDMA3 resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the DRAE/ORAE registers. If exclusive access to any given channel / TCC code is required for a region, then only that region's DRAE/ORAE should have the associated bit set.

Example 8-1. Resource Pool Division Across Two Regions

This example illustrates a judicious resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63). Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47). DRAE should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEH, DRAE = 0xFFFF0000, 0x0000FFFF QRAE = 0x0000001
Region 1: DRAEH, DRAE = 0x0000FFFF, 0xFFFF0000 QRAE = 0x00000FE
```

8.3.7.3 Region Interrupts

In addition to the EDMA3CC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register (IER), DRAE acts as a secondary interrupt enable for the respective shadow region interrupts. See [Section 8.3.9](#) for more information.

8.3.8 Chaining EDMA3 Channels

The channel chaining capability for the EDMA3 allows the completion of an EDMA3 channel transfer to trigger another EDMA3 channel transfer. The purpose is to allow you the ability to chain several events through one event occurrence.

Chaining is different from linking ([Section 8.3.3.7](#)). The EDMA3 link feature reloads the current channel parameter set with the linked parameter set. The EDMA3 chaining feature does not modify or update any channel parameter set; it provides a synchronization event to the chained channel (see [Section 8.3.4.1.3](#) for chain-triggered transfer requests).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel m (DMA/QDMA) required to chain to channel n . Channel number n (0-63) needs to be programmed into the TCC bit of channel m channel options parameter (OPT) set.

- If final transfer completion chaining (TCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel m is either submitted or completed (depending on early or normal completion).

- If intermediate transfer completion chaining (ITCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (TCCHEN = 1 and ITCCHEN = 1 in OPT) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

[Table 8-8](#) illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

Table 8-8. Chain Event Triggers

Options	(Number of chained event triggers on channel 30)	
	A-Synchronized	AB-Synchronized
TCCHEN = 1, ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
TCCHEN = 0, ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
TCCHEN = 1, ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

8.3.9 EDMA3 Interrupts

The EDMA3 interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in [Table 8-9](#). The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the DSP and ARM interrupt controllers.

Table 8-9. EDMA3 Transfer Completion Interrupts

Name	Description
EDMA3CC_INT0	EDMA3CC Transfer Completion Interrupt Shadow Region 0
EDMA3CC_INT1	EDMA3CC Transfer Completion Interrupt Shadow Region 1
EDMA3CC_INT2	EDMA3CC Transfer Completion Interrupt Shadow Region 2
EDMA3CC_INT3	EDMA3CC Transfer Completion Interrupt Shadow Region 3
EDMA3CC_INT4	EDMA3CC Transfer Completion Interrupt Shadow Region 4
EDMA3CC_INT5	EDMA3CC Transfer Completion Interrupt Shadow Region 5
EDMA3CC_INT6	EDMA3CC Transfer Completion Interrupt Shadow Region 6
EDMA3CC_INT7	EDMA3CC Transfer Completion Interrupt Shadow Region 7

Table 8-10. EDMA3 Error Interrupts

Name	Description
EDMA3CC_ERRINT	EDMA3CC Error Interrupt
EDMA3CC_MPINT	EDMA3CC Memory Protection Interrupt
EDMA3TC0_ERRINT	TC0 Error Interrupt
EDMA3TC1_ERRINT	TC1 Error Interrupt
EDMA3TC2_ERRINT	TC2 Error Interrupt
EDMA3TC3_ERRINT	TC3 Error Interrupt

8.3.9.1 Transfer Completion Interrupts

The EDMA3CC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA3 masters). The EDMA3 generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA3 interrupt generation.

The software architecture should either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code (TCC) value is directly mapped to the bits of the interrupt pending register (IPR/IPRH). For example, if TCC = 10 0001b, IPRH[1] is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See [Section 8.3.9.1.1](#) for details on enabling EDMA3 transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in IPR/IPRH is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

Table 8-11. Transfer Complete Code (TCC) to EDMA3CC Interrupt Mapping

TCC Bits in OPT (TCINTEN/ITCINTEN = 1)	IPR Bit Set	TCC Bits in OPT (TCINTEN/ITCINTEN = 1)	IPRH Bit Set ⁽¹⁾
0	IPR0	20h	IPR32/IPRH0
1	IPR1	21h	IPR33/IPRH1
2h	IPR2	22h	IPR34/IPRH2
3h	IPR3	23h	IPR35/IPRH3
4h	IPR4	24h	IPR36/IPRH4
...
1Eh	IPR30	3Eh	IPR62/IPRH30
1Fh	IPR31	3Fh	IPR63/IPRH31

⁽¹⁾ Bit fields IPR[32-63] correspond to bits 0 to 31 in IPRH, respectively.

You can program the transfer completion code (TCC) to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and you intend for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in IER/IERH and in the corresponding shadow region's DMA region access registers (DRAE/DRAEH).

You can enable Interrupt generation at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (TCCINT = 1 in OPT) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (ITCCINT = 1 in OPT) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (TCCINT = 1, and ITCCINT = 1 in OPT) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

[Table 8-12](#) shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

Table 8-12. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
TCINTEN = 1, ITCINTEN = 0	1 (Last TR)	1 (Last TR)
TCINTEN = 0, ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
TCINTEN = 1, ITCINTEN = 1	20 (All TRs)	5 (All TRs)

8.3.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA3 channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA3CC. This is in addition to setting up the TCINTEN and ITCINTEN bits in OPT of the associated PaRAM set.

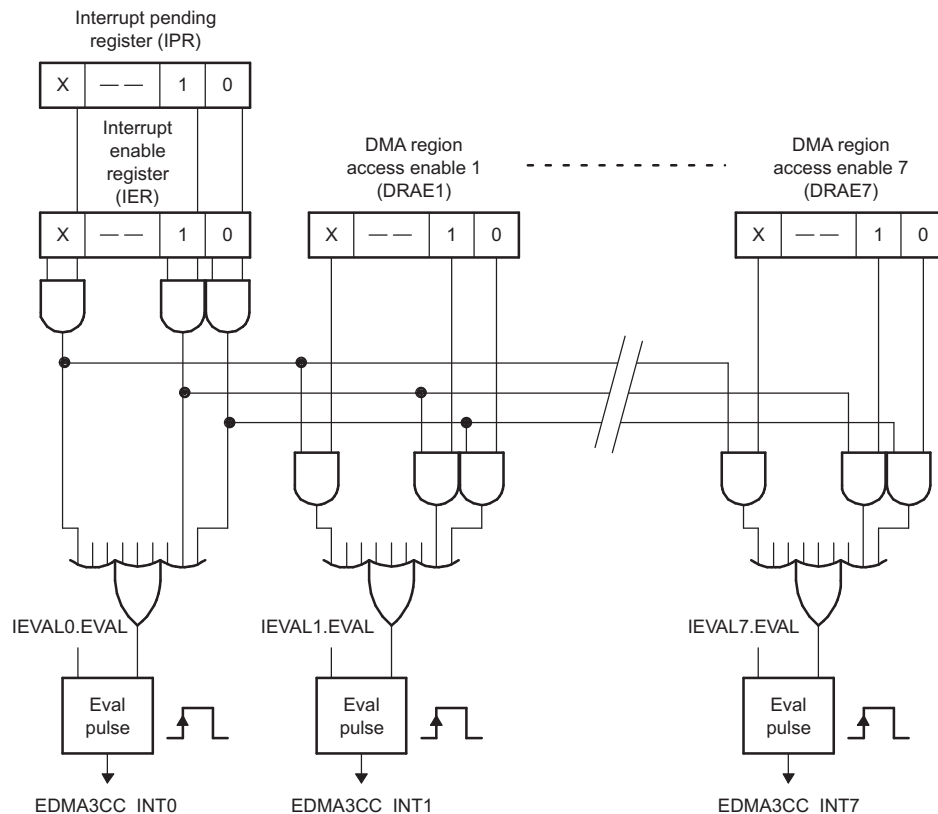

The EDMA3 channel controller has interrupt enable registers (IER/IERH) and each bit location in IER/IERH serves as a primary enable for the corresponding interrupt pending registers (IPR/IPRH).

All of the interrupt registers (IER, IESR, IECR, and IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA3 channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers (IPR/IPRH) and single set of interrupt enable registers (IER/IERH). The programmable DMA region access enable registers (DRAE/DRAEH) provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by IER/IERH. see [Figure 8-14](#)

The region interrupt outputs are gated by IER and the specific DRAE/DRAEH associated with the region. See [Figure 8-14](#).

Figure 8-14. Interrupt Diagram

For the EDMA3CC to generate the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA3CC_INT0: (IPR.E0 & IER.E0 & DRAE0.E0) | (IPR.E1 & IER.E1 & DRAE0.E1) | ...|(IPRH.E63 & IERH.E63 & DRAHE0.E63)
- EDMA3CC_INT1: (IPR.E0 & IER.E0 & DRAE1.E0) | (IPR.E1 & IER.E1 & DRAE1.E1) | ...| (IPRH.E63 & IERH.E63 & DRAHE1.E63)
- EDMA3CC_INT2 : (IPR.E0 & IER.E0 & DRAE2.E0) | (IPR.E1 & IER.E1 & DRAE2.E1) | ...|(IPRH.E63 & IERH.E63 & DRAHE2.E63)....

- Up to EDMA3CC_INT7 : (IPR.E0 & IER.E0 & DRAE7.E0) | (IPR.E1 & IER.E1 & DRAE7.E1) | ...|(IPRH.E63 & IERH.E63 & DRAEH7.E63)

NOTE: The DRAE/DRAEH for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers should be used for dynamic enable/disable of individual interrupts.

Because there is no relation between the TCC value and the DMA/QDMA channel, it is possible, for example, for DMA channel 0 to have the OPT.TCC = 63 in its associated PaRAM set. This would mean that if a transfer completion interrupt is enabled (OPT.TCINTEN or OPT.ITCINTEN is set), then based on the TCC value, IPRH.E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map, you must program the DRAE/DRAEH that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to IPRH bit that is set upon completion).

8.3.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (ICR/ICRH). For example, a write of 1 to ICR.E0 clears a pending interrupt in IPR.E0.

If an incoming transfer completion code (TCC) gets latched to a bit in IPR/IPRH, then additional bits that get set due to a subsequent transfer completion will not result in asserting the EDMA3CC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

8.3.9.2 EDMA3 Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA3 channel controller sets the appropriate bit in the interrupt pending registers (IPR/IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in IPR/IPRH, thereby enabling recognition of future interrupts. The EDMA3CC will only assert additional completion interrupts when all IPR/IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in IPR/IPRH, thereby resulting in additional interrupts. Each of the bits in IPR/IPRH may need different types of service; therefore, the ISR may check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA3CC completion interrupt are shown in [Example 8-2](#) and [Example 8-3](#).

The ISR routine in [Example 8-2](#) is more exhaustive and incurs a higher latency.

Example 8-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register (IPR/IPRH).
2. Performs the operations needed.
3. Writes to the interrupt pending clear register (ICR/ICRH) to clear the corresponding IPR/IPRH bit(s).
4. Reads IPR/IPRH again:
 - (a) If IPR/IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).
 - (b) If IPR/IPRH is equal to 0, this should assure you that all of the enabled interrupts are inactive.

Example 8-2. Interrupt Servicing (continued)

NOTE: An event may occur during step 4 while the IPR/IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

[Example 8-3](#) is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 8-3. Interrupt Servicing

If you want to leave any enabled and pending (possibly lower priority) interrupts; you must force the interrupt logic to reassert the interrupt pulse by setting the EVAL bit in the interrupt evaluation register (IEVAL).

The pseudo code is as follows:

1. Enters ISR.
2. Reads IPR/IPRH.
3. For the condition that is set in IPR/IPRH that you want to service, do the following:
 - (a) Service interrupt as the application requires.
 - (b) Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA3CC after step 2).
4. Reads IPR/IPRH prior to exiting the ISR:
 - (a) If IPR/IPRH is equal to 0, then exit the ISR.
 - (b) If IPR/IPRH is not equal to 0, then set IEVAL so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

8.3.9.3 Interrupt Evaluation Operations

The EDMA3CC has interrupt evaluate registers (IEVAL) that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers (DRAE/DRAEH). Writing a 1 to the EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via IER/IERH) is still pending (IPR/IPRH). This register assures that the CPU does not miss the interrupts (or the EDMA3 master associated with the shadow region) if the software architecture chooses not to use all interrupts. See [Example 8-3](#) for the use of IEVAL in the EDMA3 interrupt service routine (ISR).

Similarly an error evaluation register (EEVAL) exists in the global region. Writing a 1 to the EVAL bit in EEVAL causes the pulsing of the error interrupt if any pending errors are in EMR/EMRH, QEMR, or CCERR. See [Section 8.3.9.4](#) for additional information regarding error interrupts.

NOTE: While using IEVAL for shadow region completion interrupts, you should make sure that the IEVAL operated upon is from that particular shadow region memory map.

8.3.9.4 Error Interrupts

The EDMA3CC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA3CC error interrupt. If the EDMA3CC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA3CC has a single error interrupt (EDMA3CC_ERRINT) that is asserted for all EDMA3CC error conditions. There are four conditions that cause the error interrupt to pulse:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers (EMR/EMRH).
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register (QEMR).
- Threshold exceed: for all event queues. These are latched in EDMA3CC error register (CCERR).
- TCC error: for outstanding transfer requests that are expected to return completion code (TCCHEN or TCINTEN bit in OPT is set to 1) exceeding the maximum limit of 63. This is also latched in the EDMA3CC error register (CCERR).

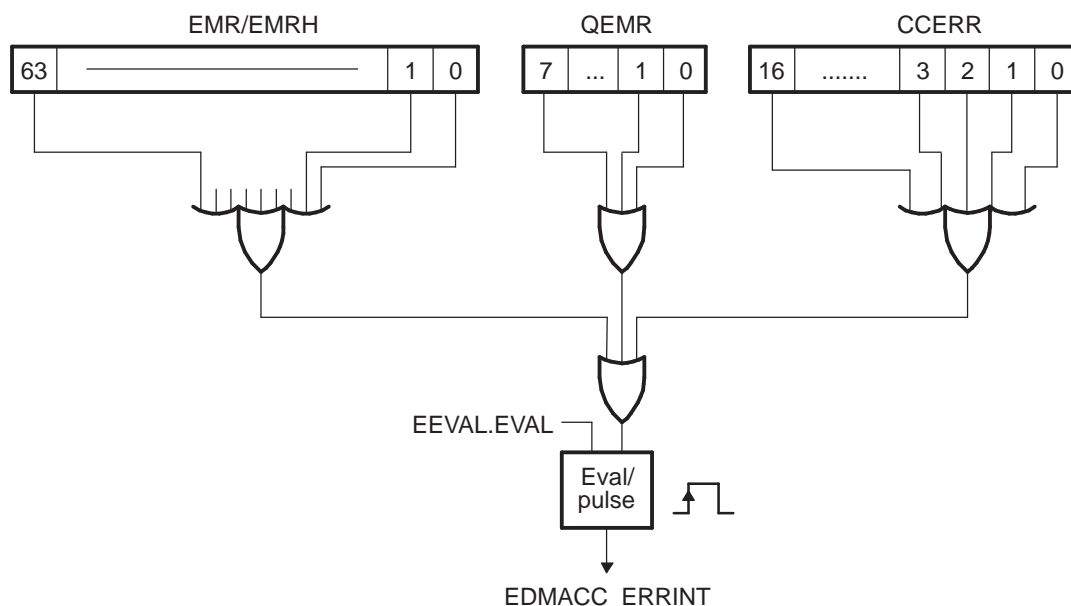

Figure 8-15 illustrates the EDMA3CC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA3CC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA3CC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA3CC does not generate additional interrupt pulses.

To reduce the burden on the software, there is an error evaluate register (EEVAL) that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register (IEVAL). You can use this so that the CPU(s) does not miss any error events.

NOTE: It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status); additionally, it provides a good debug mechanism for unexpected error conditions.

Figure 8-15. Error Interrupt Operation

8.3.10 Memory Protection

The EDMA3 channel controller supports two kinds of memory protection: active and proxy.

8.3.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses (by any EDMA3 programmer) to the EDMA3CC registers (based on permission characteristics that you program). Active memory protection is achieved by a set of memory protection permissions attribute (MPPA) registers.

The EDMA3CC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to section [Table 8-7](#).

Each of the eight shadow regions has an associated MPPA register (MPPA n) that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register (MPPAG). The MPPAG applies to the global region and to the global channel region, except the other MPPA registers themselves. For more detailed information on the list of the registers in each region, refer to the register memory-map in section [Table 8-14](#).

See [Section 8.5.1.5.4](#) for the bit field descriptions of MPPA n . The MPPA n have a certain set of access rules.

[Table 8-13](#) shows the accesses that are allowed or not allowed to the MPPAG and MPPA n . The active memory protection uses the PRIV and PRIVID attributes of the EDMA programmer. The PRIV is the privilege level (i.e., user vs. supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA3 programmer. See the device-specific data manual for the PRIVIDs that are associated with potential EDMA3 programmers.

Table 8-13. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

[Table 8-14](#) describes the MPPA register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based MPPA registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight MPPA region registers (MPPA[0-7]).

Table 8-14. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect ⁽¹⁾	Address Range
MPPAG	Global Range	0000h-1FFCh	N/A	N/A
MPPA0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPA1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPA2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPA3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPA4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPA5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPA6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
MPPA7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

⁽¹⁾ The PaRAM region is divided into 8 regions referred to as an octant.

Example Access denied.

Write access to shadow region 7's event enable set register (EESR):

1. The original value of the event enable register (EER) at address offset 0x1020 is 0x0.
2. The MPPA[7] is set to prevent user level accesses (UW = 0, UR = 0), but it allows supervisor level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).
3. An EDMA3 programmer with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register (EESR) at address offset 0x2E30. Note that the EER is a read-only register and the only way that you can write to it is by writing to the EESR. Also remember that there is only one physical register for EER, EESR, etc. and that the shadow regions only provide to the same physical set.
4. Since the MPPA[7] has UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EER is not written to.

Table 8-15. Example Access Denied

Register	Value	Description
EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and Privilege ID of 0.
MPPA[7] (offset 0x082C)	0x0000 04B0	Memory Protection Filter AID0 = 1, UW = 0, UR = 0, SW = 1, SR = 1.
	X	Access Denied
EER (offset 0x1020)	0x0000 0000	Final value of EER

Example Access Allowed

Write access to shadow region 7's event enable set register (EESR):

1. The original value of the event enable register (EER) at address offset 0x1020 is 0x0.
2. The MPPA[7] is set to allow user-level accesses (UW = 1, UR = 1) and supervisor-level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).
3. An EDMA3 programmer with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register (EESR) at address offset 0x2E30. Note that the EER is a read-only register and the only way that you can write to it is by writing to the EESR. Also remember that there is only one physical register for EER, EESR, etc. and that the shadow regions only provide to the same physical set.
4. Since the MPPA[7] has UW = 1 and AID0 = 1, the user-level write access is allowed.
5. Remember that accesses to shadow region registers are masked by their respective DRAE register. In this example, the DRAE[7] is set of 0x9FF00FC2.
6. The value finally written to EER is 0x8BC00102.

Table 8-16. Example Access Allowed

Register	Value	Description
EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and Privilege ID of 0.
MPPA[7] (offset 0x082C)	0x0000 04B3	Memory Protection Filter AID = 1, UW = 1, UR = 1, SW = 1, SR = 1.
	√ ↓	Access allowed.
DRAE[7] (offset 0x0378)	0x9FF0 0FC2	DMA Region Access Enable Filter
EESR (offset 0x2E30)	0x8BC0 0102	Value written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and a Privilege ID of 0.
EER (offset 0x1020)	↓ 0xBC0 0102	Final value of EER.

8.3.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA3 transfer programmed by a given EDMA3 programmer to have its permissions travel with the transfer through the EDMA3TC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The PRIV bit and PRIVID bit in the channel options parameter (OPT) is set with the EDMA3 programmer's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The PRIV is the privilege level (i.e., user vs. supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA3 programmer.

See the data manual for the PRIVIDs that are associated with potential EDMA3 programmers.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The PRIV is 0 for user-level and the CPU has a PRIVID of 0.

The PaRAM set is shown in [Figure 8-16](#).

Figure 8-16. PaRAM Set Content for Proxy Memory Protection Example

(a) EDMA3 Parameters

Parameter Contents		Parameter	
0010 0007h		Channel Options Parameter (OPT)	
009F 0000h		Channel Source Address (SRC)	
0001h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h		Channel Destination Address (DST)	
0001h	0001h	Destination BCNT Index (DSTBIDX)	Source BCNT Index (SRCBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DSTCIDX)	Source CCNT Index (SRCCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

Figure 8-17. Channel Options Parameter (OPT) Example

(b) Channel Options Parameter (OPT) Content

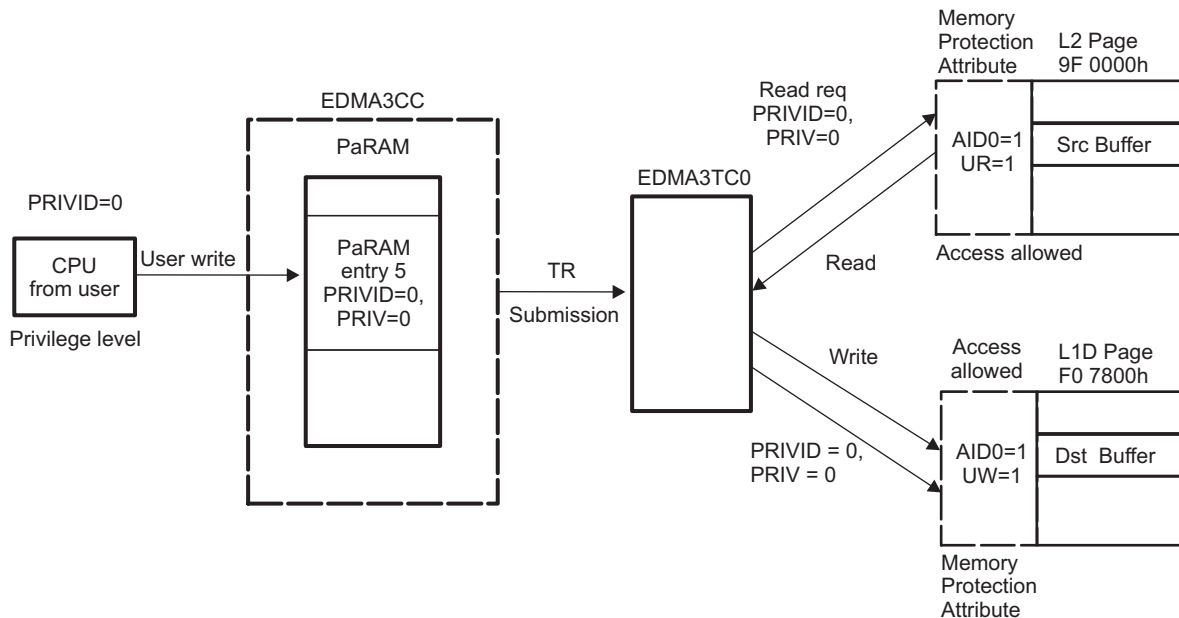

The PRIV and PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses (SR,SW), the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (SR, SW), the user-level write request above is refused. For the transfer to succeed, the source and destination pages should have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID 0. For more information regarding how to set memory protection attributes for pages of memory in L2/L1D, please refer to the *TMS320C64x/C64x+ DSP CPU and Instruction Set Reference Guide* ([SPRU732](#)).

Because the programmers privilege level and privilege identification travel with the read and write requests, EDMA3 acts as a proxy.

Figure 8-18 illustrates the propagation of PRIV and PRIVID at the boundaries of all the interacting entities (CPU, EDMA3CC, EDMA3TC, and slave memories).

Figure 8-18. Proxy Memory Protection Example

8.3.11 Event Queue(s)

Event queues are a part of the EDMA3 channel controller. Event queues form the interface between the event detection logic in the EDMA3CC and the transfer request (TR) submission logic of the EDMA3CC. Each queue is 16 entries deep; thus, each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are four event queues for the device: Queue0, Queue1, Queue2, and Queue3. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. Similarly, transfer requests that are associated with events in Queue3 are submitted to TC3.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA3 transfer controller.

Queue0 has highest priority and Queue3 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

See [Section 8.3.11.4](#) for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers (Q0E0, Q0E1, ..., Q1E15, etc.). Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. See [Section 8.5.1.4.1](#) for a description of the bit fields in the queue event entry registers.

8.3.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register (DMAQNUM) and the QDMA queue number register (QDMANUM). The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. See [Section 8.3.11.4](#).

NOTE: If an event is ready to be queued and both the event queue and the EDMA3 transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA3TC. In this case, the event is not logged in the event queue status registers.

8.3.11.2 Queue RAM Debug Visibility

There are four event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO manner. There is a queue status register (QSTAT) associated with each queue. These along with all of the 16 entries per queue can be read via registers QSTAT n and QxEy, respectively.

These registers provide user visibility and may be helpful while debugging real-time issues (typically post-mortem), involving multiple events and event sources. The event queue entry register (QxEy) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA3CC memory-mapped register. By reading the event queue, you see the history of the last 16 TRs that have been processed by the EDMA3 on a given queue. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT n) includes fields for the start pointer (STRTPTR) which provides the offset to the head entry of an event. It also includes a field called NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The STRTPTR may be used to index appropriately into the 16 event entries. NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry may be read to determine what's already de-queued and submitted to the associated transfer controller.

8.3.11.3 Queue Resource Tracking

The EDMA3CC event queue includes watermarking/threshold logic that allows you to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA3 event queue.

You can program the maximum number of events that can queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register (QWMTHRA). The maximum queue usage is recorded actively in the watermark (WM) field of the queue status register (QSTAT n) that keeps getting updated based on a comparison of number of valid entries, which is also visible in the NUMVAL bit in QSTAT n and the maximum number of entries (WM bit in QSTAT n).

If the queue usage is exceeded, this status is visible in the EDMA3CC registers: the QTHRXCDC n bit in the channel controller error register (CCERR) and the THRXCDC bit in QSTAT n , where n stands for the event queue number. Any bits that are set in CCERR also generate an EDMA3CC error interrupt.

8.3.11.4 Performance Considerations

The main system bus infrastructure (L3) (see the device-specific data manual) arbitrates bus requests from all of the masters (TCs, CPU(S), PCIe and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA3 transfer controllers with respect to other masters within the system crossbar are programmed using the Control Module INIT_PRIORITY $_n$ and INITIATOR_PRIO $_m$ registers. The QUEPRI register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA3TC (dictated by the priority set using the Control Module INIT_PRIORITY $_n$ and INITIATOR_PRIO $_m$ registers).

8.3.12 EDMA3 Transfer Controller (EDMA3TC)

The EDMA3 channel controller is the user-interface of the EDMA3 and the EDMA3 transfer controller (EDMA3TC) is the data movement engine of the EDMA3. The EDMA3CC submits transfer requests (TR) to the EDMA3TC and the EDMA3TC performs the data transfers dictated by the TR; thus, the EDMA3TC is a slave to the EDMA3CC.

8.3.12.1 Architecture Details

8.3.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in [Section 8.3.12.5](#).

The EDMA3TC attempts to issue the largest possible command size as limited by the DBS value or the ACNT/BCNT value of the TR. EDMA3TC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

[Table 8-17](#) lists the TR segmentation rules that are followed by the EDMA3TC. In summary, if the ACNT value is larger than the DBS value, then the EDMA3TC breaks the ACNT array into DBS-sized commands to the source/destination addresses. Each BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA3TC recognizes that the 2D-transfer is organized as a single dimension (ACNT == BIDX) and the ACNT value is a power of 2.

[Table 8-17](#) lists conditions in which the optimizations are performed.

Table 8-17. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

8.3.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries, which is 4.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 8-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. ACNT = 8, BCNT = 8, SRCBIDX = 8, DSTBIDX = 10, SRCADDR = 64, DSTADDR = 191

Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to ACNT = 64, BCNT = 1.

Cmd0 = 64 byte

Write Controller: Because DSTBIDX != ACNT, it is not optimized.

Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. ACNT=128, BCNT = 1, SRCADDR = 63, DSTADDR = 513

Read Controller: Read address is not aligned.

Cmd0 = 1 byte, (now the SRCADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 63 bytes

Write Controller: The write address is also not aligned.

Cmd0 = 63 bytes, (now the DSTADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 1 byte

8.3.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA3TC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA3TC is controlled by the RDRATE register. The RDRATE register defines the number of cycles that the EDMA3TC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA3TC consuming all available slave resources. The RDRATE value should be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

8.3.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA3TC and used by the EDMA3TC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA3 transfer in the channel controller.

8.3.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA3TC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.
- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is pulsed.

8.3.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA3TC status register (TCSTAT) has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The SRCACTV bit indicates whether the source active set is active.
- The DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

If the TRs are in progression, caution must be used and you must realize that there is a chance that the values read from the EDMA3TC status registers will be inconsistent since the EDMA3TC may change the values of these registers due to ongoing activities.

It is recommended that you ensure no additional submission of TRs to the EDMA3TC in order to facilitate ease of debug.

8.3.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA3TC maintains two important status details in TCSTAT that may be used during advanced debugging, if necessary. The DFSTRTPTR is a start pointer, that is, the index to the head of the destination FIFO register. The DSTACTV is a counter for the number of valid (occupied) entries. These registers may be used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- DFSTRTPTR = 0 and DSTACTV = 0 implies that no TRs are stored in the destination FIFO register.
- DFSTRTPTR = 1 and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- DFSTRTPTR = 3h and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

8.3.12.5 EDMA3TC Configuration

[Table 8-18](#) provides the configuration of the individual EDMA3 transfer controllers present on the device. The DBS for each transfer controller is configurable using the TPTC_CFG register in the chip configuration module.

Table 8-18. EDMA3 Transfer Controller Configurations

Name	TC0	TC1	TC2	TC3
FIFOSIZE	1024 bytes	1024 bytes	1024 bytes	1024 bytes
BUSWIDTH	16 bytes	16 bytes	16 bytes	16 bytes
DSTREGDEPTH	4 entries	4 entries	4 entries	4 entries
DBS	Configurable	Configurable	Configurable	Configurable

8.3.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA3CC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the ER.En/ERH.En (or CER.En/CERH.En, ESR.En/ESRH.En, QER.En) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the SER.En/SERH.En (or QSER.En) bit is set to inform the event prioritization/processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA3CC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA3CC clears the ER.En/ERH.En (or CER.En/CERH.En, ESR.En/ESRH.En, QER.En) bit and the SER.En/SERH.En bit as soon as it determines the TR is non-null. In the case of a null set, the SER.En/SERH.En bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA3CC immediately sets the interrupt pending register (IPR.I[TCC]/IPRH.I[TCC]-32).
5. If the TR was programmed for normal completion, the EDMA3CC sets the interrupt pending register (IPR.I[TCC]/IPRH.I[TCC]) when the EDMA3TC informs the EDMA3CC about completion of the transfer (returns transfer completion codes).
6. The EDMA3CC programs the associated EDMA3TCn's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA3TCn.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA3TCn then signals completion status to the EDMA3CC.

8.3.14 EDMA3 Prioritization

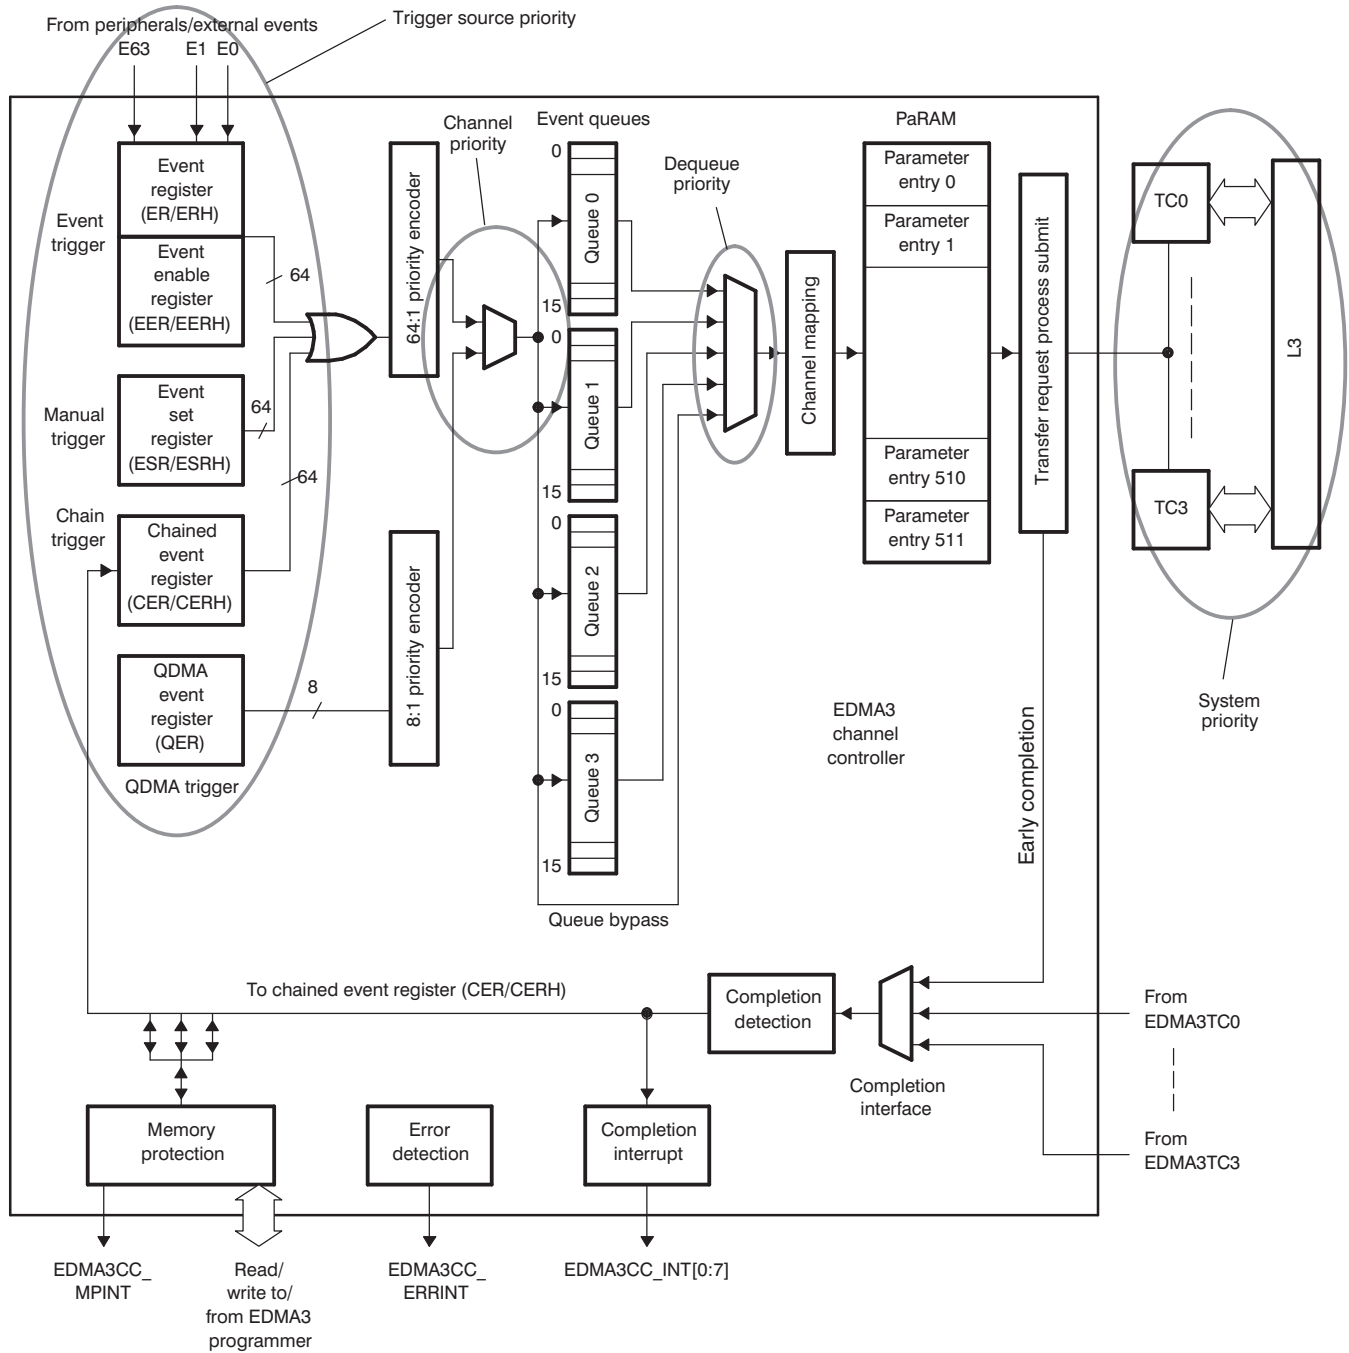

The EDMA3 controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. [Figure 8-19](#) shows the different places EDMA3 priorities come into play.

8.3.14.1 Channel Priority

The DMA event registers (ER and ERH) capture up to 64 events; likewise, the QDMA event register (QER) captures QDMA events for all QDMA channels; therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority; similarly, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

Figure 8-19. EDMA3 Prioritization

8.3.14.2 Trigger Source Priority

If a DMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel ($ER.En = 1$, $ESR.En = 1$, $CER.En = 1$), then the EDMA3CC always services these events in the following priority order: event trigger (via ER) is higher priority than chain trigger (via CER) and chain trigger is higher priority than manual trigger (via ESR).

This implies that if for channel 0, both $ER.E0 = 1$ and $CER.E0 = 1$ at the same time, then the $ER.E0$ event is always queued before the $CER.E0$ event.

8.3.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by DMAQNUM and QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 3 the lowest.

8.3.15 EDMA3 Operating Frequency (Clock Control)

The EDMA3 channel controller and transfer controller are clocked from SYSCLK4. The EDMA3 system runs at the L3 clock frequency.

8.3.16 Reset Considerations

A hardware reset resets the EDMA3 (EDMA3CC and EDMA3TC) and the EDMA3 configuration registers. The PaRAM memory contents are undefined after device reset and you should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used.

8.3.17 Power Management

The EDMA3 (EDMA3CC and EDMA3TC) can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the power reset clock management (PRCM). The PRCM acts as a master controller for power management for all peripherals on the device.

The EDMA3 controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA3CC and EDMA3TC are separate. In general, it should be verified that there are no pending activities in the EDMA3 controller

8.3.18 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA3 channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA3 is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA3 for emulation halts. EDMA3 functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts. For example, if a McASP is halted during an emulation access ($FREE = 0$ and $SOFT = 0$ or 1 in McASP registers), the McASP stops generating the McASP receive or transmit events (REVT or XEVT) to the EDMA. From the point of view of the McASP, the EDMA3 is suspended, but other peripherals (for example, a timer) still assert events and will be serviced by the EDMA.

8.4 EDMA Transfer Examples

The EDMA3 channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

8.4.1 Block Move Example

The most basic transfer performed by the EDMA3 is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 8-20. Figure 8-21 shows the parameters for this transfer.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 8-21 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The STATIC bit in OPT is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. You may program the QDMA trigger word to be the highest numbered offset in the PaRAM set that undergoes change.

8.4.2 Subframe Extraction Example

The EDMA3 can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA3 retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA3 places the subframe in internal L2 SRAM. Figure 8-22 shows the transfer of a subframe from external memory to L2. Figure 8-23 shows the parameters for this transfer.

The same PaPARAM entry options are used for QDMA channels, as well as DMA channels. The STATIC bit in OPT is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

8.4.3 Data Sorting Example

Many applications require the use of multiple data arrays; it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA3 can reorganize the data into the desired format. Figure 8-24 shows the data sorting.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SRCBIDX - Program this to be the size of the element or ACNT.
- DSTBIDX - CCNT × ACNT
- SRCCDX - ACNT × BCNT
- DSTCIDX - ACNT

The synchronization type needs to be AB-synchronized and the STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA3 channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 8-25 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

Figure 8-24. Data Sorting Example

8.4.4 Peripheral Servicing Example

The EDMA3 channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA3 channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA3 has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register (EER). When programming an EDMA3 channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

8.4.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA3 channel configuration is the same.

The McASP transmit and receive data streams are treated independently by the EDMA3. The transmit and receive data streams can have completely different counts, data sizes, and formats. [Figure 8-26](#) shows servicing incoming McASP data.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA3 channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA3 issue the transfer request for each element individually. [Figure 8-27](#) shows the parameters for this transfer. The source address of the EDMA3 channel is set to the data port address (DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 01b (increment).

Based on the premise that serial data is typically a high priority, the EDMA3 channel should be programmed to be on queue 0.

8.4.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the DSP one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory. [Figure 8-28](#) shows this example.

To transfer data from an external peripheral to an external buffer one array at a time based on EVT_n , channel n must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. [Figure 8-29](#) shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the SRCBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the DSTBIDX is set to pixel size, 2 bytes. ANCT is equal to the pixel size, 2 bytes. BCNT is set to the number of pixels in an array, 640. CCNT is equal to the total number of arrays in the block, 480. SRCCIDX is 0 because the source address undergoes no increment. The DSTCIDX is equal to the difference between the starting addresses of each array. Because a pixel is 16 bits (2 bytes), DSTCIDX is equal to 640×2 .

8.4.4.3 Continuous Operation

Configuring an EDMA3 channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA3 channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown [Figure 8-30](#).

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, the DMA channels associated with the McASP (channels 12 and 15) must be setup for 1D-to-1D transfers with A-synchronization.

[Figure 8-31](#) shows the parameter entries for the channel for these transfers. To service the McASP continuously throughout DSP operation, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA3 channels reload and continue. [Figure 8-32](#) shows the reload parameters for the channel.

8.4.4.3.1 Receive Channel

EDMA3 channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

8.4.4.3.2 Transmit Channel

EDMA3 channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA3 channel, with duplicate PaRAM set entries at PaRAM set 65.

8.4.4.4 Ping-Pong Buffering

Although the previous configuration allows the EDMA3 to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA3 very closely to process the data. The EDMA3 receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA3 transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA3 activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA3 transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA3 activity completes, they switch. The EDMA3 then writes over the old input data and transfers the new output data. [Figure 8-33](#) shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA3 channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaRAM set for the other and the data transfers continue. [Figure 8-34](#) shows the EDMA3 channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA3 channel is initially loaded with the ping parameters ([Figure 8-34](#)). The link address for the ping set is set to the PaRAM offset of the pong parameter set ([Figure 8-35](#)). The link address for the pong set is set to the PaRAM offset of the ping parameter set ([Figure 8-36](#)). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

8.4.4.4.1 Synchronization with the CPU

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA3 to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register (IPR) is set; when channel 12 empties an output buffer, the E12 bit in IPR is set. The CPU must manually clear these bits. With the channel parameters set, the CPU polls IPR to determine when to switch. The EDMA3 and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA3 to complete.

8.4.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

8.4.4.5.1 Servicing Input/Output FIFOs with a Single Event

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA3 channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event. For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA3 needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). [Figure 8-37](#) shows the EDMA3 setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register (CER) and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in CER (specified by TCCMODE:TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by TCCMODE:TCC) in the interrupt pending register (IPR), which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register (IER) is set.

Figure 8-37. Intermediate Transfer Completion Chaining Example

8.4.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

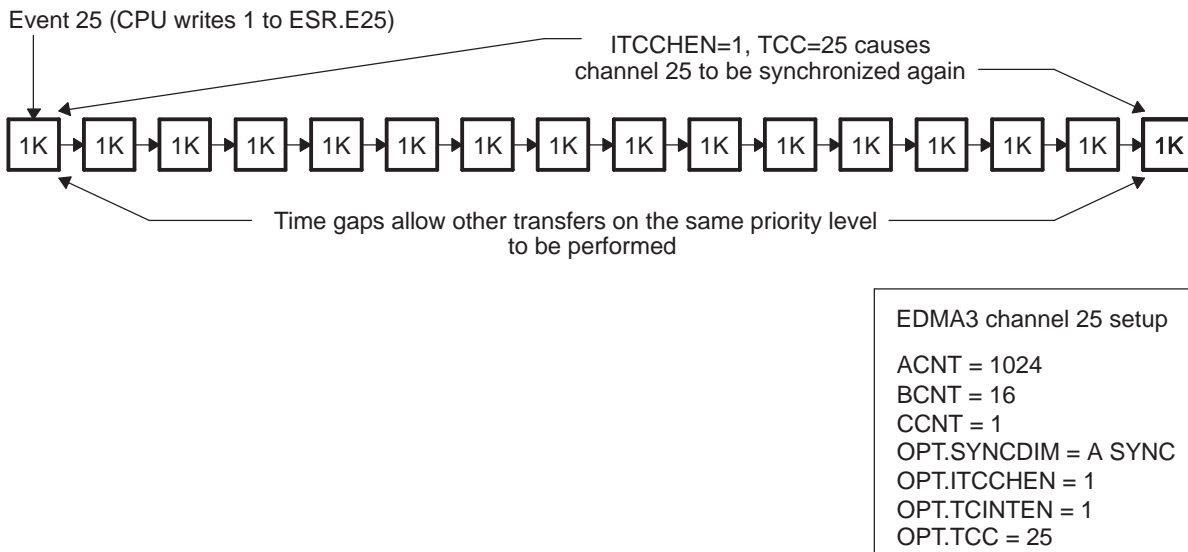

Another feature of intermediate transfer chaining (ITCCHEN) is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA3 transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. [Figure 8-38](#) shows the EDMA3 setup and illustration of an example single large block transfer.

Figure 8-38. Single Large Block Transfer Example

The intermediate transfer chaining enable (ITCCHEN) provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA3 performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA3 is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The TCC field in the channel options parameter (OPT) is set to the same value as the channel number and ITCCHEN are set. In this example, EDMA3 channel 25 is used and TCC is also set to 25. The TCINTEN may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA3 transfer by writing to the appropriate bit of the event set register (ESR.E25). The EDMA3 transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the TCC field. This intermediate transfer completion chaining event causes EDMA3 channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA3 has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. [Figure 8-39](#) shows the EDMA3 setup and illustration of the broken up smaller packet transfers.

Figure 8-39. Smaller Packet Data Transfers Example

8.5 EDMA3 Registers

8.5.1 EDMA3 Channel Controller Registers

Table 8-19 lists the memory-mapped registers for the EDMA3 channel controller (EDMACC). All other register offset addresses not listed in Table 8-19 should be considered as reserved locations and the register contents should not be modified. See your device-specific data manual for the register memory maps.

8.5.1.1 Global Registers

8.5.1.1.1 Peripheral Identification Register (PID)

The peripheral identification register (PID) uniquely identifies the EDMA3CC and the specific revision of the EDMA3CC.

The PID is shown in [Figure 8-40](#) and described in [Table 8-20](#).

Figure 8-40. Peripheral ID Register (PID)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8-20. Peripheral ID Register (PID) Field Descriptions

Bit	Field	Value	Description
31-0	PID	0-FFFF FFFFh	Peripheral identifier uniquely identifies the EDMA3CC and the specific revision of the EDMA3CC.

8.5.1.1.2 EDMA3CC Configuration Register (CCCFG)

The EDMA3CC configuration register (CCCFG) provides the features/resources for the EDMA3CC in a particular device.

The CCCFG is shown in [Figure 8-41](#) and described in [Table 8-21](#).

Figure 8-41. EDMA3CC Configuration Register (CCCFG)

Bit	Field	Value	Description
14-12	NUM_PAENTRY	0-7h	Number of PaRAM sets.
		0-3h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		5h	512 PaRAM sets.
		5h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
11	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
10-8	NUM_INTCH	0-7h	Number of interrupt channels.
		0-3h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		4h	64 interrupt channels.
		5h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
6-4	NUM_QDMACH	0-7h	Number of QDMA channels.
		0-1h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		4h	8 QDMA channels.
		3h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2-0	NUM_DMACH	0-7h	Number of DMA channels.
		0-4h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		5h	64 DMA channels.
		6h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

8.5.1.1.3 DMA Channel Map n Registers (DCHMAP n)

The DMA channel map n register (DCHMAP n) is shown in [Figure 8-42](#) and described in [Table 8-22](#).

Figure 8-42. DMA Channel Map n Registers (DCHMAP n)

LEGEND: R/W = Read/Write; R = Read only; - n = value after reset

Table 8-22. DMA Channel Map n Registers (DCHMAP n) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved
13-5	PAENTRY	0-1FFh	Points to the PaRAM set number for DMA channel n .
4-0	Reserved	0	Reserved

8.5.1.1.4 QDMA Channel Map n Registers (QCHMAP n)

Each QDMA channel in EDMA3CC can be associated with any PaRAM set available on the device. Furthermore, the specific trigger word (0-7) of the PaRAM set can be programmed. The PaRAM set association and trigger word for every QDMA channel register is configurable using the QDMA channel map n register (QCHMAP n).

The QCHMAP n is shown in [Figure 8-43](#) and described in [Table 8-23](#).

NOTE: At reset the QDMA channel map registers for all QDMA channels point to PaRAM set 0. If an application makes use of both a DMA channel that points to PaRAM set 0 and any QDMA channels, ensure that QCHMAP n is programmed appropriately to point to a different PaRAM entry.

Figure 8-43. QDMA Channel Map n Registers (QCHMAP n)

LEGEND: R/W = Read/Write; R = Read only; - n = value after reset

Table 8-23. QDMA Channel Map n Registers (QCHMAP n) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13-5	PAENTRY	0-1FFh	PAENTRY points to the PaRAM set number for QDMA channel n .
4-2	TRWORD	0-7h	Points to the specific trigger word of the PaRAM set defined by PAENTRY. A write to the trigger word results in a QDMA event being recognized.
1-0	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

8.5.1.1.5 DMA Channel Queue n Number Registers (DMAQNUM n)

The DMA channel queue number register (DMAQNUM n) allows programmability of each of the 64 DMA channels in the EDMA3CC to submit its associated synchronization event to any event queue in the EDMA3CC. At reset, all channels point to event queue 0.

The DMAQNUM n is shown in [Figure 8-44](#) and described in [Table 8-24](#). [Table 8-25](#) shows the channels and their corresponding bits in DMAQNUM n .

NOTE: Because the event queues in EDMA3CC have a fixed association to the transfer controllers, that is, Q0 TRs are submitted to TC0, Q1 TRs are submitted to TC1, etc., by programming DMAQNUM n for a particular DMA channel n also dictates which transfer controller is utilized for the data movement (or which EDMA3TC receives the TR request).

8.5.1.1.6 QDMA Channel Queue Number Register (QDMAQNUM)

The QDMA channel queue number register (QDMAQNUM) is used to program all the QDMA channels in the EDMA3CC to submit the associated QDMA event to any of the event queues in the EDMA3CC.

The QDMAQNUM is shown in [Figure 8-45](#) and described in [Table 8-26](#).

Table 8-26. QDMA Channel Queue Number Register (QDMAQNUM) Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
14-0	E_n	0-7h 0 1h 2h 3h 4h-7h	QDMA queue number. Contains the event queue number to be used for the corresponding QDMA channel. Event n is queued on Q0. Event n is queued on Q1. Event n is queued on Q2. Event n is queued on Q3. Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

8.5.1.2 Error Registers

The EDMA3CC contains a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

8.5.1.2.1 Event Missed Registers (EMR/EMRH)

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed registers (EMR/EMRH). All trigger types are treated individually, that is, manual triggered (ESR/ESRH), chain triggered (CER/CERH), and event triggered (ER/ERH) are all treated separately. The EMR/EMRH bits for a channel are also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EMR/EMRH bit is set (and all errors, including bits in other error registers (QEMR, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see *Error Interrupts*.

The EMR is shown in [Figure 8-46](#) and described in [Table 8-27](#). The EMRH is shown in [Figure 8-47](#) and described in [Table 8-28](#).

Figure 8-46. Event Missed Register (EMR)

Table 8-28. Event Missed Register High (EMRH) Field Descriptions

Bit	Field	Value	Description
31-0	<i>En</i>		Channel 32-63 event missed. <i>En</i> is cleared by writing a 1 to the corresponding bit in the event missed clear register high (EMCRH).
		0	No missed event.
		1	Missed event occurred.

8.5.1.2.2 Event Missed Clear Registers (EMCR/EMCRH)

Once a missed event is posted in the event missed registers (EMR/EMRH), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the event missed clear registers (EMCR/EMCRH). Writing a 1 to any of the bits clears the corresponding missed event (bit) in EMR/EMRH; writing a 0 has no effect.

The EMCR is shown in [Figure 8-48](#) and described in [Table 8-29](#). The EMCRH is shown in [Figure 8-49](#) and described in [Table 8-30](#).

Figure 8-48. Event Missed Clear Register (EMCR)

Table 8-30. Event Missed Clear Register High (EMCRH) Field Descriptions

Bit	Field	Value	Description
31-0	E_n		Event missed 32–63 clear. All error bits must be cleared before additional error interrupts will be asserted by the EDMA3CC.
		0	No effect.
		1	Corresponding missed event bit in the event missed register high (EMRH) is cleared ($E_n = 0$).

8.5.1.2.3 QDMA Event Missed Register (QEMR)

For a particular QDMA channel, if two QDMA events are detected without the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the QDMA event missed register (QEMR). The QEMR bits for a channel are also set if a QDMA event on the channel encounters a NULL entry (or a NULL TR is serviced). If any QEMR bit is set (and all errors, including bits in other error registers (EMR/EMRH, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see *Error Interrupts*.

The QEMR is shown in [Figure 8-50](#) and described in [Table 8-31](#).

Figure 8-50. QDMA Event Missed Register (QEMR)

LEGEND: R = Read only; -n = value after reset

Table 8-31. QDMA Event Missed Register (QEMR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	E_n	0 1	Channel 0-7 QDMA event missed. E_n is cleared by writing a 1 to the corresponding bit in the QDMA event missed clear register (QEMCR). No missed event. Missed event occurred.

8.5.1.2.4 QDMA Event Missed Clear Register (QEMCR)

Once a missed event is posted in the QDMA event missed registers (QEMR), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the QDMA event missed clear registers (QEMCR). Writing a 1 to any of the bits clears the corresponding missed event (bit) in QEMR; writing a 0 has no effect.

The QEMCR is shown in [Figure 8-51](#) and described in [Table 8-32](#).

Figure 8-51. QDMA Event Missed Clear Register (QEMCR)

LEGEND: W = Write only; -n = value after reset

Table 8-32. QDMA Event Missed Clear Register (QEMCR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	E_n	0 1	QDMA event missed clear. All error bits must be cleared before additional error interrupts will be asserted by the EDMA3CC. No effect. Corresponding missed event bit in the QDMA event missed register (QEMR) is cleared ($E_n = 0$).

8.5.1.2.5 EDMA3CC Error Register (CCERR)

The EDMA3CC error register (CCERR) indicates whether or not at any instant of time the number of events queued up in any of the event queues exceeds or equals the threshold/watermark value that is set in the queue watermark threshold register (QWMTHRA). Additionally, CCERR also indicates if when the number of outstanding TRs that have been programmed to return transfer completion code (TRs which have the TCINTEN or TCCHEN bit in OPT set) to the EDMA3CC has exceeded the maximum allowed value of 63. If any bit in CCERR is set (and all errors, including bits in other error registers (EMR/EMRH, QEMR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see *Error Interrupts*. Once the error bits are set in CCERR, they can only be cleared by writing to the corresponding bits in the EDMA3CC error clear register (CCERRCLR).

The CCERR is shown in [Figure 8-52](#) and described in [Table 8-33](#).

Figure 8-52. EDMA3CC Error Register (CCERR)

31					17	16		
Reserved					TCCERR			
R-0					R-0			
15				4	3	2	1	0
Reserved				QTHRXC3	QTHRXC2	QTHRXC1	QTHRXC0	
R-0				R-0	R-0	R-0	R-0	

LEGEND: R = Read only; -n = value after reset

Table 8-33. EDMA3CC Error Register (CCERR) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
16	TCCERR		Transfer completion code error. TCCERR is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Total number of allowed TCCs outstanding has not been reached.
		1	Total number of allowed TCCs has been reached.
15-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	QTHRXC3		Queue threshold error for queue 3. QTHRXC3 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.
2	QTHRXC2		Queue threshold error for queue 2. QTHRXC2 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.
1	QTHRXC1		Queue threshold error for queue 1. QTHRXC1 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.
0	QTHRXC0		Queue threshold error for queue 0. QTHRXC0 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.

8.5.1.2.6 EDMA3CC Error Clear Register (CCERRCLR)

The EDMA3CC error clear register (CCERRCLR) is used to clear any error bits that are set in the EDMA3CC error register (CCERR). In addition, CCERRCLR also clears the values of some bit fields in the queue status registers (QSTAT n) associated with a particular event queue. Writing a 1 to any of the bits clears the corresponding bit in CCERR; writing a 0 has no effect.

The CCERRCLR is shown in [Figure 8-53](#) and described in [Table 8-34](#).

Figure 8-53. EDMA3CC Error Clear Register (CCERRCLR)

31	Reserved				17	16
					TCCERR	
					W-0	
					4	3
15	Reserved		QTHRXC3	QTHRXC2	QTHRXC1	QTHRXC0
		W-0	W-0	W-0	W-0	W-0

LEGEND: W = Write only; -n = value after reset

Table 8-34. EDMA3CC Error Clear Register (CCERRCLR) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
16	TCCERR	0	No effect.
		1	Clears the TCCERR bit in the EDMA3CC error register (CCERR).
15-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	QTHRXC3	0	No effect.
		1	Clears the QTHRXC3 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 3 (QSTAT3).
2	QTHRXC2	0	No effect.
		1	Clears the QTHRXC2 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 2 (QSTAT2).
1	QTHRXC1	0	No effect.
		1	Clears the QTHRXC1 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 1 (QSTAT1).
0	QTHRXC0	0	No effect.
		1	Clears the QTHRXC0 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 0 (QSTAT0).

8.5.1.2.7 Error Evaluation Register (EEVAL)

The EDMA3CC error interrupt is asserted whenever an error bit is set in any of the error registers (EMR/EMRH, QEMR, and CCERR). For subsequent error bits that get set, the EDMA3CC error interrupt is reasserted only when transitioning from an “all the error bits cleared” to “at least one error bit is set”. Alternatively, a CPU write of 1 to the EVAL bit in the error evaluation register (EEVAL) results in reasserting the EDMA3CC error interrupt, if there are any outstanding error bits set due to subsequent error conditions. Writes of 0 have no effect.

The EEVAL is shown in [Figure 8-54](#) and described in [Table 8-35](#).

Figure 8-54. Error Evaluation Register (EEVAL)

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

Table 8-35. Error Evaluation Register (EEVAL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	EVAL	0	Error interrupt evaluate. No effect.
		1	EDMA3CC error interrupt will be pulsed if any errors have not been cleared in any of the error registers (EMR/EMRH, QEMR, or CCERR).

8.5.1.3 Region Access Enable Registers

The region access enable register group consists of the DMA access enable registers (DRAE m and DRAEH m) and the QDMA access enable registers (QRAE m). Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

8.5.1.3.1 DMA Region Access Enable for Region m (DRAE m)

The DMA region access enable register for shadow region m (DRAE m /DRAEH m) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region m view of the DMA channel registers. See the EDMA3CC register memory map (Table 8-19) for a list of all the DMA channel and interrupt registers mapped in the shadow region view. Additionally, the DRAE m /DRAEH m configuration determines completion of which DMA channels will result in assertion of the shadow region m DMA completion interrupt (see *EDMA3 Interrupts*).

The DRAE m is shown in Figure 8-55 and described in Table 8-36. The DRAEH m is shown in Figure 8-56 and described in Table 8-36.

**Table 8-36. DMA Region Access Enable Registers for Region M (DRAE m /DRAEH m)
Field Descriptions**

Bit	Field	Value	Description
31-0	E_n	0	DMA region access enable for bit n /channel n in region m . Accesses via region m address space to bit n in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit n . Enabled interrupt bits for bit n do not contribute to the generation of a transfer completion interrupt for shadow region m .
		1	Accesses via region m address space to bit n in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit n . Enabled interrupt bits for bit n contribute to the generation of a transfer completion interrupt for shadow region m .

8.5.1.3.2 QDMA Region Access Enable Registers (QRAEm)

The QDMA region access enable register for shadow region m (QRAEm) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all QDMA registers in the shadow region m view of the QDMA registers. This includes all 4-bit QDMA registers.

The QRAEm is shown in [Figure 8-57](#) and described in [Table 8-37](#).

Figure 8-57. QDMA Region Access Enable for Region m (QRAEm)

LEGEND: R/W = Read/Write; R = Read only; - n = value after reset

Table 8-37. QDMA Region Access Enable for Region M (QRAEm) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	E_n	0	Accesses via region m address space to bit n in any QDMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit n .
		1	Accesses via region m address space to bit n in any QDMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit n .

8.5.1.4 Status/Debug Visibility Registers

The following set of registers provide visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

8.5.1.4.1 Event Queue Entry Registers (QxEy)

The event queue entry registers (QxEy) exist for all 16 queue entries (the maximum allowed queue entries) for all event queues in the EDMA3CC.

There are Q0E0 to Q0E15, Q1E0 to Q1E15, Q2E0 to Q2E15, and Q3E0 to Q3E15. Each register details the event number (ENUM) and the event type (ETYPE). For example, if the value in Q1E4 is read as 000004Fh, this means the 4th entry in queue 1 is a manually-triggered event on DMA channel 15.

The QxEy is shown in [Figure 8-58](#) and described in [Table 8-38](#).

Figure 8-58. Event Queue Entry Registers (QxEy)

LEGEND: R = Read only; -n = value after reset; -x = value is indeterminate after reset

Table 8-38. Event Queue Entry Registers (QxEy) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-6	ETYPE	0-3h	Event entry y in queue x. Specifies the specific event type for the given entry in the event queue.
		0	Event triggered via ER.
		1h	Manual triggered via ESR.
		2h	Chain triggered via CER.
		3h	Auto-triggered via QER.
5-0	ENUM	0-3Fh	Event entry y in queue x. Event number:
		0-3h	QDMA channel number (0 to 3).
		0-3Fh	DMA channel/event number (0 to 63).

8.5.1.4.2 Queue Status Registers (QSTAT_n)

The queue status registers (QSTAT_n) is shown in [Figure 8-59](#) and described in [Table 8-39](#).

Figure 8-59. Queue Status Register *n* (QSTAT_n)

LEGEND: R = Read only; -*n* = value after reset

Table 8-39. Queue Status Register *n* (QSTAT_n) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
24	THRXC <small>D</small>	0	Threshold exceeded. THRXC <small>D</small> is cleared by writing a 1 to the corresponding QTHRXC <small>D</small> _n bit in the EDMA3CC error clear register (CCERRCLR).
		1	Threshold specified by the Q _n bit in the queue watermark threshold A register (QWMTHRA) has not been exceeded.
			Threshold specified by the Q _n bit in the queue watermark threshold A register (QWMTHRA) has been exceeded.
23-21	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
20-16	WM	0-10h	Watermark for maximum queue usage. Watermark tracks the most entries that have been in queue <i>n</i> since reset or since the last time that the watermark (WM) bit was cleared. WM is cleared by writing a 1 to the corresponding QTHRXC <small>D</small> _n bit in the EDMA3CC error clear register (CCERRCLR).
		0-10h	Legal values are 0 (empty) to 10h (full).
		11h-1Fh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15-13	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
12-8	NUMVAL	0-10h	Number of valid entries in queue <i>n</i> . The total number of entries residing in the queue manager FIFO at a given instant. Always enabled.
		0-10h	Legal values are 0 (empty) to 10h (full).
		11h-1Fh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3-0	STRTP <small>TR</small>	0-Fh	Start pointer. The offset to the head entry of queue <i>n</i> , in units of entries. Always enabled. Legal values are 0 (0th entry) to Fh (15th entry).

8.5.1.4.3 Queue Watermark Threshold A Register (QWMTHRA)

The queue watermark threshold A register (QWMTHRA) is shown in [Figure 8-60](#) and described in [Table 8-40](#).

Figure 8-60. Queue Watermark Threshold A Register (QWMTHRA)

Table 8-40. Queue Watermark Threshold A Register (QWMTHRA) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
28-24	Q3	0-1Fh 0-10h 11h 12h-1Fh	Queue threshold for queue 3 value. The QTHRCD3 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 3 (QSTAT3) are set when the number of events in queue 3 at an instant in time (visible via the NUMVAL bit in QSTAT3) equals or exceeds the value specified by Q3. The default is 16 (maximum allowed). Disables the threshold errors. Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
23-21	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
20-16	Q2	0-1Fh 0-10h 11h 12h-1Fh	Queue threshold for queue 2 value. The QTHRCD2 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 2 (QSTAT2) are set when the number of events in queue 2 at an instant in time (visible via the NUMVAL bit in QSTAT2) equals or exceeds the value specified by Q2. The default is 16 (maximum allowed). Disables the threshold errors. Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15-13	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
12-8	Q1	0-10h 11h 12h-1Fh	Queue threshold for queue 1 value. The QTHRCD1 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 1 (QSTAT1) are set when the number of events in queue 1 at an instant in time (visible via the NUMVAL bit in QSTAT1) equals or exceeds the value specified by Q1. The default is 16 (maximum allowed). Disables the threshold errors. Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-5	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
4-0	Q0	0-10h 11h 12h-1Fh	Queue threshold for queue 0 value. The QTHRCD0 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 0 (QSTAT0) are set when the number of events in queue 0 at an instant in time (visible via the NUMVAL bit in QSTAT0) equals or exceeds the value specified by Q0. The default is 16 (maximum allowed). Disables the threshold errors. Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

8.5.1.4.4 EDMA3CC Status Register (CCSTAT)

The EDMA3CC status register (CCSTAT) has a number of status bits that reflect which parts of the EDMA3CC logic is active at any given instant of time. The CCSTAT is shown in [Figure 8-61](#) and described in [Table 8-41](#).

Figure 8-61. EDMA3CC Status Register (CCSTAT)

R-0				R-0		R-0		R-0		R-0		R-0		R-0	

LEGEND: R = Read only; -n = value after reset

Table 8-41. EDMA3CC Status Register (CCSTAT) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
19	QUEACTV3	0	Queue 3 active.
		1	At least one TR is queued in queue 3.
18	QUEACTV2	0	Queue 2 active.
		1	At least one TR is queued in queue 2.
17	QUEACTV1	0	Queue 1 active.
		1	At least one TR is queued in queue 1.
16	QUEACTV0	0	Queue 0 active.
		1	At least one TR is queued in queue 0.
15-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13-8	COMPACTV	0-3Fh	Completion request active. The COMPACTV field reflects the count for the number of completion requests submitted to the transfer controllers. This count increments every time a TR is submitted and is programmed to report completion (the TCINTEN or TCCCHEN bits in OPT in the parameter entry associated with the TR are set). The counter decrements for every valid TCC received back from the transfer controllers. If at any time the count reaches a value of 63, the EDMA3CC will not service any new TRs until the count is less than 63 (or return a transfer completion code from a transfer controller, which would decrement the count).
		0	No completion requests outstanding.
		1h-3Fh	Total of 1 completion request to 63 completion requests are outstanding.
7-5	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

Table 8-41. EDMA3CC Status Register (CCSTAT) Field Descriptions (continued)

Bit	Field	Value	Description
4	ACTV		Channel controller active. Channel controller active is a logical-OR of each of the *ACTV bits. The ACTV bit remains high through the life of a TR.
		0	Channel is idle..
		1	Channel is busy.
3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2	TRACTV		Transfer request active.
		0	Transfer request processing/submission logic is inactive.
		1	Transfer request processing/submission logic is active.
1	QEVTACTV		QDMA event active.
		0	No enabled QDMA events are active within the EDMA3CC.
		1	At least one enabled QDMA event (QER) is active within the EDMA3CC.
0	EVTACTV		DMA event active.
		0	No enabled DMA events are active within the EDMA3CC.
		1	At least one enabled DMA event (ER and EER, ESR, CER) is active within the EDMA3CC.

8.5.1.5 Memory Protection Address Space

8.5.1.5.1 Memory Protection Fault Address Register (MPFAR)

The memory protection fault address register (MPFAR) is shown in [Figure 8-62](#) and described in [Table 8-42](#). A CPU write of 1 to the MPFCLR bit in the memory protection fault command register (MPFCR) causes any error conditions stored in MPFAR to be cleared.

Figure 8-62. Memory Protection Fault Address Register (MPFAR)

LEGEND: R = Read only; -n = value after reset

Table 8-42. Memory Protection Fault Address Register (MPFAR) Field Descriptions

Bit	Field	Value	Description
31-0	FADDR	0-FFFF FFFFh	Fault address. This 32-bit read-only status register contains the fault address when a memory protection violation is detected. This register can only be cleared via the memory protection fault command register (MPFCR).

8.5.1.5.2 Memory Protection Fault Status Register (MPFSR)

The memory protection fault status register (MPFSR) is shown in [Figure 8-63](#) and described in [Table 8-43](#). A CPU write of 1 to the MPFCLR bit in the memory protection fault command register (MPFCR) causes any error conditions stored in MPFSR to be cleared.

Figure 8-63. Memory Protection Fault Status Register (MPFSR)

LEGEND: R = Read only; -n = value after reset

Table 8-43. Memory Protection Fault Status Register (MPFSR) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
12-9	FID	0-Fh	Faulted identification. FID contains valid information if any of the MP error bits (UXE, UWE, URE, SXE, SWE, SRE) are nonzero (that is, if an error has been detected.) The FID field contains the privilege ID for the specific request/requestor that resulted in an MP error.
8-6	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
5	SRE	0 1	Supervisor read error. 0 No error detected. 1 Supervisor level task attempted to read from a MP page without SR permissions.
4	SWE	0 1	Supervisor write error. 0 No error detected. 1 Supervisor level task attempted to write to a MP page without SW permissions.
3	SXE	0 1	Supervisor execute error. 0 No error detected. 1 Supervisor level task attempted to execute from a MP page without SX permissions.
2	URE	0 1	User read error. 0 No error detected. 1 User level task attempted to read from a MP page without UR permissions.
1	UWE	0 1	User write error. 0 No error detected. 1 User level task attempted to write to a MP page without UW permissions.
0	UXE	0 1	User execute error. 0 No error detected. 1 User level task attempted to execute from a MP page without UX permissions.

8.5.1.5.3 Memory Protection Fault Command Register (MPFCR)

The memory protection fault command register (MPFCR) is shown in [Figure 8-64](#) and described in [Table 8-44](#).

Figure 8-64. Memory Protection Fault Command Register (MPFCR)

LEGEND: R = Read only; W = Write only; -n = value after reset

Table 8-44. Memory Protection Fault Command Register (MPFCR) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	MPFCLR	0	Fault clear register. CPU write of 0 has no effect.
		1	CPU write of 1 to the MPFCLR bit causes any error conditions stored in the memory protection fault address register (MPFAR) and the memory protection fault status register (MPFSR) to be cleared.

8.5.1.5.4 Memory Protection Page Attribute Register (MPPAn)

The memory protection page attribute register (MPPAn) is shown in [Figure 8-65](#) and described in [Table 8-45](#).

Figure 8-65. Memory Protection Page Attribute Register (MPPAn)

Table 8-45. Memory Protection Page Attribute Register (MPPAn) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15-10	AIDm	0	Requests with Privilege ID == N are not allowed to region M, regardless of permission settings (UW, UR, SW, SR).
		1	Requests with Privilege ID == N are permitted, if access type is allowed as defined by permission settings (UW, UR, SW, SR).
9	EXT	0	Requests with Privilege ID >= 6 are not allowed to region M, regardless of permission settings (UW, UR, SW, SR).
		1	Requests with Privilege ID >= 6 are permitted, if access type is allowed as defined by permission settings (UW, UR, SW, SR).
8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-6	Reserved	1	Reserved. Always write 1 to this bit.
5	SR	0	Supervisor read accesses are not allowed from region M.
		1	Supervisor write accesses are allowed from region M addresses.
4	SW	0	Supervisor write accesses are not allowed to region M.
		1	Supervisor write accesses are allowed to region N addresses.
3	SX	0	Supervisor execute accesses are not allowed from region M.
		1	Supervisor execute accesses are allowed from region M addresses.
2	UR	0	User read accesses are not allowed from region M.
		1	User read accesses are allowed from region N addresses.
1	UW	0	User write accesses are not allowed to region M.
		1	User write accesses are allowed to region M addresses.
0	UX	0	User execute accesses are not allowed from region M.
		1	User execute accesses are allowed from region M addresses.

8.5.1.6 DMA Channel Registers

The following sets of registers pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUM n) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format *reg_name* that corresponds to DMA channels 0 through 31 and *reg_name_High* that corresponds to DMA channels 32 through 64.

For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register.

The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm). The registers are described in [Section 8.5.1.3.1](#) and the details for shadow region/global region usage is explained in *EDMA3 Channel Controller Regions*.

8.5.1.6.1 Event Registers (ER, ERH)

All external events are captured in the event register (ER/ERH). The events are latched even when the events are not enabled. If the event bit corresponding to the latched event is enabled (EER.En/EERH.En = 1), then the event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. The event register bits are automatically cleared (ER.En/ERH.En = 0) once the corresponding events are prioritized and serviced. If ER.En/ERH.En are already set and another event is received on the same channel/event, then the corresponding event is latched in the event miss register (EMR.En/EMRH.En), provided that the event was enabled (EER.En/EERH.En = 1).

Event n can be cleared by the CPU writing a 1 to corresponding event bit in the event clear register (ECR/ECRH). The setting of an event is a higher priority relative to clear operations (via hardware or software). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The *Debug List* table provides the type of synchronization events and the EDMA3CC channels associated to each of these external events.

The ER is shown in [Figure 8-66](#) and described in [Table 8-46](#). The ERH is shown in [Figure 8-67](#) and described in [Table 8-47](#).

Table 8-47. Event Register High (ERH) Field Descriptions

Bit	Field	Value	Description
31-0	E_n	0	Event 32-63. Events 32-63 are captured by the EDMA3CC and are latched into ERH. The events are set ($E_n = 1$) even when events are disabled ($E_n = 0$ in the event enable register high, EERH). EDMA3CC event is not asserted.
		1	EDMA3CC event is asserted. Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

8.5.1.6.2 Event Clear Registers (ECR, ECRH)

Once an event has been posted in the event registers (ER/ERH), the event is cleared in two ways. If the event is enabled in the event enable register (EER/EERH) and the EDMA3CC submits a transfer request for the event to the EDMA3TC, it clears the corresponding event bit in the event register. If the event is disabled in the event enable register (EER/EERH), the CPU can clear the event by way of the event clear registers (ECR/ECRH).

Writing a 1 to any of the bits clears the corresponding event; writing a 0 has no effect. Once an event bit is set in the event register, it remains set until EDMA3CC submits a transfer request for that event or the CPU clears the event by setting the corresponding bit in ECR/ECRH.

The ECR is shown in [Figure 8-68](#) and described in [Table 8-48](#). The ECRH is shown in [Figure 8-69](#) and described in [Table 8-49](#).

Bit	Field	Value	Description
31-0	<i>En</i>		Event clear for event 32-63. Any of the event bits in ECRH are set to clear the event (<i>En</i>) in the event register high (ERH). A write of 0 has no effect.
		0	No effect.
		1	EDMA3CC event is cleared in the event register high (ERH).

8.5.1.6.3 Event Set Registers (ESR, ESRH)

The event set registers (ESR/ESRH) allow the CPU (EDMA3 programmers) to manually set events to initiate DMA transfer requests. CPU writes of 1 to any event set register (E_n) bits set the corresponding bits in the registers. The set event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. Writing a 0 has no effect.

The event set registers operate independent of the event registers (ER/ERH), and a write of 1 is always considered a valid event regardless of whether the event is enabled (the corresponding event bits are set or cleared in EER. E_n /EERH. E_n).

Once the event is set in the event set registers, it cannot be cleared by CPU writes, in other words, the event clear registers (ECR/ECRH) have no effect on the state of ESR/ESRH. The bits will only be cleared once the transfer request corresponding to the event has been submitted to the transfer controller. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

Manually-triggered transfers via writes to ESR/ESRH allow the CPU to submit DMA requests in the system, these are relevant for memory-to-memory transfer scenarios. If the ESR. E_n /ESRH. E_n bit is already set and another CPU write of 1 is attempted to the same bit, then the corresponding event is latched in the event missed registers (EMR. E_n /EMRH. E_n = 1).

The ESR is shown in [Figure 8-70](#) and described in [Table 8-50](#). The ESRH is shown in [Figure 8-71](#) and described in [Table 8-51](#).

31-0	<i>En</i>	0	Event set for event 32-63. No effect.
		1	Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

8.5.1.6.4 Chained Event Registers (CER, CERH)

When the OPTIONS parameter for a PaRAM entry is programmed to returned a chained completion code (ITCCHEN = 1 and/or TCCHEN = 1), then the value dictated by the TCC[5:0] (also programmed in OPT) forces the corresponding event bit to be set in the chained event registers (CER/CERH). The set chained event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. This results in a chained-triggered transfer.

The chained event registers do not have any enables. The generation of a chained event is essentially enabled by the PaRAM entry that has been configured for intermediate and/or final chaining on transfer completion. The *En* bit is set (regardless of the state of EER.En/EERH.En) when a chained completion code is returned from one of the transfer controllers or is generated by the EDMA3CC via the early completion path. The bits in the chained event register are cleared when the corresponding events are prioritized and serviced.

If the *En* bit is already set and another chaining completion code is return for the same event, then the corresponding event is latched in the event missed registers (EMR.En/EMRH.En = 1). The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The CER is shown in [Figure 8-72](#) and described in [Table 8-52](#). The CERH is shown in [Figure 8-73](#) and described in [Table 8-53](#).

8.5.1.6.5 Event Enable Registers (EER, EERH)

The EDMA3CC provides the option of selectively enabling/disabling each event in the event registers (ER/ERH) by using the event enable registers (EER/EERH). If an event bit in EER/EERH is set (using the event enable set registers, EESR/EESRH), it will enable that corresponding event. Alternatively, if an event bit in EER/EERH is cleared (using the event enable clear registers, EECR/EECRH), it will disable the corresponding event.

The event registers latch all events that are captured by EDMA3CC, even if the events are disabled (although EDMA3CC does not process it). Enabling an event with a pending event already set in the event registers enables the EDMA3CC to process the already set event like any other new event. The EER/EERH settings do not have any effect on chained events ($CER.En/CERH.En = 1$) and manually set events ($ESR.En/ESRH.En = 1$).

The EER is shown in [Figure 8-74](#) and described in [Table 8-54](#). The EERH is shown in [Figure 8-75](#) and described in [Table 8-55](#).

		1	Event is enabled. An external event latched in the event register high (ERH) is evaluated by the EDMA3CC.

8.5.1.6.6 Event Enable Clear Register (EECR, EECRH)

The event enable registers (EER/EERH) cannot be modified by directly writing to them. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable clear registers (EECR/EECRH) are used to disable events. Writes of 1 to the bits in EECR/EECRH clear the corresponding event bits in EER/EERH; writes of 0 have no effect.

The EECR is shown in [Figure 8-76](#) and described in [Table 8-56](#). The EECRH is shown in [Figure 8-77](#) and described in [Table 8-57](#).

8.5.1.6.8 Secondary Event Registers (SER, SERH)

The secondary event registers (SER/SERH) provide information on the state of a DMA channel or event (0 through 63). If the EDMA3CC receives a TR synchronization due to a manual-trigger, event-trigger, or chained-trigger source (ESR.En/ESRH.En = 1, ER.En/ERH.En = 1, or CER.En/CERH.En = 1), which results in the setting of a corresponding event bit in SER/SERH (SER.En/SERH.En = 1), it implies that the corresponding DMA event is in the queue.

Once a bit corresponding to an event is set in SER/SERH, the EDMA3CC does not prioritize additional events on the same DMA channel. Depending on the condition that lead to the setting of the SER bits, either the EDMA3CC hardware or the software (using SECR/SECRH) needs to clear the SER/SERH bits for the EDMA3CC to evaluate subsequent events (subsequent transfers) on the same channel. For additional conditions that can cause the secondary event registers to be set, see *EDMA Overview*.

The SER is shown in [Figure 8-80](#) and described in [Table 8-60](#). The SERH is shown in [Figure 8-81](#) and described in [Table 8-61](#).

		1	Event is currently stored in the event queue. Event submission/prioritization logic will not prioritize additional events.

8.5.1.6.9 Secondary Event Clear Registers (SECR, SECRH)

The secondary event clear registers (SECR/SECRH) clear the status of the secondary event registers (SER/SERH). CPU writes of 1 clear the corresponding set bits in SER/SERH. Writes of 0 have no effect.

The SECR is shown in [Figure 8-82](#) and described in [Table 8-62](#). The SECRH is shown in [Figure 8-83](#) and described in [Table 8-63](#).

8.5.1.7 Interrupt Registers

All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. The following set of registers is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see *EDMA3 Interrupts*.

8.5.1.7.1 Interrupt Enable Registers (IER, IERH)

Interrupt enable registers (IER/IERH) are used to enable/disable the transfer completion interrupt generation by the EDMA3CC for all DMA/QDMA channels. The IER/IERH cannot be written to directly. To set any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable set registers (IESR/IESRH). Similarly, to clear any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable clear registers (IECR/IECRH).

The IER is shown in [Figure 8-84](#) and described in [Table 8-64](#). The IERH is shown in [Figure 8-85](#) and described in [Table 8-65](#).

8.5.1.7.2 Interrupt Enable Clear Register (IECR, IECRH)

The interrupt enable clear registers (IECR/IECRH) are used to clear interrupts. Writes of 1 to the bits in IECR/IECRH clear the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect.

The IECR is shown in [Figure 8-86](#) and described in [Table 8-66](#). The IECRH is shown in [Figure 8-87](#) and described in [Table 8-67](#).

Bit	Field	Value	Description
31-0	<i>In</i>	0	Interrupt enable clear for channels 32-63. No effect.
		1	Corresponding bit in the interrupt enable register high (IERH) is set (<i>In</i> = 1).

8.5.1.7.4 Interrupt Pending Register (IPR, IPRH)

If the TCINTEN and/or ITCINTEN bit in the channel option parameter (OPT) is set in the PaRAM entry associated with the channel (DMA or QDMA), then the EDMA3TC (for normal completion) or the EDMA3CC (for early completion) returns a completion code on transfer or intermediate transfer completion. The value of the returned completion code is equal to the TCC bit in OPT for the PaRAM entry associated with the channel.

When an interrupt transfer completion code with $TCC = n$ is detected by the EDMA3CC, then the corresponding bit is set in the interrupt pending register (IPR. ln , if $n = 0$ to 31; IPRH. ln , if $n = 32$ to 63). Note that once a bit is set in the interrupt pending registers, it remains set; it is your responsibility to clear these bits. The bits set in IPR/IPRH are cleared by writing a 1 to the corresponding bits in the interrupt clear registers (ICR/ICRH).

The IPR is shown in Figure 8-90 and described in Table 8-70. The IPRH is shown in Figure 8-91 and described in Table 8-71.

8.5.1.7.5 Interrupt Clear Registers (ICR, ICRH)

The bits in the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bits in the interrupt clear registers (ICR/ICRH). Writes of 0 have no effect. All set bits in IPR/IPRH must be cleared to allow EDMA3CC to assert additional transfer completion interrupts.

The ICR is shown in [Figure 8-92](#) and described in [Table 8-72](#). The ICRH is shown in [Figure 8-93](#) and described in [Table 8-73](#).

		1	Corresponding bit in the interrupt pending register high (IPRH) is cleared (<i>In</i> = 0).

8.5.1.7.6 Interrupt Evaluate Register (IEVAL)

The interrupt evaluate register (IEVAL) is the only register that physically exists in both the global region and the shadow regions. In other words, the read/write accessibility for the shadow region IEVAL is not affected by the DMA/QDMA region access registers (DRAEm/DRAEHm, QRAEn/QRAEHn). IEVAL is needed for robust ISR operations to ensure that interrupts are not missed by the CPU.

The IEVAL is shown in [Figure 8-94](#) and described in [Table 8-74](#).

Table 8-74. Interrupt Evaluate Register (IEVAL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	EVAL	0 1	Interrupt evaluate. 0 No effect. 1 Causes EDMA3CC completion interrupt to be pulsed, if any enabled (IERn/IERHn = 1) interrupts are still pending (IPRn/IPRHn = 1). The EDMA3CC completion interrupt that is pulsed depends on which IEVAL is being exercised. For example, writing to the EVAL bit in IEVAL pulses the global completion interrupt, but writing to the EVAL bit in IEVAL0 pulses the region 0 completion interrupt.

8.5.1.8 QDMA Registers

The following sets of registers control the QDMA channels in the EDMA3CC. The QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address range is controlled by the QDMA region access registers (QRAEn/QRAEHn). *EDMA3 Channel Controller Regions* details shadow region/global region usage.

8.5.1.8.1 QDMA Event Register (QER)

The QDMA event register (QER) channel n bit is set ($En = 1$) when the CPU or any EDMA3 programmer (including EDMA3) performs a write to the trigger word (using the QDMA channel mapping register (QCHMAPn)) in the PaRAM entry associated with QDMA channel n (which is also programmed using QCHMAPn). The En bit is also set when the EDMA3CC performs a link update on a PaRAM address that matches the QCHMAPn settings. The QDMA event is latched only if the QDMA event enable register (QEER) channel n bit is also enabled (QEER.En = 1). Once a bit is set in QER, then the corresponding QDMA event (auto-trigger) is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. For additional conditions that can lead to the setting of QER bits, see *EDMA Overview*.

The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then the QDMA event missed register (QEMR) would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The set bits in QER are only cleared when the transfer request associated with the corresponding channels has been processed by the EDMA3CC and submitted to the transfer controller. If the En bit is already set and a QDMA event for the same QDMA channel occurs prior to the original being cleared, then the second missed event is latched in QEMR ($En = 1$).

The QER is shown in [Figure 8-95](#) and described in [Table 8-75](#).

Figure 8-95. QDMA Event Register (QER)

LEGEND: R = Read only; -n = value after reset

Table 8-75. QDMA Event Register (QER) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	En	0	No effect.
		1	Corresponding QDMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

8.5.1.8.2 QDMA Event Enable Register (QEER)

The EDMA3CC provides the option of selectively enabling/disabling each channel in the QDMA event register (QER) by using the QDMA event enable register (QEER). If any of the event bits in QEER is set (using the QDMA event enable set register, QEESR), it will enable that corresponding event. Alternatively, if any event bit in QEER is cleared (using the QDMA event enable clear register, QEECR), it will disable the corresponding QDMA channel. The QDMA event register will not latch any event for a QDMA channel, if it is not enabled via QEER.

The QEER is shown in [Figure 8-96](#) and described in [Table 8-76](#).

Figure 8-96. QDMA Event Enable Register (QEER)

LEGEND: R = Read only; -n = value after reset

Table 8-76. QDMA Event Enable Register (QEER) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	E_n	0	QDMA event enable for channels 0-7. QDMA channel n is not enabled. QDMA event will not be recognized and will not latch in the QDMA event register (QER).
		1	QDMA channel n is enabled. QDMA events will be recognized and will get latched in the QDMA event register (QER).

8.5.1.8.3 QDMA Event Enable Clear Register (QEECR)

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable clear register (QEECR) is used to disable events. Writes of 1 to the bits in QEECR clear the corresponding QDMA channel bits in QEER; writes of 0 have no effect.

The QEECR is shown in [Figure 8-97](#) and described in [Table 8-77](#).

Figure 8-97. QDMA Event Enable Clear Register (QEECR)

LEGEND: R = Read only; W = Write only; -n = value after reset

Table 8-77. QDMA Event Enable Clear Register (QEECR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	E_n	0 1	QDMA event enable clear for channels 0-7. No effect. QDMA event is disabled. Corresponding bit in the QDMA event enable register (QEER) is cleared ($E_n = 0$).

8.5.1.8.4 QDMA Event Enable Set Register (QEESR)

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable set register (QEESR) is used to enable events. Writes of 1 to the bits in QEESR set the corresponding QDMA channel bits in QEER; writes of 0 have no effect.

The QEESR is shown in [Figure 8-98](#) and described in [Table 8-78](#).

Figure 8-98. QDMA Event Enable Set Register (QEESR)

LEGEND: R = Read only; W = Write only; -n = value after reset

Table 8-78. QDMA Event Enable Set Register (QEESR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	E _n	0	No effect.
		1	QDMA event is enabled. Corresponding bit in the QDMA event enable register (QEER) is set (E _n = 1).

8.5.1.8.5 QDMA Secondary Event Register (QSER)

The QDMA secondary event register (QSER) provides information on the state of a QDMA event. If at any time a bit corresponding to a QDMA channel is set in QSER, that implies that the corresponding QDMA event is in the queue. Once a bit corresponding to a QDMA channel is set in QSER, the EDMA3CC does not prioritize additional events on the same QDMA channel. Depending on the condition that lead to the setting of the QSER bits, either the EDMA3CC hardware or the software (using QSECR) needs to clear the QSER bits for the EDMA3CC to evaluate subsequent QDMA events on the channel. Based on whether the associated TR request is valid, or it is a null or dummy TR, the implications on the state of QSER and the required user actions to submit another QDMA transfer might be different. For additional conditions that can cause the secondary event registers (QSER\SER) to be set, see *EDMA Overview*.

The QSER is shown in [Figure 8-99](#) and described in [Table 8-79](#).

Figure 8-99. QDMA Secondary Event Register (QSER)

LEGEND: R = Read only; -n = value after reset

Table 8-79. QDMA Secondary Event Register (QSER) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-0	En	0	QDMA secondary event register for channels 0-7. QDMA event is not currently stored in the event queue.
		1	QDMA event is currently stored in the event queue. EDMA3CC will not prioritize additional events.

8.5.1.8.6 QDMA Secondary Event Clear Register (QSECR)

The QDMA secondary event clear register (QSECR) clears the status of the QDMA secondary event register (QSER) and the QDMA event register (QER). CPU writes of 1 clear the corresponding set bits in QSER and QER. Writes of 0 have no effect. Note that this differs from the secondary event clear register (SECR) operation, which only clears the secondary event register (SER) bits and does not affect the event registers.

The QSECR is shown in [Figure 8-100](#) and described in [Table 8-80](#).

Figure 8-100. QDMA Secondary Event Clear Register (QSECR)

LEGEND: R = Read only; W = Write only; -n = value after reset

Table 8-80. QDMA Secondary Event Clear Register (QSECR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	E_n	0 1	QDMA secondary event clear register for channels 0-7. No effect. Corresponding bit in the QDMA secondary event register (QSER) and the QDMA event register (QER) is cleared ($E_n = 0$).

8.5.2 EDMA3 Transfer Controller Registers

Table 8-81 lists the memory-mapped registers for the EDMA3 transfer controller (EDMA3TC).

Table 8-81. EDMA3TC Registers

Offset	Acronym	Register Description	Section
03D4h	DFMPPRXY3	Destination FIFO Memory Protection Proxy Register 3	Section 8.5.2.6.15

8.5.2.1 Peripheral Identification Register (PID)

The peripheral identification register (PID) is a constant register that uniquely identifies the EDMA3TC and specific revision of the EDMA3TC. The PID is shown in [Figure 8-101](#) and described in [Table 8-82](#).

Figure 8-101. Peripheral ID Register (PID)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8-82. Peripheral ID Register (PID) Field Descriptions

Bit	Field	Value	Description
31-0	PID	0-FFFF FFFFh	Peripheral identifier.

8.5.2.2 EDMA3TC Configuration Register (TCCFG)

The EDMA3TC configuration register (TCCFG) is shown in [Figure 8-102](#) and described in [Table 8-83](#).

Figure 8-102. EDMA3TC Configuration Register (TCCFG)

	Reserved	
	R-0	
31		16
15	10 9 8 7 6 5 4 3 2	0
Reserved	DREGDEPTH	Reserved
R-0	R-x	R-0
	BUSWIDTH	Rsvd
	R-n	R-0
		FIFOSIZE
		R-x

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; -x = value is indeterminate after reset

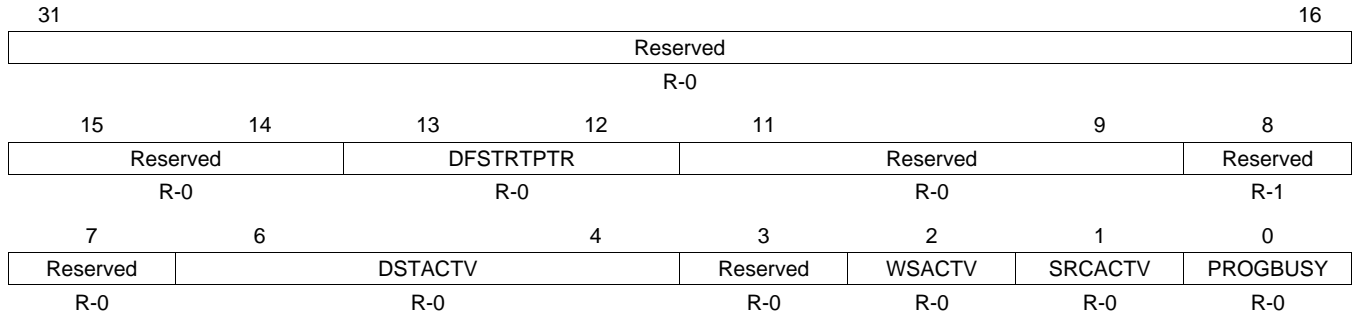

Table 8-83. EDMA3TC Configuration Register (TCCFG) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
9-8	DREGDEPTH	0-3h	Destination register FIFO depth parameterization.
		0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		1h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		2h	4 entry (for TC0, TC1, TC2, and TC3)
		3h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-6	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
5-4	BUSWIDTH	0-3h	Bus width parameterization.
		0-1h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		2h	128-bit
		3h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2-0	FIFOSIZE	0-7h	FIFO size
		0-1h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		2h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		3h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		4h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
		5h	1024 byte FIFO (for TC0, TC1, TC2 and TC3)
		6h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

8.5.2.3 EDMA3TC Channel Status Register (TCSTAT)

The EDMA3TC channel status register (TCSTAT) is shown in [Figure 8-103](#) and described in [Table 8-84](#).

Figure 8-103. EDMA3TC Channel Status Register (TCSTAT)

LEGEND: R = Read only; -n = value after reset

Table 8-84. EDMA3TC Channel Status Register (TCSTAT) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13-12	DFSTRTPTR	0-3h	Destination FIFO start pointer. Represents the offset to the head entry of the destination register FIFO, in units of entries.
11-9	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
8	Reserved	1	Reserved. Always read as 1.
7	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
6-4	DSTACTV	0-7h	<p>Destination active state. Specifies the number of transfer requests (TRs) that are resident in the destination register FIFO at a given instant. This bit field can be primarily used for advanced debugging. Legal values are constrained by the destination register FIFO depth parameterization (DSTREGDEPTH) parameter.</p> <p>0 Destination FIFO is empty. 1h Destination FIFO contains 1 TR. 2h Destination FIFO contains 2 TRs. 3h Destination FIFO contains 3 TRs. 4h Destination FIFO contains 4 TRs. (Full if DSTREGDEPTH==4).</p> <p>If the destination register FIFO is empty, then any TR written to Prog Set immediately transitions to the destination register FIFO. If the destination register FIFO is not empty and not full, then any TR written to Prog Set immediately transitions to the destination register FIFO set if the source active state (SRCACTV) bit is set to idle.</p> <p>If the destination register FIFO is full, then TRs cannot transition to the destination register FIFO. The destination register FIFO becomes not full when the TR at the head of the destination register FIFO is completed.</p>
5h-7h			Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2	WSACTV	0 1	<p>Write status active</p> <p>0 Write status is not pending. Write status has been received for all previously issued write commands. 1 Write status is pending. Write status has not been received for all previously issued write commands.</p>
1	SRCACTV	0 1	<p>Source active state</p> <p>0 Source controller is idle. Source active register set contains a previously processed transfer request. 1 Source controller is busy servicing a transfer request.</p>

Table 8-84. EDMA3TC Channel Status Register (TCSTAT) Field Descriptions (continued)

Bit	Field	Value	Description
0	PROGBUSY	0	Program register set busy
		0	Program set idle and is available for programming by the EDMA3CC.
		1	Program set busy

8.5.2.4 Error Registers

8.5.2.4.1 Error Register (ERRSTAT)

The error status register (ERRSTAT) is shown in [Figure 8-104](#) and described in [Table 8-85](#).

Figure 8-104. Error Register (ERRSTAT)

LEGEND: R = Read only; -n = value after reset

Table 8-85. Error Register (ERRSTAT) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	MMRAERR	0	MMR address error. Condition is not detected.
		1	User attempted to read or write to an invalid address in configuration memory map.
2	TRERR	0	Transfer request (TR) error event. Condition is not detected.
		1	TR detected that violates constant addressing mode transfer (SAM or DAM is set) alignment rules or has ACNT or BCNT == 0.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	BUSERR	0	Bus error event. Condition is not detected.
		1	EDMA3TC has detected an error at source or destination address. Error information can be read from the error details register (ERRDET).

8.5.2.4.2 Error Enable Register (ERREN)

The error enable register (ERREN) is shown in [Figure 8-105](#) and described in [Table 8-86](#).

When any of the enable bits are set, a bit set in the corresponding ERRSTAT causes an assertion of the EDMA3TC interrupt.

Figure 8-105. Error Enable Register (ERREN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8-86. Error Enable Register (ERREN) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	MMRAERR	0 1	Interrupt enable for MMR address error (MMRAERR). MMRAERR is disabled. MMRAERR is enabled and contributes to the state of EDMA3TC error interrupt generation
2	TRERR	0 1	Interrupt enable for transfer request error (TRERR). TRERR is disabled. TRERR is enabled and contributes to the state of EDMA3TC error interrupt generation.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	BUSERR	0 1	Interrupt enable for bus error (BUSERR). BUSERR is disabled. BUSERR is enabled and contributes to the state of EDMA3TC error interrupt generation.

8.5.2.4.3 Error Clear Register (ERRCLR)

The error clear register (ERRCLR) is shown in [Figure 8-106](#) and described in [Table 8-87](#).

Figure 8-106. Error Clear Register (ERRCLR)

LEGEND: R = Read only; W = Write only; -n = value after reset

Table 8-87. Error Clear Register (ERRCLR) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	MMRAERR	0	No effect.
		1	Clears the MMRAERR bit in ERRSTAT but does not clear the error details register (ERRDET).
2	TRERR	0	No effect.
		1	Clears the TRERR bit in ERRSTAT but does not clear the error details register (ERRDET).
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	BUSERR	0	No effect.
		1	Clears the BUSERR bit in ERRSTAT and clears the error details register (ERRDET).

8.5.2.4.4 Error Details Register (ERRDET)

The error details register (ERRDET) is shown in [Figure 8-107](#) and described in [Table 8-88](#).

Figure 8-107. Error Details Register (ERRDET)

31										18				17		16	
Reserved										R-0				TCCHEN		TCINTEN	
R-0										R-0				R-0		R-0	
15			14		13		8			7		4		3		0	
Reserved			TCC				Reserved				STAT						
R-0			R-0				R-0				R-0						

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8-88. Error Details Register (ERRDET) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
17	TCCHEN	0-1	Transfer completion chaining enable. Contains the TCCHEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
16	TCINTEN	0-1	Transfer completion interrupt enable. Contains the TCINTEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
15-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13 - 8	TCC	0-3Fh	Transfer complete code. Contains the TCC value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3-0	STAT	0-Fh	Transaction status. Stores the nonzero status/error code that was detected on the read status or write status bus. If read status and write status are returned on the same cycle, then the EDMA3TC chooses nonzero version. If both are nonzero, then the write status is treated as higher priority.
		0	No error.
		1h-7h	Read error.
		8h-Fh	Write error.

8.5.2.4.5 Error Interrupt Command Register (ERRCMD)

The error command register (ERRCMD) is shown in [Figure 8-108](#) and described in [Table 8-89](#).

Figure 8-108. Error Interrupt Command Register (ERRCMD)

LEGEND: R = Read only; W = Write only; -n = value after reset

Table 8-89. Error Interrupt Command Register (ERRCMD) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	EVAL	0	Error evaluate No effect
		1	EDMA3TC error line is pulsed if any of the error status register (ERRSTAT) bits are set.

8.5.2.5 Read Rate Register (RDRATE)

The EDMA3 transfer controller issues read commands at a rate controlled by the read rate register (RDRATE). The RDRATE defines the number of idle cycles that the read controller must wait before issuing subsequent commands. This applies both to commands within a transfer request packet (TRP) and for commands that are issued for different transfer requests (TRs). For instance, if RDRATE is set to 4 cycles between reads, there are 3 inactive cycles between reads.

RDRATE allows flexibility in transfer controller access requests to an endpoint. For an application, RDRATE can be manipulated to slow down the access rate, so that the endpoint may service requests from other masters during the inactive EDMA3TC cycles.

The RDRATE is shown in [Figure 8-109](#) and described in [Table 8-90](#).

NOTE: It is expected that the RDRATE value for a transfer controller is static, as it is decided based on the application requirement. It is not recommended to change this setting on the fly.

Figure 8-109. Read Rate Register (RDRATE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8-90. Read Rate Register (RDRATE) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2-0	RDRATE	0-7h	Read rate. Controls the number of cycles between read commands. This is a global setting that applies to all TRs for this EDMA3TC.
		0	Reads issued as fast as possible.
		1h	4 cycles between reads.
		2h	8 cycles between reads.
		3h	16 cycles between reads.
		4h	32 cycles between reads.
		5h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

8.5.2.6 EDMA3TC Channel Registers

The EDMA3TC channel registers are split into three parts: the programming registers, the source active registers, and the destination FIFO register. This section describes the registers and their functions. The program register set is programmed by the channel controller, and is for internal use. The other two sets are read-only and provided to facilitate advanced debug capabilities. The number of destination FIFO register sets depends on the destination FIFO depth.

TC0 has a FIFO depth of 2, so there are two sets of destination FIFO registers associated with TC0. TC1, TC2, and TC3 have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

8.5.2.6.1 Source Active Options Register (SAOPT)

The source active options register (SAOPT) is shown in [Figure 8-110](#) and described in [Table 8-91](#).

Figure 8-110. Source Active Options Register (SAOPT)

31	Reserved						TCCHEN	Rsvd	TCINTEN	Reserved	TCC
	R-0						R/W-0	R-0	R/W-0	R-0	R/W-0
15	TCC	Rsvd	FWID	Rsvd	PRI	Reserved	DAM	SAM			
	R/W-0	R-0	R/W-0	R-0	R/W-0	R-0	R/W-0	R/W-0			

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8-91. Source Active Options Register (SAOPT) Field Descriptions

Bit	Field	Value	Description
31-23	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
22	TCCHEN	0 1	Transfer complete chaining enable 0 Transfer complete chaining is disabled. 1 Transfer complete chaining is enabled.
21	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
20	TCINTEN	0 1	Transfer complete interrupt enable. 0 Transfer complete interrupt is disabled. 1 Transfer complete interrupt is enabled.
19-18	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
17-12	TCC	0-3Fh	Transfer complete code. This 6-bit code is used to set the relevant bit in CER or IPR of the EDMA3PCC module.
11	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
10-8	FWID	0-7h 0 1h 2h 3h 4h 5h 6h-7h	FIFO width. Applies if either SAM or DAM is set to constant addressing mode. 0 FIFO width is 8-bit. 1h FIFO width is 16-bit. 2h FIFO width is 32-bit. 3h FIFO width is 64-bit. 4h FIFO width is 128-bit. 5h FIFO width is 256-bit. 6h-7h Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

Table 8-91. Source Active Options Register (SAOPT) Field Descriptions (continued)

Bit	Field	Value	Description
6-4	PRI	0-7h 0 1h-6h 7h	Transfer priority. Reflects the values programmed in the QUEPRI register in the EDMACC. Priority 0 - Highest priority Priority 1 to priority 6 Priority 7 - Lowest priority
3-2	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
1	DAM	0 1	Destination address mode within an array Increment (INCR) mode. Destination addressing within an array increments. Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM	0 1	Source address mode within an array Increment (INCR) mode. Source addressing within an array increments. Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

8.5.2.6.2 Source Active Source Address Register (SASRC)

The source active source address register (SASRC) is shown in [Figure 8-111](#) and described in [Table 8-92](#).

Figure 8-111. Source Active Source Address Register (SASRC)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8-92. Source Active Source Address Register (SASRC) Field Descriptions

Bit	Field	Value	Description
31-0	SADDR	0-FFFF FFFFh	Source address for program register set. EDMA3TC updates value according to source addressing mode (SAM bit in the source active options register, SAOPT) .

8.5.2.6.3 Source Active Count Register (SACNT)

The source active count register (SACNT) is shown in [Figure 8-112](#) and described in [Table 8-93](#).

Figure 8-112. Source Active Count Register (SACNT)

LEGEND: R = Read only; -n = value after reset

Table 8-93. Source Active Count Register (SACNT) Field Descriptions

Bit	Field	Value	Description
31-16	BCNT	0-FFFFh	B dimension count. Number of arrays to be transferred, where each array is ACNT in length. It is decremented after each read command appropriately. Represents the amount of data remaining to be read. It should be 0 when transfer request (TR) is complete.
15-0	ACNT	0-FFFFh	A dimension count. Number of bytes to be transferred in first dimension. It is decremented after each read command appropriately. Represents the amount of data remaining to be read. It should be 0 when transfer request (TR) is complete.

8.5.2.6.4 Source Active Destination Address Register (SADST)

The source active destination address register (SADST) is shown in [Figure 8-113](#) and described in [Table 8-94](#).

Figure 8-113. Source Active Destination Address Register (SADST)

LEGEND: R = Read only; -n = value after reset

Table 8-94. Source Active Destination Address Register (SADST) Field Descriptions

Bit	Field	Value	Description
31-0	Reserved	0	Reserved. Always reads as 0.

8.5.2.6.5 Source Active Source B-Dimension Index Register (SABIDX)

The source active set B-dimension index register (SABIDX) is shown in [Figure 8-114](#) and described in [Table 8-95](#).

Figure 8-114. Source Active Source B-Dimension Index Register (SABIDX)

LEGEND: R = Read only; -n = value after reset

Table 8-95. Source Active Source B-Dimension Index Register (SABIDX) Field Descriptions

Bit	Field	Value	Description
31-16	DBIDX	0	B-Index offset between destination arrays. Represents the offset in bytes between the starting address of each destination. Always reads as 0.
15-0	SBIDX	0-FFFFh	B-Index offset between source arrays. Represents the offset in bytes between the starting address of each source array.

8.5.2.6.6 Source Active Memory Protection Proxy Register (SAMPPRXY)

The source active memory protection proxy register (SAMPPRXY) is shown in [Figure 8-115](#) and described in [Table 8-96](#).

Figure 8-115. Source Active Memory Protection Proxy Register (SAMPPRXY)

LEGEND: R = Read only; -n = value after reset

Table 8-96. Source Active Memory Protection Proxy Register (SAMPPRXY) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
8	PRIV	0 1	Privilege level. The privilege level used by the host to set up the parameter entry in the channel controller. This field is set up when the associated TR is submitted to the EDMA3TC. The privilege ID is used while issuing read and write command to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIV of the host that set up the DMA transaction. 0 User-level privilege. 1 Supervisor-level privilege.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3-0	PRIVID	0-Fh	Privilege ID. This contains the privilege ID of the host that set up the parameter entry in the channel controller. This field is set up when the associated TR is submitted to the EDMA3TC. This PRIVID value is used while issuing read and write commands to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIVID of the host that set up the DMA transaction.

8.5.2.6.7 Source Active Count Reload Register (SACNTRLD)

The source active count reload register (SACNTRLD) is shown in [Figure 8-116](#) and described in [Table 8-97](#).

Figure 8-116. Source Active Count Reload Register (SACNTRLD)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8-97. Source Active Count Reload Register (SACNTRLD) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15-0	ACNTRLD	0-FFFFh	A-count reload value. Represents the originally programmed value of ACNT. The reload value is used to reinitialize ACNT after each array is serviced.

8.5.2.6.8 Source Active Source Address B-Reference Register (SASRCBREF)

The source active source address B-reference register (SASRCBREF) is shown in [Figure 8-117](#) and described in [Table 8-98](#).

Figure 8-117. Source Active Source Address B-Reference Register (SASRCBREF)

LEGEND: R = Read only; -n = value after reset

Table 8-98. Source Active Source Address B-Reference Register (SASRCBREF) Field Descriptions

Bit	Field	Value	Description
31-0	SADDRBREF	0-FFFF FFFFh	Source address B-reference. Represents the starting address for the array currently being read.

8.5.2.6.9 Source Active Destination Address B-Reference Register (SADSTBREF)

The source active destination address B-reference register (SADSTBREF) is shown in [Figure 8-118](#) and described in [Table 8-99](#).

Figure 8-118. Source Active Destination Address B-Reference Register (SADSTBREF)

LEGEND: R = Read only; -n = value after reset

Table 8-99. Source Active Destination Address B-Reference Register (SADSTBREF) Field Descriptions

Bit	Field	Value	Description
31-0	Reserved	0	Reserved. Always reads as 0.

8.5.2.6.10 Destination FIFO Options Register (DFOPT_n)

The destination FIFO options register (DFOPT_n) is shown in [Figure 8-119](#) and described in [Table 8-100](#).

NOTE: The value for *n* varies from 0 to DSTREGDEPTH for the given EDMA3TC.

Figure 8-119. Destination FIFO Options Register (DFOPT_n)

31	Reserved						23	22	21	20	19	18	17	16
							TCCHEN	Rsvd	TCINTEN	Reserved		TCC

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 8-100. Destination FIFO Options Register (DFOPT_n) Field Descriptions

Bit	Field	Value	Description
31-23	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
22	TCCHEN	0 1	Transfer complete chaining enable 0 Transfer complete chaining is disabled 1 Transfer complete chaining is enabled
21	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
20	TCINTEN	0 1	Transfer complete interrupt enable. 0 Transfer complete interrupt is disabled. 1 Transfer complete interrupt is enabled.
19-18	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
17-12	TCC	0-3Fh	Transfer complete code. This 6-bit code is used to set the relevant bit in CER or IPR of the EDMA3PCC module.
11	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
10-8	FWID	0-7h 0 1h 2h 3h 4h 5h 6h-7h	FIFO width. Applies if either SAM or DAM is set to constant addressing mode. 0 FIFO width is 8-bit. 1h FIFO width is 16-bit. 2h FIFO width is 32-bit. 3h FIFO width is 64-bit. 4h FIFO width is 128-bit. 5h FIFO width is 256-bit. 6h-7h Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
6-4	PRI	0-7h 0 1h-6h 7h	Transfer priority 0 Priority 0 - Highest priority 1h-6h Priority 1 to priority 6 7h Priority 7 - Lowest priority
3-2	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

Table 8-100. Destination FIFO Options Register (DFOPT_n) Field Descriptions (continued)

Bit	Field	Value	Description
1	DAM	0	Increment (INCR) mode. Destination addressing within an array increments.
		1	Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM	0	Increment (INCR) mode. Source addressing within an array increments.
		1	Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

8.5.2.6.11 Destination FIFO Source Address Register (DFSRC n)

The destination FIFO source address register (DFSRC n) is shown in [Figure 8-120](#) and described in [Table 8-101](#).

NOTE: The value for n varies from 0 to DSTREGDEPTH for the given EDMA3TC.

Figure 8-120. Destination FIFO Source Address Register (DFSRC n)

LEGEND: R = Read only; - n = value after reset

Table 8-101. Destination FIFO Source Address Register (DFSRC n) Field Descriptions

Bit	Field	Value	Description
31-0	Reserved	0	Reserved. Always read as 0.

8.5.2.6.12 Destination FIFO Count Register (DFCNT n)

The destination FIFO count register (DFCNT n) is shown in [Figure 8-121](#) and described in [Table 8-102](#).

NOTE: The value for n varies from 0 to DSTREGDEPTH for the given EDMA3TC.

Figure 8-121. Destination FIFO Count Register (DFCNT n)

LEGEND: R = Read only; - n = value after reset

Table 8-102. Destination FIFO Count Register (DFCNT n) Field Descriptions

Bit	Field	Value	Description
31-16	BCNT	0-FFFFh	B-dimension count. Number of arrays to be transferred, where each array is ACNT in length. Count/count remaining for destination register set. Represents the amount of data remaining to be written.
15-0	ACNT	0-FFFFh	A-dimension count. Number of bytes to be transferred in first dimension count/count remaining for destination register set. Represents the amount of data remaining to be written.

8.5.2.6.13 Destination FIFO Destination Address Register (DFDST_{*n*})

The destination FIFO destination address register (DFDST_{*n*}) is shown in [Figure 8-122](#) and described in [Table 8-103](#).

NOTE: The value for *n* varies from 0 to DSTREGDEPTH for the given EDMA3TC.

Figure 8-122. Destination FIFO Destination Address Register (DFDST_{*n*})

LEGEND: R = Read only; -*n* = value after reset

Table 8-103. Destination FIFO Destination Address Register (DFDST_{*n*}) Field Descriptions

Bit	Field	Value	Description
31-0	DADDR	0	Destination address for the destination FIFO register set. When a transfer request (TR) is complete, the final value should be the address of the last write command issued.

8.5.2.6.14 Destination FIFO B-Index Register (DFBIDX_{*n*})

The destination FIFO B-index register (DFBIDX_{*n*}) is shown in [Figure 8-123](#) and described in [Table 8-104](#).

NOTE: The value for *n* varies from 0 to DSTREGDEPTH for the given EDMA3TC.

Figure 8-123. Destination FIFO B-Index Register (DFBIDX_{*n*})

LEGEND: R = Read only; -*n* = value after reset

Table 8-104. Destination FIFO B-Index Register (DFBIDX_{*n*}) Field Descriptions

Bit	Field	Value	Description
31-16	DBIDX	0-FFFFh	B-Index offset between destination arrays. Represents the offset in bytes between the starting address of each destination.
15-0	SBIDX	0	Always read as 0.

8.5.2.6.15 Destination FIFO Memory Protection Proxy Register (DFMPPRXY_n)

The destination FIFO memory protection proxy register (DFMPPRXY_n) is shown in [Figure 8-124](#) and described in [Table 8-96](#).

Figure 8-124. Destination FIFO Memory Protection Proxy Register (DFMPPRXY_n)

LEGEND: R = Read only; -n = value after reset

Table 8-105. Destination FIFO Memory Protection Proxy Register (DFMPPRXY_n) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
8	PRIV	0 1	Privilege level. This contains the Privilege level used by the EDMA3 programmer to set up the parameter entry in the channel controller. This field is set up when the associated TR is submitted to the EDMA3TC. The privilege ID is used while issuing read and write command to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIV of the host that set up the DMA transaction. 0 User-level privilege 1 Supervisor-level privilege
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3-0	PRIVID	0-Fh	Privilege ID. This contains the Privilege ID of the EDMA3 programmer that set up the parameter entry in the channel controller. This field is set up when the associated TR is submitted to the EDMA3TC. This PRIVID value is used while issuing read and write commands to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIVID of the host that set up the DMA transaction.

8.5.2.6.16 Destination FIFO Count Reload Register (DFCNTRLD_n)

The destination FIFO count reload register (DFCNTRLD_n) is shown in [Figure 8-125](#) and described in [Table 8-106](#).

Figure 8-125. Destination FIFO Count Reload Register (DFCNTRLD_n)

LEGEND: R = Read only; -n = value after reset

Table 8-106. Destination FIFO Count Reload Register (DFCNTRLD_n) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15-0	ACNTRLD	0-FFFFh	A-count reload value. Represents the originally programmed value of ACNT. The reload value is used to reinitialize ACNT after each array is serviced.

8.5.2.6.17 Destination FIFO Source Address B-Reference Register (DFSRCBREF_n)

The destination FIFO source address B-reference register (DFSRCBREF_n) is shown in [Figure 8-126](#) and described in [Table 8-107](#).

Figure 8-126. Destination FIFO Source Address B-Reference Register (DFSRCBREF_n)

LEGEND: R = Read only; -n = value after reset

Table 8-107. Destination FIFO Source Address B-Reference Register (DFSRCBREF_n) Field Descriptions

Bit	Field	Value	Description
31-0	Reserved	0	Reserved. Always read as 0.

8.5.2.6.18 Destination FIFO Destination Address B-Reference (DFDSTBREF_n)

The destination FIFO destination address B-reference register (DFDSTBREF_n) is shown in [Figure 8-127](#) and described in [Table 8-108](#).

Figure 8-127. Destination FIFO Destination Address B-Reference Register (DFDSTBREF_n)

LEGEND: R = Read only; -n = value after reset

Table 8-108. Destination FIFO Destination Address B-Reference Register (DFDSTBREF_n) Field Descriptions

Bit	Field	Value	Description
31-0	DADDRBREF	0-FFFF FFFFh	Destination address reference for the destination FIFO register set. Represents the starting address for the array currently being written.

8.6 Appendix A

8.6.1 Debug Checklist

This section lists some tips to keep in mind while debugging applications using the EDMA3.

The following table provides some common issues and their probable causes and resolutions.

Table 8-109. Debug List

Issue	Description/Solution
<p>The transfer associated with the channel does not happen. The channel does not get serviced.</p>	<p>The EDMA3CC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following:</p> <ol style="list-style-type: none"> 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers (ER/ERH), make sure that the event is enabled in the Event Enable Registers (EER/EERH). Similarly, for QDMA channels, make sure that QDMA events are appropriately enabled in the QDMA Event Enable Register (QEER). 2) Verify that the DMA or QDMA Secondary Event Register (SER/SERH/QSERH) bits corresponding to the particular event or channel are not set.
<p>The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.</p>	<p>It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases:</p> <ol style="list-style-type: none"> 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., OPT.STATIC = 0, LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the QEMR and QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the SER.Ex and EMR.Ex set, preventing further event prioritization. You must ensure that the number of events received is limited to the expected number of events for which the parameter set is programmed, or you must ensure that bits corresponding to particular channel or event are not set in the Secondary event registers (SER/SERH/QSER) and Event Missed Registers (EMR/EMRH/QEMR) before trying to perform subsequent transfers for the event/channel.
<p>Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.</p>	<p>You must ensure the following:</p> <ol style="list-style-type: none"> 1) The interrupt generation is enabled in the OPT of the associated PaRAM set (TCINTEN = 1 and/or ITCINTEN = 1). 2) The interrupts are enabled in the EDMA3 Channel Controller, via the Interrupt Enable Registers (IER/IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (IPR/IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 8.3.9.1.2 for details on writing EDMA3 ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (DRAE/DRAEH) are set up properly, because the DRAE/DRAEH registers act as secondary enables for shadow region completion interrupts, along with the IER/IERH registers. <p>If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code (TCC) value are also enabled in the DRAE/DRAEH registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 (OPT.TCC=63), ensure that DRAEH.E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be IPRH.I63 (not IPR.I0).</p>

8.6.2 Miscellaneous Programming/Debug Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the Event Register (ER/ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (ECR/ECRH). Similarly, the Event Enable Register (EER/EERH) bits can only be set with writes of 1 to the Event Enable Set Registers (EESR/EESRH) and cleared with writes of 1 to the corresponding bits in the Event Enable Clear Register (EECR/EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (DRAE/DRAEH/QRAE). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (DRAE/DRAEH) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts. For example, if DRAE0.E0 and DRAE1.E0 are both set, then on completion of a transfer that returns a TCC=0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the CCNT is not left to zero.
5. Enable the EDMA3CC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, you may want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, you might choose to use the early chaining option to reduce the time between the sets of transfers and increase the throughput. However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA3CC internally signals completion when the TR is submitted to the EDMA3TC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

8.7 Setting Up a Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

- Step 1. Initiating a DMA/QDMA channel
 - (a) Determine the type of channel (QDMA or DMA) to be used.
 - (b) Channel mapping
 - (i) If using a QDMA channel, program the QCHMAP with the parameter set number to which the channel maps and the trigger word.
 - (ii) If using a DMA channel, program the DCHMAP with the parameter set number to which the channel maps.
 - (c) If the channel is being used in the context of a shadow region, ensure the DRAE/DRAEH for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in [Section 8.3.7.1](#).)
 - (d) Determine the type of triggering used.
 - (i) If external events are used for triggering (DMA channels), enable the respective event in EER/EERH by writing into EESR/EESRH.
 - (ii) If QDMA Channel is used, enable the channel in QEER by writing into QEESR.
 - (e) Queue setup
 - (i) If a QDMA channel is used, set up the QDMAQNUM to map the channel to the respective event queue.
 - (ii) If a DMA channel is used, set up the DMAQNUM to map the event to the respective event queue.
- Step 2. Parameter set setup
 - (a) Program the PaRAM set number associated with the channel. Note that if it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.
See [Section 8.4](#) for parameter set field setups for different types of transfers. See the sections on chaining ([Section 8.3.8](#)) and interrupt completion ([Section 8.3.9](#)) on how to set up final/intermediate completion chaining and/or interrupts.
- Step 3. Interrupt setup
 - (a) Enable the interrupt in the IER/IERH by writing into IESR/IESRH.
 - (b) Ensure that the EDMA3CC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
 - (c) Ensure the EDMA3CC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
 - (d) Set up the interrupt controller properly to receive the expected EDMA3 interrupt.

Step 4. Initiate transfer

(a) This step is highly dependent on the event trigger source:

- (i) If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA3 events that can be latched to the ER transfer.
- (ii) For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
- (iii) Manually triggered transfers will be initiated by writes to the Event Set Registers (ESR/ESRH).
- (iv) Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

Step 5. Wait for completion

- (a) If the interrupts are enabled as mentioned in step 3 above, then the EDMA3CC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register (IPR/IPRH). The set bits must be cleared in the IPR\IPRH by writing to corresponding bit in ICR\ICRH.
- (b) If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the IPR\IPRH. Again, the set bits in the IPR\IPRH must be manually cleared via ICR\ICRH before the next set of transfers is performed for the same transfer completion code values.

3PSW Ethernet Subsystem (EMAC)

This chapter describes the three port switch (3PSW) Ethernet subsystem in the device.

Topic	Page
9.1 Introduction	1386
9.2 CPSW Architecture	1392
9.3 Software Operation	1438
9.4 Registers	1444

9.1 Introduction

The three port switch gigabit ethernet subsystem provides ethernet packet communication and can be configured as an ethernet switch. It provides the gigabit media independent interface (G/MII), reduced gigabit media independent interface (RGMII), reduced media independent interface (RMII), the management data input output (MDIO) for physical layer device (PHY) management.

9.1.1 Features

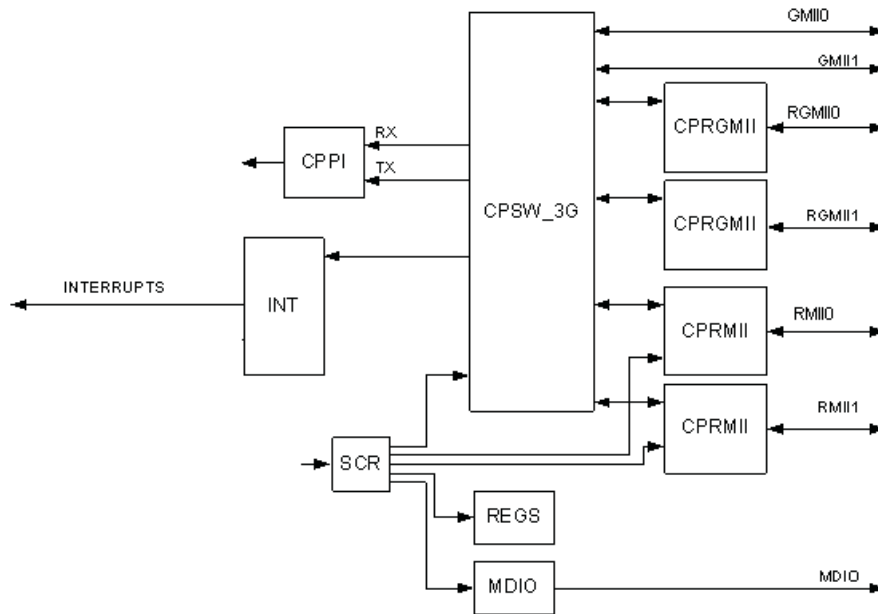

The 3PSW Ethernet Subsystem provides these functions:

- Two Ethernet ports with Selectable G/MII, RMII, and RGMII interfaces
- Synchronous 10/100/1000 Mbit operation.
- Wire rate switching (802.1d)
- Non Blocking switch fabric
- Flexible logical FIFO based packet buffer structure
- Four priority level QOS support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization
- Reset isolation
- Communications port programming interface (CPPI) 3.1 compliant DMA controllers
- Maximum frame size 2016 bytes (2020 with VLAN)
- Programmable priority escalation on transmit
- Flow Control Support (802.3x)
- MDIO module for PHY Management
- Address Lookup
 - 1024 total address lookup engine (ALE) entries of VLANs and/or MAC addresses
 - L2 address lock and L2 filtering support
 - Multicast/broadcast filtering and forwarding state control
 - Receive-based or destination-based multicast and broadcast rate limits
 - MAC address blocking
 - Source port locking
 - OUI (Vendor ID) host accept/deny feature
 - Host controlled time-based aging
 - MAC authentication (802.1x)
 - Remapping of priority level of VLAN or ports
 - Multiple spanning tree support (spanning tree per VLAN)
- VLAN support
 - 802.1Q compliant
 - Auto add port VLAN for untagged frames on ingress
 - Auto VLAN removal on egress and auto pad to minimum frame size
- Ethernet Statistics:
 - EtherStats and 802.3 Stats RMON statistics gathering (shared)
 - Programmable statistics interrupt mask when a statistic is above one half its 32-bit value
- CPGMAC_SL transmit to CPGMAC_SL receive Loopback mode (digital loopback) supported
- CPGMAC_SL receive to CPGMAC_SL transmit Loopback mode (FIFO loopback) supported
- Programmable interrupt control with selected interrupt pacing
- Programmable Transmit Inter Packet Gap (IPG)
- Half duplex mode supported only in 10/100 Mbps mode.

- Full duplex mode supported in 10/100/1000 Mbps mode
- 8k (2048 × 32) internal CPPI buffer descriptor memory
- Emulation support
- IEEE 802.3 gigabit Ethernet conformant

9.1.2 Functional Block Diagram

Figure 9-1. 3PSW Ethernet Subsystem Top Level Block Diagram

9.1.3 Interface Mode selection

The 3 port switch (3PSW) Ethernet Subsystem has two 10/100/1000 Ethernet ports with selectable G/MII, RMII, and RGMII interfaces.

The interface mode is selected by configuring the MII mode selection register (GMII_SEL) in the *Control Module* chapter.

9.1.4 Subsystem Signal Summary

The tables below provide the signals names for different Interfaces (RGMII, G/MII, RMII). These signals are pin muxed. For more details on the signal descriptions/connections please refer to section of Ethernet Mac Sliver in this document.

See the pin mux selection details in the device data manual for configuring the PINMUX as per the Interface (RGMII, G/MII, RMII) selected.

Table 9-1. G/MII Signal Description

Signal name	Width	Input/Output	Description
EMAC[0]_MtCLK	1	I	GMII0 transmit clock
EMAC[0]_Mtxd[0-7]	8	O	GMII0 transmit data
EMAC[0]_Mtxen	1	O	GMII0 transmit data enable
EMAC[0]_gMTclk	1	O	GMII0 source synchronous transmit clock
EMAC[0]_Mcol	1	I	GMII0 collision (asynchronous)
EMAC[0]_Mcrs	1	I	GMII0 carrier sense (asynchronous)
EMAC[0]_MRCIk	1	I	GMII0 receive clock
EMAC[0]_Mrxd[0-7]	8	I	GMII0 receive data

Table 9-1. G/MII Signal Description (continued)

Signal name	Width	Input/Output	Description
EMAC[0]_Mrxdv	1	I	GMII0 receive data valid
EMAC[0]_Mrxer	1	I	GMII0 receive data error
EMAC[1]_MtCLK	1	I	GMII1 transmit clock
EMAC[1]_Mtxd[0-7]	8	O	GMII1 transmit data
EMAC[1]_Mtxen	1	O	GMII1 transmit data enable
EMAC[1]_gMTclk	1	O	GMII1 source synchronous transmit clock
EMAC[1]_Mcol	1	I	GMII1 collision (asynchronous)
EMAC[1]_Mcrs	1	I	GMII1 carrier sense (asynchronous)
EMAC[1]_MRCIk	1	I	GMII1 receive clock
EMAC[1]_Mrxd[0-7]	8	I	GMII1 receive data
EMAC[1]_Mrxdv	1	I	GMII1 receive data valid
EMAC[1]_Mrxer	1	I	GMII1 receive data error

Table 9-2. RMII Signal Description

Signal name	Width	Input/Output	Description
EMAC_RMREFCLK	1	IO	RMII0/1 reference clock
EMAC[0]_RMTXD[0-1]	2	O	RMII0 transmit data
EMAC[0]_RMTXEN	1	O	RMII0 transmit data enable
EMAC[0]_RMCRSDV	1	I	RMII0 carrier sense and data valid
EMAC[0]_RMRXD[0-1]	2	I	RMII0 receive data
EMAC[0]_RMRXER	1	I	RMII0 receive error
EMAC[1]_RMTXD[0-1]	2	O	RMII1 transmit data
EMAC[1]_RMTXEN	1	O	RMII1 transmit data enable
EMAC[1]_RMCRSDV	1	I	RMII1 carrier sense and data valid
EMAC[1]_RMRXD[0-1]	2	I	RMII1 receive data
EMAC[1]_RMRXER	1	I	RMII1 receive error

Table 9-3. RGMII Signal Description

Signal name	Width	Input/Output	Description
EMAC[0]_RGTXD[0-3]	4	O	RGMII0 Transmit Data
EMAC[0]_RGTXCTL	1	O	RGMII0 Transmit Control/Enable
EMAC[0]_RGTXC	1	O	RGMII0 Transmit Clock
EMAC[0]_RGRXD[0-3]	4	I	RGMII0 Receive Data
EMAC[0]_RGRXCTL	1	I	RGMII0 Receive Control
EMAC[0]_RGRXC	1	I	RGMII0 Receive Clock
EMAC[1]_RGTXD[0-3]	4	O	RGMII1 Transmit Data
EMAC[1]_RGTXCTL	1	O	RGMII1 Transmit Control/Enable
EMAC[1]_RGTXC	1	O	RGMII1 Transmit Clock
EMAC[1]_RGRXD[0-3]	4	I	RGMII1 Receive Data
EMAC[1]_RGRXCTL	1	I	RGMII1 Receive Control
EMAC[1]_RGRXC	1	I	RGMII1 Receive Clock

9.1.5 Clocking

9.1.5.1 Subsystem Clocking

The 3 port switch (3PSW) Ethernet Subsystem clocks are derived from SATA SERDES PLL.

The SATA SERDES provides reference clocks to the modules G/MII (125 MHz), RMII (50 MHz), RGMII (50 MHz) and RGMII (5 MHz) as shown in [Figure 9-2](#).

The SATA SerDes PLL configuration registers are available in the device control module register space. The *Control Module* chapter has more details on SATA PLL Register configuration.

The 3PSW Ethernet clocking provides option to receive or output the RMII reference clock (EMAC_RMREFCLK) from the pin as shown in [Figure 9-2](#). See the RMII_REFCLK_SRC register in the device Control Module to configure the clocking option of RMII.

1588 reference clock, CPTS_RFT_CLK (250 MHz) and RGMII (250 MHz) reference clocks are provided by any of the Video-0/Video-1/Video_clk2/Audio/L3 PLLs as shown in [Figure 9-2](#). The PLL is used for generating the clocks for CPTS_RFT_CLK, RGMII shall be selected by configuring the RMII_REFCLK_SRC register in the device Control Module.

9.1.5.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

9.1.5.2.1 G/MII Interface Clocking

EMAC [0/1] _MtCLK and EMAC [0/1] _MRCLK frequencies are fixed by the 802.3 specification.

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

EMAC [0/1] _gMTclk runs at 125 MHz in all the modes of operation.

9.1.5.2.2 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

See the MII mode selection register (GMII_SEL) in the device Control Module to configure the CPRGMII Internal Delay/No Delay in Transmit Mode of Operation. See [Section 9.2.1.8.3](#) for more details.

9.1.5.2.3 RMII Interface Clocking

RMII interface clock EMAC_RMREFCLK frequencies are:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

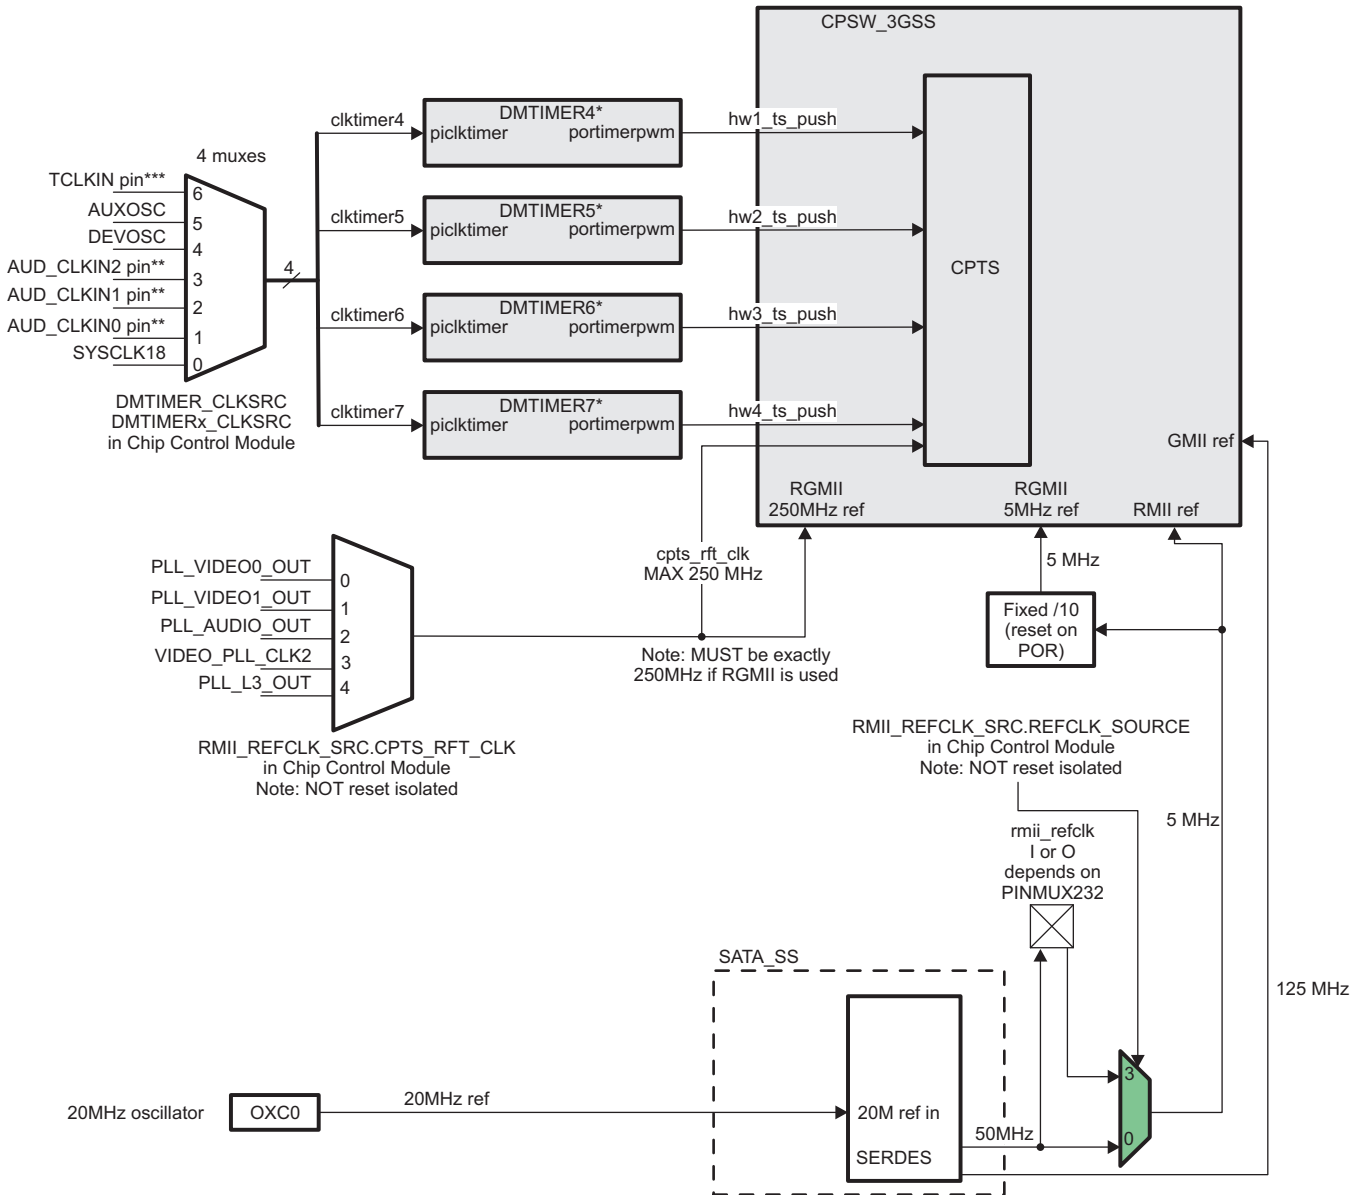

See the RMII_REFCLK_SRC register in the device Control Module to configure the Clocking Option of RMII.

9.1.5.2.4 MDIO Clocking

The MDIO clock is based on a divide-down of the peripheral clock, running at 125 MHz. The application software or driver must control the divide-down value.

See the MDIO Control Register for configuring the Clock Divider (CLKDIV) value.

Figure 9-2. 3PSW Subsystem Clocking Block Diagram

9.1.6 Interrupt Support

3PSW Ethernet Subsystem has 4 Interrupts:

- `RX_thresh_pulse` - Receive Threshold Interrupt
- `RX_pulse` - Receive Interrupt
- `TX_pulse` - Transmit Interrupt
- `Misc_pulse` - Miscellaneous Interrupt.

See [Section 9.2.5](#) for more details. See the device data manual for more details on the mapping of these interrupts at the device level.

9.1.7 Memory Map

The Addresses for the Modules in the 3 port switch (3PSW) Ethernet Subsystem are:

- CPSW_3G Module: The start address of the CPSW_3G module is 4A10 0000h. See [Section 9.4.1](#).
- MDIO Module: The start address of the MDIO module is 4A10 0800h. See [Section 9.4.2](#).
- CPSW Subsystem Module: The start address of the CPSW subsystem is 4A10 0900h. See [Section 9.4.3](#).
- CPPI Descriptors: The start address of the CPPI descriptors is 4A10 2000h.

The 8K bytes of CPPI memory begin at address 4A10 2000h from the EMAC perspective. The buffer descriptors programmed to access the CPPI RAM memory from the CPU perspective should use the address range from 4A10 2000h to 4A10 4000h.

9.1.8 3PSW Ports

Ethernet Subsystem has 3 Ports. Port 0 is the Host port (internal to the Subsystem). Ports 1 and 2 are the external ports connected to G/MII, RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the Host Port
- Port1 is referred to the interfaces GMII0/RGMII0/RMII0
- Port2 is referred to the interfaces GMII1/RGMII1/RMII1

9.2 CPSW Architecture

The 3 port switch (3PSW) Ethernet Subsystem peripheral are compliant to the IEEE Std 802.3 Specification. The 3PSW Ethernet Subsystem contains two RGMII/RMII interfaces, one CPPI 3.0 interface, Interrupt Controller, MDIO and CPSW_3G which contains two G/MII interfaces as shown in Figure 9-3.

9.2.1 CPSW_3G

The CPSW_3G G/MII interfaces are compliant to the IEEE Std 802.3 Specification.

The CPSW_3G contains two CPGMAC_SL interfaces (ports 1 and 2), one CPPI 3.0 interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and CPDMA. A top-level block diagram of the CPSW_3G is shown in Figure 9-3.

Figure 9-3. CPSW_3G Block Diagram

9.2.1.1 CPDMA RX and TX Interfaces

The CPDMA submodule is a CPPI 3.0 compliant packet DMA transfer controller. The CPPI 3.0 interface is port 0.

9.2.1.1.1 Functional Operation

After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI 3.0 protocol. The DMA controller writes the packet into the external transmit FIFO in 64-byte bursts (maximum).

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The receive DMA controller writes the receive packet data to external memory in accordance with CPPI 3.0 protocol. See the CPPI Buffer Descriptors section for detailed description of Buffer Descriptors.

9.2.1.1.2 Receive DMA Interface

The receive DMA is an eight channel CPPI 3.0 compliant interface. Each channel has a single queue for frame reception.

9.2.1.1.2.1 Receive DMA Host Configuration

To configure the RX DMA for operation the software must perform the following:

1. Initialize the receive addresses.
2. Initialize the RX_HDP registers to 0.
3. Enable the desired receive interrupts in the INTMASK register.
4. Write the RX_BUFFER_OFFSET register value.
5. Setup the receive channel(s) buffer descriptors in host memory as required by CPPI 3.0.
6. Enable the RX DMA controller by setting the RX_EN bit in the RX_CONTROL register.

9.2.1.1.2.2 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the RX_TEARDOWN register. When a teardown command is issued to an enabled receive channel the following will occur:

- Any current frame in reception will complete normally.
- The teardown_complete bit will be set in the next buffer descriptor in the chain (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- A receive interrupt for the channel will be issued to the host.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh Acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by a set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

9.2.1.1.3 Transmit DMA Interface

The transmit DMA is an eight channel CPPI 3.0 compliant interface. Priority between the eight queues may be either fixed or round robin as selected by the TX_PTYPE bit in the DMACONTROL register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7.

9.2.1.1.3.1 Transmit DMA Host Configuration

To configure the TX DMA for operation the software must do the following:

1. Initialize the TX_HDP registers to 0.
2. Enable the desired transmit interrupts in the INTMASK register.
3. Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI 3.0.
4. Configure and enable the transmit operation as desired in the TX_CONTROL register.
5. Write the appropriate TX_HDP registers with the appropriate values to start transmit operations.

9.2.1.1.3.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the TX_TEARDOWN register. When a teardown command is issued to an enabled transmit channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- An interrupt will be issued to inform the host of the channel teardown.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

9.2.1.1.4 Transmit Rate Limiting

Transmit operations can be configured to rate limit the transmit data for each transmit priority. Rate limiting is enabled for a channel when the TX_RLIM bit associated with that channel is set in the DMACONTROL register. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then TX_RLIM should be set to 11000000b with the MSB corresponding to channel 7. When any channels are configured to be rate-limiting, the priority type must be fixed for transmit. Round-robin priority type is not allowed when rate-limiting. Each of the eight transmit priorities has an associated register to control the rate at which the priority is allowed to send data (TX_PRI(0..7)_RATE) when the channel is rate-limiting. Each priority has a send count (PRI(0..7)_SEND_CNT) and an idle count (PRI(0..7)_IDLE_CNT). The transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is allowed to send is controlled by the equation:

$$\text{Priority Transfer rate in Mbit/s} = ((\text{PRI_IDLE_CNT}/(\text{PRI_IDLE_CNT} + \text{PRI_SEND_CNT})) \times \text{frequency} \times 32$$

Where the frequency is the CLK frequency.

9.2.1.1.5 Command IDLE

The CMD_IDLE bit in the DMACONTROL register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

9.2.1.2 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should be forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE_ALE bit in the ALE_CONTROL register is set. All packets are dropped when the ENABLE_ALE bit is cleared to 0.

In normal operation, the CPGMAC_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the CPGMAC_SL configuration bit(s) cef, csf, or cmf are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address.

The ALE may be configured to operate in bypass mode by setting the ALE_BYPASS bit in the ALE_CONTROL register. When in bypass mode, all CPGMAC_SL received packets are forwarded only to the host port (port 0). Packets from the two ports can be on separate RX DMA channels by configuring the CPDMA_RX_CH_MAP register. In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

The ALE may be configured to operate in OUI deny mode by setting the ENABLE_OUI_DENY bit in the ALE_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the super bit set. Unicast packets will be dropped unless the unicast address is in the table with block and secure both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

9.2.1.2.1 Address Table Entry

The ALE table contains 1024 entries. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 9-4. Learned Address Control Bits

unicast_type	11
Block	0
Secure	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40** .

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40**.

9.2.1.2.1.1 Free Table Entry

Table 9-5. Free (Unused) Address Table Entry Bit Values

71-62	61-60	59-0
Reserved	ENTRY_TYPE(00)	Reserved

9.2.1.2.1.2 Multicast Address Table Entry

Table 9-6. Multicast Address Table Entry Bit Values

71-69	68-66	65	64	63-62	61-60	59-48	47-0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (01)	Reserved	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

9.2.1.2.1.3 VLAN/Multicast Address Table Entry

Table 9-7. VLAN/Multicast Address Table Entry Bit Values

71-69	68-66	65	64	63-62	61-60	59-48	47-0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (11)	VLAN_ID	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

9.2.1.2.1.4 Unicast Address Table Entry

Table 9-8. Unicast Address Table Entry Bit Values

71-68	67-66	65	64	63-62	61-60	59-48	47-0
Reserved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (01)	Reserved	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

9.2.1.2.1.5 OUI Unicast Address Table Entry

Table 9-9. OUI Unicast Address Table Entry Bit Values

71-64	63-62	61-60	59-48	47-24	23-0
Reserved	UNICAST_TYPE(10)	ENTRY_TYPE(01)	Reserved	UNICAST_OUI	Reserved

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

9.2.1.2.1.6 VLAN/Unicast Address Table Entry

Table 9-10. Unicast Address Table Entry Bit Values

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (11)	VLAN_ID	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

9.2.1.2.1.7 VLAN Table Entry

Table 9-11. VLAN Table Entry

71-62	61-60	59-48	47-27	26-24	23-19	18-16	15-11	10-8	7-3	2-0
Reserved	ENTRY_TYPE(10)	VLAN_ID	Reserved	FORCE_UNTAGGED_EGRESS	Reserved	REG_MCAST_FLOOD_MASK	Reserved	UNREG_MCAST_FLOOD_MASK	Reserved	VLAN_MEMBER_LIST

Table Entry Type (ENTRY_TYPE)

10: VLAN entry

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)

This field causes the packet VLAN tag to be removed on egress (except on port 0).

Registered Multicast Flood Mask (REG_MCAST_FLOOD_MASK)

Mask used for multicast when the multicast address is found.

Unregistered Multicast Flood Mask (UNREG_MCAST_FLOOD_MASK)

Mask used for multicast when the multicast address is not found.

VLAN Member List (VLAN_MEMBER_LIST)

This 3-bit field indicates which port(s) are members of the associated VLAN.

9.2.1.2.2 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are Ingress Filtering, VLAN_Aware Lookup, VLAN_Unaware Lookup, and Egress.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port. The receive packet processes

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The `mcast_fwd_state` indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the `CPGMAC_SL` to the ALE. Packets with errors may be passed to the host (not aborted) by a `CPGMAC_SL` port, if the port has the `RX_CMF_EN`, `RX_CEF_EN`, or `RX_CSF_EN` bit(s) set. Error packets that are passed to the host by the `CPGMAC_SL` are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the `SL1/2_MACCONTROL` register.

RX_CEF_EN -This `CPGMAC_SL` control bit enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded.

RX_CSF_EN -This `CPGMAC_SL` bit enables short frames to be forwarded.

RX_CMF_EN -This `CPGMAC_SL` control bit enables mac control frames to be forwarded.

9.2.1.2.3 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

9.2.1.2.4 VLAN Aware Mode

The CPSW_3G is in VLAN aware mode when the VLAN_AWARE bit is set in the CPSW_CONTROL register. In VLAN aware mode, ports 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the CPSW_CONTROL register. Port 0 receive packet data is never modified. VLAN is not removed regardless of the force untagged egress bit for Port 0. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set RX_VLAN_ENCAP bit in the packet buffer descriptor.

Port 0 transmit packets are never VLAN encapsulated (encapsulation is not allowed).

In VLAN aware mode, transmitted packet data is changed depending on the packet type (pkt_type), packet priority (pkt_pri), and VLAN information.

9.2.1.2.5 VLAN Unaware Mode

The CPSW_3G is in VLAN unaware mode when the VLAN_AWARE bit is cleared to 0 in the CPSW_CONTROL register. Port 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the CPSW_CONTROL register. Port 0 transmit packets are never VLAN encapsulated.

9.2.1.3 Packet Priority Handling

Packets are received on three ports, two are CPGMAC_SL Ethernet ports and the third port is the CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is the port priority for untagged packets, and the actual packet priority for priority tagged and VLAN tagged packets. The received packet priority is mapped through the receive ports associated packet priority to header packet priority mapping register to obtain the header packet priority (the CPDMA RX and TX nomenclature is reversed from the CPGMAC_SL nomenclature).

The header packet priority is mapped through the header priority to switch priority mapping register to obtain the hardware switch priority (0 to 3, with 3 being the highest priority). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

9.2.1.4 FIFO Memory Control

Each of the three CPSW_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and four logical transmit queues (priority 0 through 3). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX_MAX_BLKs field in the FIFOs associated MAX_BLKs register determines the maximum number of 1k FIFO memory blocks to be allocated to the four logical transmit queues (transmit total). The RX_MAX_BLKs field in the FIFO's associated MAX_BLKs register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX_MAX_BLKs value plus the RX_MAX_BLKs value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports are Port1 and Port2.

9.2.1.5 FIFO Transmit Queue Control

There are four transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPDMA receive (also switch egress). The CPDMA nomenclature is reversed from the CPGMAC_SL nomenclature due to legacy reasons.

9.2.1.5.1 Normal Priority Mode

When operating in normal mode, lower priority frames are dropped before higher priority frames. The intention is to give preference to higher priority frames. Priority 3 is the highest priority and is allowed to fill the FIFO. Priority 2 will drop packets if the packet is going to take space in the last 2k available. Priority 1 will drop packets if the packet is going to take space in the last 4k available. Priority 0 will drop packets if the packet is going to take space in the last 6k available. If fewer than 4 priorities are to be implemented then the priorities should be mapped such that the highest priorities are used. For example, if two priorities are going to be used then all packets should be mapped to priorities 3 and 2 and priorities 1 and 0 should be unused. Priority escalation may be used in normal priority mode if desired. Normal priority mode is configured as described below:

- Select normal priority mode by setting TX_IN_SEL = 00 for all ports (default value in P0/1/2_TX_IN_CTL)
- Configure priority mapping to use only the highest priorities if less than 4 priorities are used. Refer to [Section 9.2.1.3](#).

9.2.1.5.2 Dual Mac Mode

When operating in dual mac mode the intention is to transfer packets between ports 0 and 1 and ports 0 and 2, but not between ports 1 and 2. Each CPGMAC_SL appears as a single MAC with no bridging between MAC's. Each CPGMAC_SL has at least one unique (not the same) mac address.

Dual mac mode is configured as described below:

- Set the ALE_VLAN_AWARE bit in the ALE_CONTROL register. This bit configures the ALE to process in VLAN aware mode. The CPSW_3G VLAN aware bit (VLAN_AWARE in CPSW_CONTROL) determines how packets VLAN's are processed on CPGMAC_SL egress and does not affect how the ALE processes packets or the packet destination. The CPSW_3G VLAN aware bit may be set or not as required (must be set, if VLAN's are to exit the switch).
- Configure the Port 1 to Port 0 VLAN
 - Add a VLAN Table Entry with ports 0 and 1 as members (clear the flood masks).
 - Add a VLAN/Unicast Address Table Entry with the Port1/0 VLAN and a port number of 0. Packets received on port 1 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Configure the Port 2 to Port 0 VLAN
 - Add a VLAN Table Entry with ports 0 and 2 as members (clear the flood masks).
 - Add a VLAN/Unicast Address Table Entry with the Port2/0 VLAN and a port number of 0. Packets received on port 2 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Packets from the host (port 0) to ports 1 and 2 should be directed. If directed packets are not desired then VLAN with addresses can be added for both destination ports.
- Select the dual mac mode on the port 0 FIFO by setting TX_IN_SEL = 01 in P0_TX_IN_CTL. The intention of this mode is to allow packets from both ethernet ports to be written into the FIFO without one port starving the other port.
- The priority levels may be configured such that packets received on port 1 egress on one CPDMA RX channel while packets received on port 2 egress on a different CPDMA RX channel.

9.2.1.6 Audio Video Bridging

IEEE802.1BA is the standard for networked Audio Video Bridging (AVB) Systems. It defines the concept of an AVB domain as the intersection of a time domain and a stream reservation domain. The time domain is established based on the IEEE 802.1AS standard, wherein each node must support the generalized Precision Time Protocol (gPTP). Typically this takes the form of a state machine running on the host processor (such as the MPU) which, among other duties, processes the associated ethernet packets carrying timing information. A necessary input is the accurate time stamping of ethernet packets. This process is facilitated on SoC by the Common Platform Time Sync (CPTS), which is able to time stamp ingress and egress packets at the MAC layer with sufficient precision and accuracy to meet the AVB standard (refer to [Common Platform Time Sync \(CPTS\)](#)). A stream reservation domain is established

between nodes, primarily through the use of two mechanisms: the Stream Reservation Protocol (SRP) and Forwarding and Queuing of Time Sensitive Streams (FQTSS). Both mechanisms are specified in the IEEE802.1Q standard (clauses 35 and 34, respectively). SRP is a software component which normally runs on the host processor and requires no hardware assistance. On the other hand, FQTSS has significant performance demands, as it requires the shaping of egress packets at small time scales. The SoC CPSW facilitates this process through the conjunction of rate-limited CPDMA channels and egress traffic shaping (refer to [CPSW 3G](#) for more details).

9.2.1.7 Hardware Example Usage

9.2.1.7.1 Rate Limit Mode

Rate-limit mode is intended to allow some CPDMA transmit (switch ingress) channels and some CPGMAC_SL FIFO priorities (switch egress) to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on non rate-limited channels and FIFO priorities. The bulk traffic does not impact the rate-limited traffic. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling). The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited traffic received on an ethernet port can be dropped. Rate-limited mode is configured as shown below:

1. Set TX_IN_SEL = 10 in P1/2_TX_IN_CTL to enable ports 1 and 2 transmit FIFO inputs to be configured for rate-limiting queues. Enabling a queue to be rate-limiting with this field affects only the packet being loaded into the FIFO, it does not configure the transmit for queue shaping.
2. Configure the number of rate-limited queues for port 1 and 2 transmit FIFO's by setting the TX_RATE_EN field in P1/2_TX_IN_CTL. Rate limited queues must be the highest number. For example, if there are two rate limited queues then 1100 would be written to this field for priorities 3 and 2. This field enables the FIFO to allow rate-limited traffic into rate-limited queues while discriminating against non rate-limited queues.
3. Set P1_PRIN_SHAPE_EN and P2_PRIN_SHAPE_EN in the CPSW_3G PTYPE register. These bits determine which queues actually shape the output data stream. In general, the same priorities that are set in TX_RATE_EN are set in these bits as well, but the FIFO input and output enable bits are separate to allow rate-limiting from the host to non shaped channels if desired. When queue shaping is not enabled for a queue then packets are selected for egress based on priority. When queue shaping is enabled then packets are selected for egress based on queue percentages. If shaping is required on a single queue then it must be priority 3 (priorities 2, 1 and 0 are strict priority). If shaping is required on two queues then it must be on priorities 2 and 3 (priorities 1 and 0 are strict priority). If shaping is required on three queues then it must be priorities 3, 2, and 1 (priority 0 would then get the leftovers). Priority shaping follows the requirements in the IEEE P802.1Qav/D6.0 specification. Priority shaping is not compatible with priority escalation (escalation must be disabled).
4. P0_TX_IN_CTL[17:16] TX_IN_SEL should be set to 00, so Port 0 egress (CPDMA RX) is not rate-limited.
5. The CPDMA is configured for rate-limited transmit (switch ingress) channels by setting the highest bits of the TX_RLIM field in the CPDMA DMACONTROL register. If there are two rate-limited channels, then TX_RLIM = 11000000 (the rate limited channels must be the highest priorities). Also, the TX_PTYPE bit in the DMACONTROL register must be set (fixed priority mode). Rate-limited channels must go to rate-limited FIFO queues, and the FIFO queue rate must not be oversubscribed.

9.2.1.7.2 Configuring the device for 802.1Qav operation:

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW_3G that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
 - CPPI TX and RX descriptors
 - VLAN and Priority tags

Table 9-12. Example of TX Configuration

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

Table 9-13. Example of RX Configuration

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
 - ALE in VLAN-ware mode, Non-ALE in bypass mode.

Table 9-14. Example of Rate-limit Configurations

Register	Value	DESCRIPTION
CPSW_PTYPE	0006 0000h	For Port1 -- 2 highest priority channels.
P1_TX_IN_CTL: TX_RATE_EN TX_IN_SEL	1100 10	2 highest priority channels are rate limited Rate limit mode
P1_SEND_PERCENT	14 3E00h	20% PRI7, 62% PRI5
DMACONTROL	C001h	Chan7, Chan6 are Rate Limited. Round-robin selection of DMA channel.
TX_PRI7_RATE	10013h	200 Mbps
TX_PRI6_RATE	10005h	~600 Mbps

9.2.1.8 Ethernet Mac Sliver (CPGMAC_SL)

The CPGMAC_SL peripheral shall be compliant to the IEEE Std 802.3 Specification. Half duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation.
- G/MII Interface.
- Hardware Error handling including CRC.
- Full Duplex Gigabit operation (half duplex gigabit is not supported).
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module.
- Transmit CRC generation selectable on a per channel basis.
- Emulation Support.
- VLAN Aware Mode Support.
- Hardware flow control.
- Programmable Inter Packet Gap (IPG)

9.2.1.8.1 G/MII Media Independent Interface

The following sections cover operation of the Media Independent Interface in 10/100/1000 Mbps modes. An IEEE 802.3 compliant Ethernet MAC controls the interface.

9.2.1.8.1.1 Data Reception

9.2.1.8.1.1.1 Receive Control

Data received from the PHY is interpreted and output. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

9.2.1.8.1.1.2 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

- An Inter-Packet Gap (IPG).
- A seven octet preamble (all octets 0x55).
- A one octet start frame delimiter (0x5D).

9.2.1.8.1.2 Data Transmission

The Gigabit Ethernet Mac Sliver (GMII) passes data to the PHY when enabled. Data is synchronized to the transmit clock rate. The smallest frame that can be sent is two bytes of data with four bytes of CRC (6 byte frame).

9.2.1.8.1.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted) the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

9.2.1.8.1.2.2 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS_CRC bit is 0. For the CPMAC_SL generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS_CRC bit is set.

9.2.1.8.1.2.3 MTXER

The GMII_MTXER signal is not used. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

9.2.1.8.1.2.4 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX_PACE bit in the MACCONTROL register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

9.2.1.8.1.2.5 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRS is de-asserted within approximately 48 bit times of MTXEN being de-asserted, then 96 bit times is measured from MTXEN. If the frame suffered a collision, or if MCRS is not de-asserted until more than approximately 48 bit times after MTXEN is de-asserted, then 96 bit times (approximately, but not less) is measured from MCRS.

The transmit IPG can be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the MACCONTROL register enables the TX_SHORT_GAP input to determine whether the transmit IPG is shorted by eight bit times.

9.2.1.8.1.2.6 Back Off

The Gigabit Ethernet Mac Sliver (GMII) implements the 802.3 binary exponential back-off algorithm.

9.2.1.8.1.2.7 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the TX_GAP register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

9.2.1.8.1.2.8 Speed, Duplex and Pause Frame Support Negotiation

The CPMAC_SL can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

9.2.1.8.1.3 G/MII Interface Signal Connections and Descriptions

G/MII Interface can operate in GIG/MII Modes.

- In GIG (1000 Mbps) Mode: 3PSW operates only in full duplex mode.
- In MII Mode (100/10 Mbps): 3PSW operates in full duplex and half duplex.

The pin connections of the G/MII Interface is shown in [Figure 9-4](#). The detailed description of the signals in GIG/MII Mode are listed in the following tables.

Figure 9-4. G/MII Interface Connections

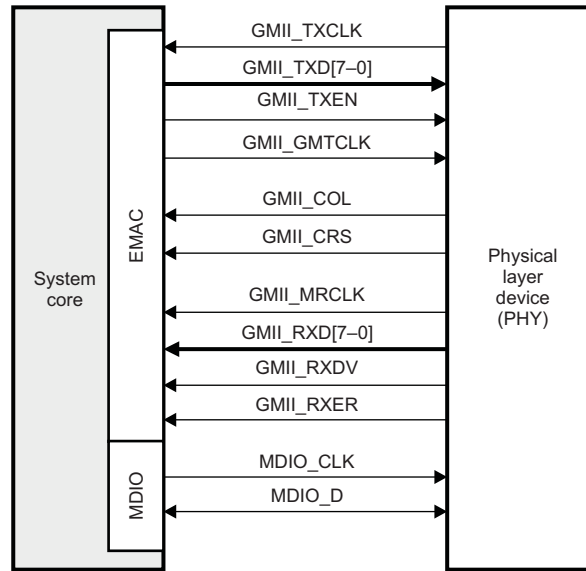

Table 9-15. G/MII Interface Signal Descriptions in GIG (1000 Mbps) Mode

Signal	Type	Description
GMTCLK	O	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The clock is generated by the CPSW and is 125 MHz at 1000 Mbps operation. It requires a free running clock on MTCLK pin. If the MTCLK is not generated by the PHY, then configure the CPGMAC_SL Mac Control Register Force Gig bit to 1, to generate the required o/p GMTCLK of 125 MHz.
MTCLK	I	The transmit clock is a continuous free running clock and is generated by the PHY.
MTXD	O	The transmit data pins are a collection of 8 data signals comprising 8 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by GMTCLK and valid only when MTXEN is asserted.
MTXEN	O	The transmit enable signal indicates that the MTXD pins are generating 8bit data for use by the PHY. It is driven synchronously by GMTCLK.
MCOL	I	In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used.
MCRS	I	In full-duplex operation, the MCRS pin should be held low.
MRCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD, MRXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 125 MHz at 1000Mbps of operation.
MRXD	I	The receive data pins are a collection of 8 data signals comprising 8 bits of data. MRXD0 is the least-significant bit (LSB). The signals are synchronized by MRCLK and valid only when MRXDV is asserted.
MRXDV	I	The receive data valid signal indicates that the MRXD pins are generating byte data for use by the 3PSW. It is driven synchronously to MRCLK.
MDCLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO	I/O	MDIO DATA (MDIO_D). MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

Table 9-16. G/MII Interface Signal Descriptions in MII (100/10 Mbps) Mode

Signal	Type	Description
GMTCLK	O	The clock is generated by the CPSW and is running at 125 MHz.
MTCLK	I	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MTXD and MTXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MTXD	O	MTXD[7-4] pins of MTXD data are not used. The transmit data pins are a collection of 4 data signals MTXD[3-0] comprising 4 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by MTCLK and valid only when MTXEN is asserted.
MTXEN	O	The transmit enable signal indicates that the MTXD pins are generating 4bit data for use by the PHY. It is driven synchronously by MTCLK.
MCOL	I	In half-duplex operation, the MCOL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MTCLK nor MRCLK. In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used.
MCRS	I	In half-duplex operation, the MCRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is de-asserted when both transmit and receive are idle. This signal is not necessarily synchronous to MTCLK nor MRCLK. In full-duplex operation, the MCRS pin should be held low.
MRCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD, MRXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MRXD	I	MRXD[7-4] bits are unused in the MII mode. The receive data pins are a collection of 4 data signals comprising 4 bits of data. MRXD0 is the least-significant bit (LSB). The signals are synchronized by MRCLK and valid only when MRXDV is asserted.
MRXDV	I	The receive data valid signal indicates that the MRXD pins are generating nibble data for use by the 3PSW. It is driven synchronously to MRCLK.
MDCLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO	I/O	MDIO DATA (MDIO_D). MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

9.2.1.8.2 RMII Interface

The CPRMII peripheral shall be compliant to the RMII specification document.

9.2.1.8.2.1 Features

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

9.2.1.8.2.2 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMRXER on any di-bit in the received packet will cause an MRXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMCERSDV toggle will issue an MRXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMCERSDV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

9.2.1.8.2.3 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the 3PSW MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The 3PSW does not source the transmit error (MII TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMTXD[1:0] for each clock that RMTXEN is de-asserted.

9.2.1.8.2.4 RMII Signal Connections and Descriptions

Figure 9-5 shows a device with integrated 3PSW and MDIO interfaced via a RMII connection in a typical system. The individual CPSW and MDIO signals for the RMII interface are summarized in Table 9-17.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

Figure 9-5. RMII Interface Connections

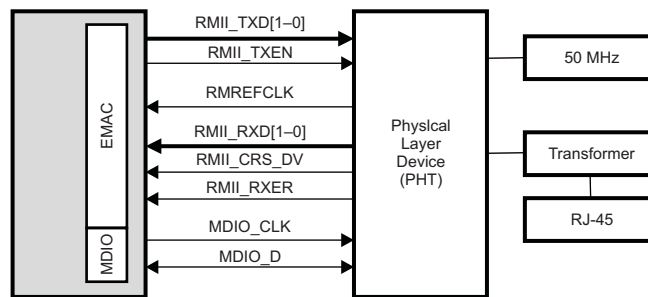

Table 9-17. RMII Signal Descriptions

Signal	Type	Description
RMTXD (1-0)	O	Transmit data (RMII_TXD). The transmit data pins are a collection of 2 bits of data. RMTDX0 is the least-significant bit (LSB). The signals are synchronized by RMREFCLK and valid only when RMTXEN is asserted.
RMXEN	O	Transmit enable (RMII_TXEN). The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMREFCLK.
RMREFCLK	I/O	RMII reference clock. (RMREFCLK). The reference clock is used to synchronize all RMII signals. RMREFCLK must be continuous and fixed at 50 MHz.
RMRXD (1-0)	I	Receive data (RMII_RXD). The receive data pins are a collection of 2 bits of data. RMRDX0 is the least-significant bit (LSB). The signals are synchronized by RMREFCLK and valid only when RMCERSDV is asserted and RMRXER is de-asserted.
RMCERSDV	I	Carrier sense/receive data valid (RMCERSDV). Multiplexed signal between carrier sense and receive data valid.
R,RXER	I	Receive error (RMII_RXER). The receive error signal is asserted to indicate that an error was detected in the received frame.
MDCLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.

Table 9-17. RMII Signal Descriptions (continued)

Signal	Type	Description
MDIO	I/O	MDIO DATA(MDIO_D). MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

9.2.1.8.3 RGMII Interface

The CPRGMII peripheral shall be compliant to the RGMII specification document.

9.2.1.8.3.1 Features

- Supports 1000/100/10 Mbps Speed
- MII mode is not supported
- Selectable internal delay on transmit

9.2.1.8.3.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

9.2.1.8.3.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the RGMII_RX_INBAND input is asserted. RGMII_RX_INPUT is asserted by configuring the EXT_EN bit to 1 of the SLn_MACCONTROL register. The link status, duplexity, and speed are determined from the RGMII input data stream as defined in the RGMII specification. The link speed is indicated as shown in [Table 9-18](#).

Table 9-18. Link Speed

RGMII_SPEED (1:0)	Link Speed
00	10 Mbs mode
01	100 Mbs mode
10	1000 Mbs mode
11	reserved

9.2.1.8.3.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the RGMII_RX_INBAND input is de-asserted. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the RGMII_FULLDUPLEX_IN and RGMII_GIG_IN inputs. If the RGMII_GIG_IN input is asserted, then operation is gigabit mode (RGMII_SPEED (1:0) = 10). If the RGMII_GIG_IN input is de-asserted, the operation is 100 Mbps mode (RGMII_SPEED (1:0) = 01).

9.2.1.8.3.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (MTXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRGMII module.

In 10/100 mode, the MTXD (7:0) data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII_LINK. Packet transmission will begin on the first GMII_MTXEN rising edge after the 4096 transmit clock count has expired.

The RGMII0/1_ID_MODE bit value in the GMII_SEL register determines whether or not the transmit delay is included in the CPRGMII or not. When RGMII0/1_ID_MODE bit is cleared to 0, the transmit delay is included. The RGMII0/1_ID_MODE input is a configuration input only and is not intended to be changed during packet operations.

See the *Control Module* chapter, MII mode selection register (GMII_SEL) to configure the CPRGMII Internal Delay/No Delay in Transmit Mode of Operation.

9.2.1.8.3.6 RGMII Signal Connections and Descriptions

Figure 9-6 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW and MDIO signals for the RGMII interface are summarized in Table 9-19.

Figure 9-6. RGMII Interface Connections

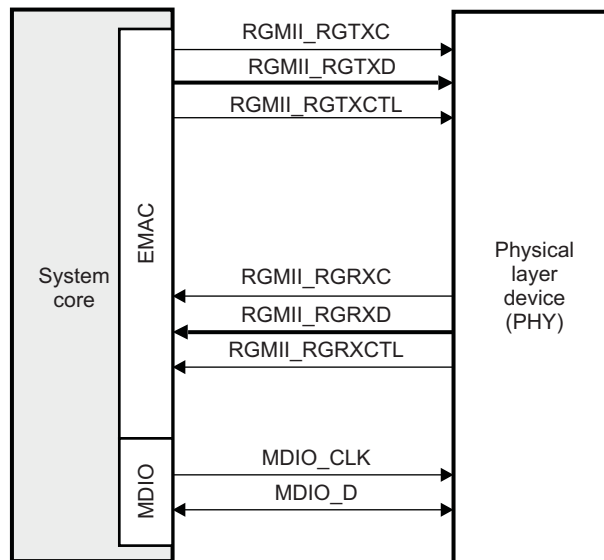

Table 9-19. RGMII Signal Descriptions

Signal	Type	Description
RGTXD[3-0]	O	The transmit data pins are a collection of 4 bits of data. RGTDX0 is the least-significant bit (LSB). The signals are valid only when RGTXCTL is asserted.
RGTXCTL	O	Transmit Control/enable. The transmit enable signal indicates that the RGTXD pins are generating data for use by the PHY.
RGTXC	O	The transmit reference clock will be 125 MHz, 25 MHz, or 2.5 MHz depending on speed of operation.
RGRXD[3-0]	I	The receive data pins are a collection of 4 bits of data. RGRDX0 is the least-significant bit (LSB). The signals are valid only when RGRXCTL is asserted
RGRXCTL	I	The receive data valid/control signal indicates that the RGRXD pins are nibble data for use by the 3PSW.
RGRXC	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDCLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.

Table 9-19. RGMII Signal Descriptions (continued)

Signal	Type	Description
MDIO	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

9.2.1.8.4 Frame Classification

Received frames are proper (good) frames if they are between 64 and RX_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the RX_MAXLEN register. The RX_MAXLEN register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain RX_MAXLEN number of bytes transferred to memory (if RX_CEF_EN = 1). An example with RX_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

9.2.1.9 Embedded Memories

Table 9-20. Embedded Memories

Memory Type Description	Number of Instances	
Single port 2560 by 64 RAM	3	(Packet FIFO's)
Single port 64-word by 1152-bit RAM	1	(ALE)
Single port 2048-word by 32-bit RAM	1	(CPPI)

9.2.1.10 Flow Control

There are two types of switch flow control: CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

9.2.1.10.1 CPPI Port Flow Control

The CPPI port has flow control available for transmit (switch ingress). CPPI receive operations (switch egress) do not require flow control. CPPI Transmit flow control is initiated when enabled and triggered. CPPI transmit flow control is enabled by setting the P0_FLOW_EN bit in the CPSW_FLOW_CONTROL register. CPPI transmit flow control is enabled by default on reset because host packets should not be dropped in any mode of operation.

9.2.1.10.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the CPGMAC_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX_PKT_CNT = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX_FLOW_EN bit in the associated CPGMAC_SL be set to 1. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for G/MII ports, then any packets that are dropped are dropped on transmit and not on receive.

9.2.1.10.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the RX_FLOW_EN bit in the MACCONTROL register. Receive flow control is triggered (when enabled) when the RX_FLOW_TRIGGER input is asserted. The CPGMAC_SL is configured for collision or IEEE 802.3X flow control via the fullduplex bit in the MACCONTROL register.

9.2.1.10.2.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in MACCONTROL). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

9.2.1.10.2.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX is set in MACCONTROL). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC_SL will transmit pause frames as:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - SL_SA(47:0).
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If RX_FLOW_EN is cleared to 0 while the pause time is nonzero, then the pause time will be cleared to 0 and a zero count pause frame will be sent.

9.2.1.10.2.2 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC_SL from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TX_FLOW_EN bits in the MACCONTROL register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the RX_CMF_EN (copy MAC frames) bit in the MACCONTROL register is set. The TX_FLOW_EN and FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- TX_FLOW_EN is set in MACCONTROL register, and
- the frame's length is 64 to RX_MAXLEN bytes inclusive, and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If TX_FLOW_EN in MACCONTROL register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
- The reserved multicast destination address 01.80.C2.00.00.01, or the SL_SA (47:0) input mac source address.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC_SL will recognize any pause frame between 64 bytes and RX_MAXLEN bytes in length.

9.2.1.11 Short Gap

The port 1 (and port 2) transmit inter-packet gap (IPG) may be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the SL1_MACCONTROL (SL2_MACCONTROL) register enables the gap to be shortened when triggered. The condition is triggered when the port 1 (port 2) transmit FIFO has a user defined number of FIFO blocks used. The port 1 transmit FIFO blocks used determines if the port 1 gap is shortened, and the port 2 transmit FIFO blocks used determines if the port 2 gap is shortened. The CPSW_GAP_THRESH register value determines the port 1 short gap threshold, and the CPSW_GAP_THRESH register value determines the port 2 short gap threshold.

9.2.1.12 Switch Latency

The CPSW_3G is a store and forward switch. The switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

Table 9-21. Switch Latency

Mode	Latency
Gig (1000)	880 ns
100	1.3 μ s
10	6.5 μ s

9.2.1.13 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW_3G operation to be completely or partially suspended. There are three CPSW_3G submodules that contain emulation control registers (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW_3G emulation control. The CPSW_3G module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

CPGMAC_SL Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the EMCONTROL register) allow CPGMAC_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

CPDMA Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the EMCONTROL register) allow CPDMA operation to be suspended. When the emulation suspend state is entered, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals

Table 9-22 shows the operations of the emulation control input and register bits.

Table 9-22. Emulation Control Input

EMUSUS P	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

9.2.1.14 Software IDLE

The submodule software idle register bits enable CPSW_3G operation to be completely or partially suspended by software control. There are three CPSW_3G submodules that contain software idle register bits (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). Each of the three submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW_3G module enters the idle state when all three submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the three submodule idle bits. The CPSW_3G is in the idle state when all three submodules are in the idle state. The CPSW_SOFT_IDLE bit may be set if desired after the submodules are in the idle state. The CPSW_SOFT_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

9.2.1.15 Software Reset

The CPSW_3G software reset register, CPSW_3GSS software reset register and the three submodule software reset registers enable the CPSW_3GSS to be reset by software. There are three CPSW_3G submodules that contain software reset registers (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). Each of the three submodules may be individually commanded to be reset by software.

For the CPDMA, the reset state is entered at packet boundaries, at which time the CPDMA reset occurs. The CPGMAC_SL soft reset is immediate. Submodule reset status is determined by reading or polling the submodule reset bit. If the submodule reset bit is read as a one, then the reset process has not yet completed. The submodule soft reset process could take up to 2ms each. The reset has completed if the submodule reset bit is read as a zero.

After all three submodules (in any order) have been reset and a read of each submodule reset bit indicates that the reset process is complete, the CPSW_3G software reset register bit may be written to complete the CPSW_3G module software reset operation. The CPSW_3G software reset bit controls the reset of the FIFO's, the statistics submodule, and the address lookup engine (ALE). The CPSW_3G software reset is immediate and will be indicated by reading a zero from the soft reset bit.

The CPSW_3GSS software reset bit controls the reset of the INT, REGS, and CPPI. The CPSW_3GSS software reset is immediate and will be indicated by reading a zero from the soft reset bit.

9.2.1.16 FIFO Loopback

FIFO loopback mode is entered when the FIFO_LOOPBACK bit in the CPSW_CONTROL register is set. FIFO loopback mode causes packets received on a port to be turned around and transmitted back on the same port. Port 0 receive is fixed on channel 0 in FIFO loopback mode. The RXSOFOVERRUN statistic is incremented for each packet sent in FIFO loopback mode. Packets sent in with errors are returned with errors (they are not dropped). FIFO loopback is intended as a simple mechanism for test purposes. FIFO loopback should be performed in full duplex mode only.

9.2.2 Common Platform Time Sync (CPTS)

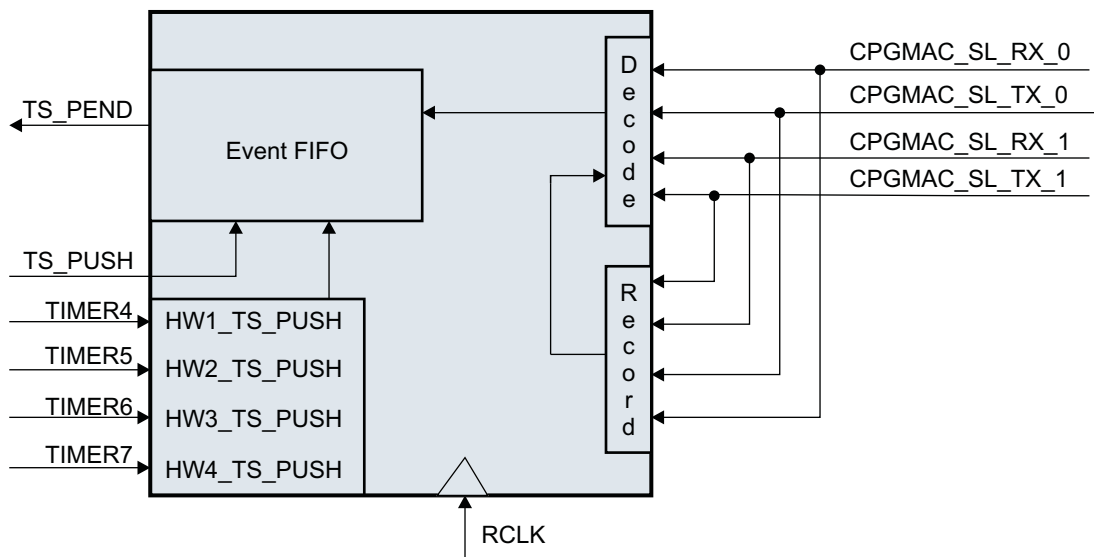

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

9.2.2.1 Architecture

Figure 9-7 shows the architecture of the CPTS module inside the 3PSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the 3PSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value through the Event FIFO

Figure 9-7. CPTS Block Diagram

The reference clock used for the time stamp (RCLK) is sourced from one of the five sources, as shown in Figure 9-8. The PLL used for sourcing RCLK can be selected by configuring the RMII_REFCLK_SRC register in the *Control Module* chapter. Note that if RGMII mode is used, RCLK must be exactly 250 MHz.

Figure 9-8. CPTS RCLK Source

9.2.2.2 Common Platform Time Sync Initialization

The CPTS module should be configured as:

1. Reset the CPTS module.
2. Clear the CPTS_EN bit in the CPTS_CONTROL register.
3. Write the CPTS_RFT_CLK value in the RMII_RFTCLK_SEL register in the Control Module with the desired reference clock selection.
4. Set the CPTS_EN bit in the CPTS_CONTROL register.
5. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the CPTS_INT_ENABLE register.

9.2.2.3 Time Stamp Value

The time stamp value is a 32-bit value that increments on each RCLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_VAL and CPTS_TS_LOAD_EN registers).

9.2.2.4 Event FIFO

All time sync events are push onto the Event FIFO. There are 16 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

9.2.2.5 Time Sync Events

Time Sync events are 64-bit values that are pushed onto the event FIFO and read in two 32-bit reads. The two 32-bit registers, CPTS_EVENT_HIGH and CPTS_EVENT_LOW, are described in [Section 9.4](#). There are five types of sync events:

- Time stamp push event
- Time stamp counter rollover event
- Time stamp counter half-rollover event
- Ethernet receive event
- Ethernet transmit event

9.2.2.5.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPTS_TS_PUSH register. The time stamp value is returned in the event, along with a time stamp push event code. Software should not push a second time stamp event on to the FIFO until the first time stamp value has been read from the event FIFO.

9.2.2.5.2 Time Stamp Counter Rollover Event

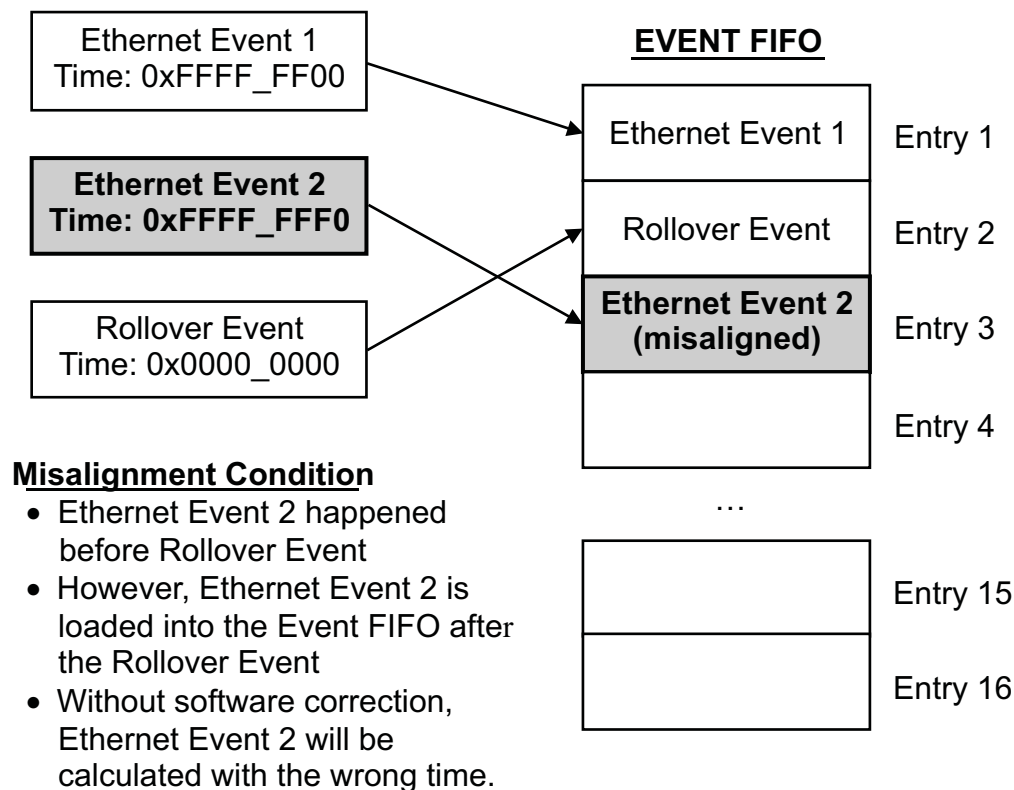

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from FFFF FFFFh to 0000 0000h, and the software maintained upper count value should be incremented.

9.2.2.5.3 Time Stamp Counter Half-rollover Event

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 7FFF FFFFh to 8000 0000h. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 9-9](#) shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0000 0000h through 7FFF FFFFh), then the event time stamp was taken after the rollover and no correction is required. If the value is high (8000 0000h through FFFF FFFFh), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

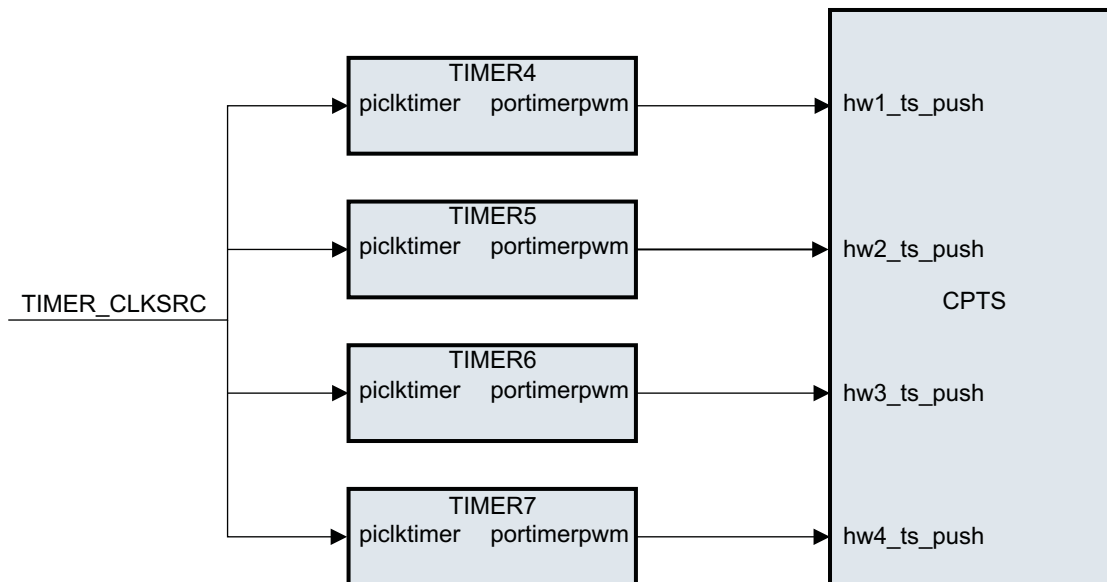

Figure 9-9. Event FIFO Misalignment Condition

9.2.2.5.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (HW1/4_TS_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each hardware time stamp input is internally connected to the PORTIMERPWM output of each timer as shown in [Figure 9-10](#).

Figure 9-10. HW1/4_TSP_PUSH Connection

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the EVENT_HIGH register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the CPTS_CONTROL register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

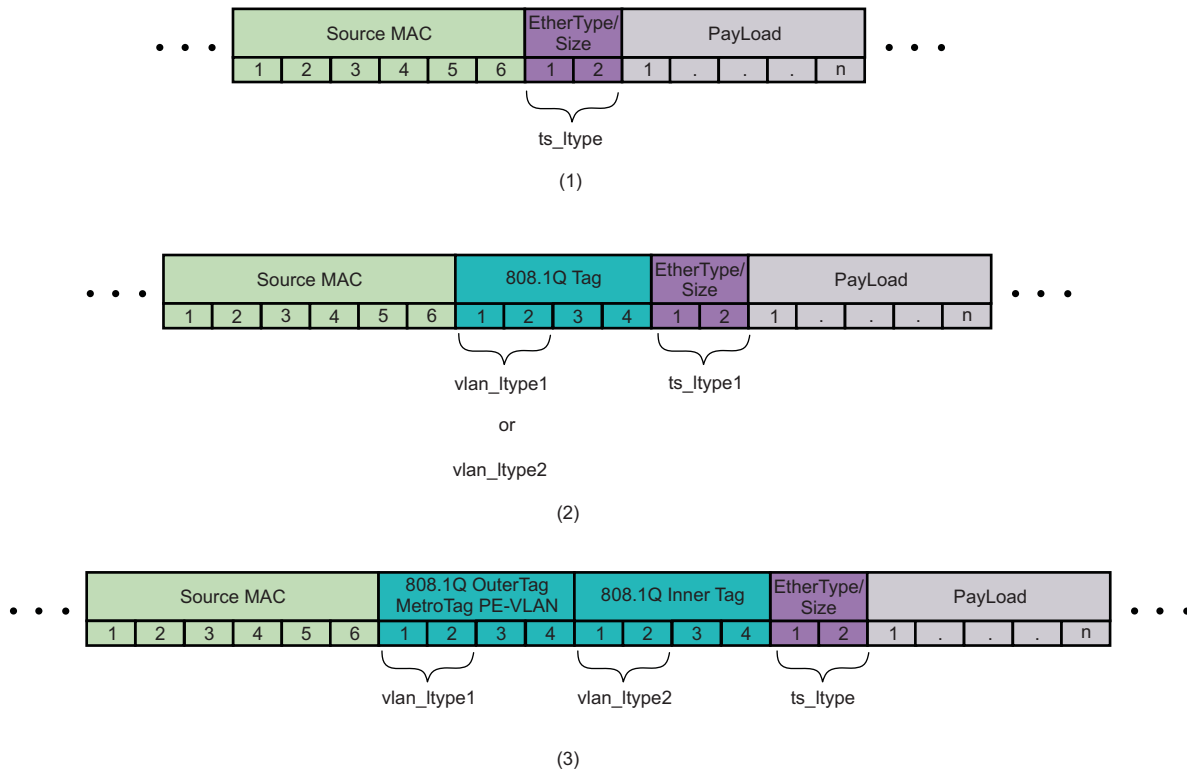

9.2.2.5.5 Ethernet Port Events

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the Payload field, as shown in Figure 9-11. For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the Pn_TS_LTYPE field in the Pn_TS_SEQ_LTYPE register, which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in Figure 9-11. To indicate to the CPTS hardware that a virtual LAN is in use, the Pn_TS_TX_VLAN_LTYPE1_EN/Pn_TS_RX_VLAN_LTYPE1_EN (or Pn_TS_TX_VLAN_LTYPE2_EN/Pn_TS_RX_VLAN_LTYPE2_EN) enable bit must be set in the Pn_TS_CTL register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the Pn_TS_VLAN_LTYPE1 (or Pn_TS_VLAN_LTYPE2 depending on which enable bit was set) field in the Pn_TS_VLAN register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 9-11. In this case, both Pn_TS_VLAN_LTYPE1 and Pn_TS_VLAN_LTYPE2 must be enabled. The outer tag must match the value of the Pn_TS_VLAN_LTYPE1 field, and the inner tag must match the value of the Pn_TS_VLAN_LTYPE2 field.

Figure 9-11. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)

To enable transmit/receive event packets on a given Ethernet port, perform the following steps, where n is the port number:

1. Set the Pn_TS_TX_EN/Pn_TS_RX_EN bit in the Pn_TS_CTL register to enable transmit/receive event packets
2. Configure the Pn_TS_SEQ_LTYPE register:
 - (a) Set the Pn_TS_LTYPE field to 88F7h, which corresponds to the Precision Time Protocol (IEEE 1588) EtherType.
 - (b) Set the Pn_TS_SEQ_ID_OFFSET field to 1Eh, which is the sequence ID offset in the common message header given in the IEEE 1588 specification.
3. To enable support for VLAN tagging (IEEE 802.1Q):
 - (a) Set the Pn_TS_TX_VLAN_LTYPE1_EN/Pn_TS_RX_VLAN_LTYPE1_EN or Pn_TS_TX_VLAN_LTYPE2_EN/Pn_TS_RX_VLAN_LTYPE2_EN bit in the Pn_TS_CTL register.
 - (b) Set the Pn_TS_VLAN_LTYPE1 or Pn_TS_VLAN_LTYPE2 field (matching what was used in step 3a) in the Pn_TS_VLAN register to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType.
4. To enable support for up to two stacked VLANs (IEEE 802.1ad):
 - (a) Set the Pn_TS_TX_VLAN_LTYPE1_EN/Pn_TS_RX_VLAN_LTYPE1_EN and Pn_TS_TX_VLAN_LTYPE2_EN/Pn_TS_RX_VLAN_LTYPE2_EN bit in the Pn_TS_CTL register.
 - (b) Set the Pn_TS_VLAN_LTYPE1 field in the Pn_TS_VLAN register to match the EtherType of the outer tag.
 - (c) Set the Pn_TS_VLAN_LTYPE2 field in the Pn_TS_VLAN register to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType of the inner tag.
5. Set the Pn_TS_MSG_TYPE_EN field in the Pn_TS_CTL register to choose which types of time stamp messages will push events onto the Event FIFO. [Table 9-23](#) lists the message types defined in the IEEE 1588-2008 specification.

Table 9-23. Values of Message Type Field

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4-7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E-F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO. The CPTS_EVENT_HIGH register contains the Message Type and Sequence ID values from the original time sync packet. The CPTS_EVENT_LOW register contains the time stamp value when the packet arrived at the corresponding port.

9.2.2.6 Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_TS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers values.
3. Set the EVENT_POP field (bit 0) of the CPTS_EVENT_POP register to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_TS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers values.
3. Set the EVENT_POP bit of the CPTS_EVENT_POP register to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four RCLK periods plus four VBUSP_CLK periods.
5. Read the TS_PEND_RAW bit in the CPTS_INTSTAT_RAW register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, go to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the CPTS_INTSTAT_RAW register to determine if a valid event is on the event FIFO.

9.2.3 CPPI Buffer Descriptors

The buffer descriptor is a central part of the 3PSW Ethernet Subsystem and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data.

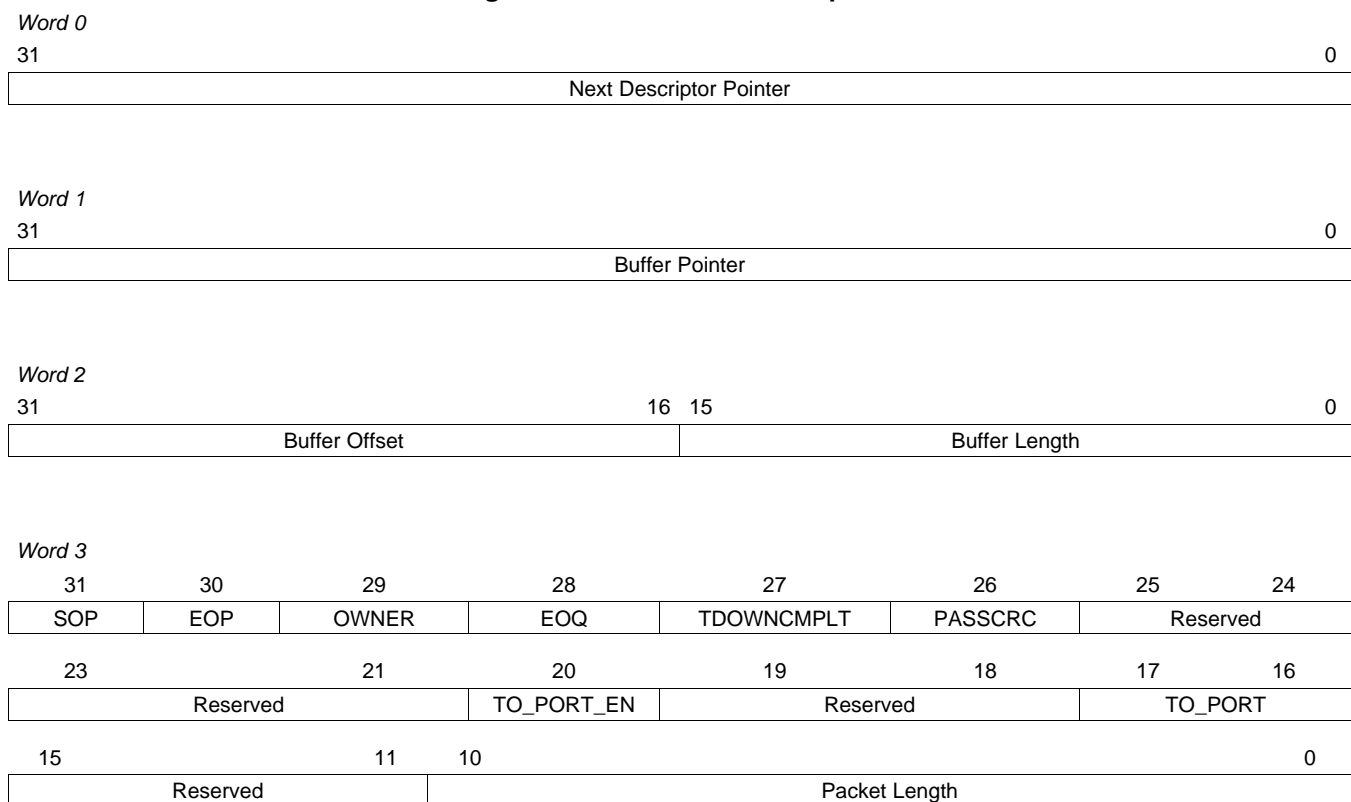

Host Software sends and receives network frames via the CPPI 3.0 compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data and free buffer queues available for received data.

NOTE: The 8K bytes of Ethernet Subsystem CPPI RAM begin at address 4A10 2000h and end at 4A10 3FFFh from the 3PSW perspective. The buffer descriptors programmed to access the CPPI RAM memory should use the address range from 4A10 2000h.

9.2.3.1 TX Buffer Descriptors

A TX buffer descriptor (Figure 9-12) is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Figure 9-12. TX Buffer Descriptor Format

9.2.3.1.1 CPPI TX Data Word 0

Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC. The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC

9.2.3.1.2 CPPI TX Data Word 1

Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the `buffer_pointer`. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

9.2.3.1.3 CPPI TX Data Word 2

Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the `Buffer_Offset` value (which may be zero to the buffer length minus 1). Valid only on SOP.

Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the `Buffer_Length` field. The host sets the `Buffer_Length`. The `Buffer_Length` must be greater than zero.

9.2.3.1.4 CPPI TX Data Word 3

Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the `Buffer_Length` fields should equal the `Packet_Length`. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not start of packet buffer.

1 - Start of packet buffer.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not end of packet buffer.

1 - End of packet buffer.

Ownership (OWNER) Flag

When set this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

0 - The packet is owned by the host

1 - The packet is owned by the port

End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

0 - The TX queue has more packets to transfer.

1 - The Descriptor buffer is the last buffer in the last packet in the queue.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission. Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

0 - The port has not completed the teardown process.

1 - The port has completed the commanded teardown process.

Pass CRC (PASSCRC) Flag

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC. When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

0 - The CRC is not included with the packet data and packet length.

1 - The CRC is included with the packet data and packet length.

TO_PORT

Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode.

- 1 - Send the packet to port 1 if TO_PORT_EN is asserted.
- 2 - Send the packet to port 2 if TO_PORT_EN is asserted.

TO_PORT_ENABLE

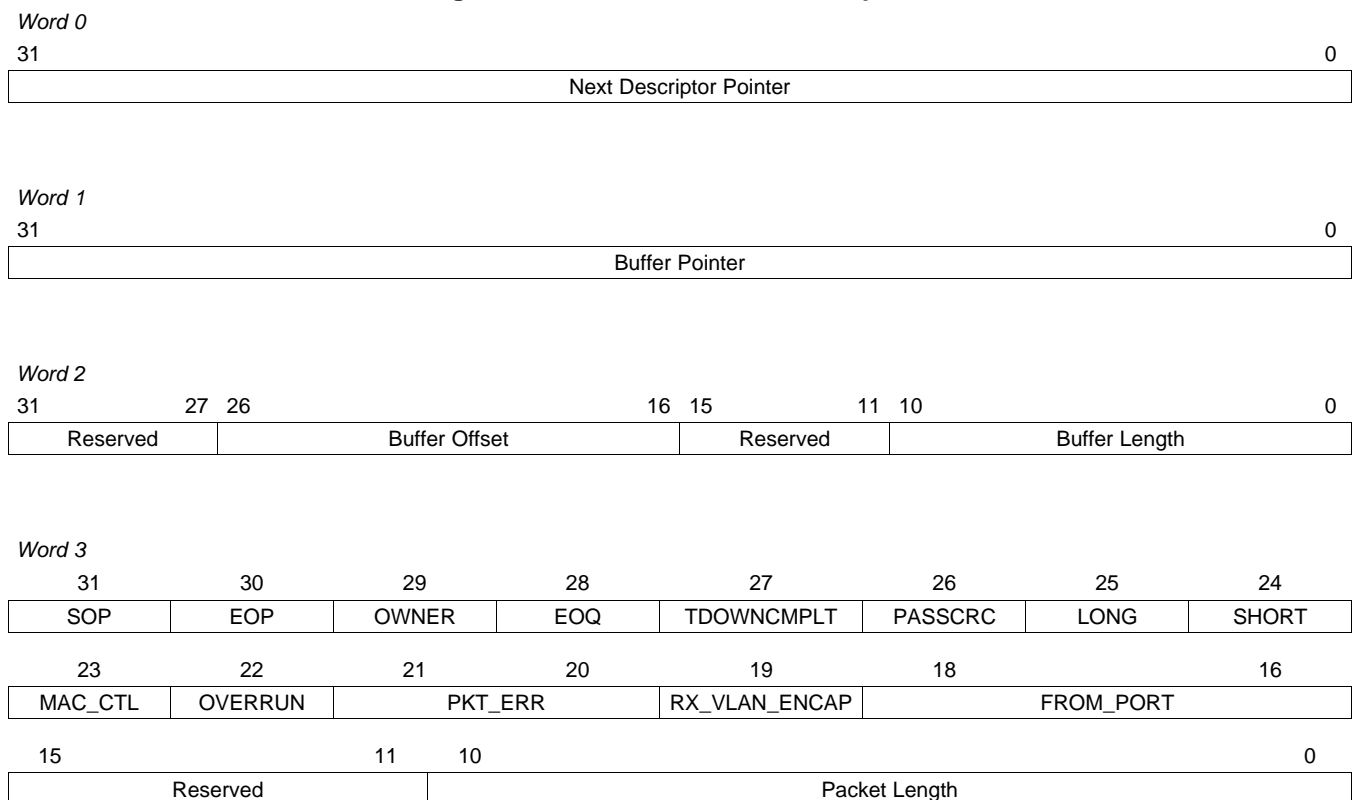

Indicates when set that the packet is a directed packet to be sent to the TO_PORT field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.

- 0 - not a directed packet
- 1 - directed packet

9.2.3.2 RX Buffer Descriptors

A RX buffer descriptor (Figure 9-13) is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Figure 9-13. Receive Buffer Descriptor Format

9.2.3.2.1 CPPI RX Data Word 0

Next Descriptor Pointer

The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the Next_Descriptor_Pointer.

9.2.3.2.2 CPPI RX Data Word 1

Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the Buffer_Pointer.

9.2.3.2.3 CPPI RX Data Word 2

Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the Buffer_Offset with the value from the RX_BUFFER_OFFSET register value. The host initializes the Buffer_Offset to zero for free buffers. The Buffer_Length must be greater than the RX_BUFFER_OFFSET register value. The buffer offset is valid only on SOP.

Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the Buffer_Length, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The Buffer_Length must be greater than zero.

9.2.3.2.4 CPPI RX Data Word 3

Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer_Length fields should equal the Packet_Length. Valid only on SOP.

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL). The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

Long (Jabber) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RX_CEF_EN bit was set in the MACCONTROL register. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

Short (Fragment) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RX_CSF_EN bit was set in the MACCONTROL register.

Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RX_CMF_EN bit was set in the MACCONTROL register.

Overrun Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

Packet Error (PKT_ERR) Flag

Packet Contained Error on Ingress:

00 - no error

01 - CRC error on ingress

10 - Code error on ingress

11 - Align error on ingress

VLAN Encapsulated Packet (RX_VLAN_ENCAP)

Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the CPSW control register RX_VLAN_ENCAP bit.

FROM_PORT

Indicates the port number that the packet was received on (ingress to the switch).

9.2.4 MDIO

The MII Management I/F module implements the 802.3 serial management interface to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Two user access registers control and monitor up to two PHYs simultaneously.

9.2.4.1 MII Management Interface Frame Formats

Table 9-24 shows the read format and Table 9-25 shows the write format of the 32-bit MII Management interface frames.

Table 9-24. MDIO Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 9-25. MDIO Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 01 pattern. The pattern assures transitions from the default logic 1 state to logic 0, and back to logic 1.

Operation Code

The operation code for a read is 10, while the operation code for a write is a 01.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

9.2.4.2 Functional Description

The MII Management I/F will remain idle until enabled by setting the enable bit in the MDIO CONTROL register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO LINK register. The LINKSEL bit in the MDIO USERPHYSEL register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO LINKINTRAW register and the MDIO LINKINTMASKED register, if enabled by the LINKINT_ENABLE bit in the MDIO USERPHYSEL register.

The MDIO ALIVE register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO ALIVE register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a MDIO USERACCESS register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW bit in the MDIO USERINTRAW register corresponding to the MDIO USERACCESS register being used. The corresponding bit in the MDIO USERINTMASKED register may also be set depending on the mask setting in the MDIO USERINTMASKSET and MDIO USERINTMASKCLR registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different MDIO USERACCESS registers. The host should check the status of the GO bit in the MDIO USERACCESS register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO USERACCESS register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the MACCONTROL register in the corresponding MAC.

9.2.5 Interrupts

The 3Port Switch Ethernet Subsystem generates four interrupt events.

9.2.5.1 Receive Packet Completion Pulse Interrupt (RX_PULSE)

The RX_PULSE interrupt is a pulse interrupt selected from the 3PSW RX_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding (RX_PEND[7:0]).

The following steps will enable the receive packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the RX_INTMASK_SET register.
2. The receive completion interrupt(s) to be routed to RX_PULSE is selected by setting one or more bits in the receive interrupt enable register (RX_EN) . The masked interrupt status can be read in the address location of RX_STAT bit in the receive status register.

When the 3PSW completes a packet reception, the subsystem issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer (RX *n*_CP) in the receive DMA state RAM.

Upon reception of an interrupt, software should perform the following:

1. Read the RX_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process received packets for the interrupting channel(s).
3. Write the 3PSW completion pointer(s) (RX *n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the subsystem (address of last buffer descriptor used by the subsystem). If the two values are not equal (which means that the 3PSW has received more packets than the CPU has processed), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the system has received), the pending interrupt is de-asserted. The value that the 3PSW is expecting is found by reading the receive channel *n* completion pointer register (RX *n*_CP).
4. Write the value 1h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the RX_INTMASK_CLEAR register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the RX_EN register.

The software could still poll for the RX_INTSTAT_RAW and RX_INTSTAT_MASKED registers if the corresponding interrupts are enabled.

9.2.5.2 Transmit Packet Completion Pulse Interrupt (TX_PULSE)

The TX_PULSE interrupt is a pulse interrupt selected from the 3PSW TX_PEND [7:0] interrupts. The transmit DMA controller has eight channels with each channel having a corresponding (TX_PEND[7:0]).

To enable the transmit packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the TX_INTMASK_SET register.
2. The transmit completion interrupt(s) to be routed to TX_PULSE is selected by setting one or more bits in the transmit interrupt enable register TX_EN .The masked interrupt status can be read in the address location of TX_STAT bit in the transmit status register.

When the 3PSW completes the transmission of a packet, the 3PSW subsystem issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon reception of an interrupt, software should perform the following:

1. Read the TX_STAT bit address location to determine which channel(s) caused the interrupt
2. Process received packets for the interrupting channel(s).
3. Write the 3PSW completion pointer(s) (TX n _CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the 3PSW (address of last buffer descriptor used by the 3PSW). If the two values are not equal (which means that the 3PSW has transmitted more packets than the CPU has processed), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the subsystem has transferred), the pending interrupt is cleared. The value that the 3PSW is expecting is found by reading the transmit channel n completion pointer register (TX n _CP).
4. Write the 2h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the TX_INTMASK_CLEAR register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the TX_EN register. The software could still poll for the TX_INTSTAT_RAW and TX_INTSTAT_MASKED registers, if the corresponding interrupts are enabled.

9.2.5.3 Receive Threshold Pulse Interrupt (RX_THRESH_PULSE)

The RX_THRESH_PULSE interrupt is an immediate (non-paced) pulse interrupt selected from the CPSW_3G RX_THRESH_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding threshold pulse interrupt (RX_THRESH_PEND[7:0]).

To enable the receive threshold pulse Interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the RX_INTMASK_SET register.
2. The receive threshold interrupt(s) to be routed to RX_THRESH_PULSE is selected by setting one or more bits in the receive threshold interrupt enable register RX_THRESH_EN. The masked interrupt status can be read in the address location of RX_THRESH_STAT bit in the receive threshold status register.

The RX_THRESH_PULSE is asserted when enabled when the channel's associated free buffer count RX n _FREEBUFFER is less than or equal to the corresponding RX n _PENDTHRESH register.

Upon reception of an interrupt, software should perform the following:

1. Read the RX_THRESH_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process the received packets in order to add more buffers to any channel that is below the threshold value.
3. Write the CPSW_3G completion pointer(s).
4. Write the value 0h to the CPDMA_EOI_VECTOR register.

The threshold pulse interrupt is an immediate interrupt intended to indicate that software should immediately process packets to preclude an overrun condition from occurring for the particular channels.

To disable the interrupt:

1. The eight channel receive threshold interrupts may be individually disabled by writing to 1 the appropriate bit in the RX_INTMASK_CLEAR register.
2. The receive threshold pulse interrupt could be disabled by clearing to Zero the corresponding bits in the RX_THRESH_EN register. The software could still poll for the RX_INTSTAT_RAW and INTSTAT_MASKED registers, if the corresponding interrupts are enabled.

9.2.5.4 Miscellaneous Pulse Interrupt (MISC_PULSE)

The MISC_PULSE interrupt is an immediate pulse interrupt selected from the miscellaneous interrupts (EVNT_PEND, STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT). The miscellaneous interrupt(s) is selected by setting one or more bits in the MISC_EN register. The masked interrupt status can be read in the MISC_STAT address location. Upon reception of an interrupt, software should perform the following:

1. Read the MISC_STAT address location to determine which caused the interrupt.
2. Process the interrupt.
3. Write the appropriate value (3h) to the CPDMA_EOI_VECTOR register.

NOTE: The MISC_STAT register's MDIO_LINKINT and MDIO_USERINT bitfields represent the Port0/Phy0 status. MDIO_LINKINT[1] and MDIO_USERINT[1] are not provided in MISC_STAT register. As such, MDIO Link and User interrupts can only be generated for Port0. For Port1, software must poll the status, visible in the LINKINTMASKED or USERINTMASKED registers.

9.2.5.4.1 EVNT_PEND(CPTS_PEND) Interrupt

See [Section 9.2.2](#) for more details on this interrupt.

9.2.5.4.2 Statistics Interrupt

The statistics level interrupt (STAT_PEND) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement all statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The raw and masked statistics interrupt status may be read by reading the TX_INTSTAT_RAW and TX_INTSTAT_MASKED registers, respectively.

9.2.5.4.3 Host Error interrupt

The host error interrupt (HOST_PEND) will be asserted, if enabled when a host error is detected during transmit or receive CPDMA transactions. The host error interrupt is intended for software debug, and is cleared by a warm reset or a system reset. The raw and masked statistics interrupt status can be read by reading the TX_INTSTAT_RAW and TXINTSTAT_MASKED registers, respectively.

The transmit host error conditions are:

- SOP error
- OWNERSHIP bit not set in SOP buffer
- next buffer descriptor pointer without EOP cleared to 0
- buffer pointer cleared to 0
- buffer length cleared to 0
- packet length error

The receive host error conditions are:

- OWNERSHIP bit not set in input buffer
- Zero buffer pointer
- Zero buffer Length on non-SOP descriptor
- SOP buffer length not greater than offset

The host error interrupt is disabled by clearing to 0 the appropriate bit in the CPDMA_INTMASK_CLEAR register.

9.2.5.4.4 MDIO Interrupts

MDIO_LINKINT is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR_MON field of the USERPHYSEL n register and the corresponding LINKINT_ENABLE bit is set. The MDIO_LINKINT event is also captured in the LINKINTMASKED register. When the GO bit in the USERACCESS n register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the USERINTMASKSET register is set, the MDIO_USERINT signal is asserted. The MDIO_USERINT event is also captured in the USERINTMASKED register.

To enable the miscellaneous pulse interrupt:

The miscellaneous interrupt(s) is selected by setting one or more bits in the miscellaneous interrupt enable register (MISC_EN).

- The Statistics interrupt is enabled by setting to 1 the STAT_INT_MASK bit in the DMA_INTMASK_SET register.
- The HOST_PEND is enabled by setting to 1 the HOST_ERR_INTMASK in the DMA_INTMASK_SET register.

Upon reception of an interrupt, software should perform the following:

- Read the MISC_STAT bit address location to determine the source of the interrupt.
- Process the interrupt.
- Write the value 3h to the CPDMA_EOI_VECTOR register.

9.2.6 Interrupt Pacing

The receive and transmit pulse interrupts can be paced. The receive threshold and miscellaneous interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (for example, 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the CPU cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the CPU instruction cache. Each CPU receive and transmit pulse interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1 ms interval of time. At the end of each 1 ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register). Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1 ms interval is derived from a 4 μ s pulse that is created from a prescale counter whose value is set in the INT_PRESCALE field in the INT_CONTROL register. The INT_PRESCALE value should be written with the number of VBUSP_CLK periods in 4 μ s. The pacing timer determines the interval during which interrupts are blocked and decrements every 4 μ s. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1 ms according to the following algorithm:

```
if (intr_count > 2*intr_max)
    pace_timer = 255;
else if (intr_count > 1.5*intr_max)
    pace_timer = last_pace_timer*2 + 1;
else if (intr_count > 1.0*intr_max)
    pace_timer = last_pace_timer + 1;
else if (intr_count > 0.5*intr_max)
    pace_timer = last_pace_timer - 1;
else if (intr_count != 0)
    pace_timer = last_pace_timer/2;
else
    pace_timer = 0;
```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be "paced" at the rate specified in the interrupt maximum register. The interrupt maximum register should be written with a value between 2 and 63 inclusive, indicating the target number of interrupts per millisecond.

9.2.7 Reset Isolation

Reset isolation for the Ethernet switch on Device is that the switch function of the ethernet IP remains active even in case of all device resets except for POR pin reset and ICEPICK COLD reset. Packet traffic to/from the 3PSW host will be flushed/dropped, but the ethernet switch will remain operational for all traffic between external devices on the switch even though the device is undergoing a device reset. Pin mux configuration for ethernet related IO and reference clocks needed by the Ethernet switch IP to be active is controlled by a protected control module bit. If reset isolation is enabled, then only a POR pin or ICEPICK COLD reset event should fully reset the Ethernet switch IP including the actual switch and also the reference clocks and pin mux control specifically associated with the Ethernet IP.

9.2.7.1 Modes of Operation

The device has two modes of operation concerning the reset of the 3PSW Ethernet switch. The mode is controlled by the ISO_CONTROL bit in the RESET_ISO register of the device Control Module. This bit defaults to 0. Any modification of this bit first requires writing an unlock pattern to lock register in device control module. After modification, the bit should again be locked by writing appropriate value to the lock register. Writes to the ISO_CONTROL bit and to the lock register must all be supervisor mode writes.

Mode1: ISO_CONTROL = 0 (reset isolation disabled)

1. This mode is selected when the ISO_CONTROL bit = 0. This should be the default state of the bit after control module reset.
2. Upon any device level resets, the entire CPSW_3GSS_R IP, SATA_SS, SATA SERDES PLL, L3/L4, control module (including all pin mux control and the ISO_CONTROL bit) is immediately reset.

Mode2: ISO_CONTROL = 1 (reset isolation enabled)

1. This mode is selected when the ISO_CONTROL bit = 1.
2. Upon any device reset source other than POR pin or ICEPICK cold (so this includes SW global cold, any watchdog reset, warm RESETn pin, ICEPICK warm, SW global warm or security violation), the following should be true:
 - (a) The CPSW_3GSS_R is put into "isolate" mode and non-switch related portions of the IP are reset.
 - (b) The 50 MHz and 125 MHz reference clocks to the 3PSW Ethernet Subsystem remains active throughout the entire reset condition.
 - (c) The control for pin multiplexing for all of the signals should maintain their current configuration throughout the entire reset condition.
 - (d) The reset isolated logic inside 3PSW Ethernet Subsystem IP which maintains the switch functionality
3. Upon any cold reset sources, the entire 3PSW Ethernet Subsystem, SATA SERDES PLL, control module (including all pin mux control and the ISO_CONTROL bit itself) is reset.

For more details on the register configuration, see the Control Module RESET_ISO register.

9.2.8 CPSW_3G Network Statistics

The CPSW_3G has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of VBUSP_RST_N. When one or more port enable (Pn_STAT_EN) bits in the CPSW_STAT_PORT_EN register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing FFFF FFFFh clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, "the port" refers to any enabled port (with a corresponding set Pn_STAT_EN bit).

The statistics interrupt (STAT_PEND) will be issued if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

See [Section 9.4](#) for more details on the registers.

9.3 Software Operation

9.3.1 Transmit Operation

After reset, the host must write zeroes to all TX DMA State head descriptor pointers. The TX port may then be enabled. To initiate packet transmission the host constructs transmit queues in memory (one or more packets for transmission) and then writes the appropriate TX DMA state head descriptor pointers. For each buffer added to a transmit queue, the host must initialize the TX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Write the Buffer Length with the number of bytes in the buffer
4. Write the Buffer Offset with the number of bytes in the offset to the data (nonzero with SOP only)
5. Set the SOP, EOP, and Ownership bits as appropriate
6. Clear the End Of Queue bit

The port begins TX packet transmission on a given channel when the host writes the channel's TX queue head descriptor pointer with the address of the first buffer descriptor in the queue (nonzero value). Each channel may have one or more queues, so each channel may have one or more head descriptor pointers. The first buffer descriptor for each TX packet must have the Start of Packet (SOP) bit and the Ownership bit set to one by the host. The last buffer descriptor for each TX packet must have the End of Packet (EOP) bit set to one by the host. The port will transmit packets until all queued packets have been transmitted and the queue(s) are empty. When each packet transmission is complete, the port will clear the Ownership bit in the packet's SOP buffer descriptor and issue an interrupt to the host by writing the packet's last buffer descriptor address to the queue's TX DMA State Completion Pointer. The interrupt is generated by the write, regardless of the value written. When the last packet in a queue has been transmitted, the port sets the End Of Queue bit in the EOP buffer descriptor, clears the Ownership bit in the SOP Descriptor, zeroes the appropriate DMA state head descriptor pointer, and then issues a TX interrupt to the host by writing to the queue's associated TX completion pointer (address of the last buffer descriptor processed by the port). The port issues a maskable level interrupt (which may then be routed through external interrupt control logic to the host).

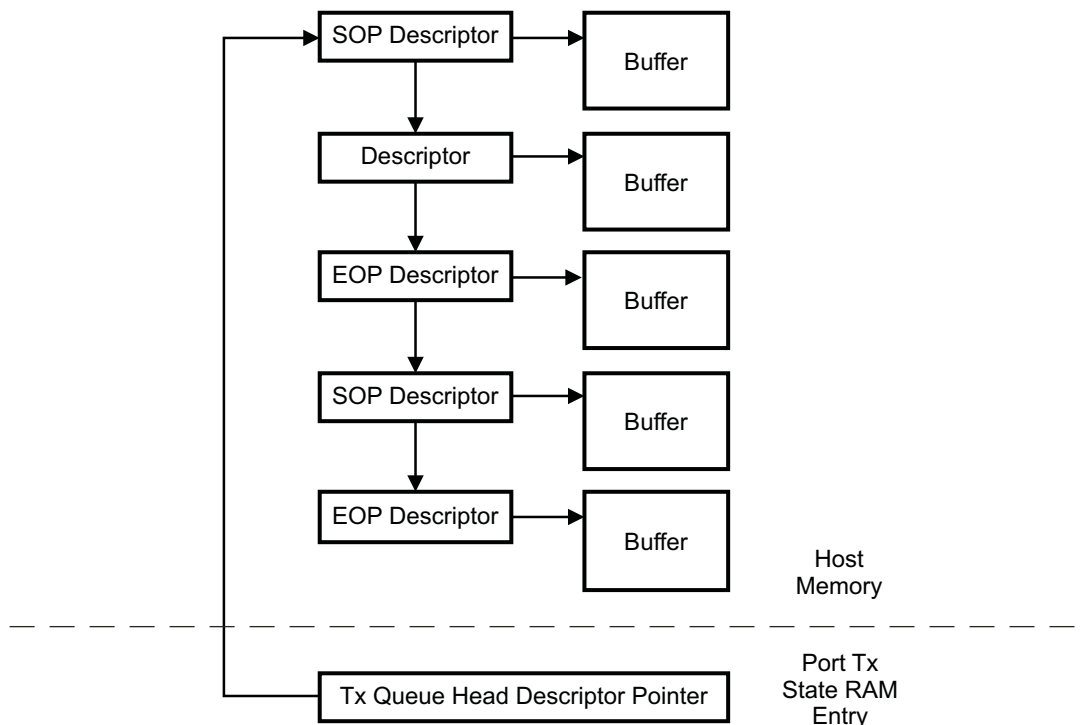

On interrupt from the port, the host processes the buffer queue, detecting transmitted packets by the status of the Ownership bit in the SOP buffer descriptor. If the Ownership bit is cleared to zero, then the packet has been transmitted and the host may reclaim the buffers associated with the packet. The host continues queue processing until the end of the queue or until a SOP buffer descriptor is read that contains a set Ownership bit indicating that the packet transmission is not complete. The host determines that all packets in the queue have been transmitted when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, the End of Queue bit is set in the last packet EOP buffer descriptor, and the Next Descriptor Pointer of the last packet EOP buffer descriptor is zero. The host acknowledges an interrupt by writing the address of the last buffer descriptor to the queue's associated TX Completion Pointer in the TX DMA State. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted. If the host written buffer address value is equal to the port written value, then the level interrupt is de-asserted. The port write to the completion pointer actually stores the value in the state register (ram). The host written value is actually not written to the register location. The host written value is compared to the register contents (which was written by the port) and if the two values are equal, the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

A mis-queued packet condition may occur when the host adds a packet to a queue for transmission as the port finishes transmitting the previous last packet in the queue. The mis-queued packet is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued packet means that the port read the last EOP buffer descriptor before the host added the new last packet to the queue, so the port determined queue empty just before the last packet was added. The host corrects the mis-queued packet condition by initiating a new packet transfer for the mis-queued packet by writing the mis-queued packet's SOP buffer descriptor address to the appropriate DMA State TX Queue head Descriptor Pointer.

The host may add packets to the tail end of an active TX queue at any time by writing the Next Descriptor Pointer to the current last descriptor in the queue. If a TX queue is empty (inactive), the host may initiate packet transmission at any time by writing the appropriate TX DMA State head descriptor pointer. The host software should always check for and reinitiate transmission for mis-queued packets during queue processing on interrupt from the port. In order to preclude software underrun, the host should avoid adding buffers to an active queue for any TX packet that is not complete and ready for transmission.

The port determines that a packet is the last packet in the queue by detecting the End of Packet bit set with a zero Next Descriptor Pointer in the packet buffer descriptor. If the End of Packet bit is set and the Next Descriptor Pointer is nonzero, then the queue still contains one or more packets to be transmitted. If the EOP bit is set with a zero Next Descriptor Pointer, then the port will set the EOQ bit in the packet's EOP buffer descriptor and then zero the appropriate head descriptor pointer previous to interrupting the port (by writing the completion pointer) when the packet transmission is complete.

Figure 9-14. TX Queue Head Descriptor

9.3.2 Receive Operation

After reset, the host must write zeroes to all RX DMA State head descriptor pointers. The RX port may then be enabled. To initiate packet reception, the host constructs receive queues in memory and then writes the appropriate RX DMA state head descriptor pointer. For each RX buffer descriptor added to the queue, the host must initialize the RX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Clear the Offset field
4. Write the Buffer Length with the number of bytes in the buffer
5. Clear the SOP, EOP, and EOQ bits
6. Set the Ownership bit

The host enables packet reception on a given channel by writing the address of the first buffer descriptor in the queue (nonzero value) to the channel's head descriptor pointer in the channel's RX DMA state. When packet reception begins on a given channel, the port fills each RX buffer with data in order starting with the first buffer and proceeding through the RX queue. If the Buffer Offset in the RX DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port performs the following operations at the end of each packet reception:

1. Overwrite the buffer length in the packet's EOP buffer descriptor with the number of bytes actually received in the packet's last buffer. The host initialized value is the buffer size. The overwritten value will be less than or equal to the host initialized value.
2. Set the EOP bit in the packet's EOP buffer descriptor.
3. Set the EOQ bit in the packet's EOP buffer descriptor if the current packet is the last packet in the queue.
4. Overwrite the packet's SOP buffer descriptor Buffer Offset with the RX DMA state value (the host initialized the buffer descriptor Buffer Offset value to zero). All non SOP buffer descriptors must have a zero Buffer Offset initialized by the host.
5. Overwrite the packet's SOP buffer descriptor buffer length with the number of valid data bytes in the buffer. If the buffer is filled up, the buffer length will be the buffer size minus buffer offset.
6. Set the SOP bit in the packet's SOP buffer descriptor.
7. Write the SOP buffer descriptor Packet Length field.
8. Clear the Ownership bit in the packet's SOP buffer descriptor.
9. Issue an RX host interrupt by writing the address of the packet's last buffer descriptor to the queue's RX DMA State Completion Pointer. The interrupt is generated by the write to the RX DMA State Completion Pointer address location, regardless of the value written.

On interrupt the host processes the RX buffer queue detecting received packets by the status of the Ownership bit in each packet's SOP buffer descriptor. If the Ownership bit is cleared then the packet has been completely received and is available to be processed by the host. The host may continue RX queue processing until the end of the queue or until a buffer descriptor is read that contains a set Ownership bit indicating that the next packet's reception is not complete. The host determines that the RX queue is empty when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and the Next Descriptor Pointer in the EOP buffer descriptor is zero.

A mis-queued buffer may occur when the host adds buffers to a queue as the port finishes the reception of the previous last packet in the queue. The mis-queued buffer is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued buffer means that the port read the last EOP buffer descriptor before the host added buffer descriptor(s) to the queue, so the port determined queue empty just before the host added more buffer descriptor(s). In the transmit case, the packet transmission is delayed by the time required for the host to determine the condition and reinitiate the transaction, but the packet is not actually lost. In the receive case, receive overrun condition may occur in the mis-queued buffer case. If a new packet reception is begun during the time that the port has determined the end of queue condition, then the received packet will overrun (start

of packet overrun). If the mis-queued buffer occurs during the middle of a packet reception then middle of packet overrun may occur. If the mis-queued buffer occurs after the last packet has completed, and is corrected before the next packet reception begins, then overrun will not occur. The host acts on the mis-queued buffer condition by writing the added buffer descriptor address to the appropriate RX DMA State Head Descriptor Pointer.

Figure 9-15. RX Queue Head Descriptor

9.3.3 MDIO Software Interface

9.3.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in CONTROL.
3. The MDIO PHY alive status register (ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (USERPHYSEL n), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) to use the MDIO user access register (USERACCESS n). Since only one PHY is used in this device, the application software can use one USERACCESS n to trigger a completion interrupt; the other USERACCESS n is not setup.

9.3.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (USERACCESS n) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS n) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in USERACCESS n corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in USERACCESS n for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS n used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

9.3.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (USERACCESS n) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS n) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in USERACCESS n corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in USERACCESS n after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in USERACCESS n . After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS n used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

9.3.4 Initialization and Configuration of CPSW

To configure the 3PSW Ethernet Subsystem for operation the host must perform the following:

1. Select the Interface (G/MII, RGMII, RMII) Mode
2. Configure pads (PIN muxing), as per the interface selected.
3. Enable the 3PSW Ethernet Subsystem Clocks
4. Configure the PRCM registers CM_ETHERNET_CLKSTCTRL, CM_ALWON_ETHERNET_0_CLKCTRL to enable power and clocks to 3PSW Ethernet Subsystem.
5. Apply Soft Reset to 3PSW Subsystem, CPSW_3G, CPGMAC_SL1/2, and CPDMA
6. Initialize the HDPs (Header Description Pointer) and CPs (Completion Pointer) to NULL
7. Configure the Interrupts
8. Configure the CPSW_3G CONTROL register
9. Configure the Statistics Port Enable register
10. Configure the ALE
11. Configure the MDIO
12. Configure the CPDMA receive DMA controller
13. Configure the CPDMA transmit DMA controller
14. Configure the CPPI TX and RX Descriptors
15. Configure CPGMAC_SL1 and CPGMAC_SL2, as per the desired mode of operations.
16. Start up RX and TX DMA (Write to HDP of RX and TX)
17. Wait for the completion of Transfer (HDP cleared to 0)

9.4 Registers

9.4.1 CPSW_3G Module

This section describes the memory-mapped registers for the CPSW_3G module. The base address of the CPSW_3G registers is 4A10 0000h. [Table 9-26](#) lists the memory-mapped registers for the CPSW_3G module.

Table 9-26. CPSW_3G Module Registers

Offset	Acronym	Register Name
000h	CPSW_ID_VER	CPSW ID Version Register
004h	CPSW_CONTROL	CPSW Switch Control Register
008h	CPSW_SOFT_RESET	CPSW Soft Reset Register
00Ch	CPSW_STAT_PORT_EN	CPSW Statistics Port Enable Register
010h	CPSW_PTYPE	CPSW Transmit Priority Type Register
014h	CPSW_SOFT_IDLE	CPSW Software Idle Register
018h	CPSW_THRU_RATE	CPSW Throughput Rate Register
01Ch	CPSW_GAP_THRESH	CPSW CPGMAC_SL Short Gap Threshold Register
020h	CPSW_TX_START_WDS	CPSW Transmit Start Words Register
024h	CPSW_FLOW_CONTROL	CPSW Flow Control Register
028h	P0_MAX_BLKs	CPSW Port 0 Maximum FIFO Blocks Register
02Ch	P0_BLK_CNT	CPSW Port 0 FIFO Block Usage Count Register (read only)
030h	P0_TX_IN_CTL	CPSW Port 0 Transmit FIFO Control Register
034h	P0_PORT_VLAN	CPSW Port 0 VLAN Register
038h	P0_TX_PRI_MAP	CPSW Port 0 TX Header Priority to Switch Priority Mapping Register
03Ch	CPDMA_TX_PRI_MAP	CPSW CPDMA TX (Port 0 RX) Packet Priority to Header Priority Mapping Register
040h	CPDMA_RX_CH_MAP	CPSW CPDMA RX (Port 0 TX) Switch Priority to DMA channel Mapping Register
050h	P1_MAX_BLKs	CPSW Port 1 Maximum FIFO Blocks Register
054h	P1_BLK_CNT	CPSW Port 1 FIFO Block Usage Count Register (read only)
058h	P1_TX_IN_CTL	CPSW Port 1 Transmit FIFO Control Register
05Ch	P1_PORT_VLAN	CPSW Port 1 VLAN Register
060h	P1_TX_PRI_MAP	CPSW Port 1 TX Header Priority to Switch Priority Mapping Register
064h	P1_TS_CTL	CPSW_3G Port 1 Time Sync Control Register
068h	P1_TS_SEQ_LTYPE	CPSW_3G Port 1 Time Sync LTYPE Register (and SEQ_ID_OFFSET)
06Ch	P1_TS_VLAN	CPSW_3G Port 1 Time Sync VLAN2 and VLAN2 Register
070h	SL1_SA_LO	CPSW CPGMAC_SL1 Source Address Low Register
074h	SL1_SA_HI	CPSW CPGMAC_SL1 Source Address High Register
078h	P1_SEND_PERCENT	CPSW Port 1 Transmit Queue Send Percentages Register
090h	P2_MAX_BLKs	CPSW Port 2 Maximum FIFO Blocks Register
094h	P2_BLK_CNT	CPSW Port 2 FIFO Block Usage Count Register (read only)
098h	P2_TX_IN_CTL	CPSW Port 2 Transmit FIFO Control Register
09Ch	P2_PORT_VLAN	CPSW Port 2 VLAN Register
0A0h	P2_TX_PRI_MAP	CPSW Port 2 TX Header Priority to Switch Priority Mapping Register
0A4h	P2_TS_CTL	CPSW_3GF Port 2 Time Sync Control Register
0A8h	P2_TS_SEQ_LTYPE	CPSW_3GF Port 2 Time Sync LTYPE Register (and SEQ_ID_OFFSET)
0ACh	P2_TS_VLAN	CPSW_3GF Port 2 Time Sync VLAN2 and VLAN2 Register
0B0h	SL2_SA_LO	CPSW CPGMAC_SL2 Source Address Low Register
0B4h	SL2_SA_HI	CPSW CPGMAC_SL2 Source Address High Register
0B8h	P2_SEND_PERCENT	CPSW Port 2 Transmit Queue Send Percentages
100h	TX_IDVER	CPDMA_REGS TX Identification and Version Register

Table 9-26. CPSW_3G Module Registers (continued)

Offset	Acronym	Register Name
104h	TX_CONTROL	CPDMA_REGS TX Control Register
108h	TX_TEARDOWN	CPDMA_REGS TX Teardown Register
110h	RX_IDVER	CPDMA_REGS RX Identification and Version Register
114h	RX_CONTROL	CPDMA_REGS RX Control Register
118h	RX_TEARDOWN	CPDMA_REGS RX Teardown Register
11Ch	SOFT_RESET	CPDMA_REGS Soft Reset Register
120h	DMACONTROL	CPDMA_REGS CPDMA Control Register
124h	DMASTATUS	CPDMA_REGS CPDMA Status Register
128h	RX_BUFFER_OFFSET	CPDMA_REGS Receive Buffer Offset Register
12Ch	EMCONTROL	CPDMA_REGS Emulation Control Register
130h	TX_PRI0_RATE	CPDMA_REGS Transmit (ingress) Priority 0 Rate Register
134h	TX_PRI1_RATE	CPDMA_REGS Transmit (ingress) Priority 1 Rate Register
138h	TX_PRI2_RATE	CPDMA_REGS Transmit (ingress) Priority 2 Rate Register
13Ch	TX_PRI3_RATE	CPDMA_REGS Transmit (ingress) Priority 3 Rate Register
140h	TX_PRI4_RATE	CPDMA_REGS Transmit (ingress) Priority 4 Rate Register
144h	TX_PRI5_RATE	CPDMA_REGS Transmit (ingress) Priority 5 Rate Register
148h	TX_PRI6_RATE	CPDMA_REGS Transmit (ingress) Priority 6 Rate Register
14Ch	TX_PRI7_RATE	CPDMA_REGS Transmit (ingress) Priority 7 Rate Register
180h	TX_INTSTAT_RAW	CPDMA_INT Transmit Interrupt Status Register (raw value)
184h	TX_INTSTAT_MASKED	CPDMA_INT Transmit Interrupt Status Register (masked value)
188h	TX_INTMASK_SET	CPDMA_INT Transmit Interrupt Mask Set Register
18Ch	TX_INTMASK_CLEAR	CPDMA_INT Transmit Interrupt Mask Clear Register
190h	CPDMA_IN_VECTOR	CPDMA_INT Input Vector (read only)
194h	CPDMA_EOI_VECTOR	CPDMA_INT End Of Interrupt Vector
1A0h	RX_INTSTAT_RAW	CPDMA_INT Receive Interrupt Status Register (raw value)
1A4h	RX_INTSTAT_MASKED	CPDMA_INT Receive Interrupt Status Register (masked value)
1A8h	RX_INTMASK_SET	CPDMA_INT Receive Interrupt Mask Set Register
1ACh	RX_INTMASK_CLEAR	CPDMA_INT Receive Interrupt Mask Clear Register
1B0h	DMA_INTSTAT_RAW	CPDMA_INT DMA Interrupt Status Register (raw value)
1B4h	DMA_INTSTAT_MASKED	CPDMA_INT DMA Interrupt Status Register (masked value)
1B8h	DMA_INTMASK_SET	CPDMA_INT DMA Interrupt Mask Set Register
1BCh	DMA_INTMASK_CLEAR	CPDMA_INT DMA Interrupt Mask Clear Register
1C0h	RX0_PENDTHRESH	CPDMA_INT Receive Channel 0 Threshold Pending Register
1C4h	RX1_PENDTHRESH	CPDMA_INT Receive Channel 1 Threshold Pending Register
1C8h	RX2_PENDTHRESH	CPDMA_INT Receive Channel 2 Threshold Pending Register
1CCh	RX3_PENDTHRESH	CPDMA_INT Receive Channel 3 Threshold Pending Register
1D0h	RX4_PENDTHRESH	CPDMA_INT Receive Channel 4 Threshold Pending Register
1D4h	RX5_PENDTHRESH	CPDMA_INT Receive Channel 5 Threshold Pending Register
1D8h	RX6_PENDTHRESH	CPDMA_INT Receive Channel 6 Threshold Pending Register
1DCh	RX7_PENDTHRESH	CPDMA_INT Receive Channel 7 Threshold Pending Register
1E0h	RX0_FREEBUFFER	CPDMA_INT Receive Channel 0 Free Buffer Register
1E4h	RX1_FREEBUFFER	CPDMA_INT Receive Channel 1 Free Buffer Register
1E8h	RX2_FREEBUFFER	CPDMA_INT Receive Channel 2 Free Buffer Register
1ECh	RX3_FREEBUFFER	CPDMA_INT Receive Channel 3 Free Buffer Register
1F0h	RX4_FREEBUFFER	CPDMA_INT Receive Channel 4 Free Buffer Register
1F4h	RX5_FREEBUFFER	CPDMA_INT Receive Channel 5 Free Buffer Register
1F8h	RX6_FREEBUFFER	CPDMA_INT Receive Channel 6 Free Buffer Register

Table 9-26. CPSW_3G Module Registers (continued)

Offset	Acronym	Register Name
1FCh	RX7_FREEBUFFER	CPDMA_INT Receive Channel 7 Free Buffer Register
200h	TX0_HDP	CPDMA_STATERAM TX Channel 0 Head Descriptor Pointer
204h	TX1_HDP	CPDMA_STATERAM TX Channel 1 Head Descriptor Pointer
208h	TX2_HDP	CPDMA_STATERAM TX Channel 2 Head Descriptor Pointer
20Ch	TX3_HDP	CPDMA_STATERAM TX Channel 3 Head Descriptor Pointer
210h	TX4_HDP	CPDMA_STATERAM TX Channel 4 Head Descriptor Pointer
214h	TX5_HDP	CPDMA_STATERAM TX Channel 5 Head Descriptor Pointer
218h	TX6_HDP	CPDMA_STATERAM TX Channel 6 Head Descriptor Pointer
21Ch	TX7_HDP	CPDMA_STATERAM TX Channel 7 Head Descriptor Pointer
220h	RX0_HDP	CPDMA_STATERAM RX 0 Channel 0 Head Descriptor Pointer
224h	RX1_HDP	CPDMA_STATERAM RX 1 Channel 1 Head Descriptor Pointer
228h	RX2_HDP	CPDMA_STATERAM RX 2 Channel 2 Head Descriptor Pointer
22Ch	RX3_HDP	CPDMA_STATERAM RX 3 Channel 3 Head Descriptor Pointer
230h	RX4_HDP	CPDMA_STATERAM RX 4 Channel 4 Head Descriptor Pointer
234h	RX5_HDP	CPDMA_STATERAM RX 5 Channel 5 Head Descriptor Pointer
238h	RX6_HDP	CPDMA_STATERAM RX 6 Channel 6 Head Descriptor Pointer
23Ch	RX7_HDP	CPDMA_STATERAM RX 7 Channel 7 Head Descriptor Pointer
240h	TX0_CP	CPDMA_STATERAM TX Channel 0 Completion Pointer Register
244h	TX1_CP	CPDMA_STATERAM TX Channel 1 Completion Pointer Register
248h	TX2_CP	CPDMA_STATERAM TX Channel 2 Completion Pointer Register
24Ch	TX3_CP	CPDMA_STATERAM TX Channel 3 Completion Pointer Register
250h	TX4_CP	CPDMA_STATERAM TX Channel 4 Completion Pointer Register
254h	TX5_CP	CPDMA_STATERAM TX Channel 5 Completion Pointer Register
258h	TX6_CP	CPDMA_STATERAM TX Channel 6 Completion Pointer Register
25Ch	TX7_CP	CPDMA_STATERAM TX Channel 7 Completion Pointer Register
260h	RX0_CP	CPDMA_STATERAM RX Channel 0 Completion Pointer Register
264h	RX1_CP	CPDMA_STATERAM RX Channel 1 Completion Pointer Register
268h	RX2_CP	CPDMA_STATERAM RX Channel 2 Completion Pointer Register
26Ch	RX3_CP	CPDMA_STATERAM RX Channel 3 Completion Pointer Register
270h	RX4_CP	CPDMA_STATERAM RX Channel 4 Completion Pointer Register
274h	RX5_CP	CPDMA_STATERAM RX Channel 5 Completion Pointer Register
278h	RX6_CP	CPDMA_STATERAM RX Channel 6 Completion Pointer Register
27Ch	RX7_CP	CPDMA_STATERAM RX Channel 7 Completion Pointer Register
400h	RXGOODFRAMES	CPSW_STATS Total number of good frames received
404h	RXBROADCASTFRAMES	CPSW_STATS Total number of good broadcast frames received
408h	RXMULTICASTFRAMES	CPSW_STATS Total number of good multicast frames received
40Ch	RXPAUSEFRAMES	CPSW_STATS Pause R xFrames
410h	RXCRCERRORS	CPSW_STATS Total number of CRC errors frames received
414h	RXALIGNCODEERRORS	CPSW_STATS Total number of alignment/code errors received
418h	RXOVERSIZEDFRAMES	CPSW_STATS Total number of oversized frames received
41Ch	RXJABBERFRAMES	CPSW_STATS Total number of jabber frames received
420h	RXUNDERSIZEDFRAMES	CPSW_STATS Total number of undersized frames received
424h	RXFRAGMENTS	CPSW_STATS RX Fragments received
430h	RXOCTETS	CPSW_STATS Total number of received bytes in good frames
434h	TXGOODFRAMES	CPSW_STATS Good TX Frames
438h	TXBROADCASTFRAMES	CPSW_STATS Broadcast TX Frames
43Ch	TXMULTICASTFRAMES	CPSW_STATS Multicast TX Frames

Table 9-26. CPSW_3G Module Registers (continued)

Offset	Acronym	Register Name
440h	TXPAUSEFRAMES	CPSW_STATS Pause TX Frames
444h	TXDEFERREDFRAMES	CPSW_STATS Deferred Frames
448h	TXCOLLISIONFRAMES	CPSW_STATS Collisions
44Ch	TXSINGLECOLLFRAMES	CPSW_STATS Single Collision TX Frames
450h	TXMULTCOLLFRAMES	CPSW_STATS Multiple Collision TX Frames
454h	TXEXCESSIVECOLLISIONS	CPSW_STATS Excessive Collisions
458h	TXLATECOLLISIONS	CPSW_STATS Late Collisions
45Ch	TXUNDERRUN	CPSW_STATS Transmit Underrun Error
460h	TXCARRIERSENSEERRORS	CPSW_STATS Carrier Sense Errors
464h	TXOCTETS	CPSW_STATS TX Octets
468h	64OCTETFRAMES	CPSW_STATS 64 Octet Frames
46Ch	65T127OCTETFRAMES	CPSW_STATS 65-127 Octet Frames
470h	128T255OCTETFRAMES	CPSW_STATS 128-255 Octet Frames
474h	256T511OCTETFRAMES	CPSW_STATS 256-511 Octet Frames
478h	512T1023OCTETFRAMES	CPSW_STATS 512-1023 Octet Frames
47Ch	1024TUPOCTETFRAMES	CPSW_STATS 1023-1518 Octet Frames
480h	NETOCTETS	CPSW_STATS Net Octets
484h	RXSOFOVERRUNS	CPSW_STATS Receive FIFO or DMA Start of Frame Overruns
488h	RXMOFOVERRUNS	CPSW_STATS Receive FIFO or DMA Mid of Frame Overruns
48Ch	RXDMAOVERRUNS	CPSW_STATS Receive DMA Start of Frame and Middle of Frame Overruns
500h	CPTS_IDVER	Identification and Version Register
504h	CPTS_CONTROL	Time Sync Control Register
508h	CPTS_RFTCLK_SEL	Reference Clock Select Register
50Ch	CPTS_TS_PUSH	Time Stamp Event Push Register
510h	CPTS_TS_LOAD_VAL	Time Stamp Load Value Register
514h	CPTS_TS_LOAD_EN	Time Stamp Load Enable Register
520h	CPTS_INTSTAT_RAW	Time Sync Interrupt Status Raw Register
524h	CPTS_INTSTAT_MASKED	Time Sync Interrupt Status Masked Register
528h	CPTS_INT_ENABLE	Time Sync Interrupt Enable Register
530h	CPTS_EVENT_POP	Event Interrupt Pop Register
534h	CPTS_EVENT_LOW	Lower 32-bits of the event value
538h	CPTS_EVENT_HIGH	Upper 32-bits of the event value
600h	ALE_IDVER	Address Lookup Engine ID/Version Register
608h	ALE_CONTROL	Address Lookup Engine Control Register
610h	ALE_PRESCALE	Address Lookup Engine Prescale Register
618h	ALE_UNKNOWN_VLAN	Address Lookup Engine Unknown VLAN Register
620h	ALE_TBLCTL	Address Lookup Engine Table Control Register
634h	ALE_TBLW2	Address Lookup Engine Table Word 2 Register
638h	ALE_TBLW1	Address Lookup Engine Table Word 1 Register
63Ch	ALE_TBLW0	Address Lookup Engine Table Word 0 Register
640h	ALE_PORTCTL0	Address Lookup Engine Port 0 Control Register
644h	ALE_PORTCTL1	Address Lookup Engine Port 1 Control Register
648h	ALE_PORTCTL2	Address Lookup Engine Port 2 Control Register
700h	SL1_IDVER	CPGMAC_SL1 ID/Version Register
704h	SL1_MACCONTROL	CPGMAC_SL1 Mac Control Register
708h	SL1_MACSTATUS	CPGMAC_SL1 Mac Status Register
70Ch	SL1_SOFT_RESET	CPGMAC_SL1 Soft Reset Register

Table 9-26. CPSW_3G Module Registers (continued)

Offset	Acronym	Register Name
710h	SL1_RX_MAXLEN	CPGMAC_SL1 RX Maximum Length Register
714h	SL1_BOFFTEST	CPGMAC_SL1 Backoff Test Register
718h	SL1_RX_PAUSE	CPGMAC_SL1 Receive Pause Timer Register
71Ch	SL1_TX_PAUSE	CPGMAC_SL1 Transmit Pause Timer Register
720h	SL1_EMCONTROL	CPGMAC_SL1 Emulation Control Register
724h	SL1_RX_PRI_MAP	CPGMAC_SL1 RX Packet Priority to Header Priority Mapping Register
740h	SL2_IDVER	CPGMAC_SL2 ID/Version Register
744h	SL2_MACCONTROL	CPGMAC_SL2 Mac Control Register
748h	SL2_MACSTATUS	CPGMAC_SL2 Mac Status Register
74Ch	SL2_SOFT_RESET	CPGMAC_SL2 Soft Reset Register
750h	SL2_RX_MAXLEN	CPGMAC_SL2 RX Maximum Length Register
754h	SL2_BOFFTEST	CPGMAC_SL2 Backoff Test Register
758h	SL2_RX_PAUSE	CPGMAC_SL2 Receive Pause Timer Register
75Ch	SL2_TX_PAUSE	CPGMAC_SL2 Transmit Pause Timer Register
760h	SL2_EMCONTROL	CPGMAC_SL2 Emulation Control Register
764h	SL2_RX_PRI_MAP	CPGMAC_SL2 RX Packet Priority to Header Priority Mapping Register

Table 9-27. Register Bit Definitions

Term	Definition
w	A writeable bit or field
wc	A Write-to-clear bit. Writing a bit of this type with a one will clear the bit to zero. Writing a zero to a bit of this type has no effect.
ws	A Write-to-set bit. Writing a bit of this type with a one will set the bit to one. Writing a zero to a bit of this type has no effect.
wi	A Write-to-increment field. Writing a value to this field increments the field value by the value written. Reads are permitted and do not alter the field value.
wd	A Write-to-decrement field. Writing a value to this field decrements the field by the value written. Reads are permitted and do not alter the field value.
r	A readable bit or field

9.4.1.1 CPSW ID Version Register (CPSW_ID_VER) (0x000)
Figure 9-16. CPSW ID Version Register (CPSW_ID_VER)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-28. CPSW ID Version Register (CPSW_ID_VER) Field Descriptions

Bit	Field	Value	Description
31-16	CPSW_3G_IDENT	0-FFFFh	CPSW_3G Identification Value.
15-11	CPSW_3G_RTL_VER	0-1Fh	CPSW_3G RTL Version Value.
10-8	CPSW_3G_MAJ_VER	0-7h	CPSW_3G Major Version Value.
7-0	CPSW_3G_MINOR_VER	0-FFh	CPSW_3G Minor Version Value.

9.4.1.2 CPSW Control Register (CPSW_CONTROL) (0x004)
Figure 9-17. CPSW Control Register (CPSW_CONTROL)

31	Reserved						8
R-0							
7	6	5	4	3	2	1	0
Reserved	P2_PASS_PRI_TAGGED	P1_PASS_PRI_TAGGED	P0_PASS_PRI_TAGGED	RX_VLAN_ENCAP	VLAN_AWARE	FIFO_LOOPBACK	
R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-29. CPSW Control Register (CPSW_CONTROL) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Read as zero.
5	P2_PASS_PRI_TAGGED	0 1	Port 2 Pass Priority Tagged Priority tagged packets have the zero VID replaced with the input port P2_PORT_VLAN[11:0] Priority tagged packets are processed unchanged.
4	P1_PASS_PRI_TAGGED	0 1	Port 1 Pass Priority Tagged Priority tagged packets have the zero VID replaced with the inputport P1_PORT_VLAN[11:0] Priority tagged packets are processed unchanged.
3	P0_PASS_PRI_TAGGED	0 1	Port 0 Pass Priority Tagged Priority tagged packets have the zero VID replaced with the inputport P0_PORT_VLAN[11:0] Priority tagged packets are processed unchanged.
2	RX_VLAN_ENCAP	0 1	Port 0 VLAN Encapsulation (egress) Port 0 receive packets (from CPSW_3G) are not VLAN encapsulated. Port 0 receive packets (from CPSW_3G) are VLAN encapsulated.
1	VLAN_AWARE	0 1	VLAN Aware Mode CPSW_3G is in the VLAN unaware mode. CPSW_3G is in the VLAN aware mode.
0	FIFO_LOOPBACK	0 1	FIFO Loopback Mode Loopback is disabled FIFO Loopback mode enabled. Each packet received is turned around and sent out on the same port's transmit path. Port 2 receive is fixed on channel zero. The RXSOFOVERRUN statistic will increment for every packet sent in FIFO loopback mode.

9.4.1.3 CPSW Software Reset Register (CPSW_SOFT_RESET) (0x008)

Figure 9-18. CPSW Software Reset Register (CPSW_SOFT_RESET)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-30. CPSW Software Reset Register (CPSW_SOFT_RESET) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Read as zero.
0	SOFT_RESET	0	If a zero is read then reset has occurred.
		1	Writing a one to this bit causes the CPSW_3G logic to be reset. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred.

9.4.1.4 CPSW Statistics Port Enable Register (CPSW_STAT_PORT_EN) (0x00C)

Figure 9-19. CPSW Statistics Port Enable Register (CPSW_STAT_PORT_EN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-31. CPSW Statistics Port Enable Register (CPSW_STAT_PORT_EN) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Read as zero.
2	P2_STAT_EN	0	Port 2 (EMAC1 and Port 2 FIFO) Statistics Enable Port 2 statistics are not enabled.
		1	Port 2 statistics are enabled.
1	P1_STAT_EN	0	Port 1 (EMAC0 and Port 1 FIFO) Statistics Enable Port 1 statistics are not enabled.
		1	Port 1 statistics are enabled.
0	P0_STAT_EN	0	Port 0 Statistics Enable Port 0 statistics are not enabled
		1	Port 0 statistics are enabled. FIFO overruns (SOFOVERRUNS) are the only port 0 statistics that are enabled to be kept.

9.4.1.5 CPSW Transmit Priority Type Register (CPSW_PTYPE) (0x010)
Figure 9-20. CPSW Transmit Priority Type Register (CPSW_PTYPE)

31	Reserved						24	
R-0								
23	22	21	20	19	18	17	16	
Reserved		P2_PRI3_SHAPE_EN	P2_PRI2_SHAPE_EN	P2_PRI1_SHAPE_EN	P1_PRI3_SHAPE_EN	P1_PRI2_SHAPE_EN	P1_PRI1_SHAPE_EN	
R-0		R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	
15	Reserved				11	10	9	8
R-0					P2_PTYPE_ESC	P1_PTYPE_ESC	P0_PTYPE_ESC	
R-0					R/W-0	R/W-0	R/W-0	
7	5	4		ESC_PRI_LD_VAL			0	
Reserved		ESC_PRI_LD_VAL						
R-0		R/W-0						

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-32. CPSW Transmit Priority Type Register (CPSW_PTYPE) Field Descriptions

Bit	Field	Value	Description
31-22	Reserved	0	Read as zero.
21	P2_PRI3_SHAPE_EN	0-1	Port 2 Queue Priority 3 Transmit Shape Enable If there is only one shaping queue then it must be priority 3.
20	P2_PRI2_SHAPE_EN	0-1	Port 2 Queue Priority 2 Transmit Shape Enable If there are two shaping queues then they must be priorities 3 and 2.
19	P2_PRI1_SHAPE_EN	0-1	Port 2 Queue Priority 1 Transmit Shape Enable If there are three shaping queues all three bits should be set.
18	P1_PRI3_SHAPE_EN	0-1	Port 1 Queue Priority 3 Transmit Shape Enable If there is only one shaping queue then it must be priority 3.
17	P1_PRI2_SHAPE_EN	0-1	Port 1 Queue Priority 2 Transmit Shape Enable If there are two shaping queues then they must be priorities 3 and 2.
16	P1_PRI1_SHAPE_EN	0-1	Port 1 Queue Priority 1 Transmit Shape Enable If there are three shaping queues all three bits should be set.
15-11	Reserved	0	Read as zero.
10	P2_PTYPE_ESC	0 1	Port 2 Priority Type Escalate 0 Port 2 priority type fixed 1 Port 2 priority type escalate. Escalate should not be used with queue shaping.
9	P1_PTYPE_ESC	0 1	Port 1 Priority Type Escalate 0 Port 1 priority type fixed 1 Port 1 priority type escalate. Escalate should not be used with queue shaping.
8	P0_PTYPE_ESC	0 1	Port 0 Priority Type Escalate 0 Port 0 priority type fixed 1 Port 0 priority type escalate. Escalate should not be used with queue shaping.
7-5	Reserved	0	Read as zero.
4-0	ESC_PRI_LD_VAL	0-1Fh	Escalate Priority Load Value When a port is in escalate priority, this is the number of higher priority packets sent before the next lower priority is allowed to send a packet. Escalate priority allows lower priority packets to be sent at a fixed rate relative to the next higher priority.

9.4.1.6 CPSW Software Idle Register (CPSW_SOFT_IDLE) (0x014)

Figure 9-21. CPSW Software Idle Register (CPSW_SOFT_IDLE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-33. CPSW Software Idle Register (CPSW_SOFT_IDLE) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Read as zero.
0	SOFT_IDLE		Software Idle Setting this bit causes the switch fabric to stop forwarding packets at the next start of packet.

9.4.1.7 CPSW Throughput Rate Register (CPSW_THRU_RATE) (0x018)

Figure 9-22. CPSW Throughput Rate Register (CPSW_THRU_RATE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-34. CPSW Throughput Rate Register (CPSW_THRU_RATE) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Read as zero.
15-12	SL_RX_THRU_RATE	0-Fh	CPGMAC_SL Switch FIFO receive through rate. This register value is the maximum throughput of the ethernet ports to the crossbar SCR. The default is one 8-byte word for every 3 CLK periods maximum.
11-4	Reserved	0	Read as zero.
3-0	CPDMA_THRU_RATE	0-Fh	CPDMA Switch FIFO receive through rate. This register value is the maximum throughput of the CPDMA host port to the crossbar SCR. The default is one 8-byte word for every 3 CLK periods maximum.

9.4.1.8 CPSW CPGMAC_SL Short Gap Threshold Register (CPSW_GAP_THRESH) (0x01C)
Figure 9-23. CPSW CPGMAC_SL Short Gap Threshold Register (CPSW_GAP_THRESH)

31	Reserved	5 4	0
	R-0		GAP_THRESH R/W-Bh

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-35. CPSW CPGMAC_SL Short Gap Threshold Register (CPSW_GAP_THRESH) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Read as zero.
4-0	GAP_THRESH	0-1Fh	CPGMAC_SL Short Gap Threshold This is the CPGMAC_SL associated FIFO transmit block usage value for triggering TX_SHORT_GAP

9.4.1.9 CPSW Transmit Start Words Register (CPSW_TX_START_WDS) (0x020)
Figure 9-24. CPSW Transmit Start Words Register (CPSW_TX_START_WDS)

31	Reserved	11 10	0
	R-0		TX_START_WDS R/W-20h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-36. CPSW Transmit Start Words Register (CPSW_TX_START_WDS) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	Read as zero.
10-0	TX_START_WDS	0-7FFh	FIFO Packet Transmit (egress) Start Words. This value is the number of required packet words in the transmit FIFO before the packet egress will begin. This value is non-zero to preclude underrun. 20h (decimal 32) is the recommended value, it should not be increased unnecessarily to prevent adding to the switch latency.

9.4.1.10 CPSW Flow Control Register (CPSW_FLOW_CONTROL) (0x024)

Figure 9-25. CPSW Flow Control Register (CPSW_FLOW_CONTROL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-37. CPSW Flow Control Register (CPSW_FLOW_CONTROL) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Read as zero.
2	P2_FLOW_EN	0-1	Port 2 Receive flow control enable.
1	P1_FLOW_EN	0-1	Port 1 Receive flow control enable.
0	P0_FLOW_EN	0-1	Port 0 Receive flow control enable.

9.4.1.11 CPSW Port 0 Maximum FIFO Blocks Register (P0_MAX_BLKs) (0x028)

Figure 9-26. CPSW Port 0 Maximum FIFO Blocks Register (P0_MAX_BLKs)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-38. CPSW Port 0 Maximum FIFO Blocks Register (P0_MAX_BLKs) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Read as zero.
8-4	P0_TX_MAX_BLKs	0-1Fh	Transmit FIFO Maximum Blocks This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 10h is the recommended value. Port 0 should remain in flow control mode. Eh is the minimum value.
3-0	P0_RX_MAX_BLKs	0-Fh	Receive FIFO Maximum Blocks This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. 4h is the recommended value, 3h is the minimum value, and 6h is the maximum value.

9.4.1.12 CPSW Port 0 FIFO Block Usage Count (Read Only) Register (P0_BLK_CNT) (0x02C)
Figure 9-27. CPSW Port 0 FIFO Block Usage Count (Read Only) Register (P0_BLK_CNT)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-39. CPSW Port 0 FIFO Block Usage Count (Read Only) Register (P0_BLK_CNT) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Read as zero.
8-4	P0_TX_BLK_CNT	0-1Fh	Port 0 Transmit Block Count Usage This value is the number of blocks allocated to the FIFO logical transmit queues.
3-0	P0_RX_BLK_CNT	0-Fh	Port 0 Receive Block Count Usage This value is the number of blocks allocated to the FIFO logical receive queues.

9.4.1.13 CPSW Port 0 Transmit FIFO Control Register (P0_TX_IN_CTL) (0x030)
Figure 9-28. CPSW Port 0 Transmit FIFO Control Register (P0_TX_IN_CTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-40. CPSW Port 0 Transmit FIFO Control Register (P0_TX_IN_CTL) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Read as zero.
23-20	TX_RATE_EN	0-Fh	Transmit FIFO Input Rate Enable
19-18	Reserved	0	Read as zero.
17-16	TX_IN_SEL	0 1h 2h 3h	Transmit FIFO Input Queue Type Select Normal priority mode Dual MAC mode Rate Limit mode Reserved Note: Dual MAC mode is not compatible with escalation or shaping because dual mac mode forces round robin priority on FIFO egress.
15-12	TX_BLKES_REM	0-Fh	Transmit FIFO Input Blocks to subtract in dual mac mode.
11-10	Reserved	0	Read as zero.
9-0	TX_PRI_WDS	0-3FFh	Transmit FIFO Words in queue.

9.4.1.14 CPSW Port 0 VLAN Register (P0_PORT_VLAN) (0x034)

Figure 9-29. CPSW Port 0 VLAN Register (P0_PORT_VLAN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-45. CPSW Port 1 Maximum FIFO Blocks Register (P1_MAX_BLKs) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Read as zero.
8-4	P1_TX_MAX_BLKs	0-1Fh	Transmit FIFO Maximum Blocks. This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 11h is the recommended value of P1_TX_MAX_BLKs, unless the port is in fullduplex flow control mode. In flow control mode, the P1_RX_MAX_BLKs will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in P1_RX_MAX_BLKs. Eh is the minimum value TX_MAX_BLKs.
3-0	P1_RX_MAX_BLKs	0-Fh	Receive FIFO Maximum Blocks. This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 3h. It should be increased in fullduplex flow control mode to 5h or 6h, depending on the required run out space. The P1_TX_MAX_BLKs value must be decreased by the amount of increase in P1_RX_MAX_BLKs. 3h is the minimum value and 6h is the maximum value.

9.4.1.28 CPSW Port 1 Transmit Queue Send Percentages Register (P1_SEND_PERCENT) (0x078)
Figure 9-43. CPSW Port 1 Transmit Queue Send Percentages Register (P1_SEND_PERCENT)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-55. CPSW Port 1 Transmit Queue Send Percentages Register (P1_SEND_PERCENT) Field Descriptions

Bit	Field	Value	Description
31-23	Reserved	0	Read as zero.
22-16	PRI3_SEND_PERCENT	0-7Fh	Priority 3 Transmit Percentage This percentage value is sent from FIFO priority 3 (maximum) when the P1_PRI3_SHAPE_EN is set (queue shaping enabled). This is the percentage of the wire that packets from priority 3 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue, then this value must be between 0 and 64h (decimal 100 (not inclusive)).
15	Reserved	0	Read as zero.
14-8	PRI2_SEND_PERCENT	0-7Fh	Priority 2 Transmit Percentage This percentage value is sent from FIFO priority 2 (maximum) when the P1_PRI2_SHAPE_EN is set (queue shaping enabled). This is the percentage of the wire that packets from priority 2 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue, then this value must be between 0 and 64h (decimal 100 (not inclusive)).
7	Reserved	0	Read as zero.
6-0	PRI1_SEND_PERCENT	0-7Fh	Priority 1 Transmit Percentage This percentage value is sent from FIFO priority 1 (maximum) when the P1_PRI1_SHAPE_EN is set (queue shaping enabled). This is the percentage of the wire that packets from priority 1 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue, then this value must be between 0 and 64h (decimal 100 (not inclusive)).

9.4.1.29 CPSW Port 2 Maximum FIFO Blocks Register (P2_MAX_BLKs) (0x090)

Figure 9-44. CPSW Port 2 Maximum FIFO Blocks Register (P2_MAX_BLKs)

31	9	8	4	3	0
Reserved			P2_TX_MAX_BLKs	P2_RX_MAX_BLKs	
R-0			R/W-11h	R/W-3h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-56. CPSW Port 2 Maximum FIFO Blocks Register (P2_MAX_BLKs) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Read as zero.
8-4	P2_TX_MAX_BLKs	0-1Fh	Transmit FIFO Maximum Blocks This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 11h is the recommended value of P2_TX_MAX_BLKs unless the port is in fullduplex flow control mode. In flow control mode, the P2_RX_MAX_BLKs will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in P2_RX_MAX_BLKs. Eh is the minimum value TX_MAX_BLKs.
3-0	P2_RX_MAX_BLKs	0-Fh	Receive FIFO Maximum Blocks This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 3h. It should be increased in fullduplex flow control mode to 5h or 6h, depending on the required runout space. The P2_TX_MAX_BLKs value must be decreased by the amount of increase in P2_RX_MAX_BLKs. 3h is the minimum value RX_MAX_BLKs and 6h is the maximum value.

9.4.1.30 CPSW Port 2 FIFO Block Usage Count (Read Only) Register (P2_BLK_CNT) (0x094)

	R-0		SOFT_RESET R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-73. CPDMA_REGS Software Reset Register (SOFT_RESET) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Read as zero
0	SOFT_RESET		Software reset. Writing a one to this bit causes the CPDMA logic to be reset. Software reset occurs when the RX and TX DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.

9.4.1.47 CPDMA_REGS Control Register (DMACONTROL) (0x120)

Figure 9-62. CPDMA_REGS Control Register (DMACONTROL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-74. CPDMA_REGS Control Register (DMACONTROL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Read as zero
15-8	TX_RLIM	0 80h C0h E0h F0h F8h FCh FEh FFh	Transmit Rate Limit Channel Bus No rate-limited channels Channel 7 is rate-limited Channels 7 to 6 are rate-limited Channels 7 to 5 are rate-limited Channels 7 to 4 are rate-limited Channels 7 to 3 are rate-limited Channels 7 to 2 are rate-limited Channels 7 to 1 are rate-limited Channels 7 to 0 are rate-limited All others invalid – this bus must be set MSB towards LSB. TX_PTYPE must be set, if any TX_RLIM bit is set for fixed priority.
7-5	Reserved	0	Read as zero
4	RX_CEF	0 1	RX Copy Error Frames Enable. Enables DMA overrun frames to be transferred to memory (up to the point of overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when RX_CEF is not set. Frames coming from the receive FIFO with other error bits set are not effected by this bit. 0 Frames containing overrun errors are filtered. 1 Frames containing overrun errors are transferred to memory.

Table 9-74. CPDMA_REGS Control Register (DMACONTROL) Field Descriptions (continued)

Bit	Field	Value	Description
3	CMD_IDLE	0	Command Idle Idle not commanded
		1	Idle Commanded (read idle in DMAStatus)
2	RX_OFFLEN_BLOCK	0	Receive Offset/Length word write block Do not block the DMA writes to the receive buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0.
		1	Block all CPDMA DMA controller writes to the receive buffer descriptor offset/buffer length words during CPPI packet processing. when this bit is set, the CPDMA will never write the third word to any receive buffer descriptor.
1	RX_OWNERSHIP	0	Receive Ownership Write Bit Value The CPDMA writes the receive ownership bit to zero at the end of packet processing as specified in CPPI 3.0.
		1	The CPDMA writes the receive ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.
0	TX_PTYPE	0	Transmit Queue Priority Type The queue uses a round robin scheme to select the next channel for transmission.
		1	The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel for transmission.

Table 9-75. CPDMA_REGS Status Register (DMASTATUS) Field Descriptions

Bit	Field	Value	Description
31	IDLE		Idle Status Bit – Indicates when set that the CPDMA is not transferring a packet on transmit or receive.
30-24	Reserved	0	Read as zero
23-20	TX_HOST_ERR_CODE	0 No error 1h SOP error 2h Ownership bit not set in SOP buffer 3h Zero Next Buffer Descriptor Pointer Without EOP 4h Zero Buffer Pointer 5h Zero Buffer Length 6h Packet Length Error (sum of buffers < packet length) 7h-Fh Reserved	TX Host Error Code – This field is set to indicate CPDMA detected TX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. A zero packet length is an error, but it is not detected.
19	Reserved	0	Read as zero
18-16	TX_ERR_CH	0-7h	TX Host Error Channel – This field indicates which TX channel (if applicable) the host error occurred on. This field is cleared to zero on a host read. The host error occurred on TX channel 0 to TX channel 7
15-12	RX_HOST_ERR_CODE	0 No error 1h Reserved 2h Ownership bit not set in input buffer 3h Reserved 4h Zero Buffer Pointer 5h Zero buffer length on non-SOP descriptor 6h SOP buffer length not greater than offset 7h-Fh Reserved	RX Host Error Code – This field is set to indicate CPDMA detected RX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover.
11	Reserved	0	Read as zero
10-8	RX_ERR_CH	0-7h	RX Host Error Channel – This field indicates which RX channel the host error occurred on. This field is cleared to zero on a host read. The host error occurred on RX channel 0 to RX channel 7
7-0	Reserved	0	Read as zero

9.4.1.49 CPDMA_REGS Receive Buffer Offset Register (RX_BUFFER_OFFSET) (0x128)
Figure 9-64. CPDMA_REGS Receive Buffer Offset Register (RX_BUFFER_OFFSET)

31	16	15	0
Reserved		RX_BUFFER_OFFSET	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-76. CPDMA_REGS Receive Buffer Offset Register (RX_BUFFER_OFFSET) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Read as zero
15-0	RX_BUFFER_OFFSET		Receive Buffer Offset Value. The RX_BUFFER_OFFSET will be written by the port into each frame SOP buffer descriptor BUFFER_OFFSET field. The frame data will begin after the RX_BUFFER_OFFSET value of bytes. A value of 0 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.

9.4.1.50 CPDMA_REGS Emulation Control Register (EMCONTROL) (0x12C)
Figure 9-65. CPDMA_REGS Emulation Control Register (EMCONTROL)

Table 9-92. CPDMA_INT DMA Interrupt Mask Clear Register (DMA_INTMASK_CLEAR) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Read as zero.
1	HOST_ERR_INT_MASK	0-1	Host Error Interrupt Mask - Write one to disable interrupt.
0	STAT_INT_MASK	0-1	Statistics Interrupt Mask - Write one to disable interrupt.

9.4.1.66 CPDMA_INT RX Channel Threshold Pending Registers (RX0_PENDTHRESH-RX7_PENDTHRESH) (0x1C0-0x1DC)

Figure 9-81. CPDMA_INT RX Channel Threshold Pending Channel Registers

31	Reserved	8 7	0
	R-0		RX(0..7)_PENDTHRESH R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-93. CPDMA_INT RX Channel Threshold Pending Channel Registers Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Read as zero.
7-0	RX(0..7)_PENDTHRESH	0-FFh	RX Flow Threshold. This field contains the threshold value for issuing receive threshold pending interrupts (when enabled).

9.4.1.67 CPDMA_INT RX Channel Free Buffer Count Registers (RX0_FREEBUFFER-RX7_FREEBUFFER) (0x1E0-0x1FC)

Figure 9-82. CPDMA_INT RX Channel Free Buffer Count Registers

31	Reserved	16 15	0
	R-0		RX(0..7)_FREEBUF WI-0

LEGEND: R/W = Read/Write; WI = Write to increment field; R = Read only; -n = value after reset

Table 9-94. CPDMA_INT RX Channel Free Buffer Count Registers Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Read as zero.
15-0	RX(0..7)_FREEBUF	0-FFFFh	RX Free Buffer Count. This field contains the count of free buffers available. The RX_PENDTHRESH value is compared with this field to determine if the receive threshold pending interrupt should be asserted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If receive threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the received frame) the associated channel register for each received frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing.

9.4.1.68 CPDMA_STATERAM TX Channel Head Descriptor Pointers (TX0_HDP-TX7_HDP) (0x200-0x21C)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; X = Unknown

Table 9-95. CPDMA_STATERAM TX Channel Head Descriptor Pointers Field Descriptions

Bit	Field	Value	Description
31-0	TX(0..7)_HDP	0-FFFF FFFFh	TX Channel (0..7) DMA Head Descriptor Pointer. Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

9.4.1.69 CPDMA_STATERAM RX Channel Head Descriptor Pointers (RX0_HDP-RX7_HDP) (0x220-0x23C)
Figure 9-84. CPDMA_STATERAM RX Channel Head Descriptor Pointers

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; X = Unknown

Table 9-96. CPDMA_STATERAM RX Channel Head Descriptor Pointers Field Descriptions

Bit	Field	Value	Description
31-0	RX(0..7)_HDP	0-FFFF FFFFh	RX DMA Head Descriptor Pointer. Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

9.4.1.70 CPDMA_STATERAM TX Channel Completion Pointer Registers (TX0_CP-TX7_CP) (0x240-0x25C)
Figure 9-85. CPDMA_STATERAM TX Channel Completion Pointer Registers

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; X = Unknown

Table 9-97. CPDMA_STATERAM TX Channel Completion Pointer Registers Field Descriptions

Bit	Field	Value	Description
31-0	TX(0..7)_CP	0-FFFF FFFFh	TX Completion Pointer Register. This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted.

9.4.1.71 CPDMA_STATERAM RX Channel Completion Pointer Registers (RX0_CP-RX7_CP) (0x260-0x27C)

The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port). The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted. The value written is not actually stored in the location. The interrupt is deasserted if the two values are equal.

Figure 9-86. CPDMA_STATERAM RX Channel Completion Pointer Registers

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; X = Unknown

Table 9-98. CPDMA_STATERAM RX Channel Completion Pointer Registers Field Descriptions

Bit	Field	Value	Description
31-0	RX(0..7)_CP	0-FFFF FFFFh	RX Completion Pointer Register. This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted.

9.4.1.72 RX (only) Statistics Descriptions (0x400-0x430)

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero 38 clocks after the rising edge of reset. When the GMII_EN bit in the MAC control register is set, all statistics registers (see [Figure 9-87](#)) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMII_EN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

LEGEND: R/W = Read/Write; WD = Write to decrement; -n = value after reset

9.4.1.72.1 Good RX Frames (0x400)

The total number of good frames received on the port. A good frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.1.72.2 Broadcast RX Frames (0x404)

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- any data or MAC control frame which was destined for address FFFF FFFF FFFFh only, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.1.72.3 Multicast RX Frames (0x408)

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- any data or MAC control frame which was destined for any multicast address other than FFFF FFFF FFFFh, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.1.72.4 Pause RX Frames (0x40C)

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- contained any unicast, broadcast, or multicast address, and
- contained the length/type field value 88.08 (hex) and the opcode 0001h, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no CRC error, alignment error or code error, and
- pause-frames had been enabled on the port (tx_flow_en = 1).

The port could have been in either half or full-duplex mode.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic

9.4.1.72.5 RX CRC Errors (0x410)

The total number of frames received on the port that experienced a CRC error. Such a frame:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no code/align error, and
- had a CRC error.

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- a frame containing an even number of nibbles, and
- fails the Frame Check Sequence test.

9.4.1.72.6 RX Align/Code Errors (0x414)

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had either an alignment error or a code error.

Over-runs have no effect upon this statistic.

An alignment error is defined to be:

- a frame containing an odd number of nibbles, and
- also fails the Frame Check Sequence test if the final nibble is ignored.

A code error is defined to be:

- a frame which has been discarded because the ports **MRXER** pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

Note: RFC 1757 etherStatsCRCAAlignErrors Ref. 1.5 can be calculated by summing **RX Align/Code Errors** and **RX CRC errors**.

9.4.1.72.7 Oversize RX Frames (0x418)

The total number of oversized frames received on the port. An oversized frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was greater than RX_MAXLEN in bytes, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.1.72.8 RX Jabbers (0x41C)

The total number of jabber frames received on the port. A jabber frame is:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was greater than RX_MAXLEN bytes long, and
- had a CRC error, an alignment error, or a code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.1.72.9 Undersize (Short) RX Frames (0x420)

The total number of undersized frames received on the port. An undersized frame is defined to be:

- any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was less than 64 bytes long, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.1.72.10 RX Fragments (0x424)

The total number of frame fragments received on the port. A frame fragment is defined to be:

- any data frame (address matching does not matter), and
- was less than 64 bytes long, and
- had a CRC error, an alignment error, or a code error, and
- was not the result of a collision caused by half duplex, collision based flow control.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.1.72.11 RX Octets (0x430)

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.1.72.12 RX Start of Frame Overruns (0x484)

The total number of frames received on the port that had a CPDMA start of frame (SOF) overrun or were dropped by due to FIFO resource limitations. SOF overrun frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > RX_MAXLEN bytes), and
- The CPDMA had a start of frame overrun or the packet was dropped due to FIFO resource limitations.

9.4.1.72.13 RX Middle of Frame Overruns (0x488)

The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > RX_MAXLEN bytes), and
- the CPDMA had a middle of frame overrun.

9.4.1.72.14 RX DMA Overruns (0x48C)

The total number of frames received on the port that had either a DMA start of frame (SOF) overrun or a DMA MOF overrun. An RX DMA overrun frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > RX_MAXLEN bytes), and
- the CPGMAC_SL was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception).

CRC errors, alignment errors and code errors have no effect upon this statistic.

9.4.1.73 TX (only) Statistics Descriptions (0x434 -0x464)

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero 38 clocks after the rising edge of reset. When the GMII_EN bit in the MAC control register is set, all statistics registers (see [Figure 9-88](#)) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMII_EN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

The maximum and minimum transmit frame size is software controllable.

Figure 9-88. Statistics Register

LEGEND: R/W = Read/Write; WD = Write to decrement; -n = value after reset

9.4.1.73.1 Good TX Frames (0x434)

The total number of good frames transmitted on the port. A good frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- was any length, and
- had no late or excessive collisions, no carrier loss and no underrun.

9.4.1.73.2 Broadcast TX Frames (0x438)

The total number of good broadcast frames transmitted on the port. A good broadcast frame is defined to be:

- any data or MAC control frame destined for address FFFF FFFF FFFFh only, and
- was of any length, and
- had no late or excessive collisions, no carrier loss and no underrun

9.4.1.73.3 Multicast TX Frames (0x43C)

The total number of good multicast frames transmitted on the port. A good multicast frame is defined to be:

- any data or MAC control frame destined for any multicast address other than FFFF FFFF FFFFh, and
- was of any length, and
- had no late or excessive collisions, no carrier loss and no underrun.

9.4.1.73.4 **Pause TX Frames (0x440)**

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64 byte multicast frames so will appear in the **TX Multicast Frames** and **64octect Frames** statistics.

9.4.1.73.5 **Deferred TX Frames (0x444)**

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced no collisions before being successfully transmitted, and
- found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic

See RFC1623 Ref. 2.6 dot3StatsDeferredTransmissions.

9.4.1.73.6 **Collisions (0x448)**

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

- When a transmit data or MAC control frame...
- was destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions).

CRC errors have no effect upon this statistic.

- When the port is in half-duplex mode, flow control is active, and a frame reception begins.

9.4.1.73.7 **Single Collision TX Frames (0x44C)**

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

9.4.1.73.8 Multiple Collision TX Frames (0x450)

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

9.4.1.73.9 Excessive Collisions (0x454)

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

9.4.1.73.10 Late Collisions (0x458)

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The **Late Collisions** statistic dominates over the **single**, **multiple**, and **excessive Collisions** statistics - if a late collision occurs the frame will not be counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect upon this statistic.

9.4.1.73.11 TX Underrun (0x45C)

There should be no transmitted frames that experience underrun.

9.4.1.73.12 Carrier Sense Errors (0x460)

The total number of frames on the port that experienced carrier loss. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- the carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.
- CRC errors and underrun have no effect upon this statistic.

9.4.1.73.13 TX Octets (0x464)

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no late or excessive collisions, no carrier loss and no underrun.

9.4.1.74 RX and TX (shared) Statistics Descriptions (0x468-0x480)

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero, 38 clocks after the rising edge of reset. When the GMII_EN bit in the MAC control register is set, all statistics registers (see Figure 9-89) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMII_EN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

Figure 9-89. Statistics Register

LEGEND: R/W = Read/Write; WD = Write to decrement; -n = value after reset

9.4.1.74.1 RX + TX 64 Octet Frames (0x468)

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

9.4.1.74.2 RX + TX 65-127 Octet Frames (0x46C)

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 65 to 127 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

9.4.1.74.3 RX + TX 128-255 Octet Frames (0x470)

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 128 to 255 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

For RX reference only, see RFC1757 Ref. 1.13 etherStatsPkts128to255Octets.

9.4.1.74.4 **RX + TX 256-511 Octet Frames (0x474)**

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 256 to 511 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

9.4.1.74.5 **RX + TX 512-1023 Octet Frames (0x478)**

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 512 to 1023 bytes long.

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

9.4.1.74.6 **RX + TX 1024_Up Octet Frames (0x47C)**

The total number of frames of size 1024 to RX_MAXLEN bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 1024 to RX_MAXLEN bytes long on receive, or any size on transmit.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

9.4.1.74.7 **Network Octet Frames (0x480)**

The total number of bytes of frame data received and transmitted on the EMAC. Each frame counted has all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address (address match does not matter)
- Was of any size (including less than 64-byte and greater than RX_MAXLEN-byte frames)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced (multiple retries are counted each time)
- Every byte received if the EMAC is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence is not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns, and underruns do not affect the recording of bytes in this statistic. The objective of this statistic is to give a reasonable indication of Ethernet utilization.

31-5	Reserved	0	Reserved
4-0	RFTCLK_SEL	0-1Fh	Reference Clock Select. This signal is used to control an external multiplexer that selects one of up to 32 clocks for time sync reference (RFTCLK). This RFTCLK_SEL value can be written only when the CPTS_EN bit is cleared to 0 in the TS_Control register.

9.4.1.78 Time Stamp Event Push Register (CPTS_TS_PUSH) (0x50C)

Figure 9-93. Time Stamp Event Push Register (CPTS_TS_PUSH)

31	Reserved	1	0
	R-0		TS_PUSH W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-102. Time Stamp Event Push Register (CPTS_TS_PUSH) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	TS_PUSH	0-1	Time stamp event push. When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero.

9.4.1.79 Time Stamp Load Value Register (CPTS_TS_LOAD_VAL) (0x510)

Figure 9-94. Time Stamp Load Value Register (CPTS_TS_LOAD_VAL)

31	TS_LOAD_VAL	0
	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-103. Time Stamp Load Value Register (CPTS_TS_LOAD_VAL) Field Descriptions

Bit	Field	Value	Description
31-0	TS_LOAD_VAL	0-FFFF FFFFh	Time Stamp Load Value. Writing the TS_LOAD_EN bit in the CPTS_TS_LOAD_EN register causes the value contained in this register to be written into the time stamp. The time stamp value is read by initiating a time stamp push event, not by reading this register. When reading this register, the value read is not the time stamp, but is the value that was last written to this register.

9.4.1.80 Time Stamp Load Enable Register (CPTS_TS_LOAD_EN) (0x514)

Figure 9-95. Time Stamp Load Enable Register (CPTS_TS_LOAD_EN)

31	1	0
Reserved		TS_LOAD_EN
R-0		W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-104. Time Stamp Load Enable Register (CPTS_TS_LOAD_EN) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	TS_LOAD_EN	0-1	Time Stamp Load. Writing a 1 to this bit enables the time stamp value to be written via the CPTS_TS_LOAD_VAL register. This feature is included for test purposes. This bit is write only.

9.4.1.81 Time Sync Interrupt Status Register Raw Register (CPTS_INTSTAT_RAW) (0x520)

Figure 9-96. Time Sync Interrupt Status Register Raw Register (CPTS_INTSTAT_RAW)

31	1	0
Reserved		TS_PEND_RAW
R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-105. Time Sync Interrupt Status Register Raw Register (CPTS_INTSTAT_RAW) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	TS_PEND_RAW	0-1	TS_PEND_RAW interrupt read (before enable). Writable when INT_TEST = 1. A 1 in this bit indicates that there is one or more events in the event FIFO.

9.4.1.82 Time Sync Interrupt Status Register Masked Register (CPTS_INTSTAT_MASKED) (0x524)

Figure 9-97. Time Sync Interrupt Status Register Masked Register (CPTS_INTSTAT_MASKED)

31	1	0
Reserved		TS_PEND
R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-106. Time Sync Interrupt Status Register Masked Register (CPTS_INTSTAT_MASKED) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	TS_PEND	0-1	TS_PEND masked interrupt read (after enable).

9.4.1.83 Time Sync Interrupt Enable Register (CPTS_INT_ENABLE) (0x528)

Figure 9-98. Time Sync Interrupt Enable Register (CPTS_INT_ENABLE)

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	TS_PEND_EN	0-1	TS_PEND masked interrupt enable.

9.4.1.84 Event Interrupt Pop Register (CPTS_EVENT_POP) (0x530)

Figure 9-99. Event Interrupt Pop Register (CPTS_EVENT_POP)

31	Reserved	1	0
			EVENT_POP
R-0			W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-108. Event Interrupt Pop Register (CPTS_EVENT_POP) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	EVENT_POP	0-1	Event Pop. When a logic high is written to this bit an event is popped off the event FIFO. The event FIFO pop occurs as part of the interrupt process after the event has been read in the EVENT_LOW and EVENT_HIGH registers. Popping an event discards the event and causes the next event, if any, to be moved to the top of the FIFO ready to be read by software on interrupt.

9.4.1.85 Event Low Register (CPTS_EVENT_LOW) (0x534)

Figure 9-100. Event Low Register (CPTS_EVENT_LOW)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-112. ALE Control Register (ALE_CONTROL) Field Descriptions

Bit	Field	Value	Description
31	ENABLE_ALE	0-1	Enable ALE
30	CLEAR_TABLE	0-1	Clear ALE address table. Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.
29	AGE_OUT_NOW	0-1	Age Out Address Table Now. Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes 4096 clocks best case (no ale packet processing during ageout) and 66550 clocks absolute worst case.
28-8	Reserved	0	Reserved
7	LEARN_NO_VID	0 1	Learn No VID 0 VID is learned with the source address 1 VID is not learned with the source address (source address is not tied to VID).
6	EN_VID0_MODE	0 1	Enable VLAN ID = 0 Mode 0 Process the packet with VID = PORT_VLAN[11:0]. 1 Process the packet with VID = 0.
5	ENABLE_OUI_DENY	0-1	Enable OUI Deny Mode. When set this bit indicates that a packet with a non OUI table entry matching source address will be dropped to the host unless the destination address matches a multicast table entry with the super bit set.
4	ALE_BYPASS	0-1	ALE Bypass. When set, all packets received on ports 1 and 2 are sent to the host (only to the host).
3	RATE_LIMIT_TX	0 1	Rate Limit Transmit mode 0 Broadcast and multicast rate limit counters are received port based 1 Broadcast and multicast rate limit counters are transmit port based.
2	ALE_VLAN_AWARE	0 1	ALE VLAN Aware. Determines what is done if VLAN not found. 0 Flood if VLAN not found 1 Drop packet if VLAN not found

Table 9-112. ALE Control Register (ALE_CONTROL) Field Descriptions (continued)

Bit	Field	Value	Description
1	ENABLE_AUTH_MODE		Enable MAC Authorization Mode. Mac authorization mode requires that all table entries be made by the host software. There are no learned address in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set).
		0	The ALE is not in MAC authorization mode
0	ENABLE_RATE_LIMIT	1	The ALE is in MAC authorization mode
		0	Enable Broadcast and Multicast Rate Limit Broadcast/Multicast rates not limited
		1	Broadcast/Multicast packet reception limited to the port control register rate limit fields.

9.4.1.89 Address Lookup Engine Prescale Register (ALE_PRESCALE) (0x610)
Figure 9-104. ALE Prescale Register (ALE_PRESCALE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-113. ALE Prescale Register (ALE_PRESCALE) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	Reserved
19-0	ALE_PRESCALE	0-F FFFFh	ALE Prescale Register. The input clock is divided by this value for use in the multicast/broadcast rate limiters. The minimum operating value is 10h. The prescaler is off when the value is zero.

9.4.1.90 Address Lookup Engine Unknown VLAN Register (ALE_UNKNOWN_VLAN) (0x618)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-119. ALE Port Control Registers Field Descriptions

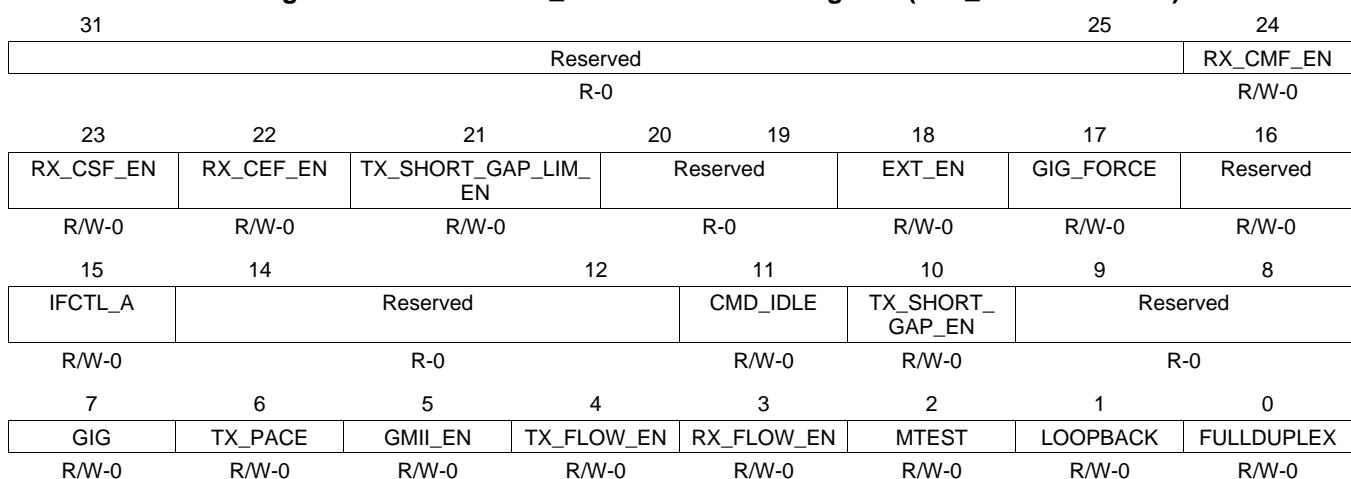

Bit	Field	Value	Description
31-24	BCAST_LIMIT	0-FFh	Broadcast packet rate limit. Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field.
23-16	MCAST_LIMIT	0-FFh	Multicast Packet Rate Limit. Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field.
15-5	Reserved	0	Reserved
4	MCAST_LIMIT	0-1	No Learn Mode. When set the port is disabled from learning or updating source addresses.
3	VID_INGRESS_CHECK	0-1	VLAN ID Ingress Check. If VLAN not found then drop the packet. Packets with an unknown (default) VLAN will be dropped.
2	DROP_UNTAGGED	0-1	Drop Untagged Packets. Drop non-VLAN tagged ingress packets.
1-0	PORT_STATE	0 1h 2h 3h	Port State Disabled Blocked Learn Forward

9.4.1.96 CPGMAC_SL1 IDVER Register (SL1_IDVER) (0x700)
Figure 9-111. CPGMAC_SL1 IDVER Register (SL1_IDVER)

LEGEND: R = Read only; -n = value after reset

Table 9-120. CPGMAC_SL1 IDVER Register (SL1_IDVER) Field Descriptions

Bit	Field	Value	Description

15-11	Z	0-1Fh	RX Z value (X.Y.Z)
10-8	X	0-7h	RX X value (major)
7-0	Y	0-FFh	RX Y value (minor)

9.4.1.97 CPGMAC_SL1 MAC Control Register (SL1_MACCONTROL) (0x704)
Figure 9-112. CPGMAC_SL1 MAC Control Register (SL1_MACCONTROL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-121. CPGMAC_SL1 MAC Control Register (SL1_MACCONTROL) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved
24	RX_CMF_EN	0 1	RX Copy MAC Control Frames Enable. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the MACCONTROL register, regardless of the value of RX_CMF_EN. Frames transferred to memory due to RX_CMF_EN will have the control bit set in their EOP buffer descriptor. 0 MAC control frames are filtered (but acted upon if enabled). 1 MAC control frames are transferred to memory.

Table 9-121. CPGMAC_SL1 MAC Control Register (SL1_MACCONTROL) Field Descriptions (continued)

Bit	Field	Value	Description
23	RX_CSF_EN	0 1	RX Copy Short Frames Enable. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RX_CSF_EN will have the fragment or undersized bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. Short frames are filtered. Short frames are transferred to memory.
22	RX_CEF_EN	0 1	RX Copy Error Frames Enable. Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when RX_CEF_EN is not set. Frames containing errors are filtered. Frames containing errors are transferred to memory.
21	TX_SHORT_GAP_LIM_EN	0-1	Transmit Short Gap Limit Enable. When set, this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed.
20-19	Reserved	0	Reserved
18	EXT_EN	0 1	Control Enable Use this setting for RMII/GMII mode Use this setting for RGMII mode
17	GIG_FORCE	0-1	Gigabit Mode Force. This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.
16	Reserved	0	Reserved
15	IFCTL_A	0 1	Interface Control A 10 Mbps mode 100 Mbps mode
14-12	Reserved	0	Reserved
11	CMD_IDLE	0 1	Command Idle. Idle not commanded Idle commanded (read IDLE in MACSTATUS register)
10	TX_SHORT_GAP_EN	0 1	Transmit Short Gap Enable. Transmit with a short IPG is disabled. Transmit with a short IPG (when TX_SHORT_GAP input is asserted) is enabled.
9-8	Reserved	0	Reserved. Read as zero
7	GIG	0 1	Gigabit Mode 10/100 mode Gigabit mode (full duplex only). The GIG_OUT output is the value of this bit.
6	TX_PACE	0 1	Transmit Pacing Enable Transmit pacing is disabled. Transmit pacing is enabled.
5	GMII_EN	0 1	G/MII Enable. G/MII RX and TX held in reset. G/MII RX and TX are released from reset.
4	TX_FLOW_EN	0 1	Transmit Flow Control Enable. Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_CMF_EN bits determine whether or not received pause frames are transferred to memory. Transmit flow control is disabled. Full-duplex mode: incoming pause frames are not acted upon. Transmit flow control is enabled. Full-duplex mode: incoming pause frames are acted upon.

Table 9-121. CPGMAC_SL1 MAC Control Register (SL1_MACCONTROL) Field Descriptions (continued)

Bit	Field	Value	Description
3	RX_FLOW_EN	0	Receive flow control is disabled. Half-duplex mode: no flow control generated collisions are sent. Full-duplex mode: no outgoing pause frames are sent.
		1	Receive flow control is enabled. Half-duplex mode: collisions are initiated when receive flow control is triggered. Full-duplex mode: outgoing pause frames are sent when receive flow control is triggered.
2	MTEST	0-1	Manufacturing Test mode. This bit must be set to allow writes to the BOFFTEST and PAUSE registers.
1	LOOPBACK	0	Loop back mode is disabled.
		1	Loop back mode is enabled.
0	FULLDUPLEX	0	Half-duplex mode is enabled.
		1	Full-duplex mode is enabled.

9.4.1.98 CPGMAC_SL1 MAC Status Register (SL1_MACSTATUS) (0x708)
Figure 9-113. CPGMAC_SL1 MAC Status Register (SL1_MACSTATUS)

Table 9-122. CPGMAC_SL1 MAC Status Register (SL1_MACSTATUS) Field Descriptions

Bit	Field	Value	Description
31	IDLE	0	CPGMAC_SL1 IDLE. The CPGMAC_SL1 is in the idle state (valid after an idle command). The CPGMAC_SL1 is not in the idle state.
		1	The CPGMAC_SL 1 is in the idle state.
30-5	Reserved	0	Reserved. Read as zero
4	EXT_GIG	0-1	External GIG. This is the value of the EXT_GIG input bit.
3	EXT_FULLDUPLEX	0-1	External Fullduplex. This is the value of the EXT_FULLDUPLEX input bit.
2	Reserved	0	Reserved Read as zero
1	RX_FLOW_ACT	0	Receive Flow Control Active. When asserted, indicates that receive flow control is enabled and triggered. Receive flow control is inactive.
		1	Receive flow control is active.
0	TX_FLOW_ACT	0	Transmit Flow Control Active. When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete. Transmit flow control is inactive.
		1	Transmit flow control is active.

9.4.1.99 CPGMAC_SL1 Software Reset Register (SL1_SOFT_RESET) (0x70C)

Figure 9-114. CPGMAC_SL1 Software Reset Register (SL1_SOFT_RESET)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-123. CPGMAC_SL1 Software Reset Register (SL1_SOFT_RESET) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	SOFT_RESET	0-1	Software reset. Writing a 1 to this bit causes the CPGMAC_SL1 logic to be reset. After writing a 1 to this bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred; if a 0 is read, then reset has occurred.

9.4.1.100 CPGMAC_SL1 RX Maximum Length Register (SL1_RX_MAXLEN) (0x710)

Figure 9-115. CPGMAC_SL1 RX Maximum Length Register (SL1_RX_MAXLEN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-124. CPGMAC_SL1 RX Maximum Length Register (SL1_RX_MAXLEN) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. Read as zero
13-0	RX_MAXLEN	0-3FFFh	RX Maximum Frame Length. This field determines the maximum length of a received frame. The reset value is 5EEh (1518 decimal). Frames with byte counts greater than the RX_MAXLEN value are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. The maximum value is 16,383.

9.4.1.101 CPGMAC_SL1 Backoff Random Number Generator Test Register (SL1_BOFFTEST) (0x714)
Figure 9-116. CPGMAC_SL1 Backoff Random Number Generator Test Register (SL1_BOFFTEST)

15	12	11	10	9
COLL_COUNT		Reserved	TX_BACKOFF	
R-0		R-0	R-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-125. CPGMAC_SL1 Backoff Random Number Generator Test Register (SL1_BOFFTEST) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved
30-26	PACEVAL	0-1Fh	Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to zero. When PACEVAL is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce capture effects improving overall network bandwidth.
25-16	RNDNUM	0-3FFh	Backoff Random Number Generator. This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when MTEST in MACCONTROL register has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset.
15-12	COLL_COUNT	0-Fh	Collision Count. The number of collisions the current frame has experienced.
11-10	Reserved	0	Reserved
9-0	TX_BACKOFF	0-3FFh	Backoff Count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.

9.4.1.102 CPGMAC_SL1 RX Pause Timer Register (SL1_RX_PAUSE) (0x718)
Figure 9-117. CPGMAC_SL1 RX Pause Timer Register (SL1_RX_PAUSE)

Reserved	
R-0	
15	0
RX_PAUSETIMER	
R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-126. CPGMAC_SL1 RX Pause Timer Register (SL1_RX_PAUSE) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. Read as zero
15-0	RX_PAUSETIMER	0-FFFFh	RX Pause Timer Value. This field allows the contents of the receive pause timer to be observed (and written in test mode). The receive pause timer is loaded with FF00h when the CPGMAC_SL sends an outgoing pause frame (with pause time of FFFFh). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to zero, then another outgoing pause frame will be sent and the load/decrement process will be repeated.

9.4.1.103 CPGMAC_SL1 TX Pause Timer Register (SL1_TX_PAUSE) (0x71C)

Figure 9-118. CPGMAC_SL1 TX Pause Timer Register (SL1_TX_PAUSE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-127. CPGMAC_SL1 TX Pause Timer Register (SL1_TX_PAUSE) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. Read as zero
15-0	TX_PAUSETIMER	0-FFFFh	TX Pause Timer Value. This field allows the contents of the transmit pause timer to be observed (and written in test mode). The transmit pause timer is loaded by a received (incoming) pause frame, and then decremented, at slottime intervals, down to zero at which time CPGMAC_SL transmit frames are again enabled.

9.4.1.104 CPGMAC_SL1 Emulation Control Register (SL1_EMCONTROL) (0x720)

Figure 9-119. CPGMAC_SL1 Emulation Control Register (SL1_EMCONTROL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-128. CPGMAC_SL1 Emulation Control Register (SL1_EMCONTROL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved. Read as zero
1	SOFT	0 1	Emulation soft bit. This bit is used in conjunction with FREE bit to determine the emulation suspend mode. This bit has no effect if FREE = 1. Soft mode is disabled. EMAC stops immediately during emulation halt. Soft mode is enabled. During emulation halt, EMAC stops after completion of current operation.
0	FREE	0 1	Emulation free bit. This bit is used in conjunction with SOFT bit to determine the emulation suspend mode. Free-running mode is disabled. During emulation halt, SOFT bit determines operation of EMAC. Free-running mode is enabled. During emulation halt, EMAC continues to operate.

9.4.1.105 CPGMAC_SL1 RX Packet Priority to Header Priority Mapping Register (SL1_RX_PRI_MAP) (0x724)
Figure 9-120. CPGMAC_SL1 RX Packet Priority to Header Priority Mapping Register (SL1_RX_Pri_Map)

Table 9-129. CPGMAC_SL1 RX Packet Priority to Header Priority Mapping Register (SL1_Pri_Map) Field Descriptions

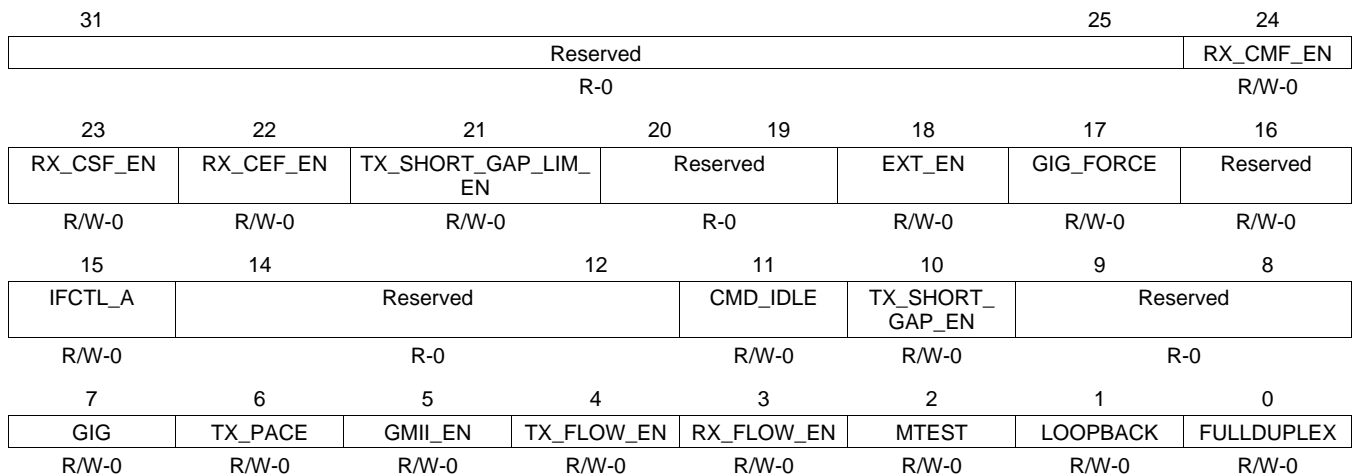

Bit	Field	Value	Description
31	Reserved	0	Reserved. Read as zero
30-28	PRI7	0-7h	Priority 7. A packet priority of 7 is mapped (changed) to this value.
27	Reserved	0	Reserved. Read as zero
26-24	PRI6	0-7h	Priority 6. A packet priority of 6 is mapped (changed) to this value.
23	Reserved	0	Reserved. Read as zero
22-20	PRI5	0-7h	Priority 5. A packet priority of 5 is mapped (changed) to this value.
19	Reserved	0	Reserved. Read as zero
18-16	PRI4	0-7h	Priority 4. A packet priority of 4 is mapped (changed) to this value.
15	Reserved	0	Reserved. Read as zero
14-12	PRI3	0-7h	Priority 3. A packet priority of 3 is mapped (changed) to this value.
11	Reserved	0	Reserved. Read as zero
10-8	PRI2	0-7h	Priority 2. A packet priority of 2 is mapped (changed) to this value.
7	Reserved	0	Reserved. Read as zero
6-4	PRI1	0-7h	Priority 1. A packet priority of 1 is mapped (changed) to this value.
3	Reserved	0	Reserved. Read as zero
2-0	PRI0	0-7h	Priority 0. A packet priority of 0 is mapped (changed) to this value.

9.4.1.106 CPGMAC_SL2 IDVER Register (SL2_IDVER) (0x740)
Figure 9-121. CPGMAC_SL2 IDVER Register (SL2_IDVER)

LEGEND: R = Read only; -n = value after reset

Table 9-130. CPGMAC_SL2 IDVER Register (SL2_IDVER) Field Descriptions

Bit	Field	Value	Description
31-16	IDENT	0-FFFFh	RX Identification Value
15-11	Z	0-1Fh	RX Z value (X.Y.Z)
10-8	X	0-7h	RX X value (major)
7-0	Y	0-FFh	RX Y value (minor)

9.4.1.107 CPGMAC_SL2 MAC Control Register (SL2_MACCONTROL) (0x744)
Figure 9-122. CPGMAC_SL2 MAC Control Register (SL2_MACCONTROL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-131. CPGMAC_SL2 MAC Control Register (SL2_MACCONTROL) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved
24	RX_CMF_EN	0 1	RX Copy MAC Control Frames Enable. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the MACCONTROL register, regardless of the value of RX_CMF_EN. Frames transferred to memory due to RX_CMF_EN will have the control bit set in their EOP buffer descriptor. 0 MAC control frames are filtered (but acted upon if enabled). 1 MAC control frames are transferred to memory.

Table 9-131. CPGMAC_SL2 MAC Control Register (SL2_MACCONTROL) Field Descriptions (continued)

Bit	Field	Value	Description
23	RX_CSF_EN	0 1	RX Copy Short Frames Enable. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RX_CSF_EN will have the fragment or undersized bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. Short frames are filtered. Short frames are transferred to memory.
22	RX_CEF_EN	0 1	RX Copy Error Frames Enable. Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when RX_CEF_EN is not set. Frames containing errors are filtered. Frames containing errors are transferred to memory.
21	TX_SHORT_GAP_LIM_EN	0-1	Transmit Short Gap Limit Enable. When set, this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed.
20-19	Reserved	0	Reserved
18	EXT_EN	0 1	Control Enable Use this setting for RMII/GMII mode Use this setting for RGMII mode
17	GIG_FORCE	0-1	Gigabit Mode Force. This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.
16	Reserved	0	Reserved
15	IFCTL_A	0 1	Interface Control A 10 Mbps mode 100 Mbps mode
14-12	Reserved	0	Reserved
11	CMD_IDLE	0 1	Command Idle. Idle not commanded Idle commanded (read IDLE in MACSTATUS register)
10	TX_SHORT_GAP_EN	0 1	Transmit Short Gap Enable. Transmit with a short IPG is disabled. Transmit with a short IPG (when TX_SHORT_GAP input is asserted) is enabled.
9-8	Reserved	0	Reserved. Read as zero
7	GIG	0 1	Gigabit Mode 10/100 mode Gigabit mode (full duplex only). The GIG_OUT output is the value of this bit.
6	TX_PACE	0 1	Transmit Pacing Enable Transmit pacing is disabled. Transmit pacing is enabled.
5	GMII_EN	0 1	G/MII Enable. G/MII RX and TX held in reset. G/MII RX and TX are released from reset.
4	TX_FLOW_EN	0 1	Transmit Flow Control Enable. Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_CMF_EN bits determine whether or not received pause frames are transferred to memory. Transmit flow control is disabled. Full-duplex mode: incoming pause frames are not acted upon. Transmit flow control is enabled. Full-duplex mode: incoming pause frames are acted upon.

Table 9-131. CPGMAC_SL2 MAC Control Register (SL2_MACCONTROL) Field Descriptions (continued)

Bit	Field	Value	Description
3	RX_FLOW_EN	0 1	Receive Flow Control Enable. 0 Receive flow control is disabled. Half-duplex mode: no flow control generated collisions are sent. Full-duplex mode: no outgoing pause frames are sent. 1 Receive flow control is enabled. Half-duplex mode: collisions are initiated when receive flow control is triggered. Full-duplex mode: outgoing pause frames are sent when receive flow control is triggered.
2	MTEST	0-1	Manufacturing Test mode. This bit must be set to allow writes to the BOFFTEST and PAUSE registers.
1	LOOPBACK	0 1	Loop Back Mode. Loopback mode forces internal fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The LOOPBACK bit should be changed only when GMII_EN is deasserted. 0 Loop back mode is disabled. 1 Loop back mode is enabled.
0	FULLDUPLEX	0 1	Full Duplex mode. Gigabit mode forces fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit. 0 Half-duplex mode is enabled. 1 Full-duplex mode is enabled.

9.4.1.108 CPGMAC_SL2 MAC Status Register (SL2_MACSTATUS) (0x748)
Figure 9-123. CPGMAC_SL2 MAC Status Register (SL2_MACSTATUS)

LEGEND: R = Read only; -n = value after reset

Table 9-132. CPGMAC_SL2 MAC Status Register (SL2_MACSTATUS) Field Descriptions

Bit	Field	Value	Description
31	IDLE	0 1	CPGMAC_SL2 IDLE. The CPGMAC_SL2 is in the idle state (valid after an idle command). The CPGMAC_SL2 is not in the idle state. The CPGMAC_SL 2 is in the idle state.
30-5	Reserved	0	Reserved. Read as zero
4	EXT_GIG	0-1	External GIG. This is the value of the EXT_GIG input bit.
3	EXT_FULLLDUPLEX	0-1	External Fullduplex. This is the value of the EXT_FULLLDUPLEX input bit.
2	Reserved	0	Reserved Read as zero
1	RX_FLOW_ACT	0 1	Receive Flow Control Active. When asserted, indicates that receive flow control is enabled and triggered. Receive flow control is inactive. Receive flow control is active.
0	TX_FLOW_ACT	0 1	Transmit Flow Control Active. When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete. Transmit flow control is inactive. Transmit flow control is active.

9.4.1.109 CPGMAC_SL2 Software Reset Register (SL2_SOFT_RESET) (0x74C)
Figure 9-124. CPGMAC_SL2 Software Reset Register (SL2_SOFT_RESET)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-133. CPGMAC_SL2 Software Reset Register (SL2_SOFT_RESET) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	SOFT_RESET	0-1	Software reset. Writing a 1 to this bit causes the CPGMAC_SL2 logic to be reset. After writing a 1 to this bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred; if a 0 is read, then reset has occurred.

9.4.1.110 CPGMAC_SL2 RX Maximum Length Register (SL2_RX_MAXLEN) (0x750)

Table 9-134. CPGMAC_SL2 RX Maximum Length Register (SL2_RX_MAXLEN) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. Read as zero
13-0	RX_MAXLEN	0-3FFFh	RX Maximum Frame Length. This field determines the maximum length of a received frame. The reset value is 5EEh (1518 decimal). Frames with byte counts greater than the RX_MAXLEN value are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. The maximum value is 16,383.

9.4.1.111 CPGMAC_SL2 Backoff Random Number Generator Test Register (SL2_BOFFTEST) (0x754)

Figure 9-126. CPGMAC_SL2 Backoff Random Number Generator Test Register (SL2_BOFFTEST)

31	30	26	25	16

COLL_COUNT		Reserved		TX_BACKOFF
R-0		R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-135. CPGMAC_SL2 Backoff Random Number Generator Test Register (SL2_BOFFTEST) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved. Read as zero
30-26	PACEVAL	0-1Fh	Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to zero. When PACEVAL is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce capture effects improving overall network bandwidth.
25-16	RNDNUM	0-3FFh	Backoff Random Number Generator. This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when MTEST in MACCONTROL register has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset.
15-12	COLL_COUNT	0-Fh	Collision Count. The number of collisions the current frame has experienced.
11-10	Reserved	0	Reserved. Read as zero
9-0	TX_BACKOFF	0-3FFh	Backoff Count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.

9.4.1.112 CPGMAC_SL2 RX Pause Timer Register (SL2_RX_PAUSE) (0x758)
Figure 9-127. CPGMAC_SL2 RX Pause Timer Register (SL2_RX_PAUSE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-136. CPGMAC_SL2 RX Pause Timer Register (SL2_RX_PAUSE) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. Read as zero
15-0	RX_PAUSETIMER	0-FFFFh	RX Pause Timer Value. This field allows the contents of the receive pause timer to be observed (and written in test mode). The receive pause timer is loaded with FF00h when the CPGMAC_SL sends an outgoing pause frame (with pause time of FFFFh). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to zero, then another outgoing pause frame will be sent and the load/decrement process will be repeated.

9.4.1.113 CPGMAC_SL2 TX Pause Timer Register (SL2_TX_PAUSE) (0x75C)
Figure 9-128. CPGMAC_SL2 TX Pause Timer Register (SL2_TX_PAUSE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-137. CPGMAC_SL2 TX Pause Timer Register (SL2_TX_PAUSE) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. Read as zero
15-0	TX_PAUSETIMER	0-FFFFh	TX Pause Timer Value. This field allows the contents of the transmit pause timer to be observed (and written in test mode). The transmit pause timer is loaded by a received (incoming) pause frame, and then decremented, at slot time intervals, down to zero at which time CPGMAC_SL transmit frames are again enabled.

9.4.1.114 CPGMAC_SL2 Emulation Control Register (SL2_EMCONTROL) (0x760)
Figure 9-129. CPGMAC_SL2 Emulation Control Register (SL2_EMCONTROL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-138. CPGMAC_SL2 Emulation Control Register (SL2_EMCONTROL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved. Read as zero
1	SOFT	0	Emulation soft bit. This bit is used in conjunction with FREE bit to determine the emulation suspend mode. This bit has no effect if FREE = 1. Soft mode is disabled. EMAC stops immediately during emulation halt.
		1	Soft mode is enabled. During emulation halt, EMAC stops after completion of current operation.
0	FREE	0	Emulation free bit. This bit is used in conjunction with SOFT bit to determine the emulation suspend mode. Free-running mode is disabled. During emulation halt, SOFT bit determines operation of EMAC.
		1	Free-running mode is enabled. During emulation halt, EMAC continues to operate.

9.4.1.115 CPGMAC_SL2 RX Packet Priority to Header Priority Mapping Register (SL2_RX_PRI_MAP) (0x764)

Table 9-139. CPGMAC_SL2 RX Packet Priority to Header Priority Mapping Register (SL2_RX_PRI_MAP) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved. Read as zero
30-28	PRI7	0-7h	Priority 7. A packet priority of 7 is mapped (changed) to this value.
27	Reserved	0	Reserved. Read as zero
26-24	PRI6	0-7h	Priority 6. A packet priority of 6 is mapped (changed) to this value.
23	Reserved	0	Reserved. Read as zero
22-20	PRI5	0-7h	Priority 5. A packet priority of 5 is mapped (changed) to this value.
19	Reserved	0	Reserved. Read as zero
18-16	PRI4	0-7h	Priority 4. A packet priority of 4 is mapped (changed) to this value.
15	Reserved	0	Reserved. Read as zero
14-12	PRI3	0-7h	Priority 3. A packet priority of 3 is mapped (changed) to this value.
11	Reserved	0	Reserved. Read as zero
10-8	PRI2	0-7h	Priority 2. A packet priority of 2 is mapped (changed) to this value.
7	Reserved	0	Reserved. Read as zero
6-4	PRI1	0-7h	Priority 1. A packet priority of 1 is mapped (changed) to this value.
3	Reserved	0	Reserved. Read as zero
2-0	PRI0	0-7h	Priority 0. A packet priority of 0 is mapped (changed) to this value.

9.4.2 MDIO Module

This section describes the memory-mapped registers for the MDIO module. The base address of the MDIO module registers is 4A10 0800h. [Table 9-140](#) lists the memory-mapped registers for the MDIO module.

Table 9-140. MDIO Module Registers

Offset	Acronym	Register Name
800h	VERSION	MDIO version register
804h	CONTROL	MDIO control register
808h	ALIVE	PHY alive status register
80Ch	LINK	PHY link status register
810h	LINKINTRAW	MDIO link status change interrupt register (raw value)
814h	LINKINTMASKED	MDIO link status change interrupt register (masked value)
820h	USERINTRAW	MDIO user command complete interrupt register (raw value)
824h	USERINTMASKED	MDIO user command complete interrupt register (masked value)
828h	USERINTMASKSET	MDIO user interrupt mask set register
82Ch	USERINTMASKCLEAR	MDIO user interrupt mask clear register
880h	USERACCESS0	MDIO user access register 0
884h	USERPHYSEL0	MDIO user PHY select register 0
888h	USERACCESS1	MDIO user access register 1
88Ch	USERPHYSEL1	MDIO user PHY select register 1

9.4.2.1 MDIO Version Register (VERSION) (800h)

Figure 9-131. MDIO Version Register (VERSION)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-141. MDIO Version Register (VERSION) Field Descriptions

Bit	Field	Value	Description
31-16	MODID	0-FFFFh	Module ID
15-8	REVMAJ	0-FFh	VBUS Management Interface module major revision value
7-0	REVMIN	0-FFh	VBUS Management Interface module minor revision value

9.4.2.2 MDIO Control Register (CONTROL) (804h)
Figure 9-132. MDIO Control (CONTROL) Register

31	30	29	28	24	23	21	20	19	18	17	16

15											0
CLKDIV											
R/W											

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-142. MDIO Control Register (CONTROL) Field Descriptions

Bit	Field	Value	Description
31	IDLE	0 1	MDIO state machine IDLE. State machine is not in idle state. State machine is in idle state.
30	ENABLE	0 1	Enable control. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit. If using byte access, the enable bit has to be the last bit written in this register. Disables the MDIO state machine. Enable the MDIO state machine.
29	Reserved	0	Reserved
28-24	HIGHEST_USER_CHANNEL	0-1Fh	Highest user channel. This field specifies the highest useraccess channel that is available in the module and is currently set to 1. This implies that USERACCESS1 is the highest available user access channel.
23-21	Reserved	0	Reserved
20	PREAMBLE	0 1	Preamble disable. Standard MDIO preamble is used. Disables this device from sending MDIO frame preambles.
19	FAULT	0 1	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit. No failure Physical layer fault; the MDIO state machine is reset.
18	FAULT_DETECT_ENABLE	0 1	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection. Disables the physical layer fault detection. Enables the physical layer fault detection.
17	INT_TEST_ENABLE		Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes.
16	Reserved	0	Reserved
15-0	CLKDIV	0- FFFh	Clock Divider. This field specifies the division ratio between CLK and the frequency of MDCLK. MDCLK is disabled when CLKDIV is cleared to 0. MDCLK frequency = clk frequency/(CLKDIV+1).

9.4.2.3 PHY Alive Status Register (ALIVE) (0x808)

Figure 9-133. PHY Alive Status Register (ALIVE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-143. PHY Alive Status Register (ALIVE) Field Descriptions

Bit	Field	Value	Description
31-0	ALIVE		MDIO Alive. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address.
		0	No effect
		1	Clears the bit

9.4.2.4 PHY Link Status Register (LINK) (0x80C)

Figure 9-134. PHY Link Status Register (LINK)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-144. PHY Link Status Register (LINK) Field Descriptions

Bit	Field	Value	Description
31-0	LINK	0-FFFF FFFFh	MDIO Link state. This register is updated after a read of the Generic Status Register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. In addition, the status of the two PHYs specified in the USERPHYSEL registers can be determined using the MLINK input pins. This is determined by the LINKSEL bit in the USERPHYSEL register.

9.4.2.5 MDIO Link Status Change Interrupt (raw value) Register (LINKINTRAW) (0x810)
Figure 9-135. MDIO Link Status Change Interrupt (raw value) Register (LINKINTRAW)

31	Reserved	2	1	0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-145. MDIO Link Status Change Interrupt (raw value) Register (LINKINTRAW) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	LINKINTRAW		MDIO link change event, raw value. When asserted '1', a bit indicates that there was an MDIO link change event (that is, change in the MDIO link register) corresponding to the PHY address in the USERPHYSEL register. LINKINTRAW[0] and LINKINTRAW[1] correspond to USERPHYSEL0 and USERPHYSEL1, respectively. If the INT_TEST_ENABLE bit in the MDIO control register is set, the host may set the LINKINTRAW bits to a '1'. This mode may be used for test purposes.
		0	No effect
		1	Clears the event

9.4.2.6 MDIO Link Status Change Interrupt (masked value) Register (LINKINTMASKED) (0x814)
Figure 9-136. MDIO Link Status Change Interrupt (masked value) Register (LINKINTMASKED)

31	Reserved	2	1	0
R-0			LINKINTMASKED R/WC-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-146. MDIO Link Status Change Interrupt (masked value) Register (LINKINTMASKED) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved		Reserved
1-0	LINKINTMASKED		MDIO link change interrupt, masked value. When asserted '1', a bit indicates that there was an MDIO link change event (that is, change in the MDIO link register) corresponding to the PHY address in the USERPHYSEL register and the corresponding LINKINT_ENABLE bit was set. LINKINTMASKED[0] and LINKINTMASKED[1] correspond to USERPHYSEL0 and USERPHYSEL1, respectively. If the INT_TEST_ENABLE bit in the MDIO control register is set, the host may set the LINKINT bits to a '1'. This mode may be used for test purposes.
		0	No effect
		1	Clears the interrupt

9.4.2.7 MDIO User Command Complete Interrupt (raw value) Register (USERINTRAW) (0x820)

Figure 9-137. MDIO User Command Complete Interrupt (raw value) Register (USERINTRAW)

31	Reserved	2	1	0
R-0			USERINTRAW R/WC-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-147. MDIO User Command Complete Interrupt (raw value) Register (USERINTRAW) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	USERINTRAW		Raw value of MDIO user command complete event for USERACCESS1 and MDIOUSERACCESS0, respectively. When asserted '1', a bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS register has completed. Writing a '1' will clear the event and writing '0' has no effect. If the INT_TEST_ENABLE bit in the MDIO control register is set, the host may set the USERINTRAW bits to a '1'. This mode may be used for test purposes.

9.4.2.8 MDIO User Command Complete Interrupt (masked value) Register (USERINTMASKED) (0x824)

Figure 9-138. MDIO User Command Complete Interrupt (masked value) Register (USERINTMASKED)

31	Reserved	2	1	0
R-0			USERINTMASKED R/WC-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-148. MDIO User Command Complete Interrupt (masked value) Register (USERINTMASKED) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	USERINTMASKED		Masked value of MDIO user command complete interrupt for USERACCESS1 and USERACCESS0, respectively. When asserted '1', a bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS register has completed and the corresponding userintmaskset bit is set to '1'. If the INT_TEST_ENABLE bit in the MDIO control register is set, the host may set the USERINTMASKED bits to a '1'. This mode may be used for test purposes.
		0	No effect
		1	Clears the interrupt

9.4.2.9 MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET) (0x828)
Figure 9-139. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)

31	Reserved	2	1	0
R-0			USERINTMASKSET R/WS-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-149. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	USERINTMASKSET	0	MDIO user interrupt mask set for USERINTMASKED[1:0], respectively. MDIO user interrupt for a particular USERACCESS register is disabled if the corresponding bit is cleared to 0.
		1	No effect Enable MDIO user command complete interrupts for that particular USERACCESS register.

9.4.2.10 MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR) (0x82C)
Figure 9-140. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR)

31	Reserved	2	1	0
R-0			USERINTMASKCLR R/WC-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-150. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	USERINTMASKCLR	0	MDIO user command complete interrupt mask clear for USERINTMASKED[1:0], respectively. .
		1	No effect Disables further user command complete interrupts for that particular MDIOUserAccess register

9.4.2.11 MDIO User Access Register 0 (USERACCESS0) (0x880)

Figure 9-141. MDIO User Access Register 0 (USERACCESS0)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-151. MDIO User Access Register 0 (USERACCESS0) Field Descriptions

Bit	Field	Value	Description
31	GO	0-1	Go. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so, this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is write able only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to the MDIOUserAccess0 register are blocked when the go bit is '1'. If byte access is being used, the go bit should be written last.
30	WRITE	0 1	Write enable. The MDIO transaction is to be a register read. The MDIO transaction is to be a register write.
29	ACK	0-1	Acknowledge. This bit is set if the PHY acknowledged the read transaction.
28-26	Reserved	0	Reserved. Writes to these bits have no effect. They always read as 0.
25-21	REGADR	0-1Fh	Register address. This field specifies the PHY register to be accessed for this transaction.
20-16	PHYADR	0-1Fh	PHY address. This field specifies the PHY to be accessed for this transaction.
15-0	DATA	0-FFFFh	User data. The data value read from or to be written to the specified PHY register.

9.4.2.12 MDIO User PHY Select Register 0 (USERPHYSEL0) (0x884)

Figure 9-142. MDIO User PHY Select Register 0 (USERPHYSEL0)

5	Reserved	0	Reserved
4-0	PHYADR_MON	0-1Fh	PHY address whose link status is to be monitored.

9.4.3 CPSW Subsystem Module

This section describes the memory-mapped registers for the CPSW subsystem module (CPSW_3GSS). The base address of the CPSW subsystem module registers is 4A10 0900h. [Table 9-155](#) lists the memory-mapped registers for the CPSW subsystem module.

Table 9-155. CPSW Subsystem Module Registers

Offset	Acronym	Register Name
900h	IDVER	Subsystem ID Version Register
904h	SOFT_RESET	Subsystem Software Reset Register
908h	CONTROL	Subsystem Control Register
90Ch	INT_CONTROL	Subsystem Interrupt Control
910h	RX_THRESH_EN	Subsystem Receive Threshold Interrupt Enable Register
914h	RX_EN	Subsystem Receive Interrupt Enable Register
918h	TX_EN	Subsystem Transmit Interrupt Enable Register
91Ch	MISC_EN	Subsystem Miscellaneous Interrupt Enable Register
940h	RX_THRESH_STAT	Subsystem RX Threshold Masked Interrupt Status Register
944h	RX_STAT	Subsystem RX Masked Interrupt Status Register
948h	TX_STAT	Subsystem TX Masked Interrupt Status Register
94Ch	MISC_STAT	Subsystem Miscellaneous Masked Interrupt Status Register
970h	RX_IMAX	Subsystem Receive Interrupts Per Millisecond
974h	TX_IMAX	Subsystem Transmit Interrupts Per Millisecond
988h	RGMII_CTL	RGMII Control Signal Register

9.4.3.1 Subsystem ID Version Register (IDVER) (0x900)

Figure 9-145. Subsystem ID Version Register (IDVER)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-156. Subsystem ID Version Register (IDVER) Field Descriptions

Bit	Field	Value	Description
31-30	SCHEME	0-3h	
29-28	Reserved	0	Read as zero.
27-16	FUNCTION	0-FFFh	Function value
15-11	RTL	0-1Fh	RTL version
10-8	MAJOR	0-7h	Major version
7-6	CUSTOM	0-3h	Custom version
5-0	MINOR	0-3Fh	Minor version

9.4.3.2 Subsystem Software Reset Register (SOFT_RESET) (0x904)

Figure 9-146. Subsystem Software Reset Register (SOFT_RESET)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-157. Subsystem Software Reset Register (SOFT_RESET) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Read as zero.
0	SOFT_RESET	0-1	Software reset - Writing a one to this bit causes the CPGMACSS_R logic to be reset (INT, REGS, CPPI). Software reset occurs on the clock following the register bit write.

9.4.3.3 Subsystem Control Register (CONTROL) (0x908)

Figure 9-147. Subsystem Control Register (CONTROL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-158. Subsystem Control Register (CONTROL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Read as zero.
3-2	MMR_STDBYMODE	0-3h	Standbymode MMR bits. This field is used to cause the CPSW_3GSS_R to go to standby mode (software standby). Smart standby is not supported.
1-0	MMR_IDLEMODE	0-3h	Idlemode MMR bits. This field is used to cause the CPSW_3GSS_R to go to idle mode (software idle). Smart idle is not supported.

9.4.3.4 Subsystem Interrupt Control Register (INT_CONTROL) (0x90C)

Figure 9-148. Subsystem Interrupt Control Register (INT_CONTROL)

31	30	22	21	16

General-Purpose I/O (GPIO) Interface

This chapter describes the general-purpose I/O (GPIO) interface.

Topic	Page
10.1 Introduction	1541
10.2 Architecture	1543
10.3 GPIO Registers	1550

10.1 Introduction

10.1.1 Purpose of the Peripheral

The general-purpose interface combines two general-purpose input/output (GPIO) banks. Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 64 (2 × 32) pins. These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.

10.1.2 Features

Each channel in the GPIO module has the following features:

- The output enable register (GPIO_OE) controls the output capability for each pin.
- The output line level reflects the value written in the data output register (GPIO_DATAOUT) through the peripheral bus.
- The input line can be fed in to the GPIO module through an optional and configurable debouncing cell.
- The input line value is sampled into the data input register (GPIO_DATAIN) and can be read from the peripheral bus.
- In Active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level (logical 0, logical 1, or both) to be used can be configured.

The global features of the GPIO module are:

- Two identical interrupt generation sub-modules process synchronous interrupt requests from each channel in order to be used independently in a bi-processor environment. Each sub-module controls its own synchronous interrupt request line and has its own interrupt enable and interrupt status registers. The interrupt enable register (GPIO_IRQENABLE_SET_x) selects the channel(s) considered for the interrupt request generation, and the interrupt status register (GPIO_IRQSTATUS_RAW_x) determines which channel(s) has/have activated the interrupt request. Event detection on GPIO channels is reflected into the interrupt status registers independently from the interrupt enable registers content.

The module provides an alternative to the atomic 'Test and Set' operations for the data output and interrupt enable registers. For these registers, the module implements the "Set and Clear protocol register update".

10.1.3 Block Diagram

Figure 10-1 details the GPIO block diagram with its configuration registers and its main functional paths:

- The synchronous path (for Active mode operations), Figure 10-2, used to generate a synchronous interrupt request upon expected event detection on any input GPIO; the synchronous interrupt request lines 0 and 1 are active according to their respective interrupt enable 0 and 1 registers.
- The blocks handling the internal clock (clock gating) and managing the Sleep mode request/acknowledge protocol (enabling the Synchronous path in Active mode).

Figure 10-1. GPIO Block Diagram

Figure 10-2. Synchronous Path Block Diagram

10.2 Architecture

This section discusses the operational details and basic functions of the GPIO peripheral.

10.2.1 Operating Modes

Four operating modes are defined for the module:

- **Active mode:** the module is running synchronously on the interface clock, interrupt can be generated according to the configuration and the external signals.
- **Idle mode:** the module is in a waiting state, interface clock can be stopped, no interrupt can be generated. Check the chip top-level functional specification for the availability of the debouncing clock while in Idle mode.
- **Inactive mode:** the module has no activity, interface clock can be stopped, no interrupt can be generated.
- **Disabled mode:** the module is not used, internal clock paths are gated, no interrupt request can be generated.

The Idle and Inactive modes are configured within the module and activated on request by the host processor through system interface sideband signals. The Disabled mode is set by software through a dedicated configuration bit. It unconditionally gates the internal clock paths not use for the system interface. All module registers are 8, 16 or 32-bit accessible through the OCP compatible interface (little endian encoding). In active mode, the event detection (level or transition) is performed in the GPIO module using the interface clock. The detection's precision is set by the frequency of this clock and the selected internal gating scheme.

10.2.2 Clocking and Reset Strategy

10.2.2.1 Clocks

GPIO module runs using two clocks:

- The debouncing clock is used for the debouncing sub-module logic (without the corresponding configuration registers). This module can sample the input line and filters the input level using a programmed delay.
- The interface clock provided by the peripheral bus (OCP compatible system interface). It is used through the entire GPIO module (except within the debouncing sub-module logic). It clocks the OCP interface and the internal logic. Clock gating features allow adapting the module power consumption to the activity.

10.2.2.2 Clocks, Gating and Active Edge Definitions

The interface clock provided by the peripheral bus (OCP compatible system interface) is used through the entire GPIO module. Two clock domains are defined: the OCP interface and the internal logic. Each clock domain can be controlled independently. Sampling operations for the data capture and for the events detection are done using the rising edge. The data loaded in the data output register (GPIO_DATAOUT) is set at the output GPIO pins synchronously with the rising edge of the interface clock.

Five clock gating features are available:

- Clock for the system interface logic can be gated when the module is not accessed, if the AUTOIDLE configuration bit in the system configuration register (GPIO_SYSCONFIG) is set. Otherwise, this logic is free running on the interface clock.
- Clock for the input data sample logic can be gated when the data in register is not accessed.
- Four clock groups are used for the logic in the synchronous events detection. Each 8 input GPIO_V2 pins group will have a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, then the corresponding clock will be gated. All channels are also gated using a 'one out of N' scheme. N can take the values 1, 2, 4 or 8. The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free running on the interface clock. When N is between 2 to 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

- In Inactive mode, all internal clock paths are gated.
- In Disabled mode, all internal clock paths not used for the system interface are gated. All GPIO registers are accessible synchronously with the interface clock.

10.2.2.3 Sleep Mode Request and Acknowledge

Upon a Sleep mode request issued by the host processor, the GPIO module goes to the Idle mode according to the IDLEMODE field in the system configuration register (GPIO_SYSCONFIG).

- IDLEMODE = 0 (Force-Idle mode): the GPIO goes in Inactive mode independently of the internal module state and the Idle acknowledge is unconditionally sent. In Force-Idle mode, the module is in Inactive mode.
- IDLEMODE = 1h (No-Idle mode): the GPIO does not go to the Idle mode and the Idle acknowledge is never sent.
- IDLEMODE = 2h (Smart-Idle mode) or IDLEMODE = 3h (Smart-Idle mode): the GPIO module evaluates its internal capability to have the interface clock switched off. Once there is no more internal activity (the data input register completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to GPIO_DEBOUNCINGTIME register pending to be synchronized), the Idle acknowledge is asserted and the GPIO enters Idle mode. When the system is awake, the Idle Request goes inactive, the Idle acknowledge signals are immediately de-asserted.

NOTE: Idle mode request and Idle acknowledge are system interface sideband signals. Once the GPIO acknowledges the Sleep mode request (Idle acknowledge has been sent), the interface clock can be stopped anytime.

Upon a Sleep mode request issued by the host processor, the GPIO module goes to the Idle mode only if there is no active bit in GPIO_IRQSTATUS_RAW_n registers.

10.2.2.4 Reset

The OCP hardware Reset signal has a global reset action on the GPIO. All configuration registers, all DFFs clocked with the Interface clock or Debouncing clock and all internal state machines are reset when the OCP hardware Reset is active (low level). The RESETDONE bit in the system status register (GPIO_SYSSTATUS) monitors the internal reset status: it is set when the Reset is completed on both OCP and Debouncing clock domains. The software Reset (SOFTRESET bit in the system configuration register) has the same effect as the OCP hardware Reset signal, and the RESETDONE bit in GPIO_SYSSTATUS is updated in the same condition.

10.2.3 Interrupt Features

10.2.3.1 Functional Description

In order to generate an interrupt request to a host processor upon a defined event (level or logic transition) occurring on a GPIO pin, the GPIO configuration registers have to be programmed as follows:

- Interrupts for the GPIO channel must be enabled in the GPIO_IRQENABLE_SET_0 and/or GPIO_IRQENABLE_SET_1 registers.
- The expected event(s) on input GPIO to trigger the interrupt request has to be selected in the GPIO_LEVELDETECT0, GPIO_LEVELDETECT1, GPIO_RISINGDETECT, and GPIO_FALLINGDETECT registers.

For instance, interrupt generation on both edges on input k is configured by setting to 1 the kth bit in registers GPIO_RISINGDETECT and GPIO_FALLINGDETECT along with the interrupt enabling for one or both interrupt lines (GPIO_IRQENABLE_SET_n).

NOTE: All interrupt sources (the 32 input GPIO channels) are merged together to issue two synchronous interrupt requests 0 and 1.

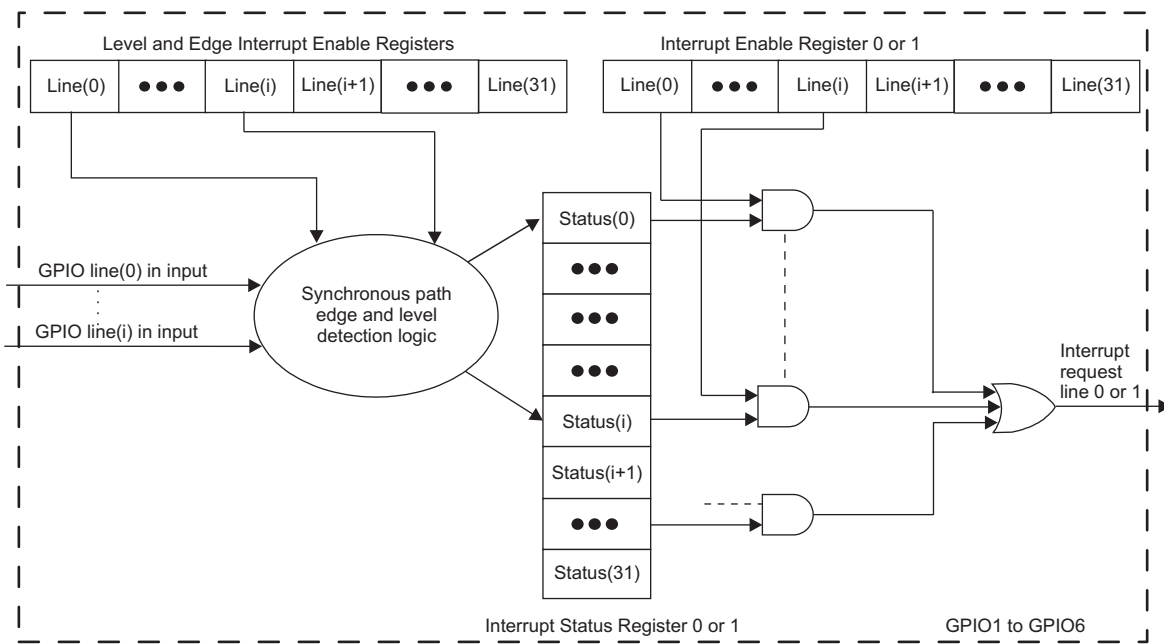

10.2.3.2 Synchronous Path: Interrupt Request Generation

In Active mode, once the GPIO configuration registers have been set to enable the interrupt generation, a synchronous path (Figure 10-3) samples the transitions and levels on the input GPIO with the internally gated interface clock. When an event matches the programmed settings, the corresponding bit in the GPIO_IRQSTATUS_RAW_n registers is set to 1 and, on the following interface clock cycle, the interrupt lines 0 and/or 1 are activated (depending on the GPIO_IRQENABLE_SET_n registers).

Due to the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period is equal to N times the interface clock period). This minimum pulse width has to be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

As the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This should not exceed 3 internally gated interface clock cycles + 2 interface clock cycles when the debouncing feature is not used. When the debouncing feature is active, the latency depends on the GPIO_DEBOUNCINGTIME register value and should be less than 3 internally gated interface clock cycles + 2 interface clock cycles + GPIO_DEBOUNCINGTIME value debouncing clock cycles + 3 debouncing clock cycles.

Figure 10-3. Interrupt Request Generation

10.2.3.3 Interrupt Line Release

When the host processor receives an interrupt request issued by the GPIO module, it can read the corresponding GPIO_IRQSTATUS_n register to find out which input GPIO has triggered the interrupt. After servicing the interrupt, the processor resets the status bit and releases the interrupt line by writing a 1 in the corresponding bit of the GPIO_IRQSTATUS_RAW_n register. If there is still a pending interrupt request to serve (all bits in the GPIO_IRQSTATUS_RAW_n register not masked by the GPIO_IRQENABLE_SET_n, which are not cleared by setting the GPIO_IRQENABLE_CLR_n), the interrupt line will be re-asserted.

10.2.4 General-Purpose Interface Basic Programming Model

10.2.4.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the registers:

- GPIO_LEVELDETECT0
- GPIO_LEVELDETECT1
- GPIO_RISINGDETECT
- GPIO_FALLINGDETECT

are set to 0101 0101h, then all clocks are active (power consumption is high);

are set to 0000 00FFh, then a single clock is active.

NOTE: When the clocks are enabled by writing to the GPIO_LEVELDETECT0, GPIO_LEVELDETECT1, GPIO_RISINGDETECT, and GPIO_FALLINGDETECT registers, the detection starts after 5 clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock has been started before a new setting is performed, the following is recommended: first, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

10.2.4.2 Set and Clear Instructions

The GPIO module implements the set-and-clear protocol register update for the data output and interrupt enable registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s).

Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

10.2.4.2.1 Clear Instruction

10.2.4.2.1.1 Clear Interrupt Enable Registers (GPIO_IRQENABLE_CLR_0 and GPIO_IRQENABLE_CLR_1):

- A write operation in the clear interrupt enable0 (or enable1) register clears the corresponding bit in the interrupt enable0 (or enable1) register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear interrupt enable0 (or enable1) register returns the value of the interrupt enable0 (or enable1) register.

10.2.4.2.1.2 Clear Data Output Register (GPIO_CLEARDATAOUT):

- A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear data output register returns the value of the data output register.

10.2.4.2.1.3 Clear Instruction Example

Assume the data output register (or one of the interrupt enable registers) contains the binary value, 0000 0001 0000 0001h, and you want to clear bit 0.

With the clear instruction feature, write 0000 0000 0000 0001h at the address of the clear data output register (or at the address of the clear interrupt enable register). After this write operation, a reading of the data output register (or the interrupt enable register) returns 0000 0001 0000 0000h; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32-bits wide, only the 16 least-significant bits are represented in this example.

Figure 10-4. Write @ GPIO_CLEARDATAOUT Register Example

10.2.4.2.2 Set Instruction

10.2.4.2.2.1 Set Interrupt Enable Registers (GPIO_IRQENABLE_SET_0 and GPIO_IRQENABLE_SET_1):

- A write operation in the set interrupt enable0 (or enable1) register sets the corresponding bit in the interrupt enable0 (or enable1) register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set interrupt enable0(or enable1) register returns the value of the interrupt enable0 (or enable1) register.

10.2.4.2.2.2 Set Data Output Register (GPIO_SETDATAOUT):

- A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set data output register returns the value of the data output register.

10.2.4.2.3 Set Instruction Example

Assume the interrupt enable0 (or enable1) register (or the data output register) contains the binary value, 0000 0001 0000 0000h, and you want to set bits 15, 3, 2, and 1.

With the set instruction feature, write 1000 0000 0000 1110h at the address of the set interrupt enable0 (or enable1) register (or at the address of the set data output register). After this write operation, a reading of the interrupt enable0 (or enable1) register (or the data output register) returns 1000 0001 0000 1110h; bits 15, 3, 2, and 1 are set.

NOTE: Although the general-purpose interface registers are 32-bits wide, only the 16 least-significant bits are represented in this example.

Figure 10-5. Write @ GPIO_SETIRQENABLEx Register Example

10.2.4.3 Data Input (Capture)/Output (Drive)

The output enable register (GPIO_OE) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module; its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in GPIO_OE), the value of the corresponding bit in the GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set and clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set data output register (GPIO_SETDATAOUT) or to the clear data output register (GPIO_CLEARDATAOUT) address. If the application uses a pin as an output and does not want interrupt generation from this pin, the application must properly configure the interrupt enable registers.

When configured as an input (the desired bit set to 1 in GPIO_OE), the state of the input can be read from the corresponding bit in the GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the interrupt enable registers to the interrupt as needed.

10.2.4.4 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

- The GPIO pin must be configured as input in the output enable register (write 1 to the corresponding bit of the GPIO_OE register).
- The debouncing time must be set in the debouncing value register (GPIO_DEBOUNCINGTIME). The GPIO_DEBOUNCINGTIME register is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31 microseconds long) to be used.

The following formula describes the required input stable time to be propagated to the debounced output:

$$\text{Debouncing time} = (\text{DEBOUNCETIME} + 1) \times 31 \mu\text{s}$$

Where the DEBOUNCETIME field value in the GPIO_DEBOUNCINGTIME register is from 0 to 255.

- The debouncing feature must be enabled in the debouncing enable register (write 1 to the corresponding DEBOUNCEENABLE bit in the GPIO_DEBOUNCENABLE register).

10.2.4.5 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface (Figure 10-6). You can dedicate channels based on the keyboard matrix size. Figure 10-6 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pull-up. Column channels are configured as outputs and drive a low level.

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 10.2.3).

When the keyboard interrupt is received, the processor can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

Figure 10-6. General-Purpose Interface Used as a Keyboard Interface

10.3 GPIO Registers

All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little-endian encoding). Access to registers is direct; no shadow registers are implemented.

Table 10-1. GPIO Registers

Offset	Acronym	Register Name	Section
0h	GPIO_REVISION	GPIO Revision Register	Section 10.3.1
10h	GPIO_SYSCONFIG	System Configuration Register	Section 10.3.2
20h	GPIO_EOI	End of Interrupt Register	Section 10.3.3

194h	GPIO_SETDATAOUT	Set Data Output Register	Section 10.3.24

10.3.1 GPIO_REVISION Register

The GPIO revision register is a read only register containing the revision number of the GPIO module. A write to this register has no effect, the same as the reset.

Figure 10-7. GPIO_REVISION Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-2. GPIO_REVISION Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	Used to distinguish between old Scheme and current.
29-28	Reserved	R	1h	Reserved
27-16	FUNC	R	60h	Indicates a software compatible module family.
15-11	RTL	R	1Fh	RTL version
10-8	MAJOR	R	0h	Major Revision
7-6	CUSTOM	R	0h	Indicates a special version for a particular device.
5-0	MINOR	R	1Fh	Minor Revision

10.3.2 GPIO_SYSCONFIG Register

The GPIO_SYSCONFIG register controls the various parameters of the L4 interconnect.

NOTE: When the AUTOIDLE bit is set, the GPIO_DATAIN read command has a 3 OCP cycle latency due to the data in sample gating mechanism. When the AUTOIDLE bit is not set, the GPIO_DATAIN read command has a 2 OCP cycle latency.

Figure 10-8. GPIO_SYSCONFIG Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-3. GPIO_SYSCONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	Reserved	R	0h	Reserved
4-3	IDLEMODE	R/W	0h	Power Management, Req/Ack control 0 = Force-idle. An idle request is acknowledged unconditionally 1 = No-idle. An idle request is never acknowledged 2 = Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module 3 = Smart-idle.
2	Reserved	R/W	0h	Reserved. Always write the default value for future device compatibility.
1	SOFTRESET	R/W	0h	Software reset. This bit is automatically reset by the hardware. During reads, it always returns 0. 0 = Normal mode 1 = The module is reset
0	AUTOIDLE	R/W	0h	Internal interface clock gating strategy 0 = Internal Interface OCP clock is free-running 1 = Automatic internal OCP clock gating, based on the OCP interface activity

10.3.3 GPIO_EOI Register

The GPIO_EOI register provides software end of interrupt (EOI) control.

Figure 10-9. GPIO_EOI Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-4. GPIO_EOI Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	Reserved
0	LINE_NUMBER	R/W	0h	Software End Of Interrupt (EOI) control. Write number of interrupt output. Write 0 = EOI for interrupt output line #0 Write 1 = EOI for interrupt output line #1 Read 0 = Reads always 0 (no EOI memory)

10.3.4 GPIO_IRQSTATUS_RAW_0 Register

The GPIO_IRQSTATUS_RAW_0 register provides core status information for the interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit sets it to 1, that is, triggers the IRQ (mostly for debug). Writing a 0 has no effect, that is, the register value is not modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

Figure 10-10. GPIO_IRQSTATUS_RAW_0 Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-5. GPIO_IRQSTATUS_RAW_0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	INTLINE[n]	R/W	0h	Interrupt n status. 0 = No effect 1 = IRQ is triggered.

10.3.5 GPIO_IRQSTATUS_RAW_1 Register

The GPIO_IRQSTATUS_RAW_1 register provides core status information for the interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit sets it to 1, that is, triggers the IRQ (mostly for debug). Writing a 0 has no effect, that is, the register value is not modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

Figure 10-11. GPIO_IRQSTATUS_RAW_1 Register

Table 10-6. GPIO_IRQSTATUS_RAW_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	INTLINE[n]	R/W	0h	Interrupt n status. 0 = No effect 1 = IRQ is triggered.

10.3.6 GPIO_IRQSTATUS_0 Register

The GPIO_IRQSTATUS_0 register provides core status information for the interrupt handling, showing all enabled events (enabled interrupts only). The fields are read-write. Writing a 1 to a bit clears the bit to 0, that is, clears the IRQ. Writing a 0 has no effect, that is, the register value is not modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

Figure 10-12. GPIO_IRQSTATUS_0 Register

LEGEND: R/W = Read/Write; W1C = Write a 1 to clear to 0, a write of 0 has no effect; -n = value after reset

Table 10-7. GPIO_IRQSTATUS_0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	INTLINE[n]	R/W1C	0h	Interrupt n status. 0 = No effect 1 = IRQ is triggered.

10.3.7 GPIO_IRQSTATUS_1 Register

The GPIO_IRQSTATUS_1 register provides core status information for the interrupt handling, showing all enabled events (enabled interrupts only). The fields are read-write. Writing a 1 to a bit clears the bit to 0, that is, clears the IRQ. Writing a 0 has no effect, that is, the register value is not modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

Figure 10-13. GPIO_IRQSTATUS_1 Register

LEGEND: R/W = Read/Write; W1C = Write a 1 to clear to 0, a write of 0 has no effect; -n = value after reset

Table 10-8. GPIO_IRQSTATUS_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	INTLINE[n]	R/W1C	0h	Interrupt n status. 0 = No effect 1 = IRQ is triggered.

10.3.8 GPIO_IRQENABLE_SET_0 Register

All 1-bit fields in the GPIO_IRQENABLE_SET_0 register enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit enables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

Figure 10-14. GPIO_IRQENABLE_SET_0 Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-9. GPIO_IRQENABLE_SET_0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	INTLINE[n]	R/W	0h	Interrupt n enable 0 = No effect 1 = Enable IRQ generation.

10.3.9 GPIO_IRQENABLE_SET_1 Register

All 1-bit fields in the GPIO_IRQENABLE_SET_1 register enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit enables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

Figure 10-15. GPIO_IRQENABLE_SET_1 Register

LEGEND: R/W = Read/Write; -n = value after reset

Bit	Field	Type	Reset	Description
31-0	INTLINE[n]	R/W	0h	Interrupt n enable 0 = No effect 1 = Disable IRQ generation.

10.3.11 GPIO_IRQENABLE_CLR_1 Register

All 1-bit fields in the GPIO_IRQENABLE_CLR_1 register clear a specific interrupt event. Writing a 1 to a bit disables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

Figure 10-17. GPIO_IRQENABLE_CLR_1 Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-12. GPIO_IRQENABLE_CLR_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	INTLINE[n]	R/W	0h	Interrupt n enable 0 = No effect 1 = Disable IRQ generation.

10.3.12 GPIO_SYSSTATUS Register

The GPIO_SYSSTATUS register provides the reset status information about the GPIO module. It is a read-only register; a write to this register has no effect.

Figure 10-18. GPIO_SYSSTATUS Register

LEGEND: R = Read only; -n = value after reset

Table 10-13. GPIO_SYSSTATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	Reserved
0	RESETDONE	R	0h	Reset status information. 0 = Internal Reset is on-going 1 = Reset completed

10.3.13 GPIO_CTRL Register

The GPIO_CTRL register controls the clock gating functionality. The DISABLEMODULE bit controls a clock gating feature at the module level. When set, this bit forces the clock gating for all internal clock paths. Module internal activity is suspended. System interface is not affected by this bit. System interface clock gating is controlled with the AUTOIDLE bit in the system configuration register (GPIO_SYSCONFIG). This bit is to be used for power saving when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

Figure 10-19. GPIO_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-14. GPIO_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-3	Reserved	R	0h	Reserved
2-1	GATINGRATIO	R/W	1h	Gating Ratio. Controls the clock gating for the event detection logic. 0 = Functional clock is interface clock. 1 = Functional clock is interface clock divided by 2. 2 = Functional clock is interface clock divided by 4. 3 = Functional clock is interface clock divided by 8.
0	DISABLEMODULE	R/W	0h	Module Disable 0 = Module is enabled, clocks are not gated. 1 = Module is disabled, clocks are gated.

10.3.14 GPIO_OE Register

The GPIO_OE register is used to enable the pins output capabilities. At reset, all the GPIO related pins are configured as input and output capabilities are disabled. This register is not used within the module, its only function is to carry the pads configuration. When the application is using a pin as an output and does not want interrupt generation from this pin, the application can/has to configure properly the Interrupt Enable registers.

Figure 10-20. GPIO_OE Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-15. GPIO_OE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	OUTPUTEN[n]	R/W	FFFF FFFFh	Output Data Enable 0 = The corresponding GPIO port is configured as an output. 1 = The corresponding GPIO port is configured as an input.

10.3.15 GPIO_DATAIN Register

The GPIO_DATAIN register is used to register the data that is read from the GPIO pins. The GPIO_DATAIN register is a read-only register. The input data is sampled synchronously with the interface clock and then captured in the GPIO_DATAIN register synchronously with the interface clock. So, after changing, GPIO pin levels are captured into this register after two interface clock cycles (the required cycles to synchronize and to write the data).

NOTE: When the AUTOIDLE bit in the system configuration register (GPIO_SYSCONFIG) is set, the GPIO_DATAIN read command has a 3 OCP cycle latency due to the data in sample gating mechanism. When the AUTOIDLE bit is not set, the GPIO_DATAIN read command has a 2 OCP cycle latency.

Figure 10-21. GPIO_DATAIN Register

LEGEND: R = Read only; -n = value after reset

Table 10-16. GPIO_DATAIN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	DATAIN	R	x	Sampled Input Data

10.3.16 GPIO_DATAOUT Register

The GPIO_DATAOUT register is used for setting the value of the GPIO output pins. Data is written to the GPIO_DATAOUT register synchronously with the interface clock. This register can be accessed with direct read/write operations or using the alternate 'Set/Clear' feature. This feature enables to set or clear specific bits of this register with a single write access to the set data output register (GPIO_SETDATAOUT) or to the clear data output register (GPIO_CLEARDATAOUT) address.

Figure 10-22. GPIO_DATAOUT Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-17. GPIO_DATAOUT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	DATAOUT	R/W	0	Data to set on output pins

10.3.17 GPIO_LEVELDETECT0 Register

The GPIO_LEVELDETECT0 register is used to enable/disable for each input lines the low-level (0) detection to be used for the interrupt request generation.

NOTE: Enabling at the same time high-level detection and low-level detection for one given pin makes a constant interrupt generator.

Figure 10-23. GPIO_LEVELDETECT0 Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-18. GPIO_LEVELDETECT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	LEVELDETECT0[n]	R/W	0h	Low Level Interrupt Enable 0 = Disable the IRQ assertion on low-level detect. 1 = Enable the IRQ assertion on low-level detect.

10.3.18 GPIO_LEVELDETECT1 Register

The GPIO_LEVELDETECT1 register is used to enable/disable for each input lines the high-level (1) detection to be used for the interrupt request generation.

NOTE: Enabling at the same time high-level detection and low-level detection for one given pin makes a constant interrupt generator.

Figure 10-24. GPIO_LEVELDETECT1 Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-19. GPIO_LEVELDETECT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	LEVELDETECT1[n]	R/W	0h	High Level Interrupt Enable 0 = Disable the IRQ assertion on high-level detect. 1 = Enable the IRQ assertion on high-level detect.

10.3.19 GPIO_RISINGDETECT Register

The GPIO_RISINGDETECT register is used to enable/disable for each input lines the rising-edge (transition 0 to 1) detection to be used for the interrupt request generation.

Figure 10-25. GPIO_RISINGDETECT Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-20. GPIO_RISINGDETECT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	RISINGDETECT[n]	R/W	0h	Rising Edge Interrupt Enable 0 = Disable IRQ on rising-edge detect. 1 = Enable IRQ on rising-edge detect.

10.3.20 GPIO_FALLINGDETECT Register

The GPIO_FALLINGDETECT register is used to enable/disable for each input lines the falling-edge (transition 1 to 0) detection to be used for the interrupt request generation.

Figure 10-26. GPIO_FALLINGDETECT Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-21. GPIO_FALLINGDETECT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	FALLINGDETECT[n]	R/W	0h	Falling Edge Interrupt Enable 0 = Disable IRQ on falling-edge detect. 1 = Enable IRQ on falling-edge detect.

10.3.21 GPIO_DEBOUNCENABLE Register

The GPIO_DEBOUNCENABLE register is used to enable/disable the debouncing feature for each input line.

Figure 10-27. GPIO_DEBOUNCENABLE Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-22. GPIO_DEBOUNCENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	DEBOUNCEENABLE[n]	R/W	0h	Input Debounce Enable 0 = Disable debouncing feature on the corresponding input port. 1 = Enable debouncing feature on the corresponding input port.

10.3.22 GPIO_DEBOUNCINGTIME Register

The GPIO_DEBOUNCINGTIME register controls debouncing time (the value is global for all ports). The debouncing cell is running with the debouncing clock (32 kHz), this register represents the number of the clock cycle(s) (31µs long) to be used.

Figure 10-28. GPIO_DEBOUNCINGTIME Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-23. GPIO_DEBOUNCINGTIME Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	Reserved	R/W	0h	Reserved
7-0	DEBOUNCETIME	R/W	0h	Input Debouncing Value in 31 microsecond steps. Debouncing time = (DEBOUNCETIME + 1) × 31 microseconds

10.3.23 GPIO_CLEARDATAOUT Register

Writing a 1 to a bit in the GPIO_CLEARDATAOUT register clears to 0 the corresponding bit in the GPIO_DATAOUT register; writing a 0 has no effect. A read of the GPIO_CLEARDATAOUT register returns the value of the data output register (GPIO_DATAOUT).

Figure 10-29. GPIO_CLEARDATAOUT Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-24. GPIO_CLEARDATAOUT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	INTLINE [n]	R/W	0h	Clear Data Output Register 0 = No effect 1 = Clear the corresponding bit in the GPIO_DATAOUT register.

10.3.24 GPIO_SETDATAOUT Register

Writing a 1 to a bit in the GPIO_SETDATAOUT register sets to 1 the corresponding bit in the GPIO_DATAOUT register; writing a 0 has no effect. A read of the GPIO_SETDATAOUT register returns the value of the data output register (GPIO_DATAOUT).

Figure 10-30. GPIO_SETDATAOUT Register

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-25. GPIO_SETDATAOUT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	INTLINE [n]	R/W	0h	Set Data Output Register 0 = No effect 1 = Set the corresponding bit in the GPIO_DATAOUT register.

General-Purpose Memory Controller (GPMC)

This chapter describes the general-purpose memory controller (GPMC).

Topic	Page
11.1 Introduction	1566
11.2 Architecture	1568
11.3 Basic Programming Model	1647
11.4 Use Cases And Tips	1666
11.5 Registers	1678

11.1 Introduction

11.1.1 Overview

The general-purpose memory controller (GPMC) is an unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-multiplexed mode) burst NOR flash devices
- NAND Flash
- Pseudo-SRAM devices

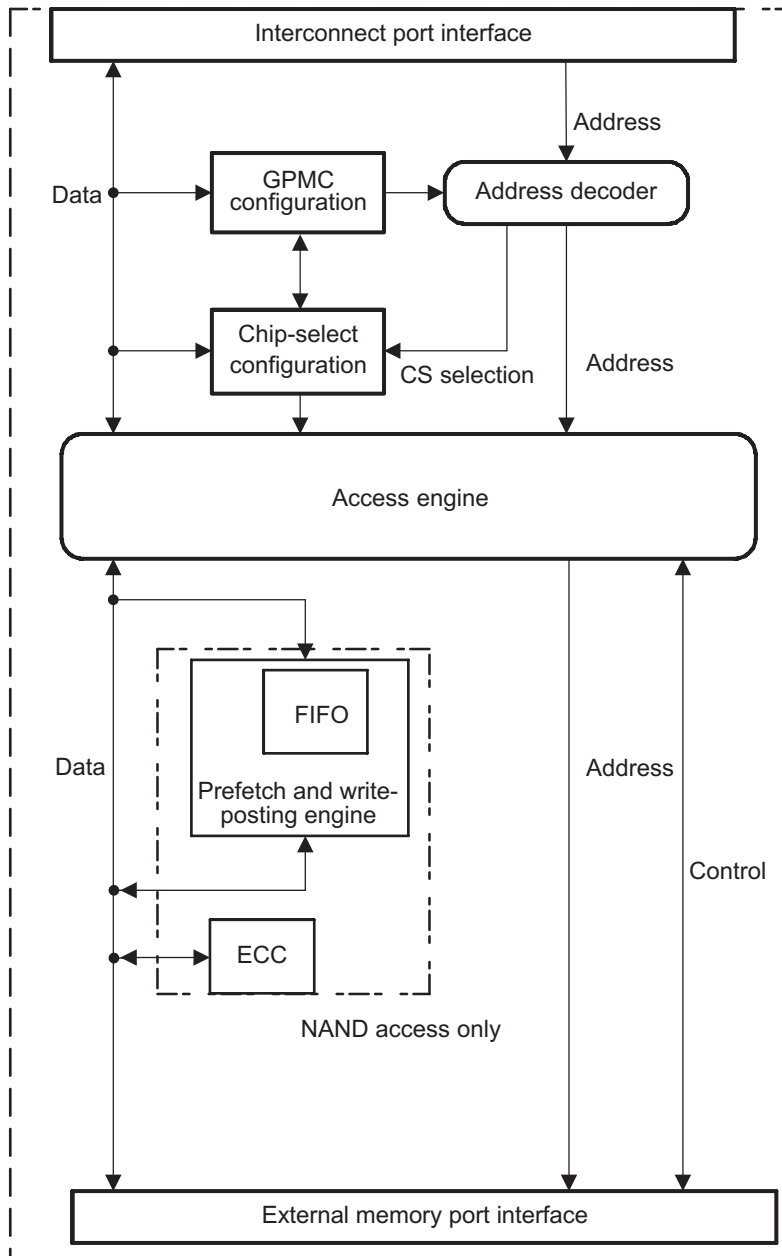

11.1.2 Block Diagram

The GPMC can access various external devices through the L3 Slow Interconnect. The flexible programming model allows a wide range of attached device types and access schemes. Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type. Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

[Figure 11-1](#) shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 11-1. GPMC Block Diagram

11.2 Architecture

11.2.1 GPMC Signals

Table 11-1 lists the GPMC subsystem I/O pins.

NOTE: In this chapter, the *i* in GPMC_CONFIGx_i represents GPMC chip-select *i*, where *i* = 0 to 5.

Table 11-1. GPMC I/O Description

Pin Name	I/O	Description
GPMC_A[27:0]	O	Address
GPMC_D[15:0]	I/O	Data
$\overline{\text{GPMC_CS}}[5:0]$	O	Chip-selects (active low)
GPMC_CLK	O	Clock generated for the external memory or device
GPMC_ $\overline{\text{ADV_ALE}}$	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
$\overline{\text{GPMC_OE_RE}}$	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
$\overline{\text{GPMC_WE}}$	O	Write enable (active low)
GPMC_BE $\overline{0_CLE}$	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
$\overline{\text{GPMC_BE1}}$	O	Upper-byte enable (active low)
GPMC_WAIT	I	External wait signal for NOR and NAND protocol memories. The wait signal can be mapped on any of the chip-selects.

Table 11-2 shows the use of address and data GPMC controller pins based on the type of external device.

Table 11-2. GPMC Pin Multiplexing Options

GPMC Pin	Non Multiplexed Address Data 16- Bit Device	Non Multiplexed Address Data 8- Bit Device	Multiplexed Address Data 16- Bit Device	16-Bit NAND Device	8-Bit NAND Device

GPMC_D[11]	D11	Not Used	A12/D11	D11	Not Used
GPMC_D[10]	D10	Not Used	A11/D10	D10	Not Used
GPMC_D[9]	D9	Not Used	A10/D9	D9	Not Used
GPMC_D[8]	D8	Not Used	A9/D8	D8	Not Used
GPMC_D[7]	D7	D7	A8/D7	D7	D7
GPMC_D[6]	D6	D6	A7/D6	D6	D6
GPMC_D[5]	D5	D5	A6/D5	D5	D5
GPMC_D[4]	D4	D4	A5/D4	D4	D4
GPMC_D[3]	D3	D3	A4/D3	D3	D3
GPMC_D[2]	D2	D2	A3/D2	D2	D2
GPMC_D[1]	D1	D1	A2/D1	D1	D1
GPMC_D[0]	D0	D0	A1/D0	D0	D0

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

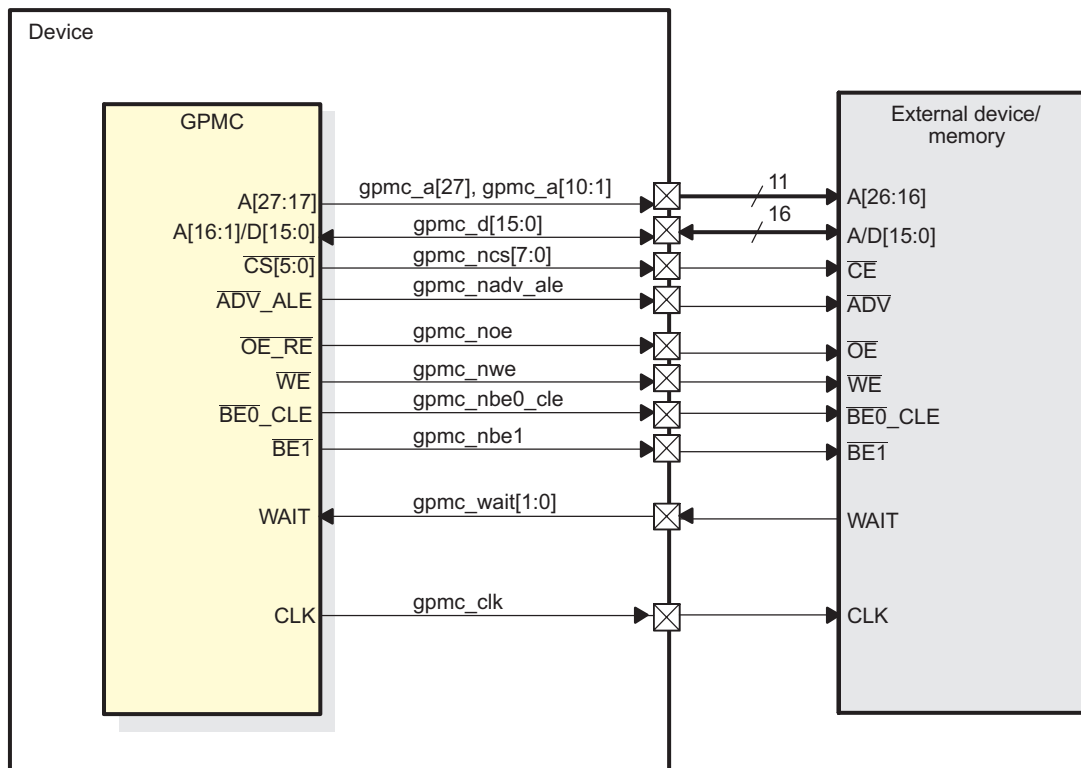

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i[9-8] MUXADDDATA bit field (i = 0 to 5).
- Asynchronous page mode is not supported for multiplexed address and data devices.

11.2.2 GPMC Modes

This section shows three GPMC external connections options:

- [Figure 11-2](#) shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol use less address pins) external memory device.
- [Figure 11-3](#) shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device .
- [Figure 11-4](#) shows a connection between the GPMC and a 8-bit NAND device

Figure 11-2. GPMC to 16-Bit Address/Data-Multiplexed Memory

- A If ROM boot from the NOR device is required, some high-order address lines must be driven or pulled low by external hardware during ROM operation. See the *ROM Code Memory and Peripheral Booting* chapter, XIP Memory section, and the device data manual for details.

Figure 11-3. GPMC to 16-Bit Nonmultiplexed Memory

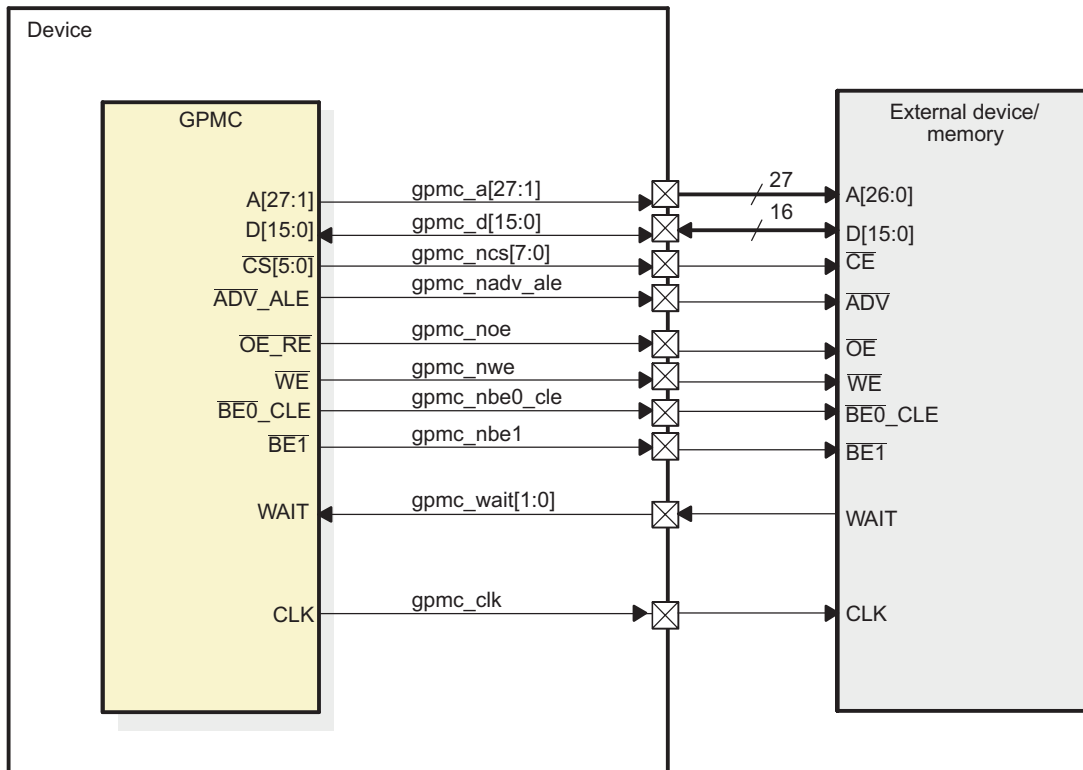

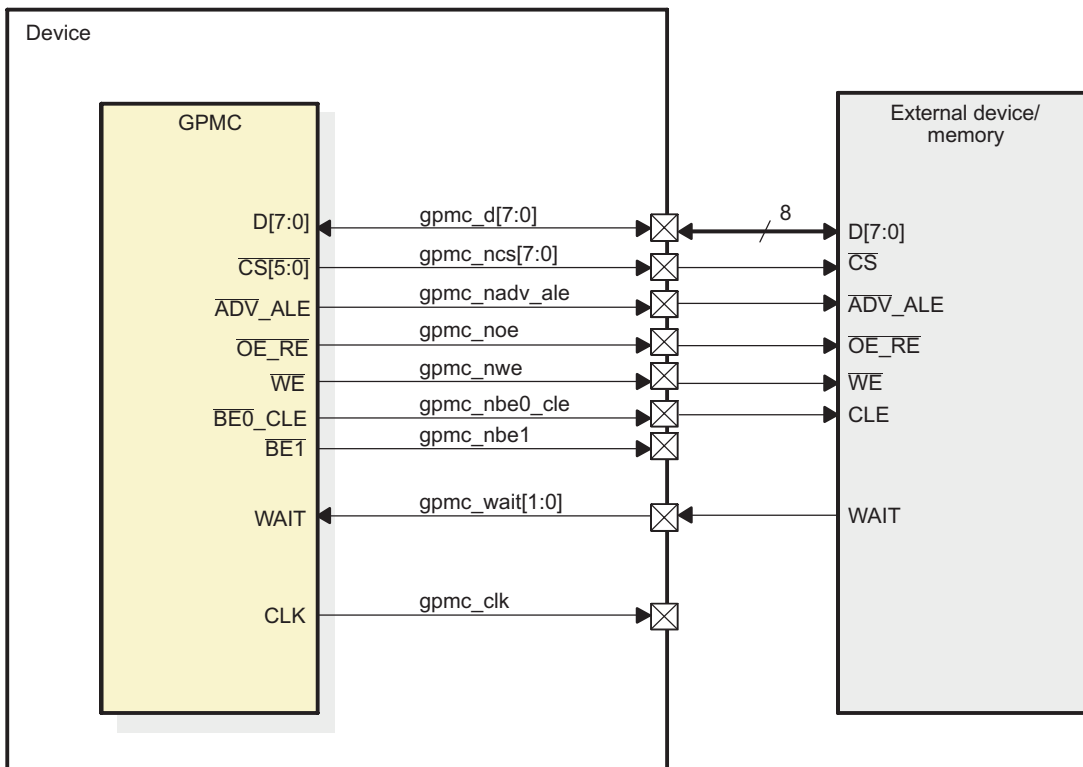

Figure 11-4. GPMC to 8-Bit NAND Device

11.2.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No STANDBY hardware handshake
- No wake-up request
- One system direct memory access (eDMA) request
- One interrupt request to the Cortex-A8 MPU Interrupt Controller (MA_IRQ)
- One clock for functional and interface domains

Figure 11-5 shows GPMC integration. Table 11-3 through Table 11-5 summarize the integration of the module in the device.

Figure 11-5. GPMC Integration

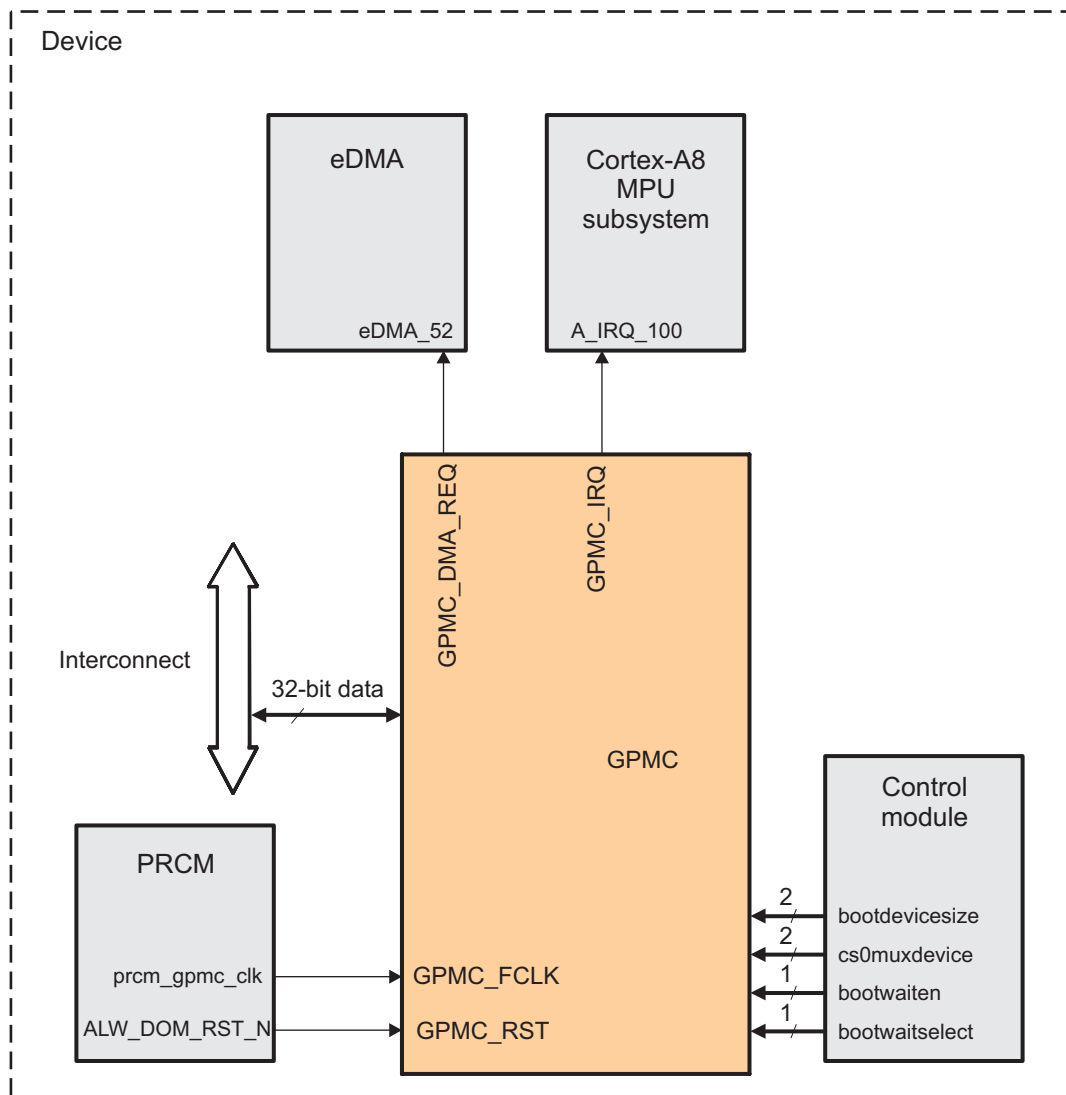

Table 11-3. GPMC Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-up Capability	Interconnect
GPMC	ALWAYS_ON	No	L3_Slow

11.2.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the six configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

11.2.4.1 GPMC Clock Configuration

Table 11-6 describes the GPMC clocks.

Table 11-6. GPMC Clocks

Signal	I/O	Description
GPMC_FCLK	I	Functional and interface clock
GPMC_CLK	O	External clock provided to synchronous external memory devices.

The GPMC_CLK is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in Table 11-4. The GPMC_CLK is configured via the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field (for i = 0 to 3) as shown in Table 11-7.

Table 11-7. GPMC_CONFIG1_i Configuration

Source Clock	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	GPMC_CLK Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/4
	11	GPMC_FCLK/8

11.2.4.2 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. The software must ensure that the software reset completes before doing GPMC operations.

11.2.4.3 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines. Table 11-8 describes power-management features available for the GPMC module.

Table 11-8. GPMC Local Power Management Features

Feature	Registers	Description
Clock Auto Gating	GPMC_SYSCONFIG[0] AUTOIDLE] bit	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave Idle Modes	GPMC_SYSCONFIG[4-3] SIDLEMODE bit field	Force-idle, No-idle and Smart-idle wakeup modes are available
Clock Activity	N/A	Feature not available
Master Standby Modes	N/A	Feature not available
Global Wake-up Enable	N/A	Feature not available
Wake-up Sources Enable	N/A	Feature not available

11.2.4.4 GPMC Interrupt Requests

The GPMC generates one interrupt event as shown in [Figure 11-5](#).

- The interrupt request goes from GPMC (GPMC_IRQ) to the Cortex-A8 MPU subsystem: A_IRQ_100
- [Table 11-9](#) lists the event flags, and their mask, that can cause module interrupts.

Table 11-9. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Map to	Description
GPMC_IRQSTATUS[9] WAIT1EDGEDETECTIO NSTATUS	GPMC_IRQENABLE[9] WAIT1EDGEDETECTIO NENABLE	Edge	A_IRQ_100	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGEDETECTIO NSTATUS	GPMC_IRQENABLE[8] WAIT0EDGEDETECTIO NENABLE	Edge	A_IRQ_100	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINALCOUNTSTAT US	GPMC_IRQENABLE[1] TERMINALCOUNTENA BLE	Level	A_IRQ_100	Terminal count event: Triggered on prefetch process completion, that is when the number of currently remaining data to be requested reaches 0.
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	A_IRQ_100	FIFO event interrupt: Indicates FIFO levels availability for in Write-Posting mode and prefetch mode. GPMC_PREFETCH_CONFIG[2] DMAMODE bit shall be cleared to 0.

11.2.4.5 GPMC DMA Requests

The GPMC generates one DMA event as shown in [Figure 11-5](#).

- From GPMC (GPMC_DMA_REQ) to the eDMA: e_DMA_53

11.2.4.6 L3 Slow Interconnect Interface

The GPMC L3 Slow interconnect interface is a pipelined interface including an 16 × 32-bit word write buffer. Any system host can issue external access requests through the GPMC. The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32 or 16 × 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the GPMC_CONFIG1_i ATTACHEDDEVICEPAGELENGTH field ([24-23]) according to the effective attached device page length and to enable the GPMC_CONFIG1_i WRAPBURST bit ([31]) if the attached device supports wrapping burst. However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

11.2.4.7 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: GPMC_D[15-8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: GPMC_A[27-0].
- 8-bit wide NAND devices do not use GPMC I/O: GPMC_A[27-0] and GPMC I/O: GPMC_D[15-8].

11.2.4.7.1 GPMC I/O Configuration Setting

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 10
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 01

To select an address/data-nonmultiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 00

11.2.4.8 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). [Section 11.5](#) provides the GPMC register locations. For the map of GPMC memory locations, see [Table 11-54](#).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

11.2.4.8.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-Mbyte contiguous address space. For details, see [Table 11-54](#).

The GPMC 512 Mbyte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16 Mbytes to 256 Mbytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in [Figure 11-6](#) (with A0 as the device system byte-address line). Base address is programmed through the GPMC_CONFIG7_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field cleared to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11-8] MASKADDRESS bit field.

Figure 11-6. Chip-Select Address Mapping and Decoding Mask

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (i = 0 to 5). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select. Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

Although the GPMC interface can drive up to six chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

11.2.4.8.2 Access Protocol

11.2.4.8.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11-10] DEVICETYPE parameter (where i = 0 to 5) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 11.2.4.12](#) and [Section 11.2.4.12.1](#).

11.2.4.8.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13-12] DEVICESIZE field (i = 0 to 5) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

11.2.4.8.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[[9-8] MUXADDDATA bit (i = 0 to 5). The \overline{ADV} signal must be used as the external device address latch control signal. For the associated chip-select configuration, \overline{ADV} assertion and deassertion time and \overline{OE} assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device (see [Section 11.2.3](#)).

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol (see [Section 11.2.4.12](#)).

11.2.4.8.3 External Signals

11.2.4.8.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC features two input wait pin:gpmc_wait1, and gpmc_wait0. This pin allow control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC_CONFIG1_i[17-16] WAITPINSELECT bit (where i = 0 to 5) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured per CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

11.2.4.8.3.2 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

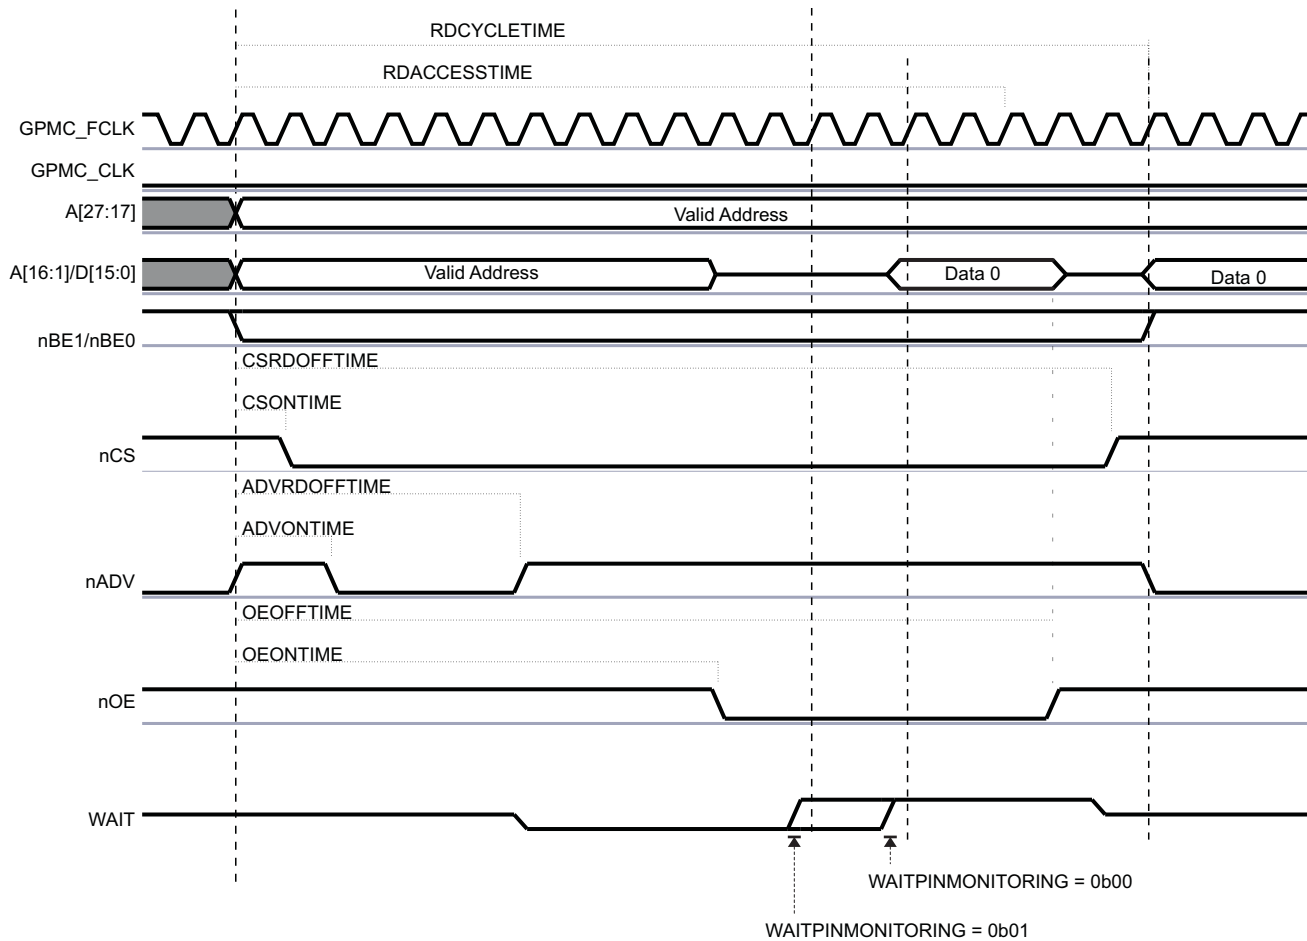

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit (i = 0 to 5).

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 11-7 shows wait behavior during an asynchronous single read access.

Figure 11-7. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

The WAIT signal is active low. GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 00b or 01b.

11.2.4.8.3.3 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_][19-18] WAITMONITORINGTIME bit (i = 0 to 5).

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, GPMC_CONFIG1_][1-0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

11.2.4.8.3.4 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC_CONFIG1_][19-18] WAITMONITORINGTIME bit (i = 0 to 5), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC_CONFIG1_][22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

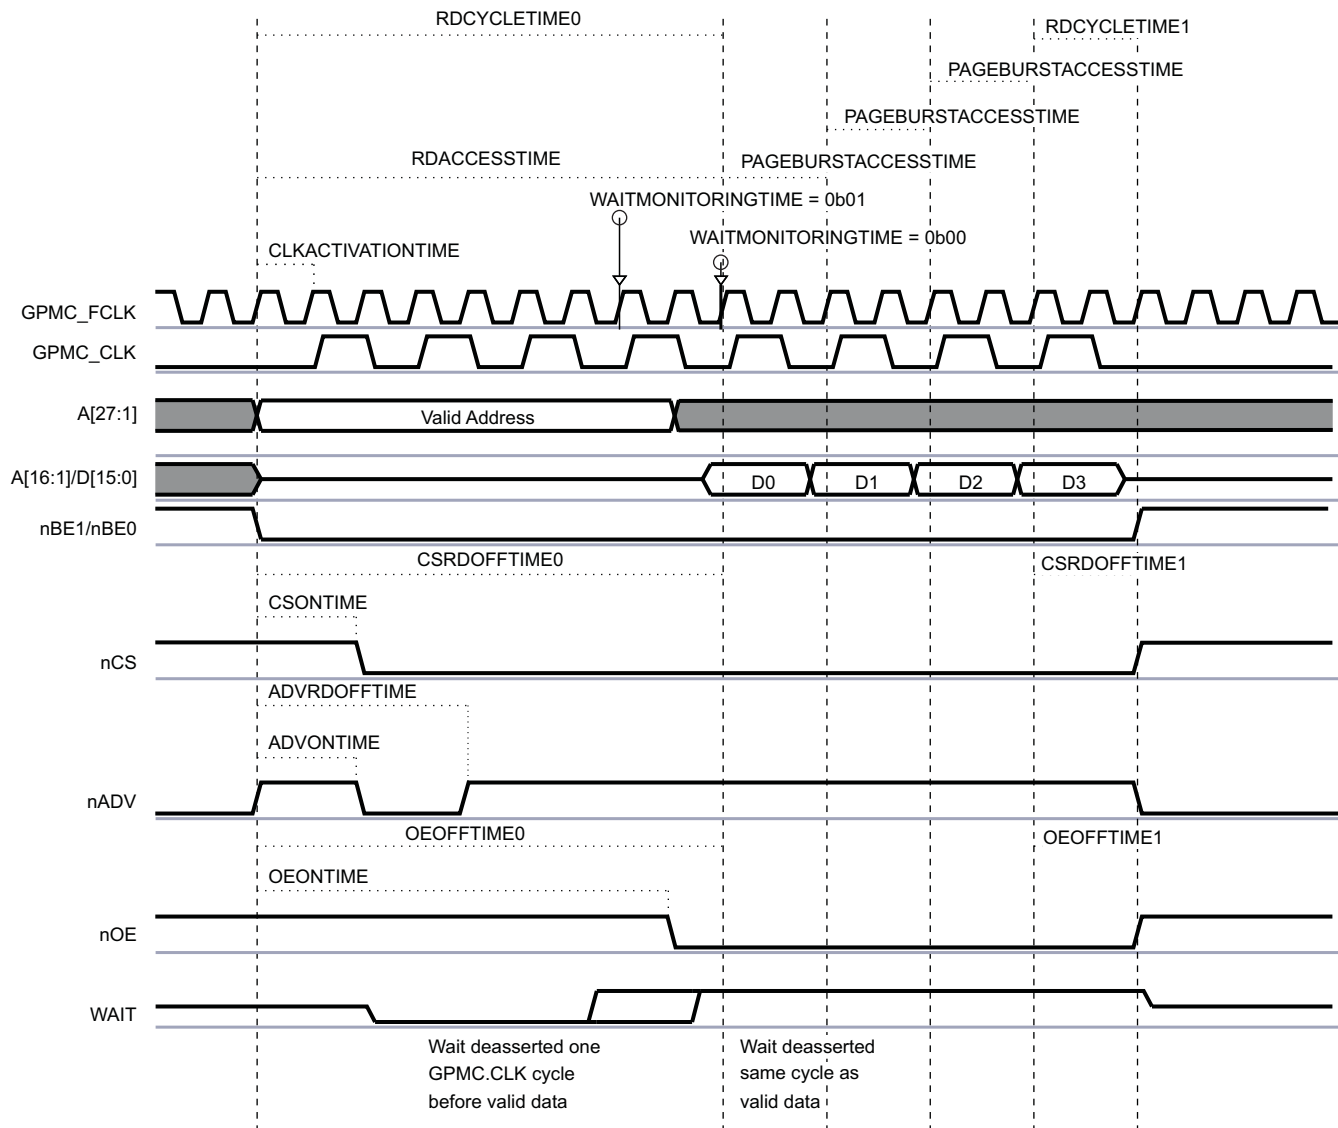

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 11-8 shows wait behavior during a synchronous read burst access.

Figure 11-8. Wait Behavior During a Synchronous Read Burst Access

The WAIT signal is active low. $WAITMONITORINGTIME = 00b$ or $01b$.

11.2.4.8.3.5 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the $WAITWRITEMONITORING$ bit), the wait pin is captured synchronously with $GPMC_CLK$, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with $WRACCESSTIME$ to delay the effective memory device $GPMC_CLK$ capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At $WRACCESSTIME$ completion if $WAITMONITORINGTIME = 0$
- In the $WAITMONITORINGTIME \times (GPMCFCLKDIVIDER + 1)$ $GPMC_FCLK$ cycles before $WRACCESSTIME$ completion if $WAITMONITORINGTIME$ not equal to 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

Wait monitoring is supported for all configurations except for GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 0 (where i = 0 to 3) for write bursts with a clock divider of 1 or 2 (GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field equal to 0 or 1, respectively).

11.2.4.8.3.6 WAIT With NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see [Section 11.2.4.12.2](#).

11.2.4.8.3.7 Idle Cycle Control Between Successive Accesses

11.2.4.8.3.7.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the $\overline{CS}/\overline{OE}$ de-assertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after \overline{CS} or \overline{OE} de-assertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3-0] BUSTURNAROUND bit (i = 0 to 5).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Bus keeping starts after bus turnaround completion. The bus will not have enough time to go into high-impedance even though it could be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3-0] CYCLE2CYCLEDELAY delays. It should be noted that BUSTURNAROUND is a timing parameter for the ending chip-select access while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access. See [Figure 11-9](#) to [Figure 11-11](#).

Another way to prevent bus contention is to define an earlier \overline{CS} or \overline{OE} deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

Figure 11-9. Read to Read for an Address-Data Multiplexed Device, On Different CS, Without Bus Turnaround (CS0 Attached to Fast Device)

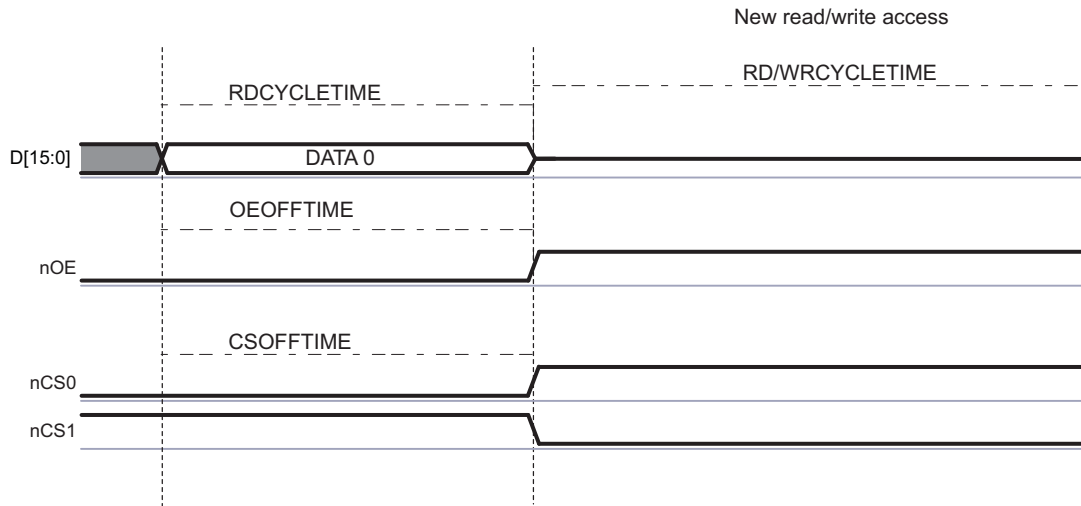

Figure 11-10. Read to Read / Write for an Address-Data Multiplexed Device, On Different CS, With Bus Turnaround

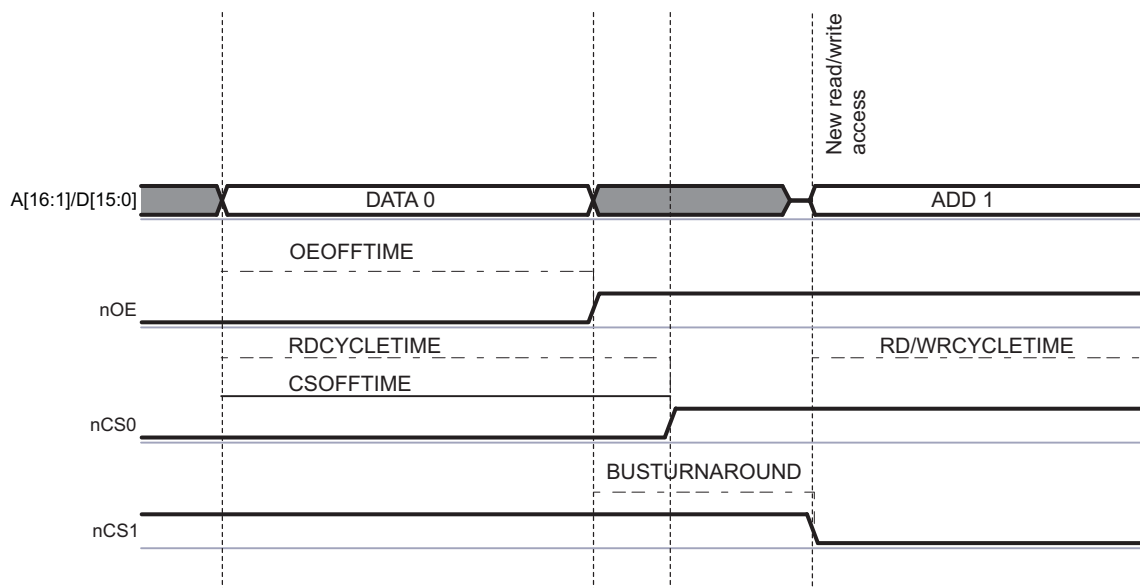

Figure 11-11. Read to Read / Write for a Address-Data or AAD-Multiplexed Device, On Same CS, With Bus Turnaround

11.2.4.8.3.7.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMEECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMEECSEN bit (i = 0 to 5) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11-8] CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMEECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

11.2.4.8.3.7.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFECSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (\overline{CS} , $\overline{ADV_ALE}$, $\overline{BE0_CLE}$, $\overline{OE_RE}$, \overline{WE}) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (\overline{WE} , $\overline{OE_RE}$) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFECSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See [Section 11.2.4.8.3.7.1](#) for more details on bus turnaround.

[Table 11-10](#) describes the configuration required for idle cycle insertion.

Table 11-10. Idle Cycle Insertion Configuration

First Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Addr/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	>0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	>0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	>0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	>0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	>0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	>0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	>0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

11.2.4.8.3.8 Slow Device Support (*TIMEPARAGRANULARITY* Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i = 0 to 5). Increasing all access timing parameters allows support of slow devices.

11.2.4.8.3.9 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see Power, Reset, and Clock Management.

The PRCM module provides an input pin, `global_rst_n`, to the GPMC:

- The `global_rst_n` pin is activated during device warm reset and cold reset.
- The `global_rst_n` pin initializes the internal state-machine and the internal configuration registers.

11.2.4.8.3.10 Byte Enable ($\overline{BE1}/\overline{BE0}$)

Byte enable signals ($\overline{BE1}/\overline{BE0}$) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

11.2.4.8.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the `GPMC_ERR_TYPE` register and the address of the illegal access is stored in the `GPMC_ERR_ADDRESS` register. The GPMC keeps only the first error abort information until the `GPMC_ERR_TYPE` register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the `GPMC_ERR_TYPE[0]ERRORVALID` bit.

- `ERRORNOTSUPPADD` occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.
- `ERRORNOTSUPPMCMD` occurs when an unsupported command request is decoded at the L3 Slow interconnect interface
- `ERRORTIMEOUT`: A time-out mechanism prevents the system from hanging. The start value of the

9-bit time-out counter is defined in the `GPMC_TIMEOUT_CONTROL` register and enabled with the `GPMC_TIMEOUT_CONTROL[0]TIMEOUTENABLE` bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at the interconnect level.

11.2.4.9 Timing Setting

The GPMC offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information on `GPMC_CLK` and `GPMC_FCLK` see [Section 11.2.4.9.6](#).

In the following sections, the start access time refer to the time at which the access begins.

11.2.4.9.1 Read Cycle Time and Write Cycle Time ($RDCYCLETIME$ / $WRCYCLETIME$)

The `GPMC_CONFIG5_i[4-0]RDCYCLETIME` and `GPMC_CONFIG5_i[12-8]WRCYCLETIME` bit ($i = 0$ to 5) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of `GPMC_CLK` between accesses, $RDCYCLETIME$ and $WRCYCLETIME$ are expressed in `GPMC_FCLK` cycles and must be multiples of the `GPMC_CLK` cycle. $RDCYCLETIME$ and $WRCYCLETIME$ bit fields can be set with a granularity of 1 or 2 through `GPMC_CONFIG1_i[4]TIMEPARAGRANULARITY`.

When either $RDCYCLETIME$ or $WRCYCLETIME$ completes, if they are not already deasserted, all control signals (\overline{CS} , $\overline{ADV_ALE}$, $\overline{OE_RE}$, \overline{WE} , and $\overline{BE0_CLE}$) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (\overline{CS} , $\overline{ADV_ALE}$, $\overline{BE0_CLE}$, \overline{WE} , and $\overline{OE_RE}$) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

11.2.4.9.2 \overline{CS} : Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3-0] CSONTIME field (where i = 0 to 5) defines the \overline{CS} signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i[12-8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20-16] CSWROFFTIME (write access) bit fields define the \overline{CS} signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

\overline{CS} signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the \overline{CS} assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters controlling \overline{CS} transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the \overline{CS} signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

11.2.4.9.3 $\overline{ADV_ALE}$: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY / ADVAADMUXONTIME / ADVAADMUXRDOFFTIME / ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3-0] ADVONTIME field (where i = 0 to 5) defines the $\overline{ADV_ALE}$ signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12-8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20-16] ADVWROFFTIME (write access) bit fields define the $\overline{ADV_ALE}$ signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before $\overline{ADV_ALE}$ assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after $\overline{ADV_ALE}$ de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

$\overline{ADV_ALE}$ signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{ADV_ALE}$ assertion and deassertion time to assure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling $\overline{ADV_ALE}$ transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than $\overline{ADV_ALE}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

The GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. It is the user responsibility to make sure ADVAADMUXxxOFFTIME is programmed to a value lower than or equal to ADVxxOFFTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high \overline{ADV} pulse is needed between the two AAD-mux address phases, which is the typical case in synchronous mode. In this configuration, \overline{ADV} is kept low until it reaches the correct ADVxxOFFTIME.

See [Section 11.2.4.12](#) for more details on ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME, ADVAADMUXWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

11.2.4.9.4 $\overline{OE_RE}$: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3-0] OEONTIME bit (where i = 0 to 5) defines the $\overline{OE_RE}$ signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC_CONFIG4_i[12-8] OEOFFTIME field defines the $\overline{OE_RE}$ signal deassertion time relative to start access time. It is applicable only to read accesses. $\overline{OE_RE}$ is not asserted during a write cycle.

OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before $\overline{OE_RE}$ assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after $\overline{OE_RE}$ assertion.

OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. It is the user responsibility to make sure OEAADMUXOFFTIME is programmed to a value lower than OEONTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME shall never be equal to OEONTIME because the AAD-mux protocol requires a second address phase with the \overline{OE} signal de-asserted before \overline{OE} can be asserted again to define a read command.

The $\overline{OE_RE}$ signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{OE_RE}$ assertion and deassertion time to assure proper setup and hold time relative to GPMC_CLK. If enabled, OEXTRADELAY applies to all parameters controlling $\overline{OE_RE}$ transitions.

OEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than $\overline{OE_RE}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until \overline{OE} assertion time.

11.2.4.9.5 \overline{WE} : Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19-16] WEONTIME field (where i = 0 to 3) defines the \overline{WE} signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28-24] WEOFFTIME field defines the \overline{WE} signal-deassertion time relative to start access time. These bit fields only apply to write accesses. \overline{WE} is not asserted during a read cycle.

WEONTIME can be used to control an address and byte enable valid setup time control before \overline{WE} assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after \overline{WE} assertion.

\overline{WE} signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on \overline{WE} assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling \overline{WE} transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the \overline{WE} signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

11.2.4.9.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 4, or 8, depending on the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit (where i = 0 to 3), with an assured 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit (i = 0 to 5) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.

To ensure a correct external clock cycle, the following rules must be applied:

- $(RDCYCLETIME - CLKACTIVATIONTIME)$ must be a multiple of $(GPMCFCLKDIVIDER + 1)$.
- The PAGEBURSTACCESSTIME value must be a multiple of $(GPMCFCLKDIVIDER + 1)$.

11.2.4.9.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit (i = 0 to 5) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

11.2.4.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently through GPMC_CONFIG5_i[20-16] RDACCESSTIME and GPMC_CONFIG6_i[28-24] WRACCESSTIME bit (i = 0 to 5). This allows \overline{OE} and GPMC data capture timing parameters to be independent of \overline{WE} and memory device data capture timing parameters. RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

11.2.4.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, GPMC_CONFIG5_i[[20-16] RDACCESSTIME bit (i = 0 to 5) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. GPMC_CONFIG5_i[4-0] RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see [Section 11.2.4.8.1](#).

11.2.4.9.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see [Section 11.2.4.8.1](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see [Section 11.2.4.8.1](#).

11.2.4.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit (i = 0 to 5) can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[[4] TIMEPARAGRANULARITY.

11.2.4.9.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see [Section 11.2.4.8.1](#).

11.2.4.9.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see [Section 11.2.4.8.1](#).

11.2.4.9.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

11.2.4.10 NOR Access Description

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (i = 0 to 5). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit (i = 0 to 5).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

The address bus and $\overline{BE}[1:0]$ are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

11.2.4.10.1 Asynchronous Access Description

This section describes:

- Asynchronous single read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

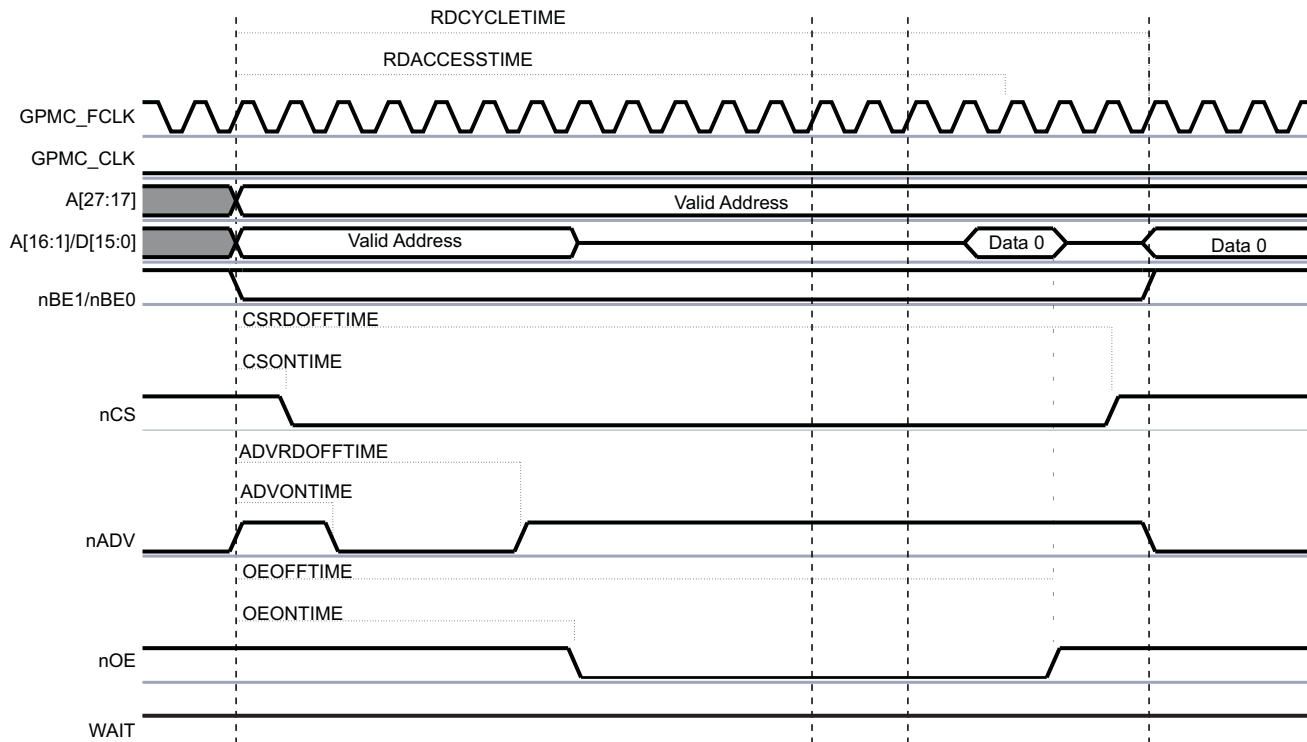

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

11.2.4.10.1.1 Access on Address/Data Multiplexed Devices

11.2.4.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 11-12 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 11-12. Asynchronous Single Read Operation on an Address/Data Multiplexed Device

11.2.4.10.1.1.2 Asynchronous Single Read on an Address/Data-Multiplexed Device

See [Section 11.3.6.1](#) for formulas to calculate timing parameters.

[Table 11-40](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until \overline{OE} assertion time. For details, see [Section 11.2.4.8.2.3](#).

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits GPMC_A[25:16] are placed on the address bus.

- Chip-select signal \overline{CS}
 - \overline{CS} assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME field. It controls the address setup time to \overline{CS} assertion.
 - \overline{CS} deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME field. It controls the address hold time from \overline{CS} deassertion
- Address valid signal \overline{ADV}
 - \overline{ADV} assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
 - \overline{ADV} deassertion time is controlled by the GPMC_CONFIG3_i[[12-8] ADVRDOFFTIME field.

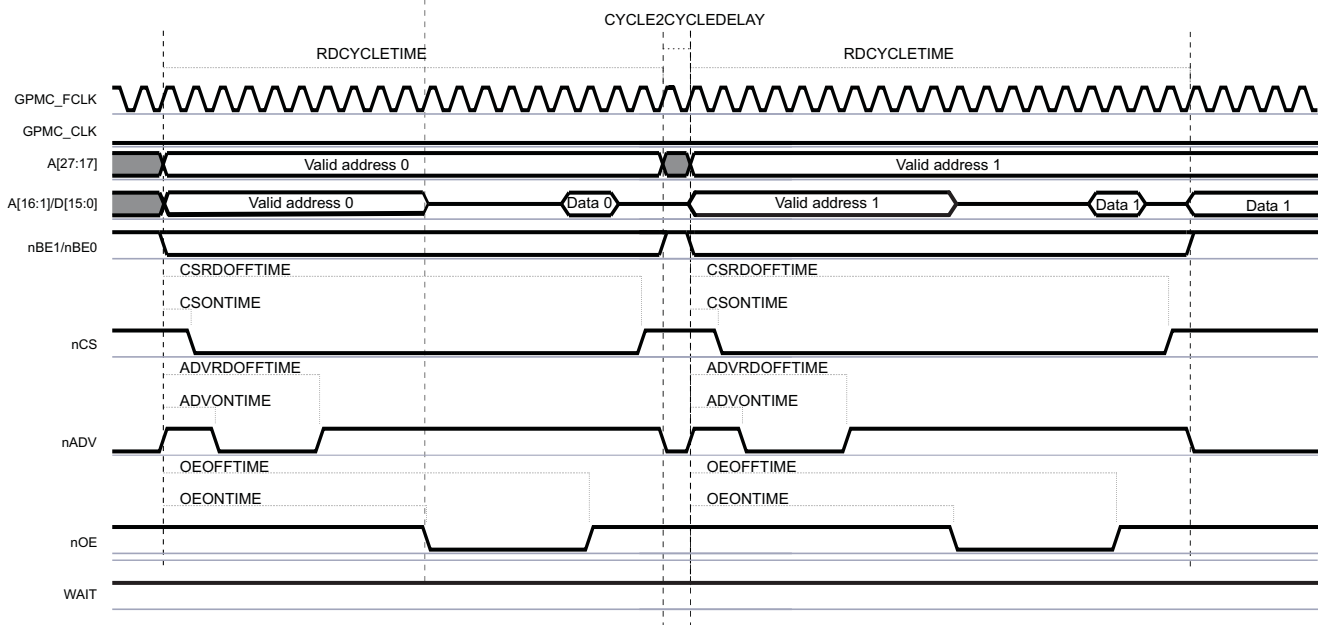

- Output enable signal \overline{OE}
 - \overline{OE} assertion indicates a read cycle.
 - \overline{OE} assertion time is controlled by the GPMC_CONFIG4_i[[3-0] OEONTIME field.
 - OE deassertion time is controlled by the GPMC_CONFIG4_i[[12-8] OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[[20-16] RDACCESSTIME field.
- The end of the access is defined by the GPMC_CONFIG5_i[[4-0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 11.2.4.10.5. Between two successive accesses, if an \overline{CS} pulse is needed:

- The GPMC_CONFIG6_i[[11-8] CYCLE2CYCLEDELAY field can be programmed with GPMC_CONFIG6_i[[7] CYCLE2CYCLESAMECSSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

Figure 11-13 shows two asynchronous single-read accesses on an address/data-multiplexed devices.

Figure 11-13. Two Asynchronous Single Read Accesses on an Address/Data Multiplexed Device (32-Bit Read Split Into 2 x 16-Bit Read)

11.2.4.10.1.1.3 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 11-14 shows an asynchronous single write operation on an address/data-multiplexed device.

Figure 11-14. Asynchronous Single Write on an Address/Data-Multiplexed Device

11.2.4.10.1.1.4 Asynchronous Single Write on an Address/Data-Multiplexed Device

See Section 11.3.6.1 for formulas to calculate timing parameters.

Table 11-40 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode. When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until \overline{WE} assertion time. For more information, see Section 11.2.4.8.2.3.

The \overline{CS} and \overline{ADV} signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Write enable signal \overline{WE}
 - \overline{WE} assertion indicates a write cycle.
 - \overline{WE} assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME field.
 - \overline{WE} deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME field.
- The end of the access is defined by the GPMC_CONFIG5_i[12-8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS time.

Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 11.2.4.9.10.

11.2.4.10.1.1.5 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices. If GPMC_CONFIG1_i[28] WRITEMULTIPLE is enabled (1) with GPMC_CONFIG1_i[27] WRITETYPE as asynchronous (0), the GPMC processes single asynchronous accesses.

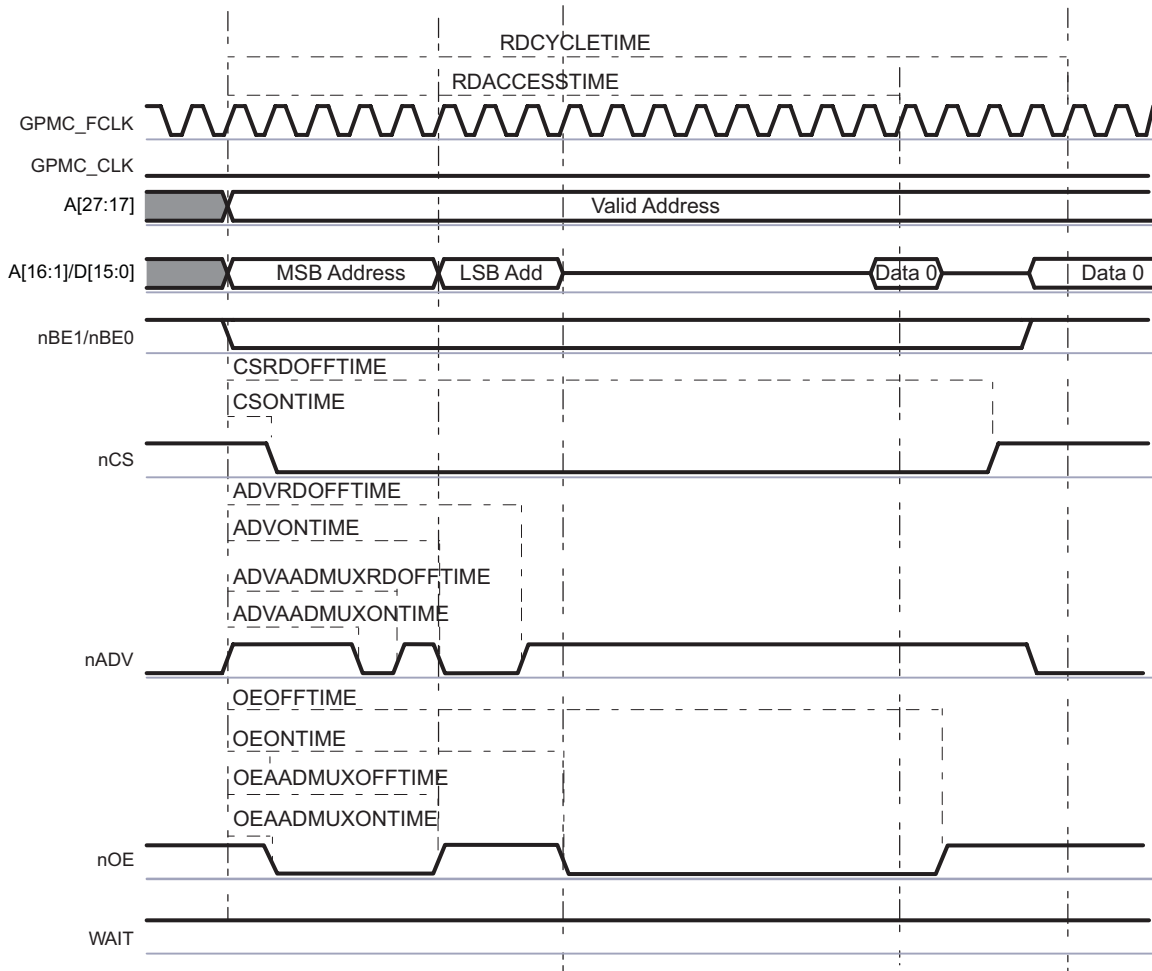

For accesses on non-multiplexed devices, see [Section 11.2.4.10.3](#).

11.2.4.10.1.2 Access on Address/Address/Data (AAD) Multiplexed Devices

11.2.4.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

[Figure 11-15](#) shows an asynchronous single read operation on an AAD-multiplexed device.

Figure 11-15. Asynchronous Single-Read on an AAD-Multiplexed Device

11.2.4.10.1.2.2 Asynchronous Single Read on an AAD-Multiplexed Device

See [Section 11.3.6.1](#) for formulas to calculate timing parameters.

[Table 11-40](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with \overline{OE} driven low. The first address phase ends at the first \overline{OE} deassertion time. The second phase for LSB address is qualified with \overline{OE} driven high. The second address phase ends at the second \overline{OE} assertion time.

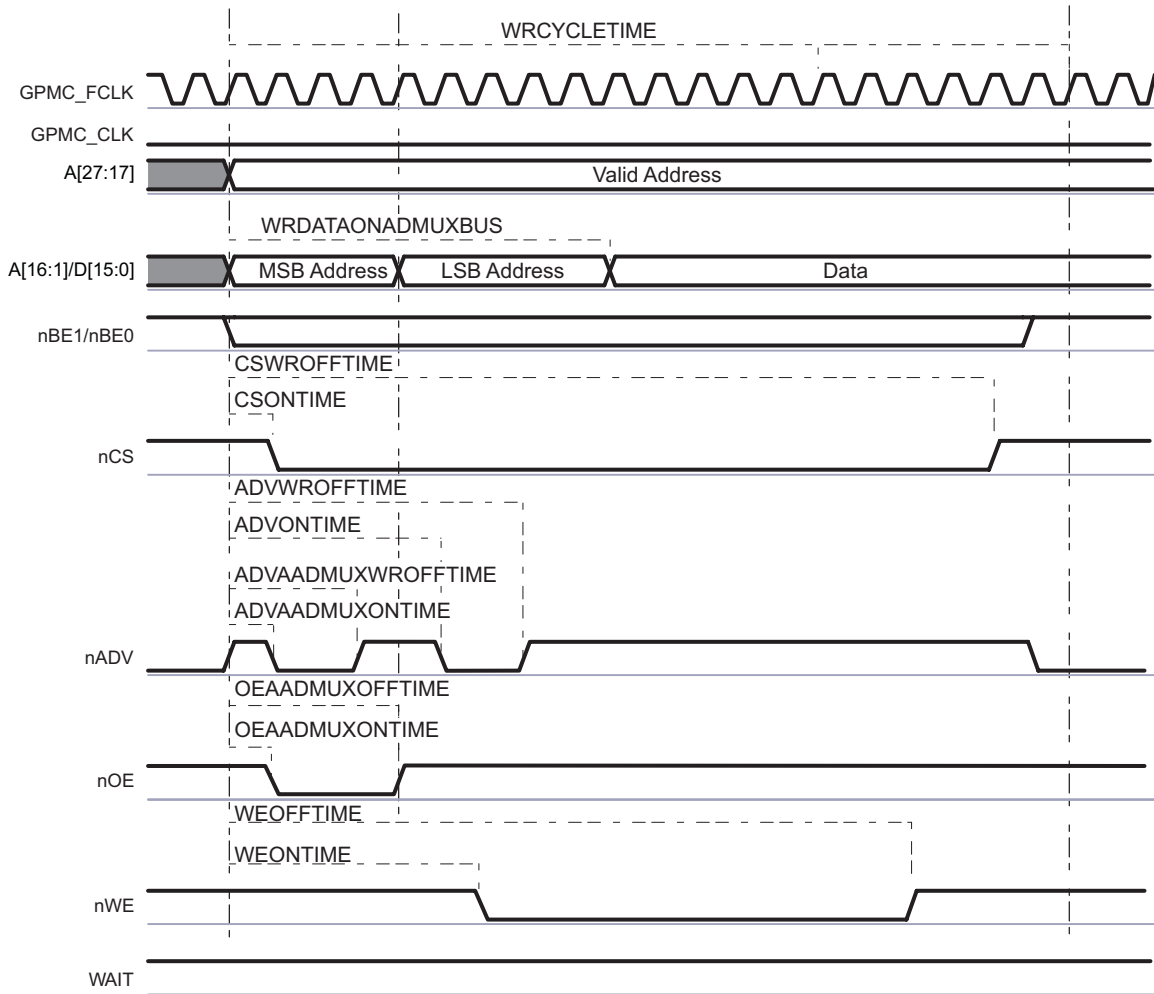

The \overline{CS} signal is controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Address valid signal \overline{ADV} . \overline{ADV} is asserted and deasserted twice during a read transaction:
 - \overline{ADV} first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
 - \overline{ADV} first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME field.
 - \overline{ADV} second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
 - \overline{ADV} second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output Enable signal \overline{OE} . \overline{OE} is asserted and deasserted twice during a read transaction (\overline{OE} second assertion indicates a read cycle):
 - \overline{OE} first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
 - \overline{OE} first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.
 - \overline{OE} second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
 - \overline{OE} second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

11.2.4.10.1.2.3 Asynchronous Single Write Operation on an AAD-Multiplexed Device

Figure 11-16 shows an asynchronous single write operation on an AAD-multiplexed device.

Figure 11-16. Asynchronous Single Write on an AAD-Multiplexed Device

See [Section 11.3.6.1](#) for formulas to calculate timing parameters.

[Table 11-40](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with \overline{OE} driven low. The second phase for LSB address is qualified with \overline{OE} driven high. The address phase ends at \overline{WE} assertion time.

The \overline{CS} and \overline{WE} signals are controlled in the same way as for asynchronous single write operation on an address/data-multiplexed device.

- Address valid signal \overline{ADV} is asserted and deasserted twice during a write transaction
 - \overline{ADV} first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
 - \overline{ADV} first deassertion time is controlled by the GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME field.
 - \overline{ADV} second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
 - \overline{ADV} second deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME field.
- Output Enable signal \overline{OE} is asserted during the address phase of a write transaction
 - \overline{OE} assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
 - \overline{OE} deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.

The address bits for the first address phase are driven onto the data bus until \overline{OE} deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS parameter.

11.2.4.10.1.2.4 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If GPMC_CONFIG1_i[28] WRITEMULTIPLE is enabled (1) with GPMC_CONFIG1_i[27] WRITETYPE as asynchronous (0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see [Section 11.2.4.10.3](#).

11.2.4.10.2 Synchronous Access Description

This section details read and write synchronous accesses on address/data multiplexed. All information in this section can be applied to any type of memory - non-multiplexed, address and data multiplexed or AAD-multiplexed - with a difference limited to the address phase. For accesses on non-multiplexed devices, see [Section 11.2.4.10.3](#).

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field. In the following section, *i* stands for the chip-select number, *i* = 0 to 3.
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completion.

11.2.4.10.2.1 Synchronous Single Read

Figure 11-17 and Figure 11-18 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 11-17. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

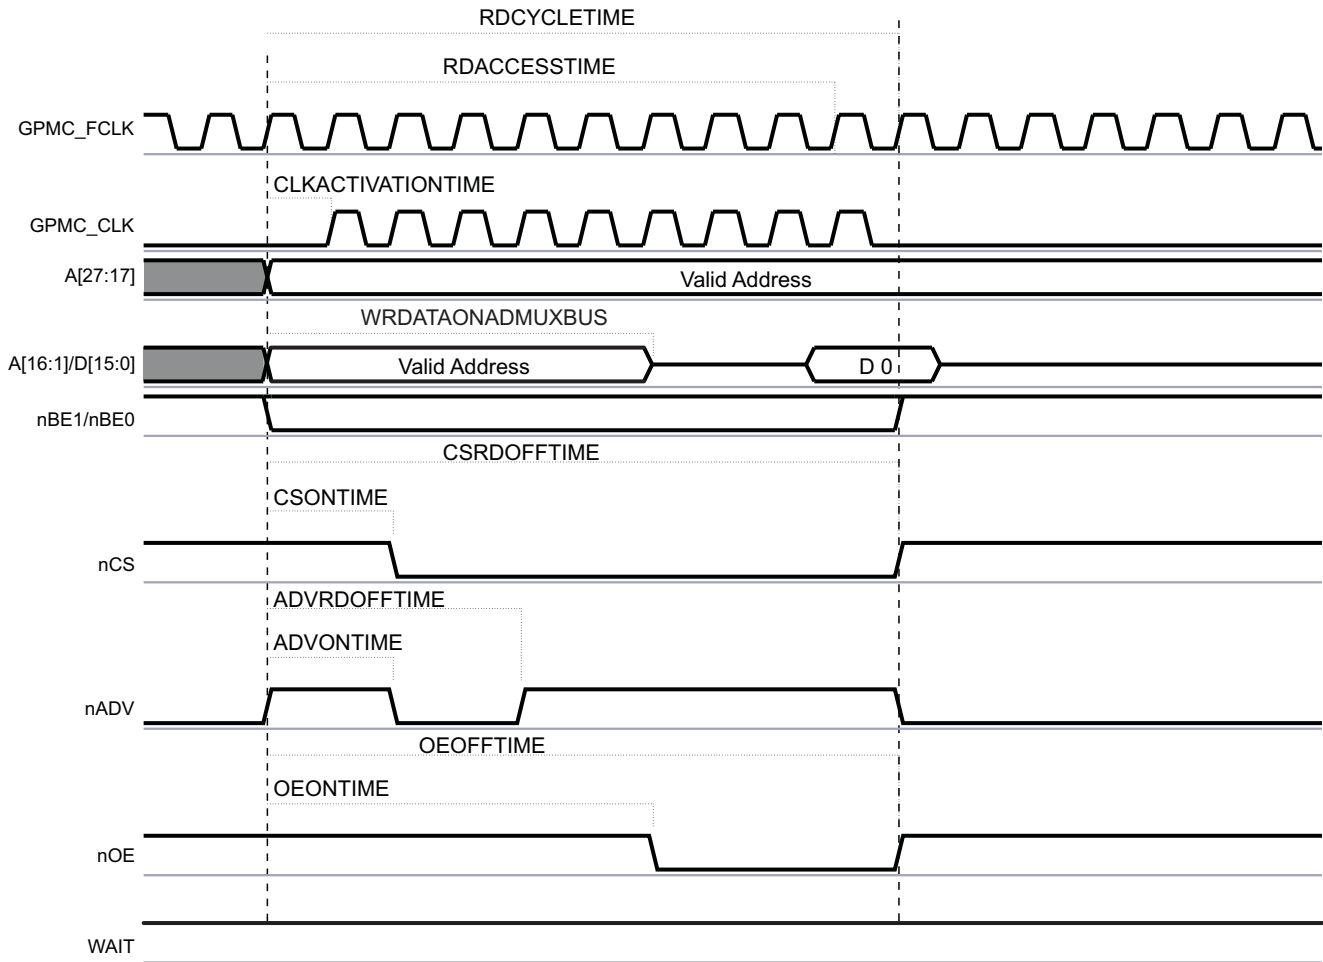

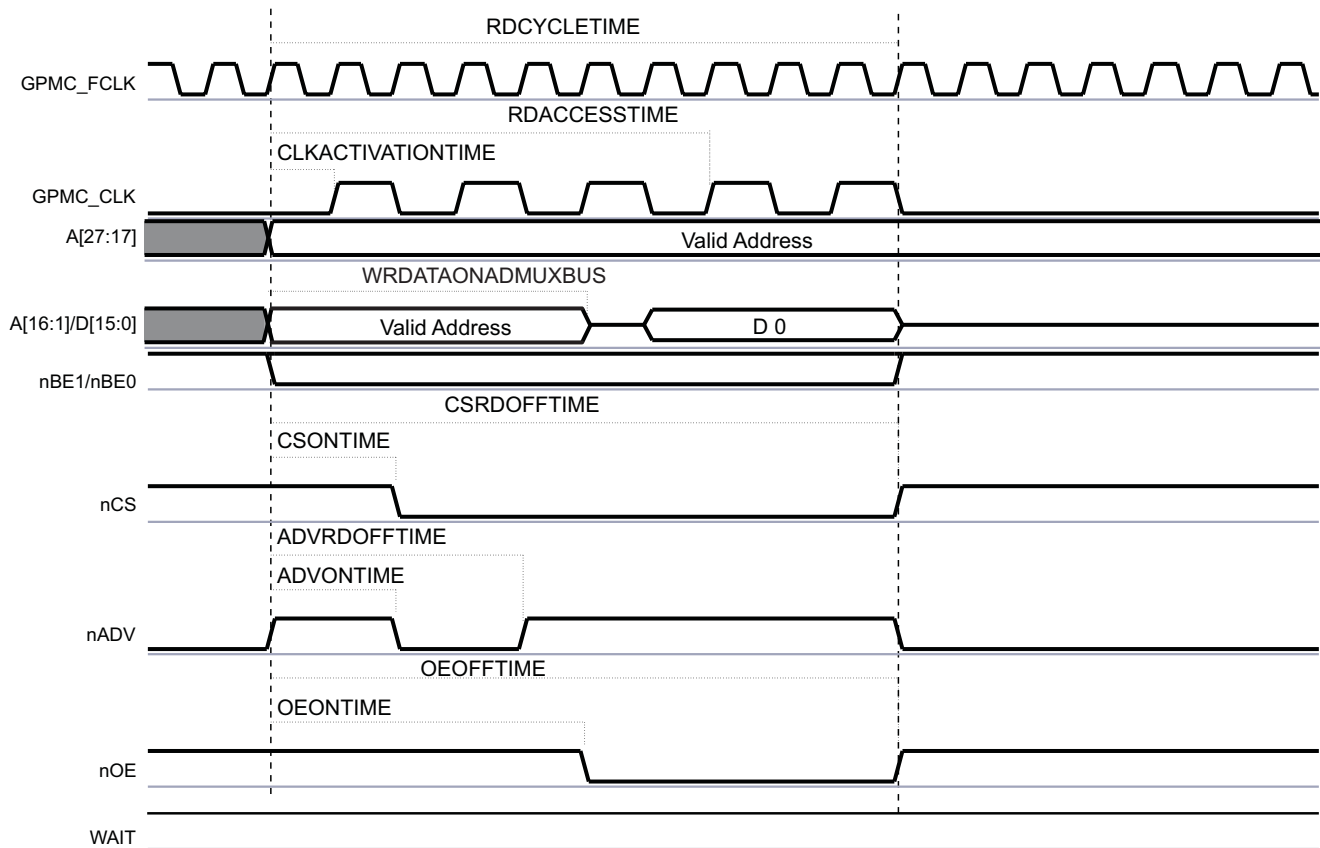

Figure 11-18. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

See [Section 11.3.6.1](#) for formulas to calculate timing parameters.

[Table 11-40](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until \overline{OE} assertion time. For details, see [Section 11.2.4.8.2.3](#).

- Chip-select signal \overline{CS}
 - \overline{CS} assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME field and ensures address setup time to \overline{CS} assertion.
 - \overline{CS} deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME field and ensures address hold time to \overline{CS} deassertion.
- Address valid signal \overline{ADV}
 - \overline{ADV} assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
 - \overline{ADV} deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output enable signal \overline{OE}
 - \overline{OE} assertion indicates a read cycle.
 - \overline{OE} assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
 - \overline{OE} deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20-16] RDACCESSTIME or by monitoring the WAIT signal.
- Total access time (GPMC_CONFIG5_i[4-0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from \overline{CS} deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with \overline{OE} driven low. The second phase for LSB address is qualified with \overline{OE} driven high. The address phase ends at \overline{WE} assertion time.

The \overline{CS} signal is controlled in the same way as for synchronous single read operation on an address/data-multiplexed device.

- Address valid signal \overline{ADV} is asserted and deasserted twice during a read transaction
 - \overline{ADV} first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
 - \overline{ADV} first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME field.
 - \overline{ADV} second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
 - \overline{ADV} second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output Enable signal \overline{OE} is asserted and deasserted twice during a read transaction (\overline{OE} second assertion indicates a read cycle)
 - \overline{OE} first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
 - \overline{OE} first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.
 - \overline{OE} second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
 - \overline{OE} second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 11.2.4.9.10](#).

11.2.4.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word 16 Burst With Wraparound Capability)

Figure 11-19 and Figure 11-20 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 11-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

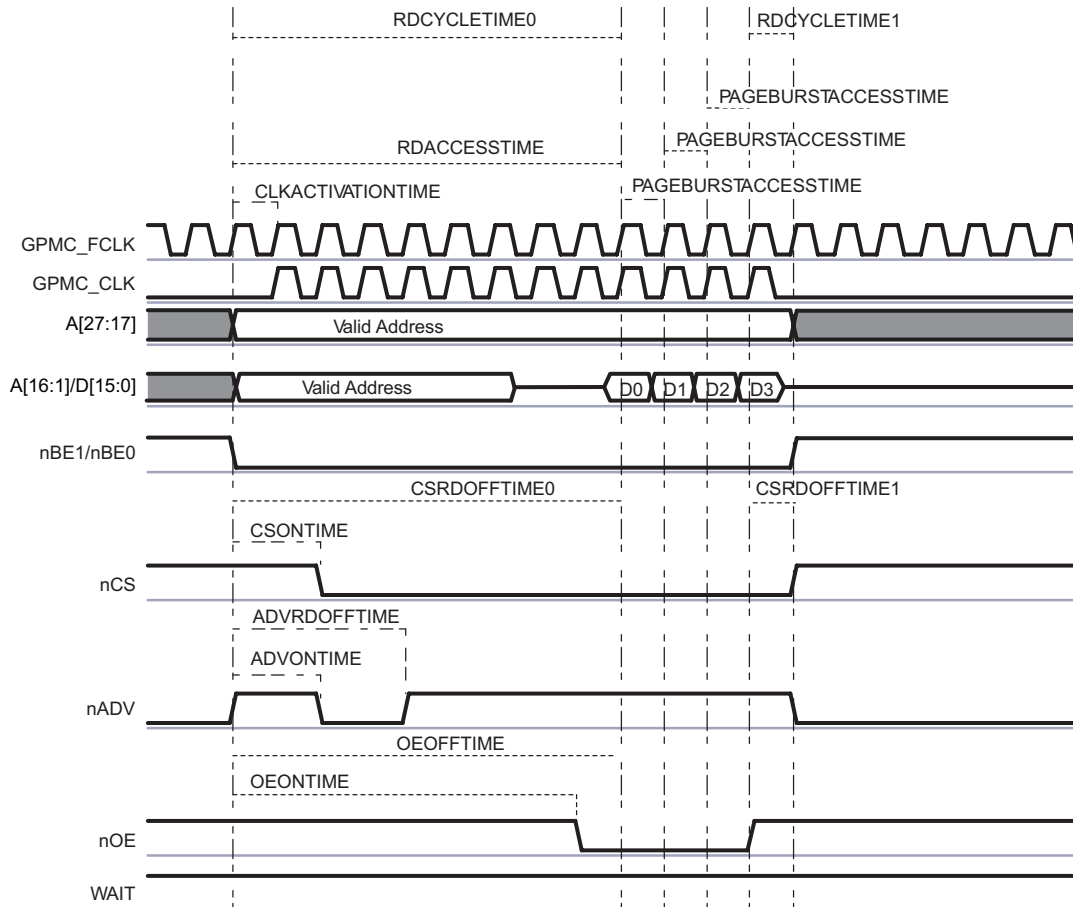

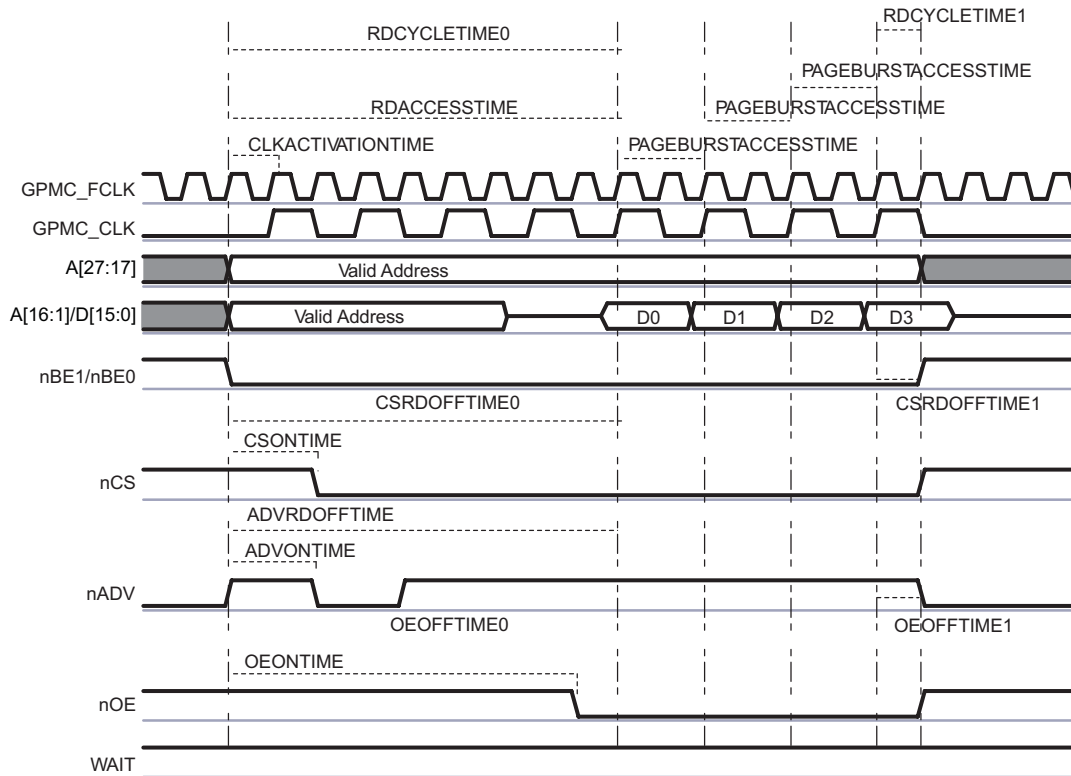

Figure 11-20. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

When GPMC_CONFIG5_i[20-16] RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

The \overline{CS} , \overline{ADV} , and \overline{OE} signals are controlled in the same way as for synchronous single read operation. See Section 11.2.4.10.2.1.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER and the memory-device internal configuration. Depending on the device page length, the GPMC checks device page crossing during a new burst request and purposely insert initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from \overline{CS} deassertion. In Figure 11-19, RDCYCLETIME programmed value equals to RDCYCLETIME0 + RDCYCLETIME1.

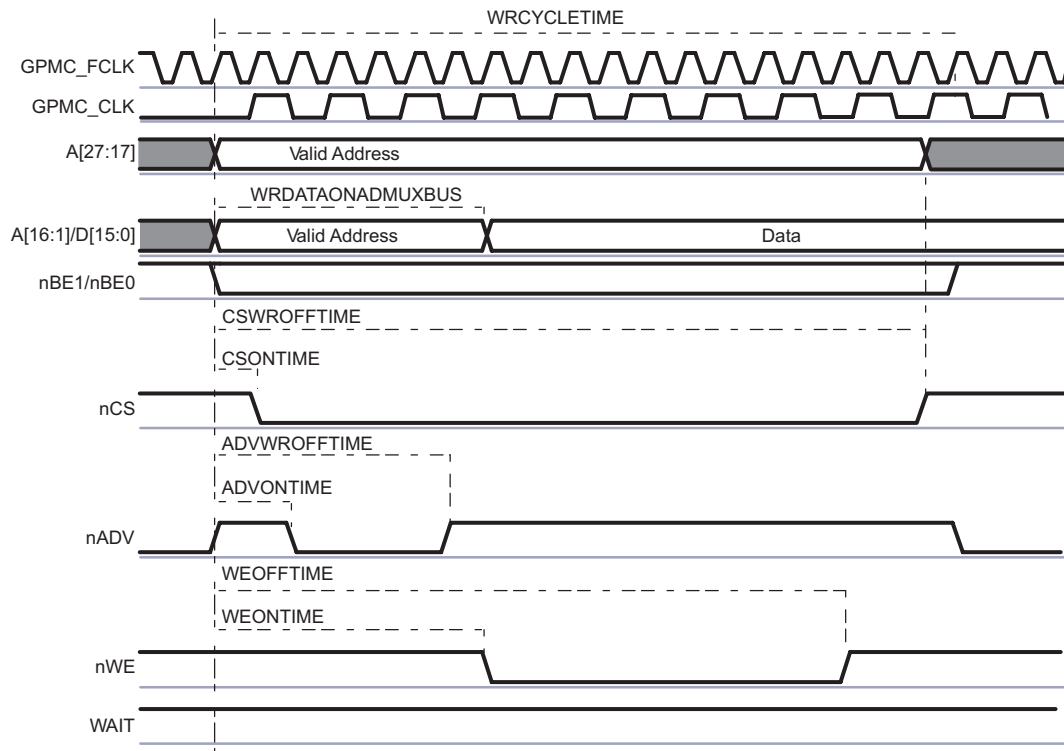

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 11.2.4.9.10.

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH.

11.2.4.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses (see [Figure 11-21](#)).

Figure 11-21. Synchronous Single Write on an Address/Data-Multiplexed Device

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until [19:16] WRDATAONADMUXBUS time. First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

11.2.4.10.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses. Figure 11-22 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 11-22. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

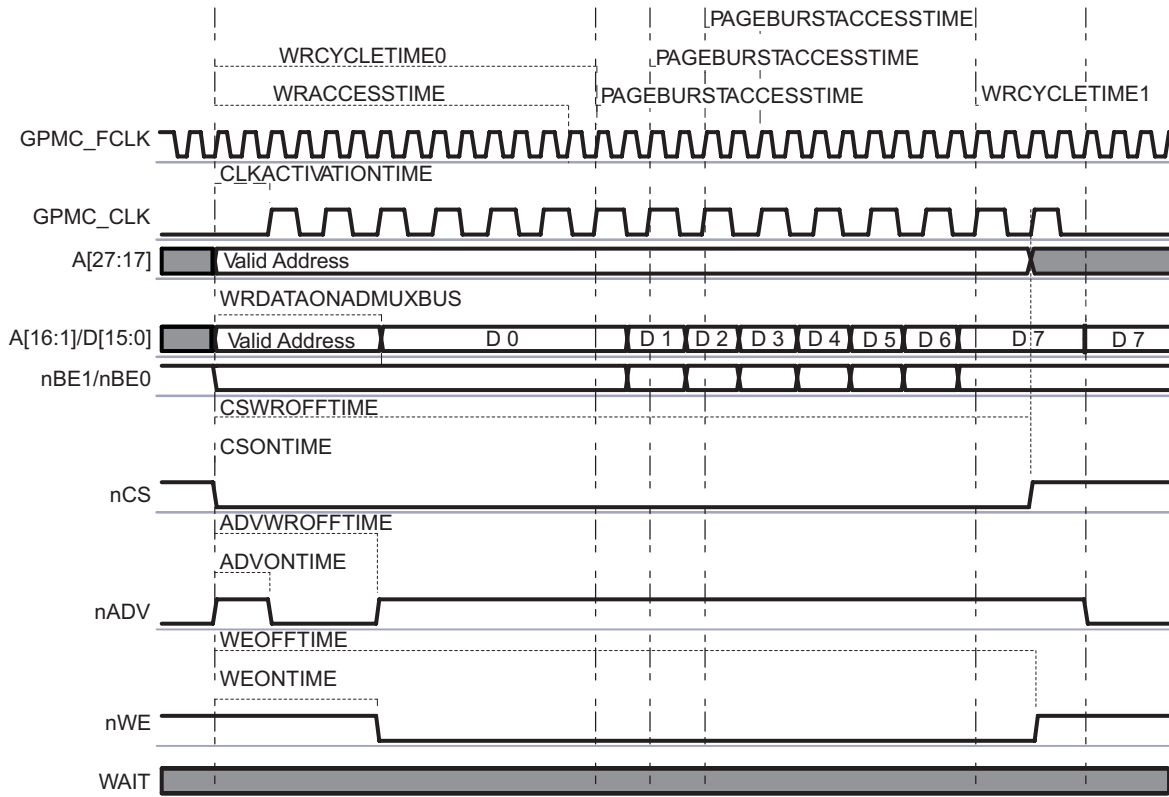

Figure 11-23 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

Figure 11-23. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode

The first data of the burst is driven on the A/D bus at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until OE assertion time. For details, see [Section 11.2.4.8.2.3](#).

- Chip-select signal \overline{CS}
 - \overline{CS} assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit ($i = 0$ to 5) and ensures address setup time to \overline{CS} assertion.
 - \overline{CS} deassertion time controlled by the GPMC_CONFIG2_i[20-16] CSWROFFTIME field and ensures address hold time to \overline{CS} deassertion.
- Address valid signal \overline{ADV}
 - \overline{ADV} assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
 - \overline{ADV} deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME field.

- Write enable signal \overline{WE}
 - \overline{WE} assertion indicates a read cycle.
 - \overline{WE} assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME field.
 - \overline{WE} deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME field.

The \overline{WE} falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the \overline{WE} signal at low during the address phase.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with \overline{OE} driven low. The second phase for LSB address is qualified with \overline{OE} driven high. The address phase ends at \overline{WE} assertion time.

The \overline{CS} signal is controlled as detailed above.

- Address valid signal \overline{ADV} is asserted and deasserted twice during a read transaction
 - \overline{ADV} first assertion time is controlled by the GPMC_CONFIG3_i[[6-4] ADVAADMUXONTIME field.
 - \overline{ADV} first deassertion time is controlled by the GPMC_CONFIG3_i[[26-24] ADVAADMUXRDOFFTIME field.
 - \overline{ADV} second assertion time is controlled by the GPMC_CONFIG3_i[[3-0] ADVONTIME field.
 - \overline{ADV} second deassertion time is controlled by the GPMC_CONFIG3_i[[12-8] ADVRDOFFTIME field.
- Output Enable signal \overline{OE} is asserted and deasserted twice during a read transaction (\overline{OE} second assertion indicates a read cycle)
 - \overline{OE} first assertion time is controlled by the GPMC_CONFIG4_i[[6-4] OEAADMUXONTIME field.
 - \overline{OE} first deassertion time is controlled by the GPMC_CONFIG4_i[[15-13] OEAADMUXOFFTIME field.
 - \overline{OE} second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
 - \overline{OE} second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28-24] register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from \overline{CS} deassertion. In [Figure 11-23](#) the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 11.2.4.9.10](#).

11.2.4.10.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is only available in non-multiplexed mode.

- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

11.2.4.10.3.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 11-24 shows an asynchronous single read operation on a nonmultiplexed device.

Figure 11-24. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device

The 27-bit address is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at GPMC_CONFIG1_5[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4-0] RDCYCLETIME parameter.

$\overline{\text{CS}}$, $\overline{\text{ADV}}$, and $\overline{\text{OE}}$ signals are controlled in the same way as address/data multiplexed accesses, see [Section 11.2.4.10.1.1.2](#).

11.2.4.10.3.2 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 11-25 shows an asynchronous single write operation on a nonmultiplexed device.

Figure 11-25. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

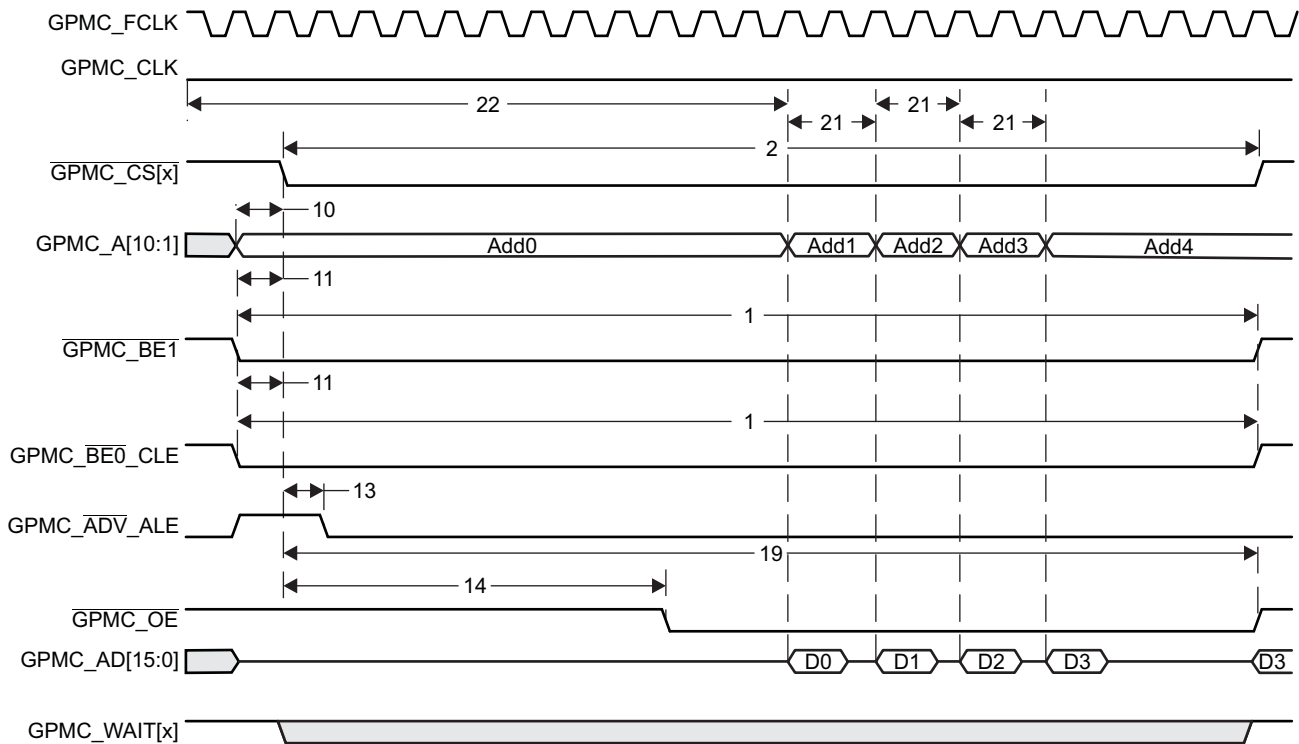

The 27-bit address is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

\overline{CS} , \overline{ADV} , and \overline{WE} signals are controlled in the same way as address/data multiplexed accesses, see Section 11.2.4.10.1.1.3.

11.2.4.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

Figure 11-26 shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two word32 host read accesses to the GPMC are split into one multiple (page mode of 4 word 16) read access to the attached device.

Figure 11-26. Asynchronous Multiple (Page Mode) Read

The WAIT signal is active low.

\overline{CS} , \overline{ADV} , and \overline{OE} signals are controlled in the same way as address/data multiplexed accesses, see Section 11.2.4.10.1.1.2.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20-16] RDACCESSTIME completion time (i = 0 to 5). The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the \overline{CS} deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4-0] RDCYCLETIME field.
- In Figure 11-26, the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

11.2.4.10.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 11.3.3.

11.2.4.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITEMULTIPLE bits (i = 0 to 5) are associated with the READTYPE and WRITETYPE parameters.

- Asynchronous write page mode is not supported.
- 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

11.2.4.10.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit (i = 0 to 5). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (i = 0 to 5) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

11.2.4.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[[11-10] DEVICETYPE field (i = 0 to 3) shall be cleared to 0b00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum CS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

11.2.4.12 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices.

This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be de-asserted if accesses to other chip-selects are requested.

11.2.4.12.1 NAND Memory Device in Byte or 16-Bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the $\overline{ADV_ALE}$ signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the $\overline{BE0_CLE}$ signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

11.2.4.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 5) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in [Table 11-11](#). Failure to comply with these settings corrupts the NAND interface protocol.

The GPMC_CONFIG1_i to GPMC_CONFIG4_i register (where i = 0 to 5) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

Table 11-11. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i	0	Single access
READTYPE	GPMC_CONFIG1_i	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i	0	Single access
WRITETYPE	GPMC_CONFIG1_i	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i		Select which wait is monitored by edge detectors
DEVICESTRATEGY	GPMC_CONFIG1_i	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i	0b00	Nonmultiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i	0	Timing achieved with best GPMC clock granularity
GPMCCLKDIVIDER	GPMC_CONFIG1_i	Don't care	Asynchronous mode

11.2.4.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) register locations with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with \overline{OE} and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) register locations must be posted for faster operations. The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- A GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) registers are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to a GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i can be used, and any of the four byte locations of the registers are valid.

The same applies to GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid

11.2.4.12.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i (where i = 0 to 5) register location places the data as the NAND command value on the bus, using a regular asynchronous write access.

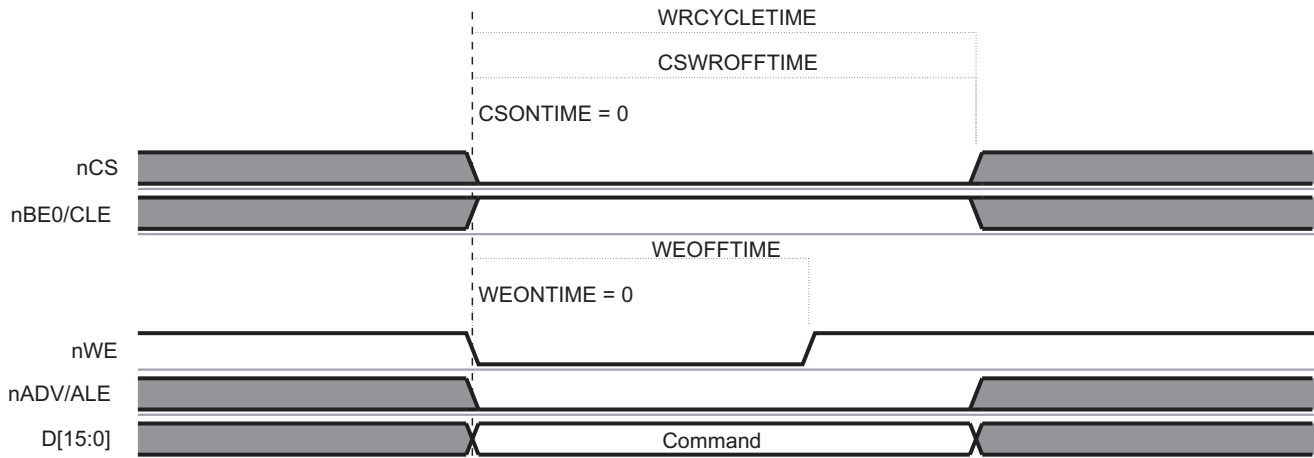

- \overline{CE} is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- WE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and \overline{RE} (\overline{OE}) are maintained inactive.

Figure 11-27 shows the NAND command latch cycle.

CLE is shared with the $\overline{BE0}$ output signal and has an inverted polarity from $\overline{BE0}$. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, $\overline{BE0}$ (also $\overline{BE1}$) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

Figure 11-27. NAND Command Latch Cycle

11.2.4.12.1.4 Address Latch Cycle

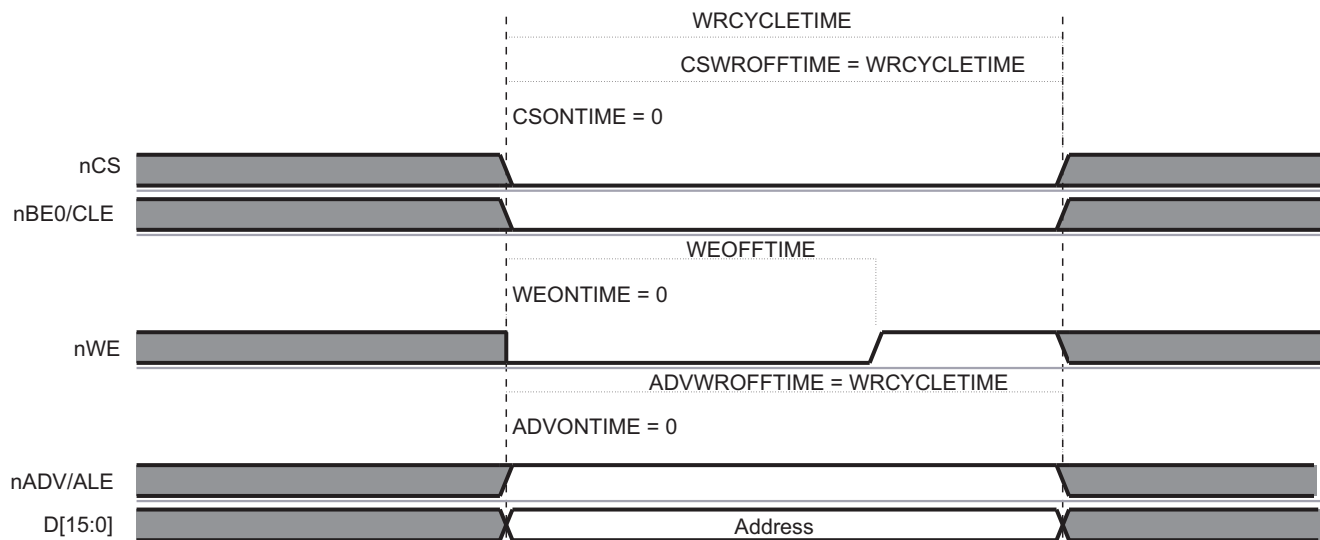

Writing data at the GPMC_NAND_ADDRESS_i (where i = 0 to 5) register location places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- \overline{CS} is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- \overline{WE} is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and \overline{RE} (\overline{OE}) are maintained inactive.

Figure 11-28 shows the NAND address latch cycle.

ALE is shared with the \overline{ADV} output signal and has an inverted polarity from \overline{ADV} . The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

Figure 11-28. NAND Address Latch Cycle

11.2.4.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i (where i = 0 to 5) register location mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable \overline{RE} or \overline{WE} signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- \overline{CS} is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- \overline{RE} is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of \overline{RE} high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after \overline{RE} deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and \overline{WE} are maintained inactive.

Figure 11-29 shows the NAND data read cycle.

Figure 11-29. NAND Data Read Cycle

Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- \overline{CS} is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- \overline{WE} is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and \overline{RE} (\overline{OE}) are maintained inactive.

Figure 11-30 shows the NAND data write cycle.

Figure 11-30. NAND Data Write Cycle

11.2.4.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by \overline{CS} -to-data-valid timing and has faster \overline{RE} -to-data-valid timing. Successive accesses with \overline{CS} deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that \overline{CS} always stays low between two accesses to the same chip-select. Moreover, an \overline{CS} deassertion time between the same chip-select NAND accesses is likely to be required as follows: the \overline{CS} deassertion requires programming $CYCLETIME$ and $RDACCESSTIME$ according to the \overline{CS} -to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce $RDCYCLETIME$, $WRCYCLETIME$, $RDACCESSTIME$, $WRACCESSTIME$, $CSRDOFFTIME$, $CSWROFFTIME$, $ADVRDOFFTIME$, $ADVWROFFTIME$, $OEOFFTIME$, and $WEOFFTIME$ on back-to-back NAND accesses (to the same memory) and suppress the minimum \overline{CS} high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 11.2.4.12.4](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum \overline{CS} high pulse width must be set. For this, $CYCLE2CYCLESAMECSEN$ and $CYCLE2CYCLEDELAY$ must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important \overline{RE} high to data bus in tristate mode. This requires a bus turnaround setting ($BUSTURNAROUND = 1$), so that the next access to a different chip-select is delayed until the $BUSTURNAROUND$ delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

11.2.4.12.1.7 Read and Write Access Size Adaptation

11.2.4.12.1.7.1 8-Bit Wide NAND Device

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

11.2.4.12.1.7.2 16-Bit Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

11.2.4.12.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 μ s) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[[22] WAITREADMONITORING bits to 0, where $i = 0$ to 5), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit ($n = 0$ to 1) of the GPMC_STATUS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE [11-8] bits).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

11.2.4.12.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit ($x = 0$ or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

11.2.4.12.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits ($x = 0$ or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit ($x = 0$ or 1) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

11.2.4.12.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

- Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
- BCH (Bose-Chaudhuri-Hocquenghem) code for 4- to 16-bit error correction

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3-1] ECCCS bit field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

11.2.4.12.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

11.2.4.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3-0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each register, j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZES bits (j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j= 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZES bits are cleared to 0, and the ECC9RESULTSIZES bit is set to 1.

11.2.4.12.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3-1] ECCCS field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZES (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

[Table 11-12](#) describes the ECC enable settings.

Table 11-12. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-3h	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0-1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0-7h	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0-7h	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0-FFh	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0-FFh	Defines ECCSIZE0
ECCjRESULTSIZE	GPMC_ECC_SIZE_CONFIG	0-1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

11.2.4.12.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 11-31 and Figure 11-32. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

$P1o = \text{bit7 XOR bit5 XOR bit3 XOR bit1}$ on each byte of the data stream

$P1e = \text{bit6 XOR bit4 XOR bit2 XOR bit0}$ on each byte of the data stream

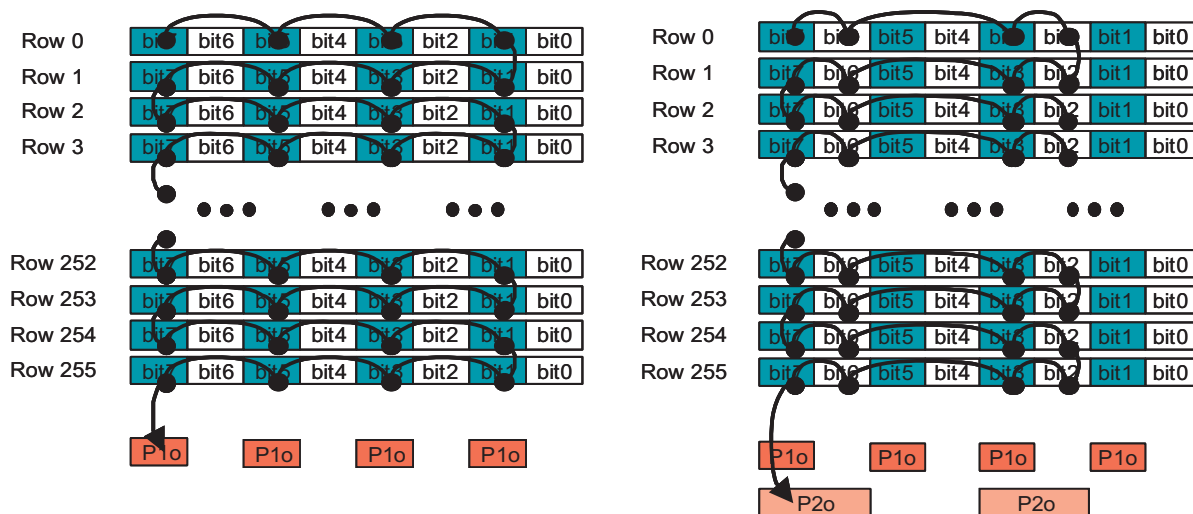

$P2o = \text{bit7 XOR bit6 XOR bit3 XOR bit2}$ on each byte of the data stream

$P2e = \text{bit5 XOR bit4 XOR bit1 XOR bit0}$ on each byte of the data stream

$P4o = \text{bit7 XOR bit6 XOR bit5 XOR bit4}$ on each byte of the data stream

$P4e = \text{bit3 XOR bit2 XOR bit1 XOR bit0}$ on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 11-31. Hamming Code Accumulation Algorithm (1 of 2)

For line parities, the bits of each new data are XORed together, and line parity bits are computed as:

$$P8e = \text{row0 XOR row2 XOR row4 XOR ... XOR row254}$$

$$P8o = \text{row1 XOR row3 XOR row5 XOR ... XOR row255}$$

$$P16e = \text{row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253}$$

$$P16o = \text{row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255}$$

Unused parity bits in the result registers are cleared to 0.

Figure 11-32. Hamming Code Accumulation Algorithm (2 of 2)

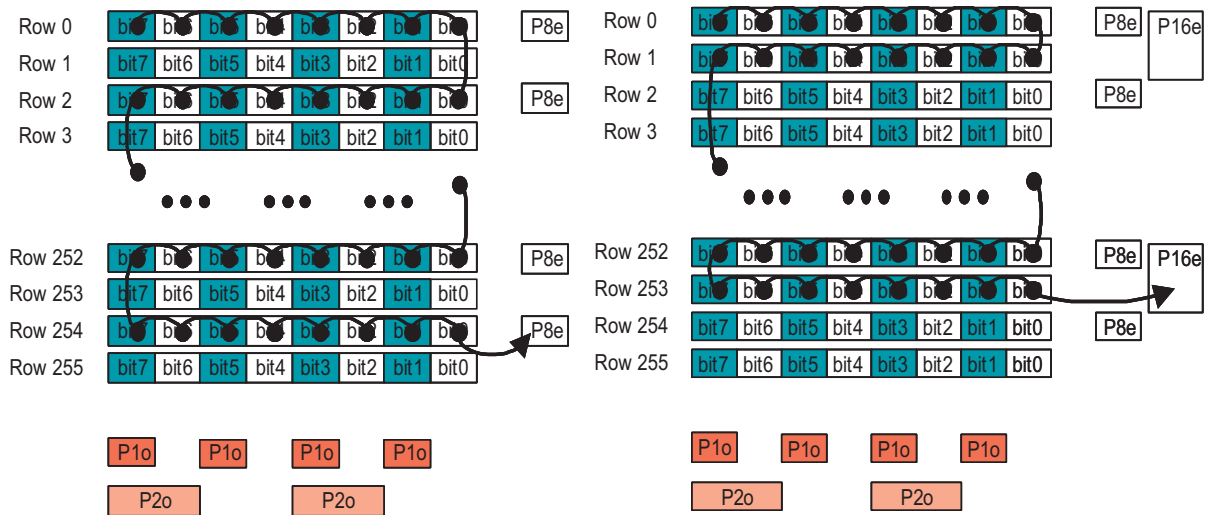

Figure 11-33 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 11-33. ECC Computation for a 256-Byte Data Stream (Read or Write)

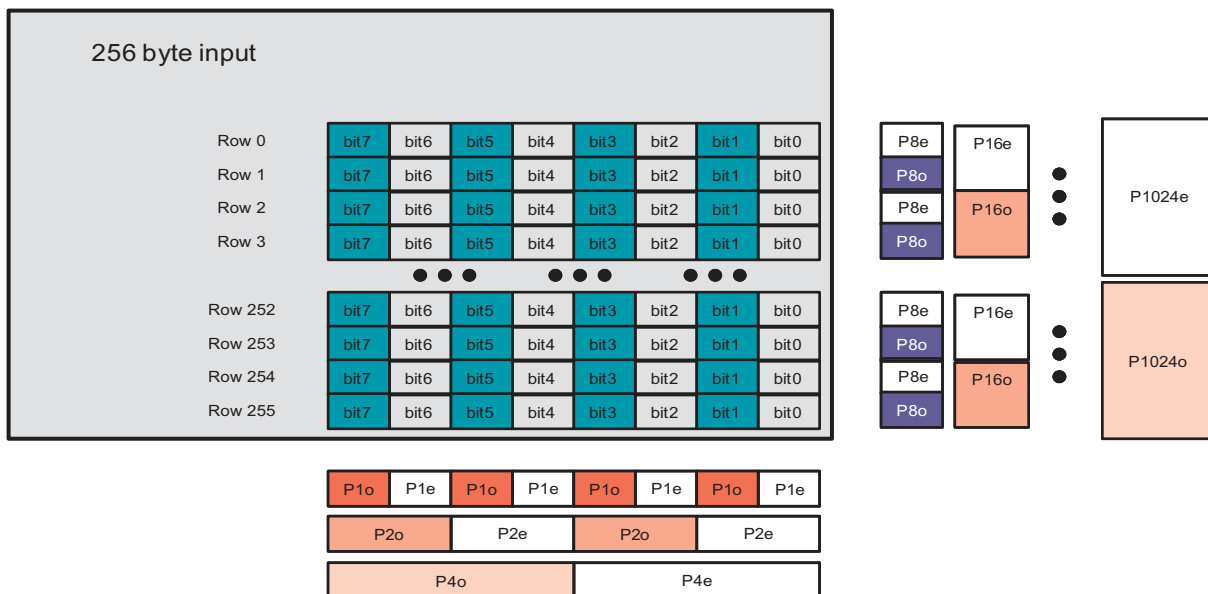

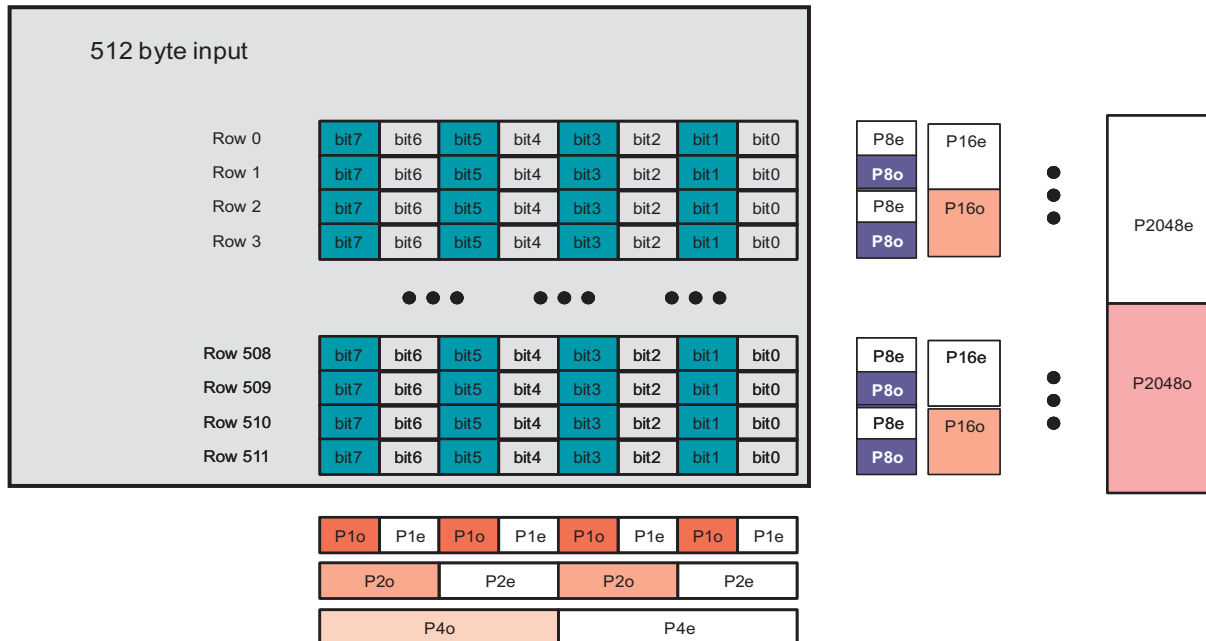

Figure 11-34 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (j = 1 to 9).

Figure 11-34. ECC Computation for a 512-Byte Data Stream (Read or Write)

11.2.4.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

11.2.4.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

11.2.4.12.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be cleared to 0 when interfacing an 8-bit wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. Figure 11-35 and Figure 11-36.

Figure 11-35. 128 Word16 ECC Computation

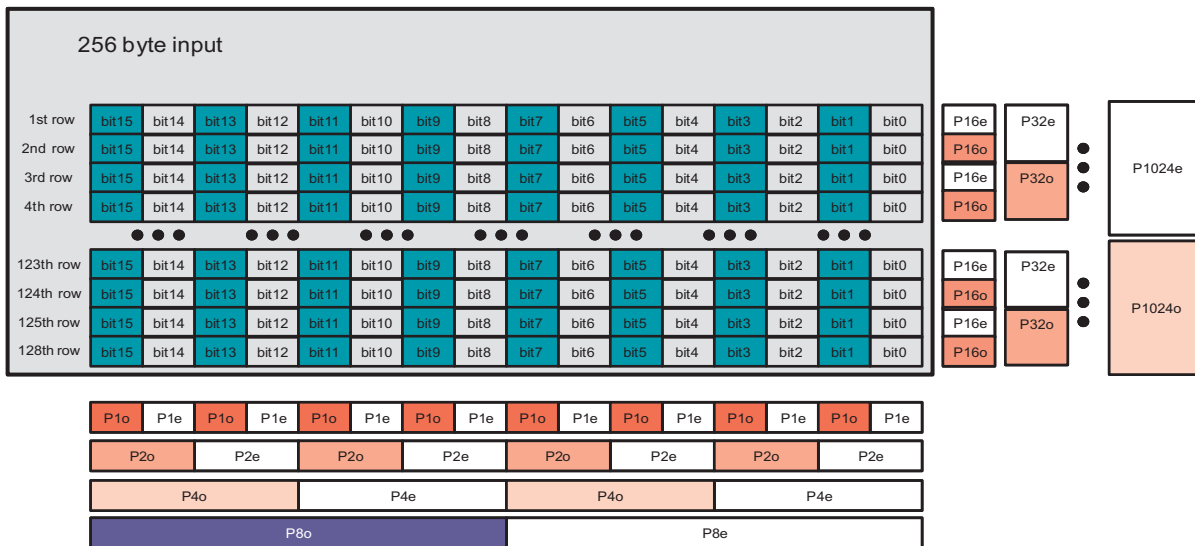

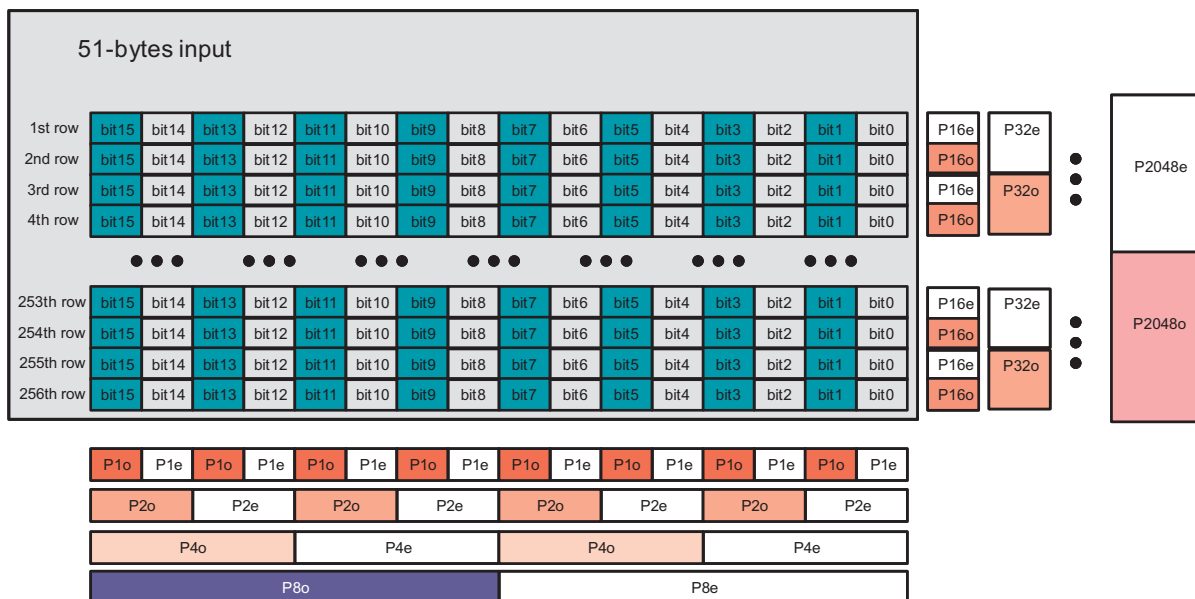

Figure 11-36. 256 Word16 ECC Computation

11.2.4.12.3.2 BCH Code (Bose-Chaudhuri-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

11.2.4.12.3.2.1 Requirements

Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.

Typical page write sequence:

- Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array

Typical page read sequence:

- Sequential read of a page. ECC is calculated on the fly.
- ECC module buffers status determines the presence of errors.
- Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
- Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 x 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.

- NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
- The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

11.2.4.12.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message $M(x)$. In our standard case, 512 bytes of data (that is, 2 bits = 4096 bits) are seen as a polynomial of degree $2^{13} - 1 = 4095$, with parameters ranging from M_0 to M_{4095} . For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial $R(x)$ of degree 103 (or 51, depending on the selected mode). The complete codeword $C(x)$ is the concatenation of $M(x)$ and $R(x)$ as shown in [Table 11-13](#).

Table 11-13. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

Bit number	Message $M(x)$	ECC $R(x)$				
	M_{4095}	...	M_0	R_{103}	...	R_0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message $M(x)$ of degree $((512 + 3) \times 8) - 1 = 4119$, for a total of $3 + 13 = 16$ spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in i , $i+1$, and $i+2$ (where $i = 0$ to 5).

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

11.2.4.12.3.2.3 Memory Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b_7 - b_0 (with b_0 the LS bit) represents a segment of polynomial $b_7 \times x + b_6 \times x^2 + \dots + b_0 \times x^8$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described in the following.

[Table 11-14](#) and [Table 11-15](#) show the mapping of the same 512-byte vector (typically a BCH message) in the NAND memory space. Note that the byte 'address' is only an offset modulo 512 (200h), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M_0 and $M_{(2^{13}-1)}$ of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

Table 11-14. Aligned Message Byte Mapping in 8-bit NAND

Byte Offset	8-Bit Word
0	(msb) Byte 511 (1FFh)
1h	Byte 510 (1FEh)
⋮	⋮
1FFh	Byte 0 (0) (LSB)

Table 11-15. Aligned Message Byte Mapping in 16-bit NAND

Byte Offset	16-Bit Words MSB	16-Bit Words LSB
0	Byte 510 (1FEh)	(msb) Byte 511 (1FFh)
2h	Byte 508 (1FCh)	Byte 509 (1FDh)
⋮	⋮	⋮
1FEh	Byte 0 (0)	(lsb) Byte 1 (1)

Table 11-16 and Table 11-17 show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

Table 11-16. Aligned Nibble Mapping of Message in 8-bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Less Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
⋮	⋮	⋮
S/2 - 2	Nibble 3	Nibble 2
S/2 - 1	Nibble 1	Nibble 0 (LSB)

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
⋮	⋮	⋮	⋮	⋮
$(S+3)/2 - 4$	Nibble 2	Nibble 1	Nibble 4	Nibble 3
$(S+3)/2 - 2$			Nibble 0 (LSB)	

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

11.2.4.12.3.2.4 Memory Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a softwarecontrolled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

11.2.4.12.3.2.5 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 11.2.4.12.3.3](#).

For each mode:

- A sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for $t = 4$ ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

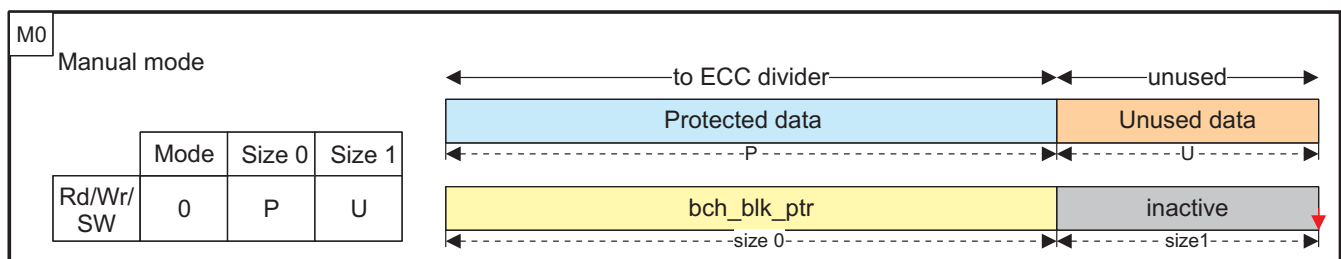

11.2.4.12.3.2.6 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2×16 -bit accesses: we must program size0 = 5, size1 = 3).

Figure 11-37 shows the manual mode sequence and mapping. In this figure, size and size0 are the same parameter.

Figure 11-37. Manual Mode Sequence and Mapping

Section processing sequence:

- One time with buffer
 - size0 nibbles of data, processing ON
 - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

11.2.4.12.3.2.7 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

11.2.4.12.3.2.8 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - 1 nibble pad spare, processing OFF
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

11.2.4.12.3.2.9 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

11.2.4.12.3.2.10 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

11.2.4.12.3.2.11 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

11.2.4.12.3.2.12 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1 + size1))

11.2.4.12.3.2.13 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

11.2.4.12.3.2.14 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1 + size1))

11.2.4.12.3.2.15 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

11.2.4.12.3.2.16 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

11.2.4.12.3.2.17 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

11.2.4.12.3.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 11.2.4.12.3.2.3](#).

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In [Figure 11-38](#) to [Figure 11-40](#), tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, $S = 2$ sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of $n = 2 - 1 = 8191$ bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

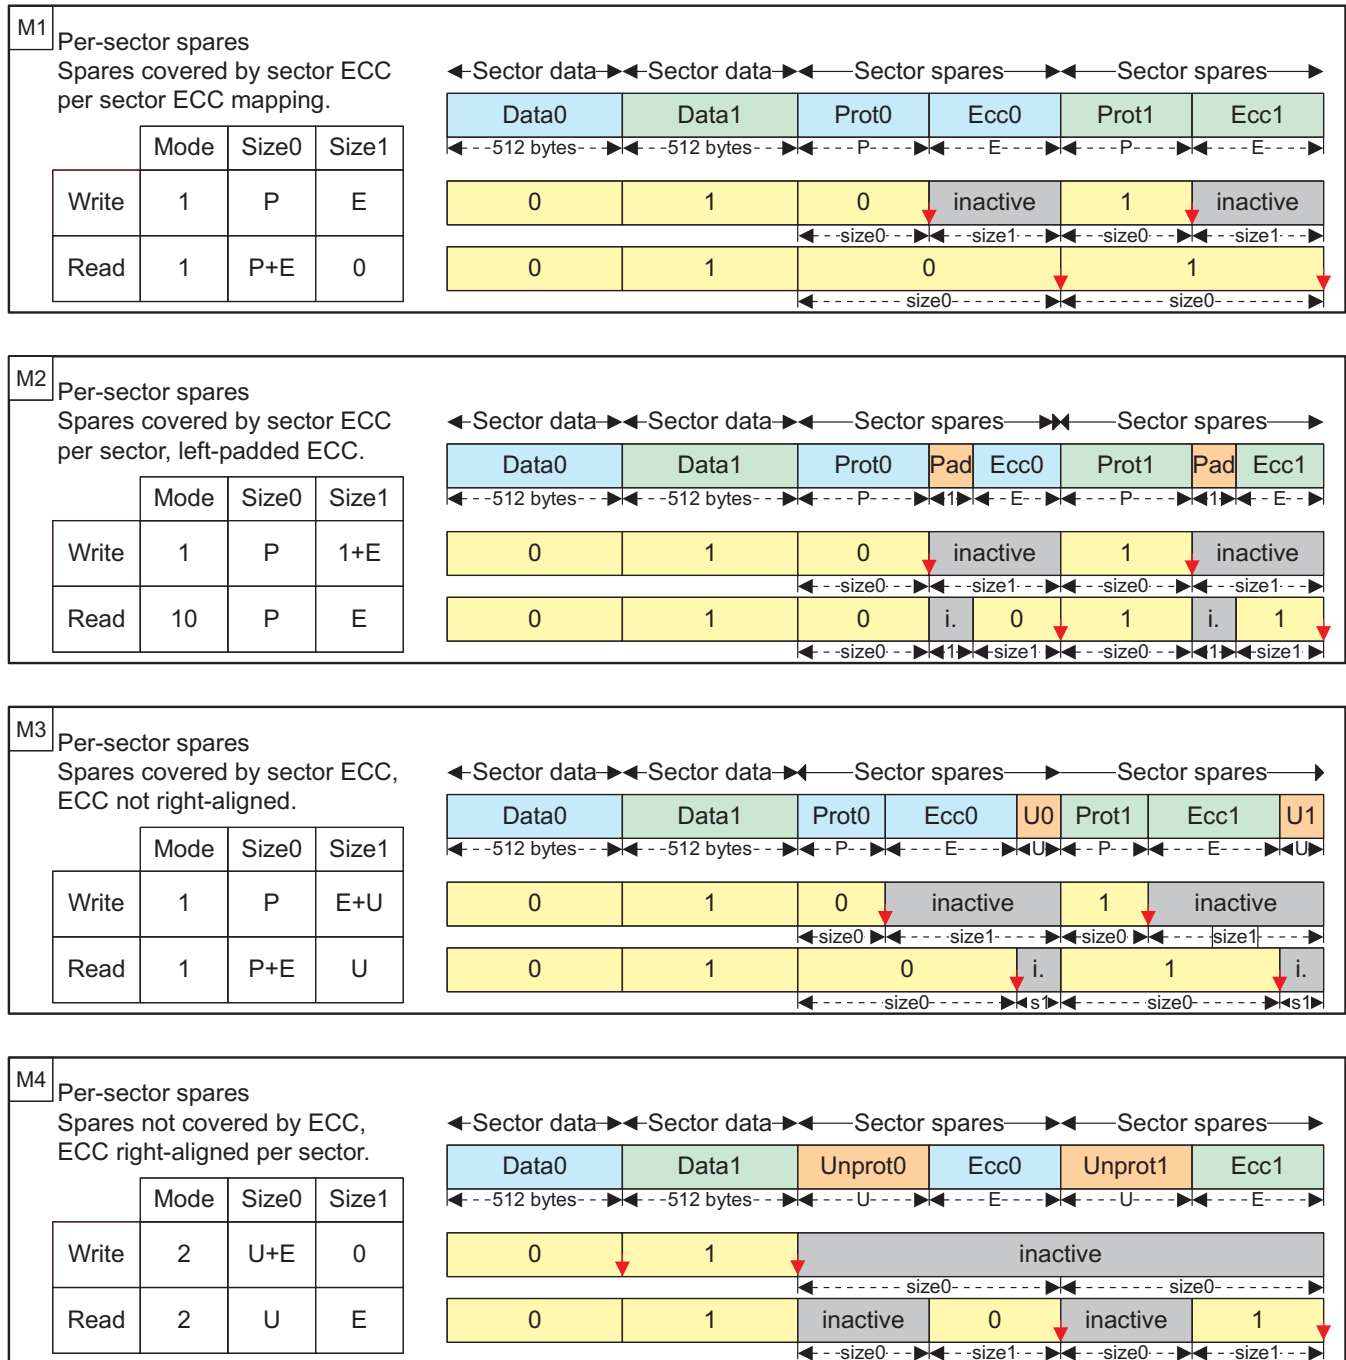

- Spares mapped and protected per sector ([Figure 11-38](#): see M1-M2-M3-M9-M10):
 - all sectors: $(512) + P + E$
- Spares pooled and protected by sector 0 ([Figure 11-38](#): see M5-M6):
 - sector 0 codeword: $(512) + P + E$
 - other sectors: $(512) + E$
- Unprotected spares ([Figure 11-38](#): see M4-M7-M8-M11-M12):
 - all codewords $(512) + E$

11.2.4.12.3.3.1 Per-Sector Spare Mappings

In these schemes (Figure 11-38), each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 11-38. NAND Page Mapping and ECC: Per-Sector Schemes

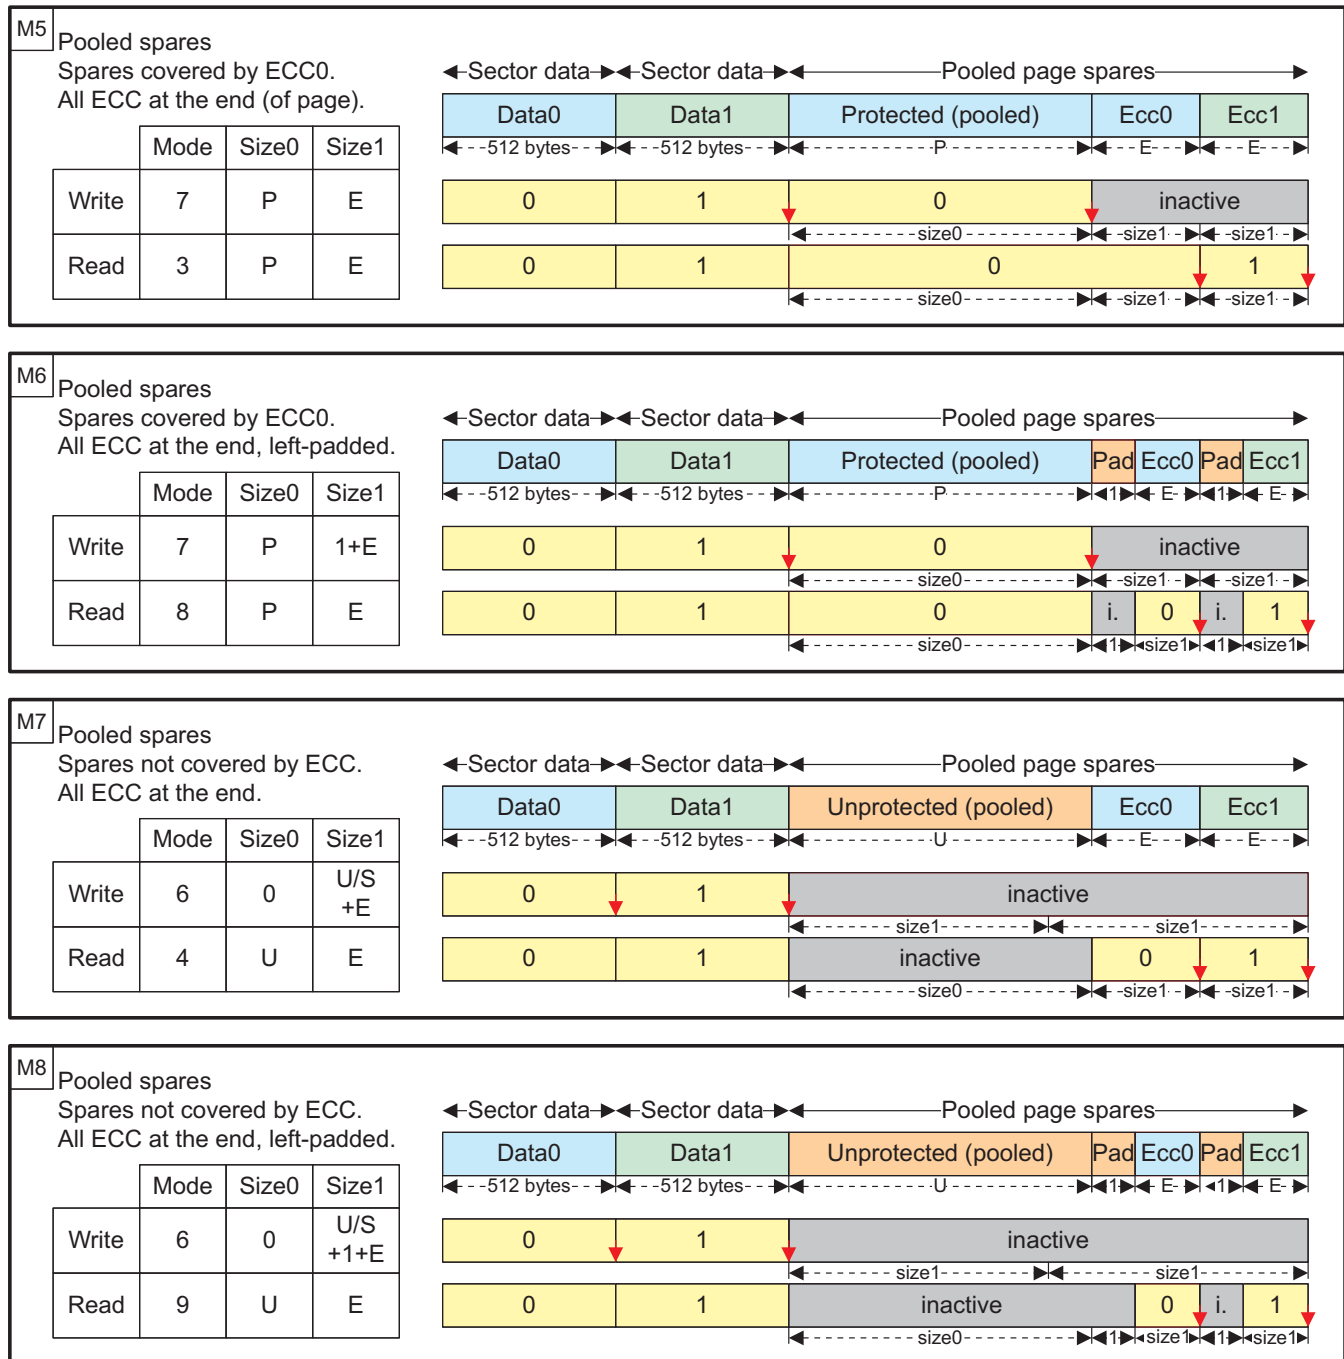

11.2.4.12.3.3.2 Pooled Spare Mapping

In these schemes (Figure 11-39), the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

Figure 11-39. NAND Page Mapping and ECC: Pooled Spare Schemes

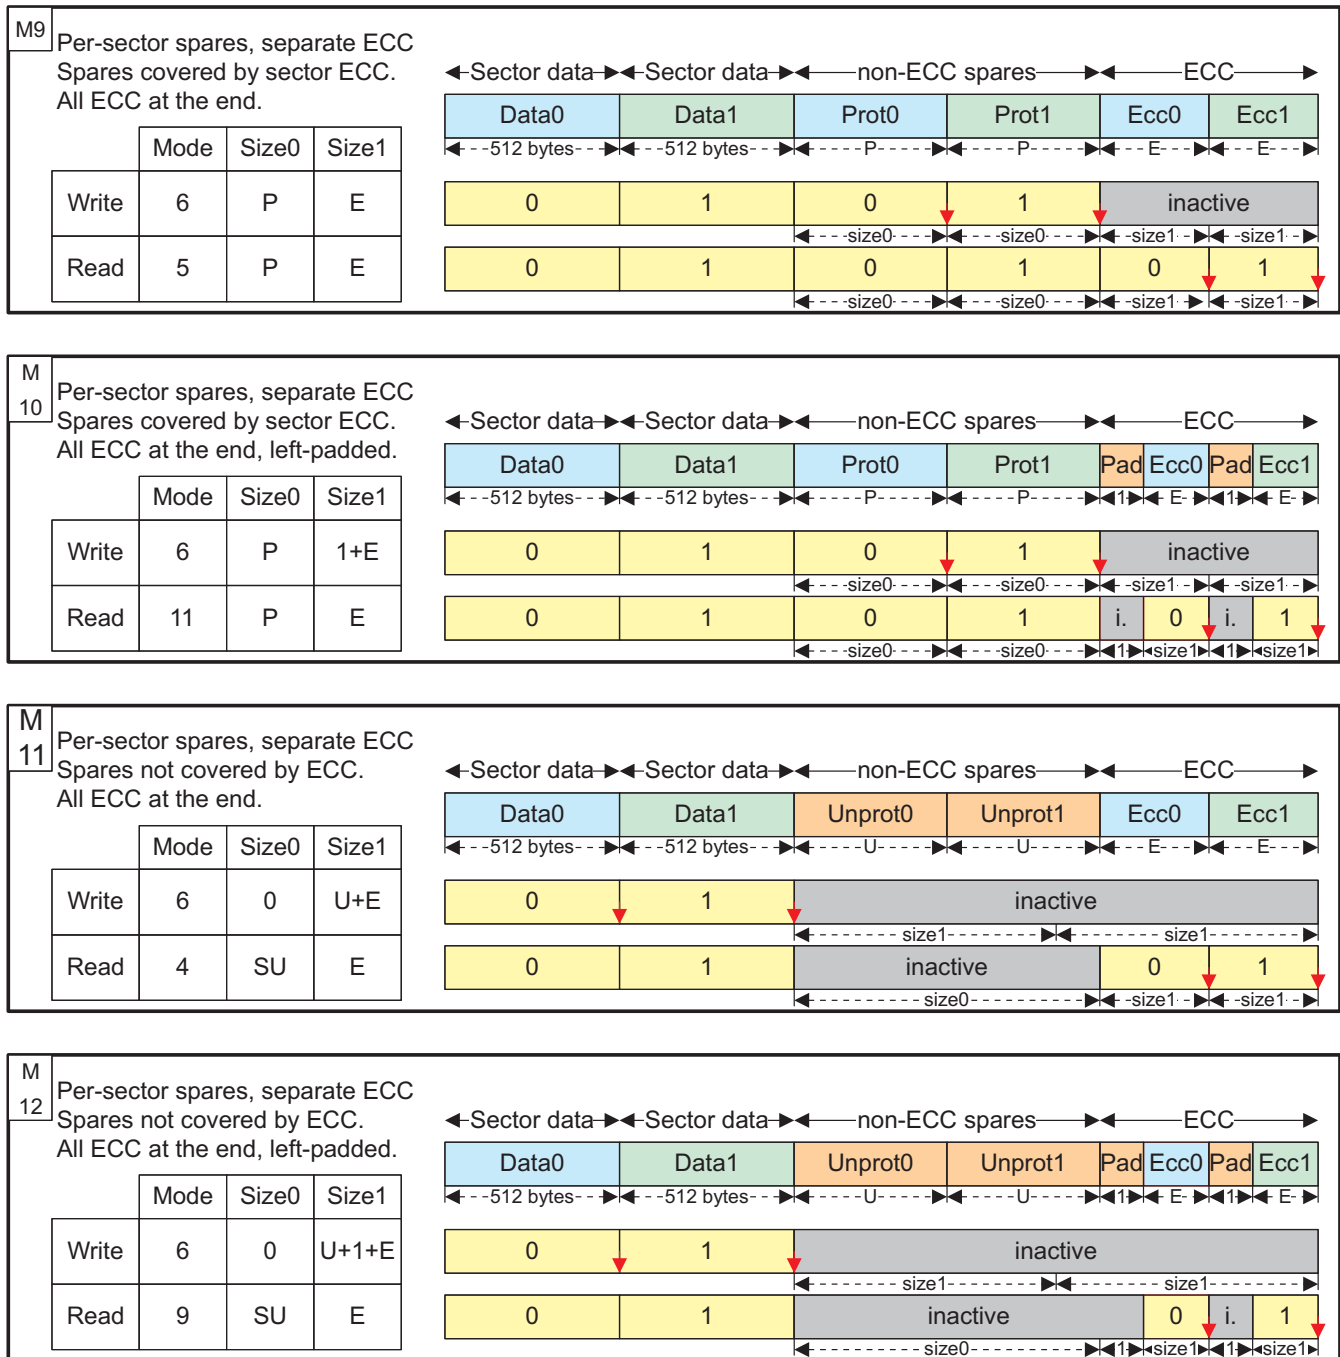

11.2.4.12.3.3.3 Per-Sector Spare Mapping, With ECC Separated at the End of the Page

In these schemes (Figure 11-40), each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 11-40. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC

11.2.4.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

11.2.4.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectively uses byte or 16-bit word access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of 16-bit word.

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through these registers (where $i = 0$ to 5):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the L3 interconnect port can be accessed with Byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

11.2.4.12.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (i.e., reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see [Section 11.2.4.12.2.2](#). The GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT field.

[Table 11-22](#) describes the prefetch mode configuration.

Table 11-22. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL	0	Prefetch engine can be configured only if STARTENGINE is cleared to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1	0 to 3h	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG1		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1	0/1	See Section 11.2.4.12.4.6
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONFIG1	1	Starts the prefetch engine

11.2.4.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an eDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30-24] FIFOPointer field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPointer indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

11.2.4.12.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL	0	Write-posting engine can be configured only if STARTENGINE is cleared to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1	0 to 3h	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1	0/1	See Section 11.2.4.12.4.6
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL	1	Starts the prefetch engine

11.2.4.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

11.2.4.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated \overline{CS} signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMEECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i (where , i = 0 to 5) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 11-41, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMEECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION field.

Figure 11-41. NAND Read Cycle Optimization Timing Description

11.2.4.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 2h. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

11.3 Basic Programming Model

11.3.1 GPMC High-Level Programming Model Overview

The high-level programming model introduces a top-down approach for users that need to configure the GPMC module. [Figure 11-42](#) shows a programming model top-level diagram for the GPMC. Each block of the diagram is described in one of the following subsections through a set of registers to configure. [Table 11-23](#) and [Table 11-24](#) list each step in the model.

Table 11-23. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 11-26
NOR Chip-Select Configuration	See Table 11-27
NOR Timings Configuration	See Table 11-28
Wait Pin Configuration	See Table 11-29
Enable Chip-Select	See Table 11-30

Table 11-24. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 11-31
NAND Chip-Select Configuration	See Table 11-32
Write Operations (Asynchronous)	See Table 11-33
Read Operations (Asynchronous)	See Table 11-33
ECC Engine	See Table 11-34
Prefetch and Write-Posting Engine	See Table 11-35
Wait Pin Configuration	See Table 11-36
Enable Chip-Select	See Table 11-37

Figure 11-42. Programming Model Top-Level Diagram

11.3.2 GPMC Initialization

Table 11-25 describes the settings required to reset the GPMC.

Table 11-25. Reset GPMC

Sub-process Name	Register / Bitfield	Value
Start a software reset	GPMC_SYSCONFIG[1] SOFTRESET	1
Wait until	GPMC_SYSSTATUS[0] RESETDONE	1

11.3.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC. Table 11-26 through Table 11-30 list the steps to configure the GPMC in NOR mode.

NOTE: In the tables of this section, 'x' in Value column stands for 'depends on configuration'.

Table 11-26. NOR Memory Type

Sub-process Name	Register / Bitfield	Value
Set the NOR protocol	GPMC_CONFIG1_i[11-10] DEVICETYPE	0
Set a device size	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Select an address and data multiplexing protocol	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length	GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	x
Choose an output clock activation time	GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations	GPMC_CONFIG1_i[27] WRITETYPE	x

Table 11-27. NOR Chip-Select Configuration

Sub-process Name	Register / Bitfield	Value
Select the chip-select base address	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select mask address	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

Table 11-28. NOR Timings Configuration

Sub-process Name	Register / Bitfield	Value
Configure adequate timing parameters in various memory modes	See Section 11.3.6	

Table 11-29. WAIT Pin Configuration

Sub-process Name	Register / Bitfield	Value
Enable or disable wait pin monitoring for read operations	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time	GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select	GPMC_CONFIG1_i[17-16] WAITPINSELECT	x

Table 11-30. Enable Chip-Select

Sub-process Name	Register / Bitfield	Value
When all parameters are configured, enable the chip-select	GPMC_CONFIG7_i[6] CSVALID	x

11.3.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to NAND memory connected to the GPMC.

Table 11-31. NAND Memory Type

Sub-process Name	Register / Bitfield	Value
Set the NAND protocol	GPMC_CONFIG1_i[11-10] DEVICETYPE	2h
Set a device size	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device	GPMC_CONFIG1_i[9] MUXADDDATA	0
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations	See Section 11.3.5	x

Table 11-32. NAND Chip-Select Configuration

Sub-process Name	Register / Bitfield	Value
Select the chip-select base address	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select minimum granularity (16M bytes)	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

Table 11-33. Asynchronous Read and Write Operations

Sub-process Name	Register / Bitfield	Value
Configure adequate timing parameters in asynchronous modes	See Section 11.3.6	

Table 11-34. ECC Engine

Sub-process Name	Register / Bitfield	Value
Select the ECC result register where the first ECC computation is stored (Only applies to Hamming)	GPMC_ECC_CONTROL[3-0] ECCPOINTER	x
Clear all ECC result registers	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear
Define ECCSIZE0 and ECCSIZE1	GPMC_ECC_SIZE_CONFIG[19-12] ECCSIZE0 and GPMC_ECC_SIZE_CONFIG[29-22] ECCSIZE1	x
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1)	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZ where j = 1 to 9	x
Select the chip-select where ECC is computed	GPMC_ECC_SIZE_CONFIG[3-1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use	GPMC_ECC_SIZE_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation	GPMC_ECC_SIZE_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process	GPMC_ECC_SIZE_CONFIG[13-12] ECCBCHTSEL and GPMC_ECC_SIZE_CONFIG[6-4] ECCTOPSECTOR	x
Enable the ECC computation	GPMC_ECC_SIZE_CONFIG[0] ECCENABLE	1

Table 11-35. Prefetch and Write-Posting Engine

Sub-process Name	Register / Bitfield	Value
Disable the engine before configuration	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0
Select the chip-select associated with a NAND device where the prefetch engine is active	GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request	GPMC_PREFETCH_CONFIG1[14-8] FIFOTHRESHOLD	x
Select either DMA synchronized mode or SW manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (For all back-to-back accesses to the NAND flash but not the first one)	GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION	x
Enable the prefetch postwrite engine	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	1
Select the number of bytes to be read or written by the engine to the selected chip-select	GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT	x
Start the prefetch engine	GPMC_PREFETCH_CONTROL[0] STARTENGINE	1

Table 11-36. WAIT Pin Configuration

Sub-process Name	Register / Bitfield	Value
Selects when the engine starts the access to CS	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x

Table 11-37. Enable Chip-Select

Sub-process Name	Register / Bitfield	Value
When all parameters are configured, enable the chip-select	GPMC_CONFIG7_i[6] CSVALID	x

11.3.5 Set Memory Access

This section details the bit field to configure to set the GPMC in various memory modes.

Table 11-38. Mode Parameters Check List Table

Register	Bit	Bit Field Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0	-	1	N/S	0	-	1	-
GPMC_CONFIG1_i	29	READTYPE	0	-	0	N/S	1	-	1	-
GPMC_CONFIG1_i	28	WRITEMULTIPLE	-	0		N/S	-	0	-	1
GPMC_CONFIG1_i	27	WRITETYPE	-	0		N/S	-	1	-	1

Table 11-39. Access Type Parameters Check List Table

Register	Bit	Bit Field Name	Access Type		
			Non-Mux	Address/Data Mux	AAD Mux
GPMC_CONFIG1_i	9-8	MUXADDDATA	0	2h	1

11.3.6 GPMC Timing Parameters

Figure 11-43 shows a programming model diagram for the NOR interfacing timing parameters.

Table 11-40 lists bit fields to configure adequate timing parameter in various memory modes.

Figure 11-43. NOR Interfacing Timing Parameters Diagram

11.3.6.1 GPMC Timing Parameters Formulas

This section intends to help the user to calculate the GPMC timing bit fields values. Formulas are not listed exhaustively.

The section details:

- NAND Flash Interface Timing Parameters Formulas
- Synchronous NOR Flash Timing Parameters Formulas
- Asynchronous NOR Flash Timing Parameters Formulas

11.3.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to use in order to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_[11-10] DEVICETYPE = 2h. [Table 11-41](#) details NAND timing parameters.

Table 11-41. NAND Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - $\overline{\text{GPMC_WE}}$ valid time
B	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_WE}}$ valid
C	ns	Delay time - GPMC_BE0_CLE/GPMC_ADV_ALE high to $\overline{\text{GPMC_WE}}$ valid
D	ns	Delay time - GPMC_AD[15:0] valid to $\overline{\text{GPMC_WE}}$ valid
E	ns	Delay time - $\overline{\text{GPMC_WE}}$ invalid to GPMC_AD[15:0] invalid
F	ns	Delay time - $\overline{\text{GPMC_WE}}$ invalid to GPMC_BE0_CLE/GPMC_ADV_ALE invalid
G	ns	Delay time - $\overline{\text{GPMC_WE}}$ invalid to $\overline{\text{GPMC_CS}}$ invalid
H	ns	Cycle time - Write cycle time
I	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_OE}}$ valid
J	ns	Setup time - GPMC_AD[15:0] valid to $\overline{\text{GPMC_OE}}$ invalid
K	ns	Pulse duration - $\overline{\text{GPMC_OE}}$ valid time
L	ns	Cycle time - Read cycle time
M	ns	Delay time - $\overline{\text{GPMC_OE}}$ invalid to $\overline{\text{GPMC_CS}}$ invalid

The configuration parameters are calculated through the following formulas.

$$A = (\text{WEOffTime} - \text{WEOnTime}) \times (\text{TimeParaGranularity} + 1) \times \text{GPMC_FCLK period}$$

$$B = ((\text{WEOnTime} - \text{CSOnTime}) \times (\text{TimeParaGranularity} + 1) + 0.5 \times (\text{WEEExtraDelay} - \text{CSEExtraDelay})) \times \text{GPMC_FCLK period}$$

$$C = ((\text{WEOnTime} - \text{ADVOnTime}) \times (\text{TimeParaGranularity} + 1) + 0.5 \times (\text{WEEExtraDelay} - \text{ADVExtraDelay})) \times \text{GPMC_FCLK period}$$

$$D = (\text{WEOnTime} \times (\text{TimeParaGranularity} + 1) + 0.5 \times \text{WEEExtraDelay}) \times \text{GPMC_FCLK period}$$

$$E = (\text{WrCycleTime} - \text{WEOffTime} \times (\text{TimeParaGranularity} + 1) - 0.5 \times \text{WEEExtraDelay}) \times \text{GPMC_FCLK period}$$

$$F = (\text{ADVWrOffTime} - \text{WEOffTime} \times (\text{TimeParaGranularity} + 1) + 0.5 \times (\text{ADVExtraDelay} - \text{WEEExtraDelay})) \times \text{GPMC_FCLK period}$$

$$G = (\text{CSWrOffTime} - \text{WEOffTime} \times (\text{TimeParaGranularity} + 1) + 0.5 \times (\text{CSEExtraDelay} - \text{WEEExtraDelay})) \times \text{GPMC_FCLK period}$$

$$H = \text{WrCycleTime} \times (1 + \text{TimeParaGranularity}) \times \text{GPMC_FCLK period}$$

$$I = ((\text{OEOnTime} - \text{CSOnTime}) \times (\text{TimeParaGranularity} + 1) + 0.5 \times (\text{OEEExtraDelay} - \text{CSEExtraDelay})) \times \text{GPMC_FCLK period}$$

$$J = ((\text{RdAccessTime} - \text{OEOffTime}) \times (\text{TimeParaGranularity} + 1) - 0.5 \times \text{OEEExtraDelay}) \times \text{GPMC_FCLK period}$$

$$K = (\text{OEOffTime} - \text{OEOnTime}) \times (1 + \text{TimeParaGranularity}) \times \text{GPMC_FCLK period}$$

$$L = \text{RdCycleTime} \times (1 + \text{TimeParaGranularity}) \times \text{GPMC_FCLK period}$$

$$M = (\text{CSRdOffTime} - \text{OEOffTime} \times (\text{TimeParaGranularity} + 1) + 0.5 \times (\text{CSExtraDelay} - \text{OEEExtraDelay}) \times \text{GPMC_FCLK period}$$

Figure 11-44 shows a command latch cycle timing simplified example where formulas are associated with signal waves.

Figure 11-44. NAND Command Latch Cycle Timing Simplified Example

11.3.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_[11-10] DEVICETYPE = 0 and when READTYPE or WRITETYPE are set to synchronous mode.

Table 11-42. Synchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - GPMC_CS low
B	ns	Delay time - address bus valid to GPMC_CLK first edge
C	ns	Pulse duration - GPMC_BE0_CLE/GPMC_BE1 low
D	ns	Delay time - GPMC_CLK rising edge to GPMC_BE0_CLE/GPMC_BE1 invalid Delay time - GPMC_CLK rising edge to GPMC_ADV_ALE invalid
E	ns	Delay time - GPMC_CLK rising edge to GPMC_CS invalid Delay time - GPMC_CLK rising edge to GPMC_OE invalid
F	ns	Delay time - GPMC_CLK rising edge to GPMC_CS transition
G	ns	Delay time - GPMC_CLK rising edge to GPMC_ADV_ALE transition
H	ns	Delay time - GPMC_CLK rising edge to GPMC_OE transition
I	ns	Delay time - GPMC_CLK rising edge to GPMC_WE transition
J	ns	Delay time - GPMC_CLK rising edge to GPMC_AD data bus transition Delay time - GPMC_CLK rising edge to GPMC_BE0_CLE/GPMC_BE1 transition
K	ns	Pulse duration - GPMC_ADV_ALE low
L	ns	Delay time - GPMC_WAIT invalid to first data latching GPMC_CLK edge

The configuration parameters are calculated through the following formulas.

For single read accesses:

$$A = (\text{CSRDOFFTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$$

$$C = \text{RDCYCLETIME} \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$$

$$D = (\text{RDCYCLETIME} - \text{RDACCESSTIME}) \times \text{GPMC_FCLK period}$$

$$E = (\text{CSRDOFFTIME} - \text{RDACCESSTIME}) \times \text{GPMC_FCLK period}$$

For burst read accesses (where n is the page burst access number):

$$A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (n - 1) \times \text{PAGEBURSTACCESSTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$$

$$C = (\text{RDCYCLETIME} + (n - 1) \times \text{PAGEBURSTACCESSTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$$

$$D = (\text{RDCYCLETIME} - (\text{RDACCESSTIME} + (n - 1) \times \text{PAGEBURSTACCESSTIME})) \times \text{GPMC_FCLK period}$$

$$E = (\text{CSRDOFFTIME} - (\text{RDACCESSTIME} + (n - 1) \times \text{PAGEBURSTACCESSTIME})) \times \text{GPMC_FCLK period}$$

For burst write accesses (where n is the page burst access number):

$$A = (\text{CSWROFFTIME} - \text{CSONTIME} + (n - 1) \times \text{PAGEBURSTACCESSTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$$

$$C = (\text{WRCYCLETIME} + (n - 1) \times \text{PAGEBURSTACCESSTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$$

$$D = (\text{WRCYCLETIME} - (\text{WRACCESSTIME} + (n - 1) \times \text{PAGEBURSTACCESSTIME})) \times \text{GPMC_FCLK period}$$

$$E = (\text{CSWROFFTIME} - (\text{WRACCESSTIME} + (n - 1) \times \text{PAGEBURSTACCESSTIME})) \times \text{GPMC_FCLK period}$$

For all accesses:

For $\overline{\text{CS}}$ falling edge ($\overline{\text{CS}}$ activated):

- Case where $\text{GPMC_CONFIG1_i}[1-0] \text{ GPMCFCLKDIVIDER} = 0$

$$F = 0.5 \times \text{CSEXTRADELAY} \times \text{GPMC_FCLK period}$$

- Case where $\text{GPMCFCLKDIVIDER} = 1$

$$F = 0.5 \times \text{CSEXTRADELAY} \times \text{GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)}$$

$$F = (1 + 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period, otherwise}$$

- Case where $\text{GPMCFCLKDIVIDER} = 2$

$$F = 0.5 \times \text{CSEXTRADELAY} \times \text{GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3}$$

$$F = (1 + 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3}$$

$$F = (2 + 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3}$$

For $\overline{\text{CS}}$ rising edge ($\overline{\text{CS}}$ de-activated) in reading mode:

- Case where $\text{GPMC_CONFIG1_i}[1-0] \text{ GPMCFCLKDIVIDER} = 0$

$$F = 0.5 \times \text{CSEXTRADELAY} \times \text{GPMC_FCLK period}$$

- Case where $\text{GPMCFCLKDIVIDER} = 1$

$$F = 0.5 \times \text{CSEXTRADELAY} \times \text{GPMC_FCLK period, when (CLKACTIVATIONTIME and$$

CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)

$F = (1 + 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period, otherwise}$

- Case where GPMCFCLKDIVIDER = 2
 $F = 0.5 \times \text{CSEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{CSRDOFFTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $F = (1 + 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{CSRDOFFTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $F = (2 + 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{CSRDOFFTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3

For $\overline{\text{CS}}$ rising edge ($\overline{\text{CS}}$ de-activated) in writing mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0
 $F = 0.5 \times \text{CSEXTRADELAY} \times \text{GPMC_FCLK period}$
- Case where GPMCFCLKDIVIDER = 1
 $F = 0.5 \times \text{CSEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and CSWROFFTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and CSWROFFTIME are even)
 $F = (1 + 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period}$, otherwise
- Case where GPMCFCLKDIVIDER = 2
 $F = 0.5 \times \text{CSEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{CSWROFFTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $F = (1 + 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{CSWROFFTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $F = (2 + 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{CSWROFFTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3

For $\overline{\text{ADV}}$ falling edge ($\overline{\text{ADV}}$ activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0
 $G = 0.5 \times \text{ADVEXTRADELAY} \times \text{GPMC_FCLK period}$
- Case where GPMCFCLKDIVIDER = 1
 $G = 0.5 \times \text{ADVEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and ADVONTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and ADVONTIME are even)
 $G = (1 + 0.5 \times \text{ADVEXTRADELAY}) \times \text{GPMC_FCLK period}$, otherwise
- Case where GPMCFCLKDIVIDER = 2
 $G = 0.5 \times \text{ADVEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{ADVONTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $G = (1 + 0.5 \times \text{ADVEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{ADVONTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $G = (2 + 0.5 \times \text{ADVEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{ADVONTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3

For $\overline{\text{ADV}}$ rising edge ($\overline{\text{ADV}}$ de-activated) in reading mode:

- Case where [1-0] GPMCFCLKDIVIDER = 0
 $G = 0.5 \times \text{ADVEXTRADELAY} \times \text{GPMC_FCLK period}$
- Case where GPMCFCLKDIVIDER = 1
 $G = 0.5 \times \text{ADVEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and ADVRDOFFTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and ADVRDOFFTIME are even)
 $G = (1 + 0.5 \times \text{ADVEXTRADELAY}) \times \text{GPMC_FCLK period}$, otherwise

- Case where GPMCFCLKDIVIDER = 2
 $G = 0.5 \times \text{ADVEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{ADVRDOFFTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $G = (1 + 0.5 \times \text{ADVEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{ADVRDOFFTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $G = (2 + 0.5 \times \text{ADVEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{ADVRDOFFTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3

For $\overline{\text{ADV}}$ rising edge ($\overline{\text{ADV}}$ de-activated) in writing mode:

- Case where [1-0] GPMCFCLKDIVIDER = 0
 $G = 0.5 \times \text{ADVEXTRADELAY} \times \text{GPMC_FCLK period}$
- Case where GPMCFCLKDIVIDER = 1
 $G = 0.5 \times \text{ADVEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and ADVWROFFTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and ADVWROFFTIME are even)
 $G = (1 + 0.5 \times \text{ADVEXTRADELAY}) \times \text{GPMC_FCLK period}$, otherwise
- Case where GPMCFCLKDIVIDER = 2
 $G = 0.5 \times \text{ADVEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{ADVWROFFTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $G = (1 + 0.5 \times \text{ADVEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{ADVWROFFTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $G = (2 + 0.5 \times \text{ADVEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{ADVWROFFTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3

For $\overline{\text{OE}}$ falling edge ($\overline{\text{OE}}$ activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0
 $H = 0.5 \times \text{OEEXTRADELAY} \times \text{GPMC_FCLK period}$
- Case where GPMCFCLKDIVIDER = 1
 $H = 0.5 \times \text{OEEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and OEONTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and OEONTIME are even)
 $H = (1 + 0.5 \times \text{OEEXTRADELAY}) \times \text{GPMC_FCLK period}$, otherwise
- Case where GPMCFCLKDIVIDER = 2
 $H = 0.5 \times \text{OEEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{OEONTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $H = (1 + 0.5 \times \text{OEEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{OEONTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $H = (2 + 0.5 \times \text{OEEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{OEONTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3

For $\overline{\text{OE}}$ rising edge ($\overline{\text{OE}}$ de-activated):

- Case where [1-0] GPMCFCLKDIVIDER = 0
 $H = 0.5 \times \text{OEEXTRADELAY} \times \text{GPMC_FCLK period}$
- Case where GPMCFCLKDIVIDER = 1
 $H = 0.5 \times \text{OEEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and OEOFFTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and OEOFFTIME are even)
 $H = (1 + 0.5 \times \text{OEEXTRADELAY}) \times \text{GPMC_FCLK period}$, otherwise

- Case where GPMCFCLKDIVIDER = 2
 $H = 0.5 \times \text{OEEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{OEOFFTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $H = (1 + 0.5 \times \text{OEEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{OEOFFTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $H = (2 + 0.5 \times \text{OEEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{OEOFFTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3

For $\overline{\text{WE}}$ falling edge ($\overline{\text{WE}}$ activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0
 $I = 0.5 \times \text{WEEXTRADELAY} \times \text{GPMC_FCLK period}$
- Case where GPMCFCLKDIVIDER = 1
 $I = 0.5 \times \text{WEEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and WEONTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and WEONTIME are even)
 $I = (1 + 0.5 \times \text{WEEXTRADELAY}) \times \text{GPMC_FCLK period}$, otherwise
- Case where GPMCFCLKDIVIDER = 2
 $I = 0.5 \times \text{WEEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{WEONTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $I = (1 + 0.5 \times \text{WEEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{WEONTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $I = (2 + 0.5 \times \text{WEEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{WEONTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3

For $\overline{\text{WE}}$ rising edge ($\overline{\text{WE}}$ de-activated):

- Case where [1-0] GPMCFCLKDIVIDER = 0
 $I = 0.5 \times \text{WEEXTRADELAY} \times \text{GPMC_FCLK period}$
- Case where GPMCFCLKDIVIDER = 1
 $I = 0.5 \times \text{WEEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{CLKACTIVATIONTIME}$ and WEOFFTIME are odd) or $(\text{CLKACTIVATIONTIME}$ and WEOFFTIME are even)
 $I = (1 + 0.5 \times \text{WEEXTRADELAY}) \times \text{GPMC_FCLK period}$ otherwise
- Case where GPMCFCLKDIVIDER = 2
 $I = 0.5 \times \text{WEEXTRADELAY} \times \text{GPMC_FCLK period}$, when $(\text{WEOFFTIME} - \text{CLKACTIVATIONTIME})$ is a multiple of 3
 $I = (1 + 0.5 \times \text{WEEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{WEOFFTIME} - \text{CLKACTIVATIONTIME} - 1)$ is a multiple of 3
 $I = (2 + 0.5 \times \text{WEEXTRADELAY}) \times \text{GPMC_FCLK period}$, when $(\text{WEOFFTIME} - \text{CLKACTIVATIONTIME} - 2)$ is a multiple of 3

For GPMC_ADV low pulse duration:

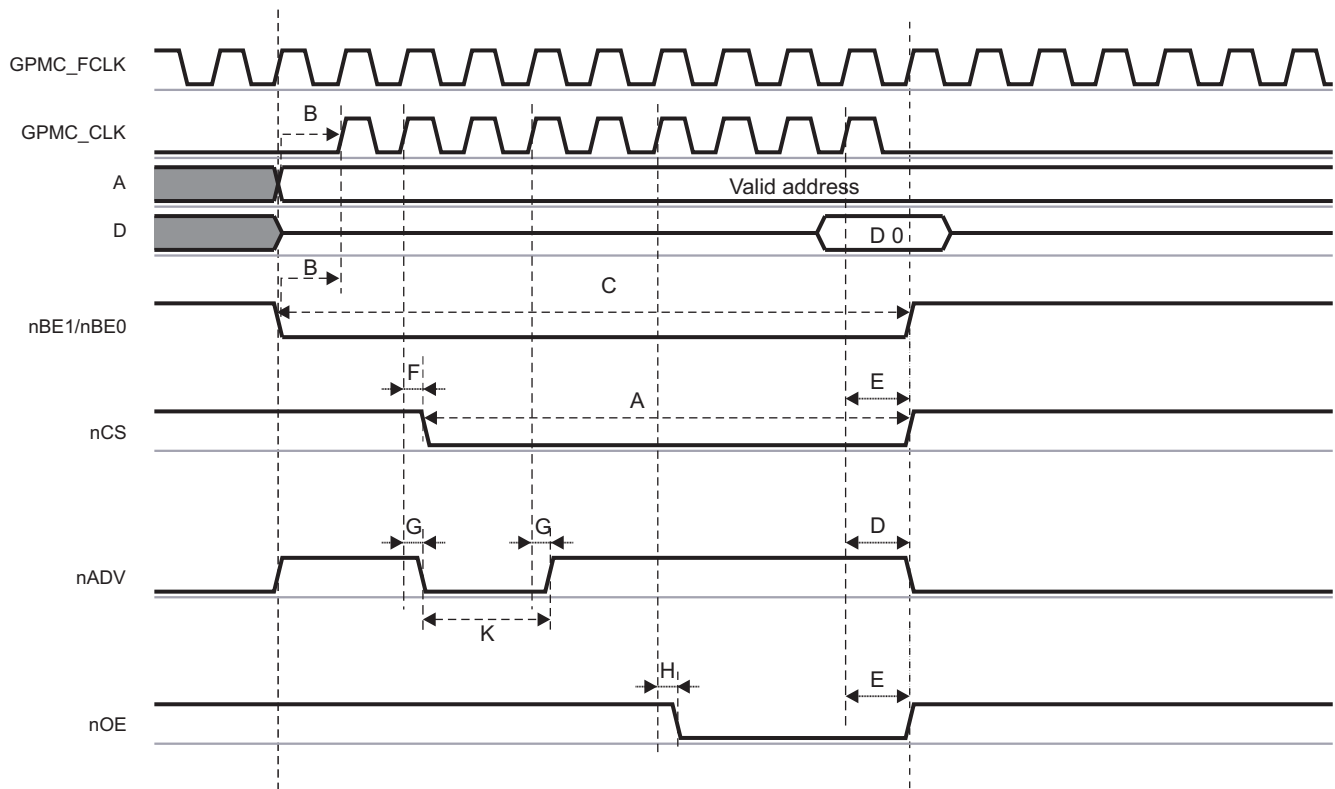

- Read operation
 $K = (\text{ADVRDOFFTIME} - \text{ADVONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$
- Write operation
 $K = (\text{ADVWROFFTIME} - \text{ADVONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$

For GPMC_WAIT invalid to first data latching GPMC_CLK edge:

$$L = \text{WAITMONITORINGTIME} \times (\text{GPMCFCLKDIVIDER} + 1) \times \text{GPMC_FCLK period} + \text{GPMC_CLK period}$$

Figure 11-45 shows a synchronous NOR single read simplified example where formulas are associated with signal waves.

Figure 11-45. Synchronous NOR Single Read Simplified Example

11.3.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate asynchronous NOR timing parameters. This is the case when [11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode.

Table 11-43. Asynchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - $\overline{\text{GPMC_CS}}$ low
B	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to GPMC_ADV_ALE invalid
C	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_OE}}$ invalid (single read)
D	ns	Pulse duration - address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_WE}}$ valid
F	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_WE}}$ invalid
G	ns	Address invalid duration between 2 successive R/W accesses
H	ns	Setup time - read data valid before $\overline{\text{GPMC_OE}}$ high
I	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_OE}}$ invalid (burst read)
J	ns	Delay time - address bus valid to $\overline{\text{GPMC_CS}}$ valid
		Delay time - data bus valid to $\overline{\text{GPMC_CS}}$ valid
		Delay time - $\text{GPMC_BE0_CLE}/\text{GPMC_BE1}$ valid to $\overline{\text{GPMC_CS}}$ valid
K	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to GPMC_ADV_ALE valid
L	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_OE}}$ valid
M	ns	Delay time - GPMC_CS valid to first data latching edge
N	ns	Pulse duration - $\text{GPMC_BE0_CLE}/\text{GPMC_BE1}$ valid time
O	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to GPMC_ADV_ALE valid

The configuration parameters are calculated through the following formulas. Note that these formulas are not exhaustive.

$\overline{\text{GPMC_CS}}$ low pulse:

For single read: $A = (\text{CSRDOFFTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$

For burst read: $A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (N - 1) \times \text{PAGEBURSTACCESSTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$, where N = page burst access number

For single write: $A = (\text{CSWROFFTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$

For burst write: $A = (\text{CSWROFFTIME} - \text{CSONTIME} + (N - 1) \times \text{PAGEBURSTACCESSTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$, where N = page burst access number

$\overline{\text{GPMC_CS}}$ valid to GPMC_ADV_ALE invalid delay:

For reading: $B = ((\text{ADVRDOFFTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) + 0.5 \times (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) \times \text{GPMC_FCLK period}$

For writing: $B = ((\text{ADVWROFFTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) + 0.5 \times (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) \times \text{GPMC_FCLK period}$

$C = ((\text{OEOFFTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) + 0.5 \times (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) \times \text{GPMC_FCLK period}$

$D = \text{PAGEBURSTACCESSTIME} \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$

$E = ((\text{WEONTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) + 0.5 \times (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) \times \text{GPMC_FCLK period}$

$F = ((\text{WEOFFTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) + 0.5 \times (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) \times \text{GPMC_FCLK period}$

$G = \text{CYCLE2CYCLEDELAY} \times \text{GPMC_FCLK period}$

$H = ((\text{OEOFFTIME} - \text{RDACCESSTIME}) \times (\text{TIMEPARAGRANULARITY} + 11) + 0.5 \times \text{OEEXTRADELAY}) \times \text{GPMC_FCLK period}$

$I = ((\text{OEOFFTIME} + (N - 1) \times \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) + 0.5 \times (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) \times \text{GPMC_FCLK period}$, where N = page burst access number

$J = (\text{CSONTIME} \times (\text{TIMEPARAGRANULARITY} + 1) + 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period}$

$K = ((\text{ADVONTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) + 0.5 \times (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) \times \text{GPMC_FCLK period}$

$L = ((\text{OEONTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) + 0.5 \times (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) \times \text{GPMC_FCLK period}$

$M = ((\text{RDACCESSTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) - 0.5 \times \text{CSEXTRADELAY}) \times \text{GPMC_FCLK period}$

GPMC_BE0_CLE/GPMC_BE1 pulse:

For single read: $N = \text{RDCYCLETIME} \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$

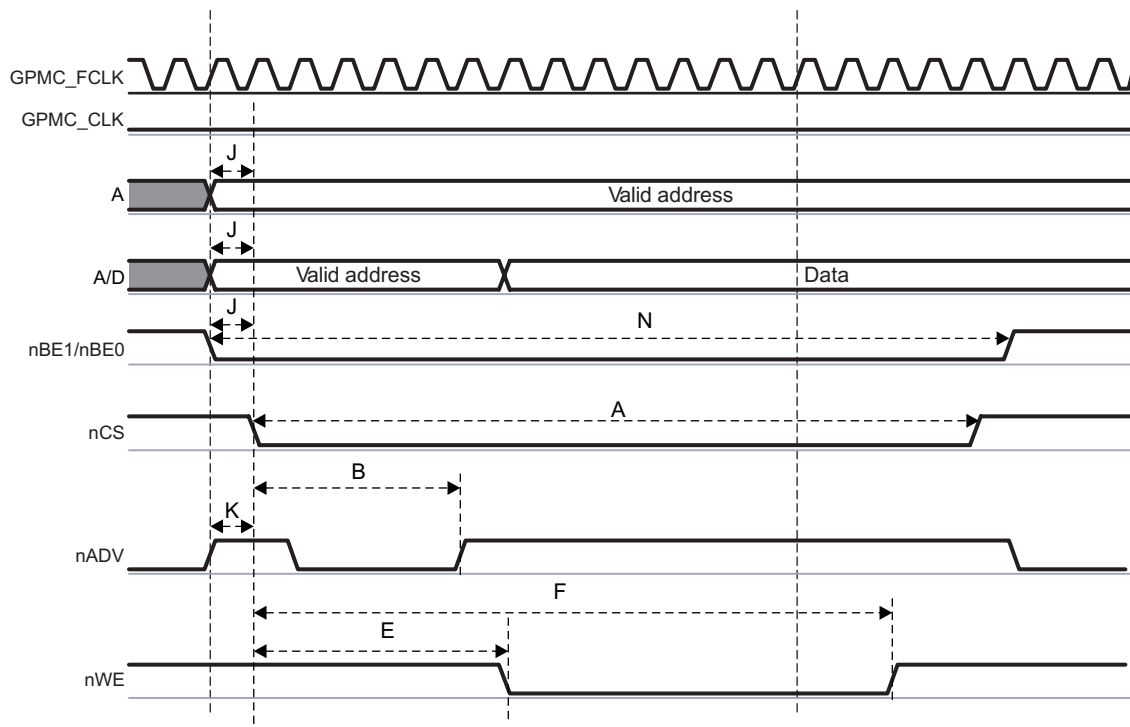

For burst read: $N = (\text{RDCYCLETIME} + (N - 1) \times \text{PAGEBURSTACCESSTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$, where N = page burst access number

For burst write: $N = (\text{WRCYCLETIME} + (N - 1) \times \text{PAGEBURSTACCESSTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) \times \text{GPMC_FCLK period}$, where N = page burst access number

$O = ((\text{WRCYCLETIME} + (N - 1) \times \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) \times (\text{TIMEPARAGRANULARITY} + 1) + 0.5 \times (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) \times \text{GPMC_FCLK period}$

Figure 11-46 shows an asynchronous NOR single write simplified example where formulas are associated with signal waves.

Figure 11-46. Asynchronous NOR Single Write Simplified Example

Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

11.4 Use Cases And Tips

11.4.1 How to Set GPMC Timing Parameters for Typical Accesses

11.4.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 100 MHz clock frequency
- Read access time: 80 ns

11.4.1.2 Typical GPMC Setup

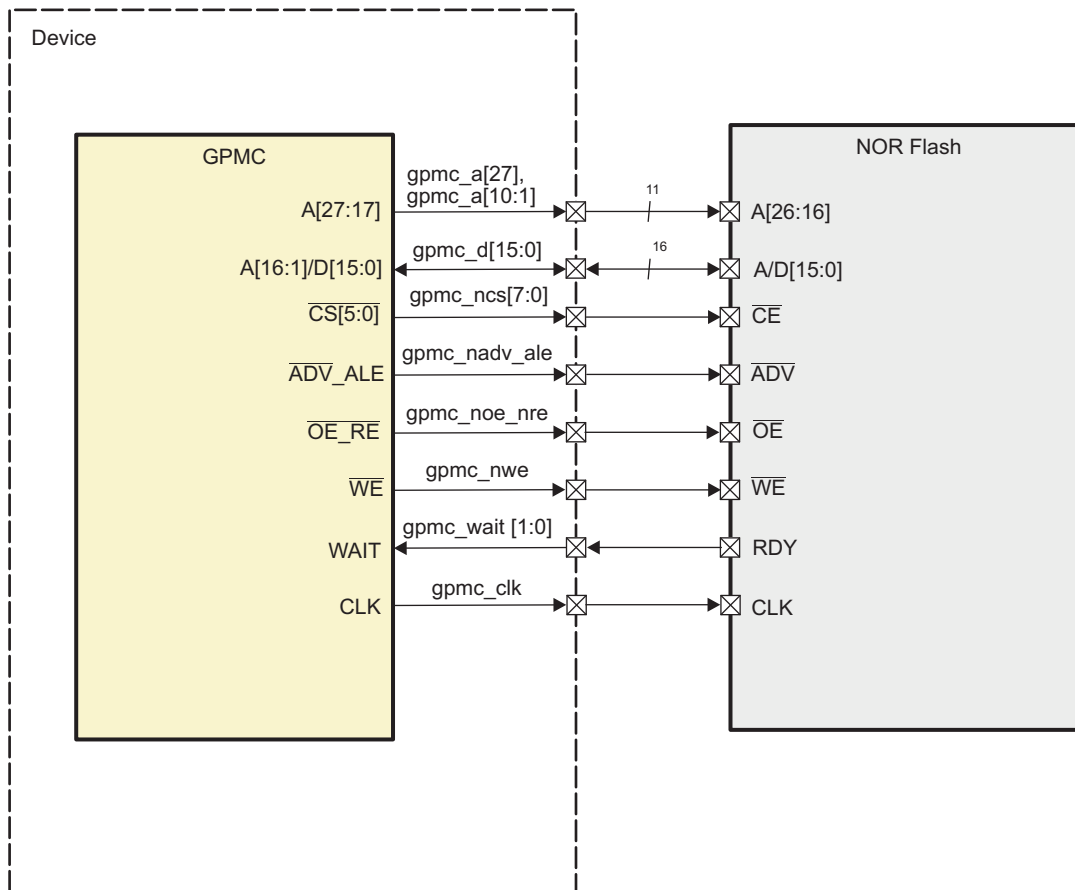

[Table 11-44](#) lists some of the I/Os of the GPMC module.

Table 11-44. GPMC Signals

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
GPMC_CLK	O	External clock provided to the external device for synchronous operations
GPMC_A[27:17]	O	Address
GPMC_D[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
$\overline{\text{GPMC_CS}}_x$	O	Chip-select (where x = 0, or 1)
$\overline{\text{GPMC_ADV_ALE}}$	O	Address valid enable
$\overline{\text{GPMC_OE_RE}}$	O	Output enable (read access only)
$\overline{\text{GPMC_WE}}$	O	Write enable (write access only)
GPMC_WAIT	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 11-47 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 11-47. GPMC Connection to an External NOR Flash Memory

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

11.4.1.3 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 100 MHz ($f = 100 \text{ MHz}$; $T = 10 \text{ ns}$).

Table 11-45 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-46 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-48 shows the synchronous burst read access.

Table 11-45. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	$\overline{\text{CS}}$ setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Impedance	7
tOEZ	Output enable to High-Impedance	7
tAVC	$\overline{\text{ADV}}$ setup time	6
tAVD	$\overline{\text{AVD}}$ pulse	6
tACH	Address hold time from clock	3

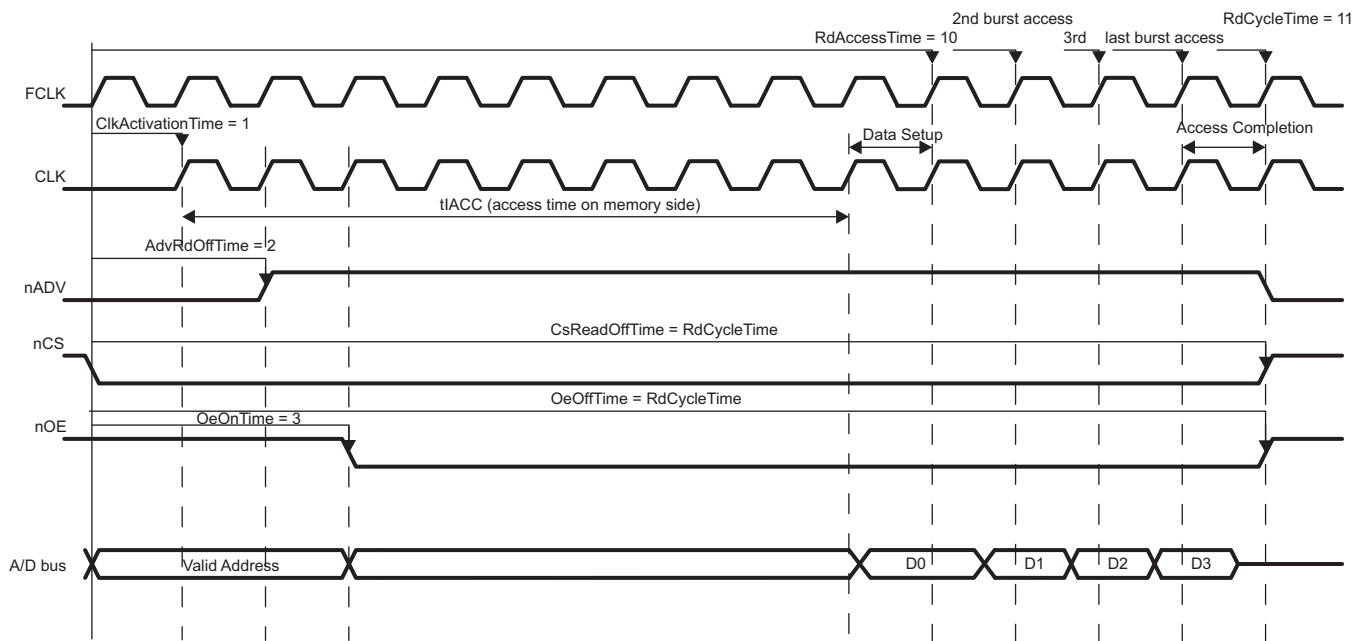

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ($T = 10 \text{ ns}$). The read access time between 2 bursts of data is $t\text{BACC} = 5,2 \text{ ns}$. Therefore, data setup time is a clock period - $t\text{BACC} = 4,8 \text{ ns}$ of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: $\overline{\text{CS}}/\overline{\text{OE}}$ hold time ($\overline{\text{CS}}$ and $\overline{\text{OE}}$ must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 11-46. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 100 MHz)	GPMC Register Configurations
GPMC FCLK Divider	-	-	-	GPMCFCLKDIVIDER = 0
ClkActivationTime	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94,8: (10 + 80 + 4,8)	10 : roundmax (94,8 / 10)	RDACCESSTIME = Ah
PageBurstAccessTime	roundmax (tBACC)	roundmax (5,2)	1	PAGEBURSTACCESSTIME = 1
RdCycleTime	RdAccessTime + max (tCEZ, tOEZ)	101,8: (94,8 + 7)	11	RDCYCLETIME = Bh
CsOnTime	tCES	0	0	CSONTIME = 0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = Bh
AdvOnTime	tAVC	0	0	ADVONTIME = 0
AdvRdOffTime	tAVD + tAVC	12	2	ADVRDOFFTIME = 2h
OeOnTime	(ClkActivationTime + tACH) < OeOnTime < (ClkActivationTime + tIACC)	-	3, for instance	OEONTIME = 3h
OeOffTime	RdCycleTime	-	11	OEOFFTIME = Bh

Figure 11-48. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

11.4.1.4 GPMC Configuration for Asynchronous Read Access

The clock runs at 100 MHz ($f = 100 \text{ MHz}$; $T = 10 \text{ ns}$).

Table 11-47 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-48 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-49 shows the asynchronous read access.

Table 11-47. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from $\overline{\text{CS}}$ low	80
tAAVDS	Address setup time to rising edge of $\overline{\text{ADV}}$	3
tAVDP	$\overline{\text{ADV}}$ low time	6
tCAS	$\overline{\text{CS}}$ setup time to $\overline{\text{ADV}}$	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Impedance	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

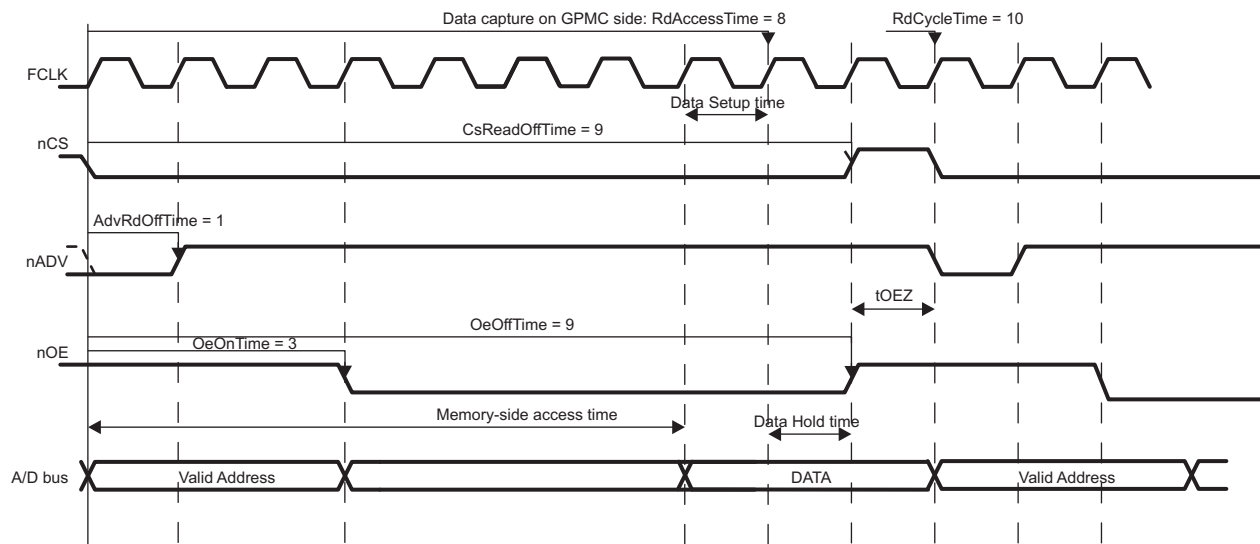

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 11-48: the number of clock cycles between the address capture ($\overline{\text{ADV}}$ rising edge) and the data valid on the output bus.

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

- To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no $\overline{\text{OE}}/\overline{\text{CS}}$ deassertion while reading the data). This data hold time is 1 clock cycle (that is, RdAccessTime + 1).
- To complete the access, $\overline{\text{OE}}/\overline{\text{CS}}$ signals are driven to high-impedance. RdAccessTime + 1 cycle + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begins.

Table 11-48. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 100 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
RdAccessTime	round max (tCE)	80	8	RDACCESSTIME = 8h
PageBurstAccessTime	n/a (single access)			
RdCycleTime	RdAccessTime + 1cycle + tOEZ	97	10	RDCYCLETIME = Ah
CsOnTime	tCAS	0	0	CSONTIME = 0
CsReadOffTime	RdAccessTime + 1 cycle	90	9	CSRDOFFTIME = 9h
AdvOnTime	tAAVDS	3	1	ADVONTIME = 1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 1
OeOnTime	OeOnTime ≥ AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 3h
OeOffTime	RdAccessTime + 1cycle	90	9	OEOFFTIME = 9h

Figure 11-49. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

11.4.1.5 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 100 MHz: ($f = 100 \text{ MHz}$; $T = 10 \text{ ns}$).

Table 11-49 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-50 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-50 shows the synchronous burst write access.

Table 11-49. AC Characteristics for Asynchronous Single Write (Memory Side)

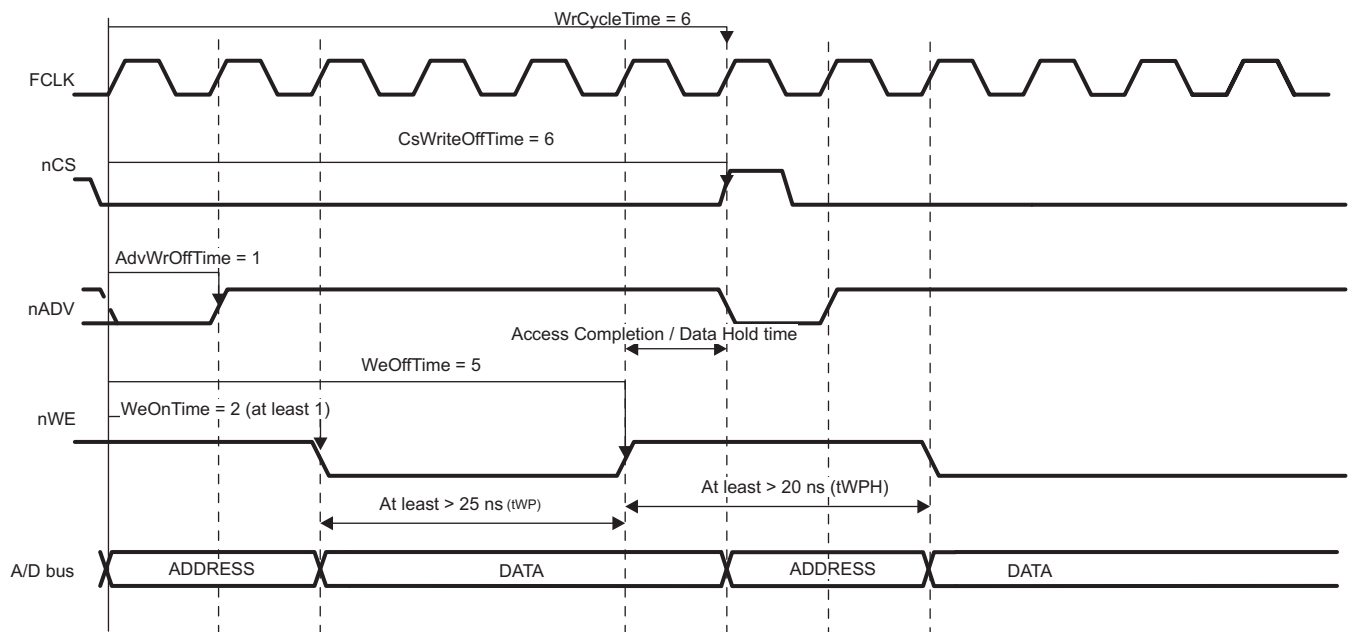

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	$\overline{\text{ADV}}$ low time	6
tWPH	Write pulse width high	20
tCS	$\overline{\text{CS}}$ setup time to $\overline{\text{WE}}$	3
tCAS	$\overline{\text{CS}}$ setup time to $\overline{\text{ADV}}$	0
tAVSC	$\overline{\text{ADV}}$ setup time	3

For asynchronous single write access, write cycle time is $\text{WrCycleTime} = \text{WeOffTime} + \text{AccessCompletion} = \text{WeOffTime} + 1$. For the AccessCompletion, the GPMC requires 1 cycle of data hold time ($\overline{\text{CS}}$ de-assertion).

Table 11-50. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 100 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
WrAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	n/a (single access)			
WrCycleTime	WeOffTime + AccessCompletion	58	6	WRCYCLETIME = 6h
CsOnTime	tCAS	0	0	CSONTIME = 0
CsWrOffTime	WeOffTime + 1 cycle	58	6	CSWROFFTIME = 6h
AdvOnTime	tAVSC	3	1	ADVONTIME = 1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 1
WeOnTime	tCS	3	WEONTIME = 1	
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 5h

Figure 11-50. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)

11.4.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

11.4.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, , ...)
- 8- and 16-bit NAND flash device

11.4.2.2 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories (see [Table 11-51](#)).

Table 11-51. Supported Memory Interfaces

Function	16-bit Address/Data Non-Muxed Flash	16-bit Address/Data Muxed pSRAM or NOR Flash	OneNAND	16-bit NAND	8-bit NAND

11.4.2.3 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 11-52 summarizes the NAND interface signals level applied to external device or memories.

Table 11-52. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	CE	WE	RE
Read (cmd input)	H	L	L	RE	H
Read (add input)	L	H	L	RE	H
Write (cmd input)	H	L	L	RE	H
Write (add input)	L	H	L	RE	H
Data input	L	L	L	RE	H
Data output	L	L	L	H	FE
Busy (during read)	x	x	H	H	H
Busy (during program)	x	x	x	x	x
Busy (during erase)	x	x	x	x	x
Write protect	x	x	x	x	x
Stand-by	x	x	H	x	x

11.4.2.4 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; i.e., it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 11-53 summarizes the NOR interface signals level applied to external device or memories.

Table 11-53. NOR Interface Bus Operations Summary

Bus Operation	CLK	ADV	CS	OE	WE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

11.4.2.5 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND Flash is a high-density and low-power memory device. It is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

11.4.2.6 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

11.4.2.7 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 3.3V
- Maximum GPMC addressing capability: 256 MBytes divided into six chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

11.5 Registers

Table 11-54 provides a summary of the GPMC registers. All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except the GPMC_NAND_DATA_i register, are little-endian. If the GPMC_NAND_DATA_i register is accessed, the endianness is access-dependent.

In this section, i corresponds to the chip-select number, i = 0 to 5.

Table 11-54. GPMC Registers

11.5.1 GPMC_REVISION

This register contains the IP revision code.

Figure 11-51. GPMC_REVISION

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 11-55. GPMC_REVISION Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	REV	0-FFh	IP revision. Major revision is [7-4]. Minor revision is [3-0]. Examples: 10h for revision 1.0, 21h for revision 2.1.

11.5.2 GPMC_SYSCONFIG

This register controls the various parameters of the OCP interface.

Figure 11-52. GPMC_SYSCONFIG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 11-56. GPMC_SYSCONFIG Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4-3	SIDLEMODE	0	Force-idle. An idle request is acknowledged unconditionally
		1h	No-idle. An idle request is never acknowledged
		2h	Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module
		3h	Reserved
2	Reserved	0	Reserved
1	SOFTRESET		Software reset (Set 1 to this bit triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0)
		0	Normal mode
		1	The module is reset
0	AUTOIDLE		Internal OCP clock gating strategy
		0	Interface clock is free-running
		1	Automatic Interface clock gating strategy is applied, based on the Interconnect activity

11.5.3 GPMC_SYSSTATUS

This register provides status information about the module, excluding the interrupt status information.

Figure 11-53. GPMC_SYSSTATUS

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

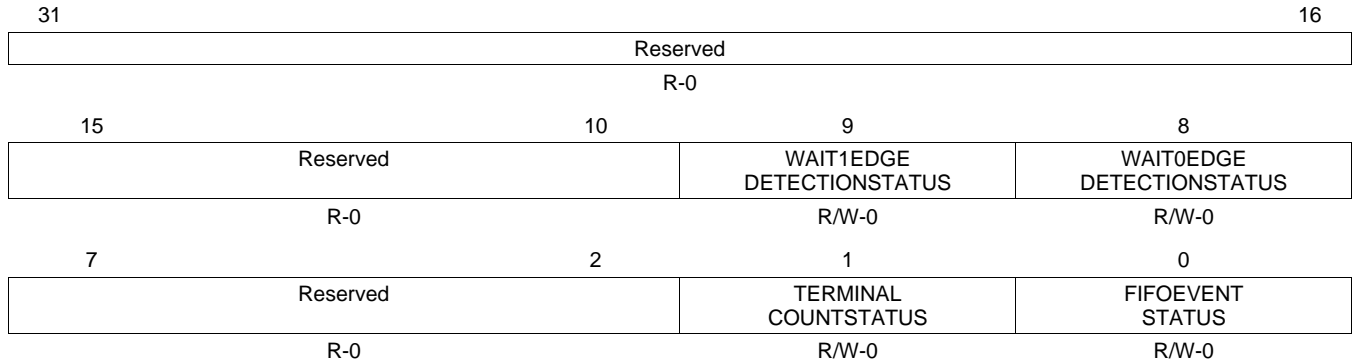

Table 11-57. GPMC_SYSSTATUS Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	RESETDONE	R0	Internal reset monitoring
		R1	Internal module reset in on-going
		R1	Reset completed

11.5.4 GPMC_IRQSTATUS

This interrupt status register regroups all the status of the module internal events that can generate an interrupt.

Figure 11-54. GPMC_IRQSTATUS

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

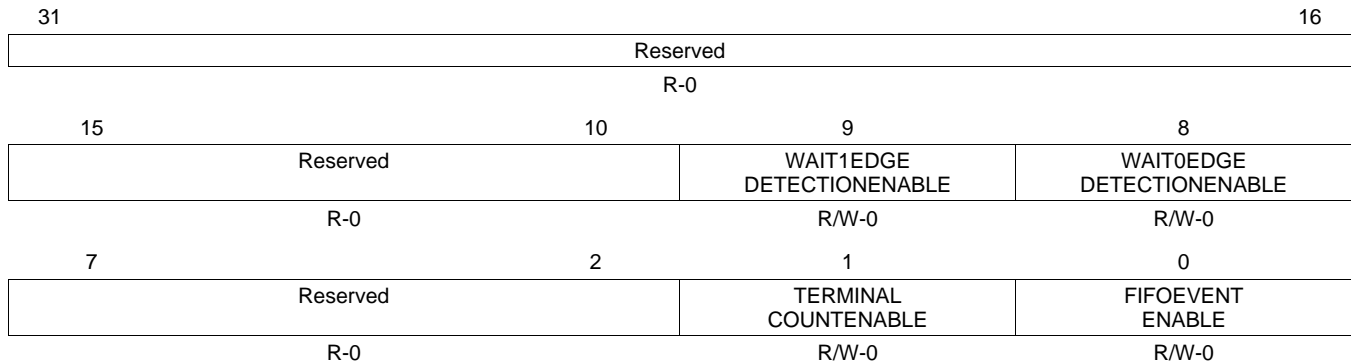

Table 11-58. GPMC_IRQSTATUS Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	WAIT1EDGEDETECTIONSTATUS	R0 W0 R1 W1	Status of the Wait1 Edge Detection interrupt A transition on WAIT1 input pin has not been detected WAIT1EDGEDETECTIONSTATUS bit unchanged A transition on WAIT1 input pin has been detected WAIT1EDGEDETECTIONSTATUS bit is reset
8	WAIT0EDGEDETECTIONSTATUS	R0 W0 R1 W1	Status of the Wait0 Edge Detection interrupt A transition on WAIT0 input pin has not been detected WAIT0EDGEDETECTIONSTATUS bit unchanged A transition on WAIT0 input pin has been detected WAIT0EDGEDETECTIONSTATUS bit is reset
7-2	Reserved	0	Reserved
1	TERMINALCOUNTSTATUS	R0 W0 R1 W1	Status of the TerminalCountEvent interrupt Indicates that CountValue is greater than 0 TERMINALCOUNTSTATUS bit unchanged Indicates that CountValue is equal to 0 TERMINALCOUNTSTATUS bit is reset
0	FIFOEVENTSTATUS	R0 W0 R1 W1	Status of the FIFOEvent interrupt Indicates than less than GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and less than FIFOTHRESHOLD bytes free places are available in write-posting mode. FIFOEVENTSTATUS bit unchanged Indicates than at least GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and at least FIFOTHRESHOLD bytes free places are available in write-posting mode. FIFOEVENTSTATUS bit is reset

11.5.5 GPMC_IRQENABLE

The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.

Figure 11-55. GPMC_IRQENABLE

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 11-59. GPMC_IRQENABLE Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	WAIT1EDGEDETECTIONENABLE	0	Enables the Wait1 Edge Detection interrupt Wait1EdgeDetection interrupt is masked
		1	Wait1EdgeDetection event generates an interrupt if occurs
8	WAIT0EDGEDETECTIONENABLE	0	Enables the Wait0 Edge Detection interrupt Wait0EdgeDetection interrupt is masked
		1	Wait0EdgeDetection event generates an interrupt if occurs
7-2	Reserved	0	Reserved
1	TERMINALCOUNTEVENTENABLE	0	Enables TerminalCountEvent interrupt issuing in pre-fetch or write posting mode TerminalCountEvent interrupt is masked
		1	TerminalCountEvent interrupt is not masked
0	FIFOEVENTENABLE	0	Enables the FIFOEvent interrupt FIFOEvent interrupt is masked
		1	FIFOEvent interrupt is not masked

11.5.6 GPMC_TIMEOUT_CONTROL

The GPMC_TIMEOUT_CONTROL register allows the user to set the start value of the timeout counter

Figure 11-56. GPMC_TIMEOUT_CONTROL

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 11-60. GPMC_TIMEOUT_CONTROL Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved
12-4	TIMEOUTSTARTVALUE	0-1FFh	Start value of the time-out counter (000 corresponds to 0 GPMC.FCLK cycle, 1h corresponds to 1 GPMC.FCLK cycle, and 1FFh corresponds to 511 GPMC.FCLK cycles)
3-1	Reserved	0	Reserved
0	TIMEOUTENABLE	0 1	Enable bit of the TimeOut feature TimeOut feature is disabled TimeOut feature is enabled

11.5.7 GPMC_ERR_ADDRESS

The GPMC_ERR_ADDRESS register stores the address of the illegal access when an error occurs.

Figure 11-57. GPMC_ERR_ADDRESS

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

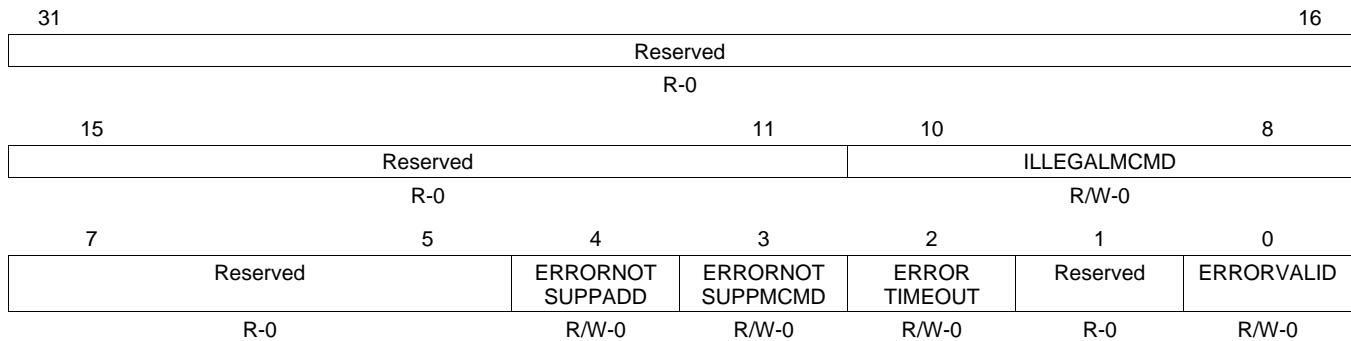

Table 11-61. GPMC_ERR_ADDRESS Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved
30-0	ILLEGALADD	0-7FFF FFFFh	Address of illegal access: A30 (0 for memory region, 1 for GPMC register region) and A29-A0 (1GByte maximum)

11.5.8 GPMC_ERR_TYPE

The GPMC_ERR_TYPE register stores the type of error when an error occurs.

Figure 11-58. GPMC_ERR_TYPE

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

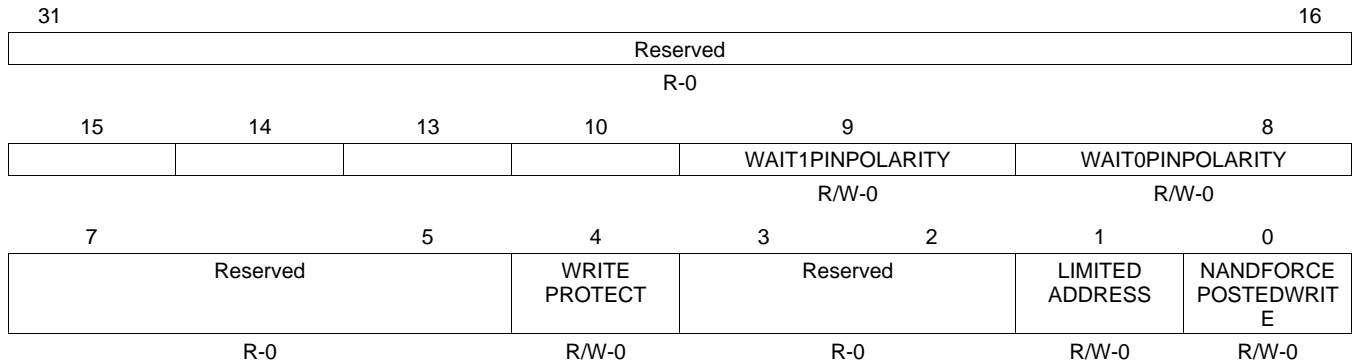

Table 11-62. GPMC_ERR_TYPE Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	Reserved
10-8	ILLEGALMCMD	0-7h	System Command of the transaction that caused the error
7-5	Reserved	0	Reserved
4	ERRORNOTSUPPADD	0 1	Not supported Address error 0 No error occurs 1 The error is due to a non supported Address
3	ERRORNOTSUPPMCMD	0 1	Not supported Command error 0 No error occurs 1 The error is due to a non supported Command
2	ERRORTIMEOUT	0 1	Time-out error 0 No error occurs 1 The error is due to a time out
1	Reserved	0	Reserved
0	ERRORVALID	0 1	Error validity status - Must be explicitly cleared with a write 1 transaction 0 All error fields no longer valid 1 Error detected and logged in the other error fields

11.5.9 GPMC_CONFIG

The configuration register allows global configuration of the GPMC.

Figure 11-59. GPMC_CONFIG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

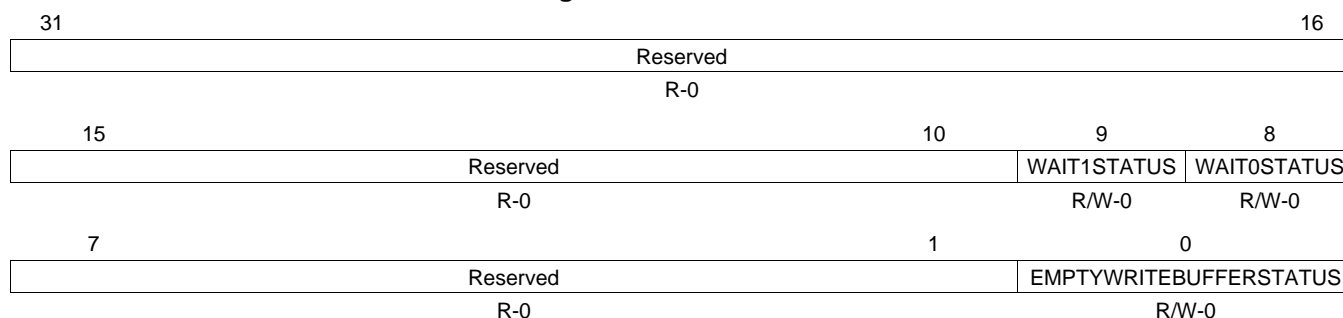

Table 11-63. GPMC_CONFIG Field Descriptions

Bit	Field	Value	Description
31-10	Reserved		Reserved
9	WAIT1PINPOLARITY	0 1	Selects the polarity of input pin WAIT1 WAIT1 active low WAIT1 active high
8	WAIT0PINPOLARITY	0 1	Selects the polarity of input pin WAIT0 WAIT0 active low WAIT0 active high
7-5	Reserved		Reserved
4	WRITEPROTECT	0 1	Controls the \overline{WP} output pin level \overline{WP} output pin is low \overline{WP} output pin is high
1	LIMITEDADDRESS	0 1	Limited Address device support. Enabling this function forces A[27:11] high on the GPMC I/O. Thus only devices with 2 kbytes of addressing space can be used. No effect (normal addressing) GPMC_A[27:11] are driven high and not modified during memory accesses
0	NANDFORCEPOSTEDWRITE	0 1	Enables the Force Posted Write feature to NAND Cmd/Add/Data location Disables Force Posted Write Enables Force Posted Write

11.5.10 GPMC_STATUS

The status register provides global status bits of the GPMC.

Figure 11-60. GPMC_STATUS

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 11-64. GPMC_STATUS Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	WAIT1STATUS	0 1	Is a copy of input pin WAIT1. (Reset value is WAIT1 input pin sampled at IC reset) 0 WAIT1 asserted (inactive state) 1 WAIT1 de-asserted
8	WAIT0STATUS	0 1	Is a copy of input pin WAIT0. (Reset value is WAIT0 input pin sampled at IC reset) 0 WAIT0 asserted (inactive state) 1 WAIT0 de-asserted
7-1	Reserved	0	Reserved
0	EMPTYWRITEBUFFERSTATUS	0 1	Stores the empty status of the write buffer 0 Write Buffer is not empty 1 Write Buffer is empty

11.5.11 GPMC_CONFIG1_i

The configuration 1 register sets signal control parameters per chip select.

Figure 11-61. GPMC_CONFIG1_i

12.9 Standard-Definition Video Encoder (SD-VENC) Module	1723
12.10 Video Input Parser (VIP) Module	1724
12.11 Other Video Input Ports.....	1731

12.1 Introduction

The high definition video processing subsystem (HDVPSS) includes video/graphics display and capture processing using the latest TI developed algorithms, flexible compositing and blending engine, and a full range of external video interfaces in order to deliver high quality video contents to the end devices.

12.1.1 Acronyms & Definitions

Table 12-1. HDVPSS: Acronyms

Acronym	Definition
HDVPSS	High Definition Video Processing Subsystem
DEI	De-Interlacer
DVO	Digital Video Output
GRPX	Graphics Pipeline
HDMI	High Definition Multimedia Interface
NF	Noise Filter
NTSC	National Television System Committee
PAL	Phase Alternating Line
SC	Scaler
SD	Standard Definition
SDK	Software Development Kit
COMP	Compositor
VENC	Video Encoder
VIP	Video Input Port
VPDMA	Video Port Direct Memory Access

Table 12-2. HDVPSS Data Format

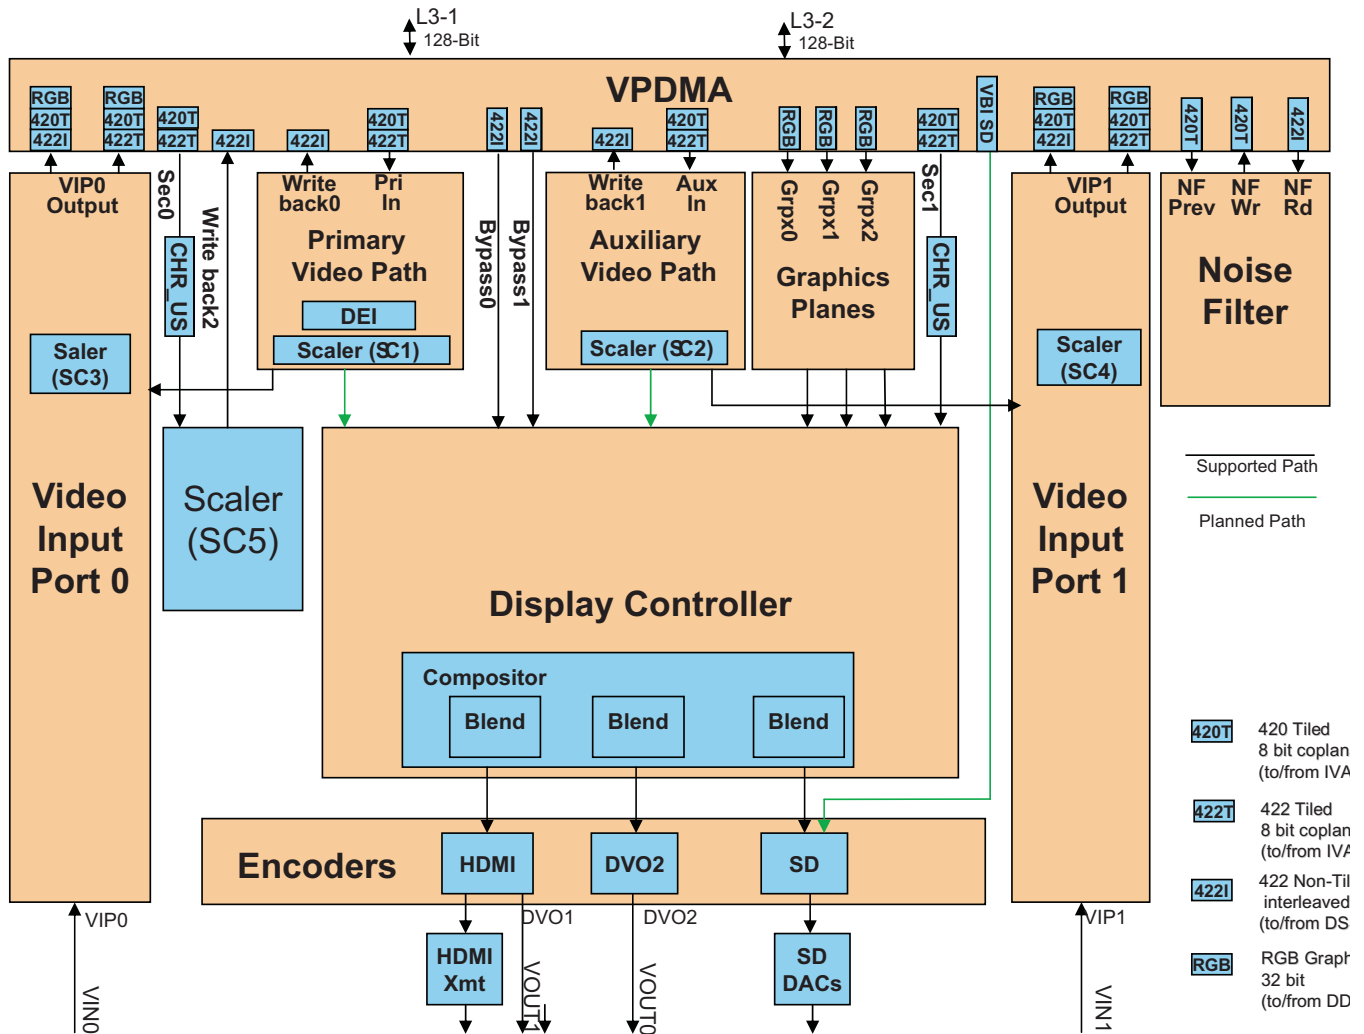

Name	DataFormat	Arrangement	Tiler Support
422I	YUV422I_YUYV	Single Buffer: Y U Y V Y U Y V	No
420T	YUV420SP_UV	Y Buffer: Y Y Y Y buffer: U V U V	Y: 8-bit container UV: 16-bit container
422T	YUV422SP_UV	Y Buffer: Y Y Y Y UV Buffer: U V U V	Y: 8-bit container UV: 16-bit container
422T	YUV422I_YUYV	Single Buffer: Y U Y V Y U Y V	No

NOTE: For the 422T input port, the maximum input width is 960 pixels if the data format is YUV422I_YUYV.

12.1.2 HD_VPSS Block Diagram

The functional block diagram for the HD_VPSS broad market is illustrated in Figure 12-1.

Figure 12-1. Functional Block Diagram

12.1.3 Features

12.1.3.1 Overall Features

- Two independent Video Capture input ports up to 165MHz, each VIP instance supports scaling, pixel format conversion, and up to 1 1080P60 or 8-channel multiplexed D1 data.
- One Video processing engine with de-interlacing, scaling, format conversion (aspect-ratio, and pixel format).
- The HDVPSS is able to accept the HDVICP2 Video Decoder output formats and adjust to several video formats. This includes (but not limited to) tiled and raster data formats, scan format conversion, aspect-ratio conversion, and frame-size conversion.
- Three independent graphics processing engines with scaling capability, alpha-blending, chroma keying.
- Three independent compositors (2HD + 1SD) supports composition of video and graphics overlays to provide various display combinations, each compositor support up to 5 display overlays(2 video + 3 graphics) , alpha-blending, chroma keying and display order reshuffling.
- Three VENCs (2 HD Digital, one SD analog) supports up to two HD (up to 1080P60) + 1 SD display

simultaneously

- The HDVPSS handles both video and graphics efficiently to create high-quality user interfaces. This includes (but not limited to) de-interlacing, scaling, noise reduction, alpha blending, chroma keying, flicker filtering, and pixel format conversion.
- HDMI 1.3a compliant transmitter up to 162MHz

12.1.3.2 Video Processing Features

- Two parallel video processing pipelines (primary and auxiliary) for concurrent video stream processing are supported.
- The Primary video pipeline is used for processing the video for the full size HD video output. The pipeline employs an algorithm that includes a motion-adaptive 3D de-interlacer and a non-edge adaptive scaler.
- The auxiliary video pipeline is used for processing the video for the full HD/SD video output. The pipeline employs an area-efficient algorithm that includes a non-edge adaptive scaler
- The noise filter (NF) performs a memory to memory spatial/temporal noise filter algorithm on a 422 raster input source and produces a 420 tiled output source.
- Supported video input formats are 4:2:0 (aligned-chroma, semi-planar, frame/field), and 4:2:2 (planar, semi-planar, frame/field). YUV420, the output formats of the HDVICP2 and video formats of captured external digital video data, is supported.
- Scan format conversion (i.e., interlaced to progressive and vice versa) is supported. Especially the interlaced to progressive conversion employs a high quality motion-adaptive 3D de-interlacer to properly render both static and dynamic objections in scenes.
- The output of the video processing is sent to either compositor or external memory. When the output is sent to external memory, context switching between multiple inputs is handled efficiently, i.e. multi-CH mode of operation.
- Both the main and auxiliary video pipelines include a write-back path to the external memory to support memory to memory scaling of video frames independently from the display output frame timing.
- Color keying (transparency) is supported.

12.1.3.3 Graphics Features

- Three independently generated graphics layers are supported.
- Each graphic layer supports full-screen resolution graphics.
- Each of the graphics pipelines includes an up/down scaler optimized for graphics application. The scaler supports scaling ratios from 0.25x to 4x with 0.01 scaling step size.
- Supported graphics formats are:
 - 32-bit: ARGB8888, RGBA8888,
 - 24-bit: RGB888, ARGB6666, RGBA6666
 - 16-bit: ARGB1555, RGB565, ARGB4444, RGBA5551, RGB4444
 - Bitmap: 1, 2, 4, 8-bit CLUT table
- Global and pixel-level alpha blending value is supported (256 levels). For pixel-level blending, the alpha value can come from either source or CLUT table.
- Color keying (transparency) is supported.
- Stenciling (pixel masking with a separate 1-bit mask plane) is supported independently for each graphics layer.

12.1.3.4 HD/SD Compositor Features

- Three independently controlled compositors (HDMI/DVO1, DVO2, SD) are supported to drive the corresponding display encoder outputs.
- The HD compositor supports composition of video and graphics layers to provide full-size video display, graphics overlay, and video-in-graphics HD video outputs.
- The SD compositor supports video display, graphics overlay, and video-in-graphics for SD video

outputs.

- Each input layer is given a display order priority that determines the display and blending orders.
- Each output supports independent layer visibility control.
- The compositor supports 256-level alpha blending of two overlapping layers.

12.1.3.5 HD/SD Video Signal Encoding Features (Video Displays)

- A single HDMI 1.3a compliant interface.
- Two DVO (VOUT) interfaces that support up to 1080p@60 8/16/24 YCbCr/RGB formats are included.
- Each VOUT port supports both embedded and separated sync outputs.
- SD Composite/S-video(NTSC/PAL): meets all requirements defined in ITU-R BT 470.6 (TBD: SECAM support).
- Supported VESA resolutions up to 165MHz. Note that the maximum supported line width is 1920 pixels. Furthermore, width and height values must always be an even number.
- Support Simultaneous HD and SD output.

12.1.3.6 Video Capture Features

- The HDVPSS supports two independently configurable external video input capture ports with up to 165MHz.
- Each video input capture port can be operated as one 24-bit mode to support RGB capture or 16-bit input channel (with separate Y and Cb/Cr inputs) or two clock independent 8-bit input channels (with interleaved Y/C data input).
- Support both embedded sync and discrete sync
- The video capture port channel supports de-multiplexing of both pixel-to-pixel and line-to-line multiplexed streams.
- Up to 1920x1200@60 Hz (165 MHz) input data rate supports 16-bit mode input port.
- Each video capture port supports one scaler capable of both up and down scaling of one non-multiplexed input stream (one of two 8-bit channel inputs or 16-bit channel input data). Note that if the source is from external video decoder/camera, only down scaling is supported.
- Each video capture port supports one programmable color space conversion to convert between 24-bit RGB data and YCbCr data.
- The VIP supports data storage in RGB, 422, and 420 formats.
- Each video capture port channel supports chroma down-sampling (422 to 420) for any non-multiplexed input data. The chroma down-sampling for multiplexed streams is done as memory to memory operations outside of HDVPSS on an individual frame data.

12.1.3.7 Other Features

- The HDVPSS supports 2 secondary video input sources in 420 or 422 tiled format used for memory-memory operations and SD output display.
- The HDVPSS supports 2 bypass video input sources in YUV422(YUYV interleaved format), non-tiled format for display.
- The HDVPSS supports video data display for following; there is no processing performed, i.e, no scaler, de-interlacing, format conversion.
 1. Secondary 1 video input source in the SD display only.
 2. 2 bypass video input sources in YUV422 YUYV interleaved format for display.
- The HDVPSS supports video data write back paths (memory to memory) for following:
 1. Scaled video from secondary 0 video input sources - saved as YUV422 YUYV interleaved format video.
 2. Scaled video from Aux video channel saved as YUV422 YUYV interleaved format video
 3. Independent scaled video from primary DEI output - saved as a 420 video using the scaler and chroma_downsampler resources in VIN0 port

4. Scaled video from Primary DEI video channel saved as YUV422 YUYV interleaved format video
5. Independent scaled video from Aux output saved as a 420 video using the scaler and chroma_downsampler resources in the VIN1 port.

12.2 Chroma Up-Sampler (CHR_US) Module

The chroma up-sampler (CHR_US) module is used to convert from YCbCr 4:2:0 data format input to YCbCr 4:2:2 format output.

12.2.1 CHR_US Functional Description

The up-sampling is performed by an interpolation filter which uses Catmull-Rom algorithm.

12.2.2 CUR_US Features

The CHR_US features include:

- **Input**
 - YUV420 Semi-planar Tiled Memory
 - YUV422 Semi-planar Tiled Memory
 - YUV420 Semi-planar Non-Tiled Memory
 - YUV422 Semi-planar Non-Tiled Memory
 - YUV422 YUYV Interleaved Non-Tiled Memory
- **Output**
 - YUV422 YUYV Interleave non-Tiled Memory
- Supports both interlaced and progressive inputs
- Support bypass mode for 4:2:2 input

12.3 De-Interlacer Module (DEI)

The DE-Interlacer (DEI) module is basically used to generate progressive data output from interlaced input format (de-interlacing).

The DEI is primarily used to convert interlaced video source material to progressive form, which is based on the motion-adaptive de-interlacing. It performs both temporal and spatial interpolation via edge directed interpolation. It also incorporates four fields of motion detection to produce high quality output. The DEI can perform de-interlacing on up to 1080i video input source, producing 1080p video output.

12.3.1 DEI Features

The DEI features include:

- **Input**
 - YUV420 semi-planar tiled memory
 - YUV422 semi-planar tiled memory
 - YUV420 semi-planar non-Tiled memory
 - YUV422 semi-planar non-Tiled memory
 - YUV422 YUYV interleaved Non-Tiled memory
- **Output**
 - Output is always tied to the scalar input
- Motion-adaptive de-interlacing
- Edge-directed Interpolation (EDI)
- Bad edit detection (BED)
- Interlace bypass
 - For Interlaced Input, the module can pass the inputs data directly to the outputs in a bypass

configuration. No internal processing is performed.

12.3.2 *DEI Functional Description*

12.3.2.1 **Modes of Operation**

The DEI can be operated in two modes: bypass mode, and de-interlacer mode.

- **Bypass Mode:** In the bypass mode, input luma and chroma are buffered and sent to the stage after DEI without processing.
- **De-Interlace Mode:** In the interlace mode, DEI takes in alternative field YUV data and sent out a sequential frame YUV data by interpolation techniques mentioned below. DEI supports four interpolation modes when converting interlaced pictures to progressive pictures.

12.3.2.2 **Modes of Interpolation**

The DEI offers four modes of interpolation and they are explain below.

- **Interpolation Mode 0.** In mode 0, the interpolated field is created by simple line averaging from the original YUV data. That is, the interpolated line is created by averaging its top and bottom line. Setting of MDT mode has no effect on output pictures.
- **Interpolation Mode 1.** In mode 1, the interpolated field is created by averaging pixels from fields before and after the current field. In other words, if the current field is a top field, the interpolated bottom field picture is created by averaging pixels from bottom field pictures before and after the current field. MDT setting has no effect on the result.
- **Interpolation Mode 2 (EDI).** Mode 2 is an edge assisted interlace mode with edges detected from the luma information of a 2x7 (HxW) frame window. It detects seven possible edges between 45 and 135 degrees. Edges with slopes greater than 135 degrees are treated as 135 degree lines, and edges with slopes less than 45 degrees are treated as 45 degree lines. Luma for missing lines were interpolated using original luma along the detected edge. Motion value (MV) from the MDT module is used to select coefficients from a look up table on how 2D interpolation from the current field and 3D interpolation from 2 fields adjacent to the current fields are blended. The way to perform blending for chroma is slightly different from for luma, because the MV is based on luma and thus extra care needs to be taken when blending is applied to chroma. At this mode, edge-directed interpolation is applied to Luma only. Vertical interpolation is performed for Chroma data.
- **Interpolation Mode 3 (EDI).** The edge detection method used in this mode is the same as the one at Interpolation mode 2. The only difference is that the edge-directed interpolation is performed on both Luma and Chroma. Chroma is interpolated similarly according to the edge vectors obtained based on luma information. The reason why chroma is interpolated slightly differently is because of the down-sampled chroma data.

12.3.2.3 **Motion Detection (MDT)**

Motion values from the MDT module are calculated only based on luma information. The motion value is used to determine how 2D and 3D interpolated results should be blended. The motion detection module in DEI supports 4-field mode.

12.4 **Compositor Module (COMP)**

The compositor (COMP) module is used to blend the input video and graphics sources into a single stream to drive video encoders.

12.4.1 **COMP Features**

The COMP features include:

- Three independently controlled compositors
- Support three displays: 2 HD and 1 SD
- Support up to 5 input layers for each display: two video layers and three graphics layers
- Support 256-level cascade alpha blending for up to 2 video input layers first and up to three graphic

input layers later

- Support programmable display priority for input layers
- Support programmable background color

12.4.2 COMP Functional Description

The COMP module has three independently controlled blenders (compositors), each of which can take up to five input layers (two videos and three graphics) to generate one composite output layer. Each blender is associated with one of the three VENCs to drive the display data. The accessibility of each blender to the input layer is shown in [Table 12-3](#).

Table 12-3. Input Layers and Associated Blenders

Input Layers\Compositor	HDMI	DVO2	SD
Primary HD Video	Y	N	N
HD-Constrained Video	N	Y	N
SD Video	N	N	Y
HD Aux Video	Y	Y	N
GRPX0	Y	Y	Y
GRPX1	Y	Y	Y
GRPX2	Y	Y	Y

Each of the above input layers can be associated to one or more VENCs in HD-VPSS. All the input layers associated with a VENC should have the same size and type (progressive or interlaced) of the display. This implies that if an input layer is shared with multiple VENCs, all those VENCs should have the same size, type and frame rate. For example, if the 1080p HDMI output is desired to have Primary video input and aux video input with 1 graphics overlay, then the primary and aux video input must be 1080p, and one of the graphics must be 1080p. If another blender is set up to 480i, it cannot use either the primary or aux video inputs, and must use a different graphics input.

Input layers associated to a VENC are grouped together, reordered according to the user programmable display priority order list, and blended using embedded alpha values between overlapped layers.

12.4.2.1 Input Sources

Each blender in COMP module receives up to five input sources to blend and send the composited output to the corresponding VENC as described above. All the inputs that are connected to a single blender should:

- Have the same size of its corresponding VENC display size. This is done by forming a WINDOW (shown below) in the upstream modules. Please note that it does NOT imply any restriction on the actual input video sizes in external memory to be the same. For example, video-0 can be 1920x1080 and video-1 can be 720x480 in the memory.
- Carry their priority level to re-order themselves as layers on the final display stream (only for graphic inputs).
- Carry alpha values used to blend with each other using the above priority levels.

If the size of any input is not the same as the display size, background color is inserted in the remaining portion as shown below.

12.4.2.2 Blender

Compositor blends two video input sources together to generate single video output first, and then re-shuffle video and graphics inputs to allow flexible display order based on programmable display priority, finally blends all of them together to generate single display output to VENC.

When two input sources, say input1 and input2, are blended, the resulting source is calculated as follows:

$$\text{Blended Output} = (a) \cdot \text{input1} + (1-a) \cdot \text{input2} \text{ if input1 is top layer and input2 is bottom layer} \\ = (1-b) \cdot \text{input1} + (b) \cdot \text{input2} \text{ if input2 is top layer and input1 is bottom layer}$$

Where a and b are alpha values of input1 and input2 windows respectively. The layer order (top or bottom) is decided by priority levels of the two inputs.

12.4.2.3 Background Color

There is a programmable background color in COMP module. Background color is configured in RGB format with 10-bit in each R, G, and B. Any pixel with an alpha value of 0 will be replaced by this color. If the video bottom layer is disabled, the video top layer will be blended with background color. If both video layers are disabled, the background color is used as output of video alpha blending. For the SD channel, only one video stream comes in and it will be blended with the background color.

12.5 Graphics (GRPX) Module

The graphics module (GRPX) is graphics processor that composes RGB or bit map data to create a display plane input for the video compositor (COMP) module.

12.5.1 GRPX Features

The GRPX features include:

- Non-tiled memory only
- **Input**
 - RGB565
 - RGB888
 - ARGB1555
 - ARGB4444
 - ARGB6666
 - ARGB8888
 - RGBA5551
 - RGBA4444
 - RGBA6666
 - RGBA8888
 - Bitmap data (8/4/2/1bit) with configurable CLUT
 - Non-tiled memory
 - Supports optional stenciling (1-bit mask) table
- **Output**
 - Output data format is ARGB32
- Width, height, placement (X&Y) parameters
- Display priority
- Scalar enable/disable
- Scaling ratio attributes
- Support for global, color and pixel level blending
- Configurable chroma keying options
- Bounding box enable

12.5.2 GRPX Functional Description

The GRPX module takes in RGB or bitmap data, applies attributes, and sends out the data output to the COMP module.

12.5.2.1 Disp_Priority

An inter-graphics-pipeline display priority level may be used to switch the order from two GRPX pipelines. The GRPX simply passes these values along with each pixel data to the COMP module and the COMP uses it to reorder between two GRPX data. This should be used only when both GRPX output is tied to the same display output format and rate.

12.5.2.2 Scaler

The scaler used in GRPX module consists of 5-tap/8-phase horizontal and 4-tap/8-phase vertical polyphase filters.

12.5.2.3 Anti-Flicker Filter Implementation

When data is scaled up or down, the poly-phase vertical filter will inherently provide anti-flicker filtering. Even when a data is not needed to be scaled, the scaler can still be enabled to perform low-pass filtering along the vertical direction with scaling ratio=1.

12.5.2.4 Boundary Box Blending

The GRPX supports overwriting alpha values of pixels that make up a 1-pixel wide boundary box with a semi-transparent (alpha) value (default 0x80) so that the flickering around the edges can be minimized. A programmed boundary box alpha value is assigned to each boundary pixel.

12.5.2.5 Blending

The GRPX supports four blending modes (no-blending, global, CLUT, pixel). When no-blending is selected, the GRPX forces each ALPHA to 0xFF. In global-blending, a programmed alpha value is assigned to each pixel. For color or pixel blending, the alpha value with CLUT mapping or embedded Alpha value (argb format source) is used respectively. The blending level supported is from 0 (transparent) to 255 (totally opaque).

12.5.2.6 Transparency Handling

The GRPX supports a transparency mode to determine how alpha value for each pixel is set. When transparency is enabled, each pixel color is compared against the programmed transparency color (RGB888) to determine whether the pixel is to be transparent or not. If the colors match, the alpha value is forced to 0x00. Otherwise, the alpha value remains as programmed. During the comparison, Application can assign LSB bit masking to tell the modul which LSB bits is masked. GRPX supports three different LSB bit mask: masking LSB bit0; masking LSB bit[1:0] and masking LSB[2:0]. For example, if Masking LSB[2:0] is selected, then top 5 bits of R/G/B component data are compared to the corresponding 5 bits of programmed transparency R/G/B color. Because the alpha value is also scaled in the same way the color components (RGB) are scaled, all enabled blending/transparency related tasks are performed in the following order:

- Application of no-blending (force alpha=0xFF) or Global-blending (force alpha=programmed global blend level)
- Transparency check to force alpha=0 for transparent pixels
- Stenciling application to force masked pixels (stencil data=1) with alpha=0
- Scaling of alpha (if scaling enabled)
- Box blending (force alpha=programmed box_blend_level)

12.6 High-Definition Video Encoder (HD_VENC) Module

There are two HD_VENCs in the HDVPSS. The HD VENC module encodes the active video data from COMP module and sends it to up to 30-bit wide digital video output (DVO) port by generating timing signals to control the data flow.

12.6.1 HD_VENC Features Supported

- Two independent DVO ports (DVO1 and DVO2)

- The DVO ports will support the output data rate up to 165MHz
- The DVO1(VOUT1) port supports 30-bit wide output with embedded sync or discrete sync
- The DVO2(VOUT0) port supports up to 24-bit wide output with embedded sync or discrete sync
- Display timing generator: generates the display timing signals VS, HS, FID, HBI, VBI, and ACT_VID for OSD
- Color Space Conversion

12.6.2 HD_VENC Functional Description

HD VENC primarily has two blocks: OSD and encoder. OSD module is used to get the data from COMP module using the sync signals generated by encoder module. In the device, HD VENC supports digital (HDMI/DVO1, DVO2) output only. The following table shows the possible display ports and corresponding VENC names.

Table 12-4. Display Port and VENC Name

Display Port Name	Type	VENC Name	Port Num for Pin
HDMI/DVO1	Digital	HDMI	VOUT1
DVO2	Digital	DVO2	VOUT0
SD	Analog	SD	N/A

12.6.2.1 OSD Interface

The interface between OSD and video display encoder are consisting of a 30-bit data bus, a pixel clock and five sync signals. By default 30-bit RGB video data will be passed from OSD to encoders on every rising edge of the pixel clock during active video period.

Table 12-5. OSD Interface Signals

Signal Names	Descriptions
FID	Field ID Signal. This signal will toggle between "1" and "0" on every field in interlace mode. It will toggle between "1" and "0" on every frame in progressive mode.
VS	Vertical sync signal. This signal is a one-line long pulse. This pulse indicates the first line of each in interlace mode. In progressive, it indicates the first line of each frame.
VBI	Vertical blank interval signal. This signal goes to "1" during non-active video period; it stays at "0" during active video period.
HS	Horizontal sync signal. This is the horizontal sync signal.
HBI	This is a four-pixels-wide and active-high signal. It appears once every video line.
ACT_VID	This is active-video qualification signal. When this signal is high, encoder is expecting active video data output from OSD after one clock delay.

12.6.2.2 Digital Video Output

The following table lists all formats that the DVO supports.

Table 12-6. DVO Formats

Formats	Bits
single-stream 656	YCbCr-10bits
dual-stream 656	Y/CbCr-20bits
triple-stream 656	Y/Cb/Cr/R/G/B - 30bits
YUV422 20bit with discrete sync	Y/CbCr - 20bits
30bit with discrete sync	Y/Cb/Cr/R/G/B - 30bits

DVO can output both embedded sync and discrete sync. In embedded sync, DVO supports single/dual/triple stream. In the discrete sync mode, the followings are the sync signal that DVO outputs:

- HS
- VS
- ACT_VID
- FID

12.6.2.3 Color Space Conversion (CSC)

The CSC module is used to convert the input data from one color space to another by 3*3 matrix.

12.7 Noise Filter (NF) Module

The video noise filter (NF) module is used to reduce noise in a video sequence in order to improve video image quality and compression efficiency.

12.7.1 NF Features

The video noise filter features include:

- **Input**
 - YUV422 YUYV interleaved Non-Tiled memory
- **Output:**
 - YUV420 Semi-Planar Tiled Memory YUV420 Semi-Planar Non-Tiled Memory
- Spatial video noise filtering
- Spatial video noise filtering bypass
- Temporal video noise filtering
- Temporal video noise filtering bypass
- Chroma down-sampling

12.7.2 NF Functional Description

The video noise filter is a combination of spatial and temporal IIR filters and chroma down-sampling. The spatial filter is performed with neighboring pixels in the current frame while the temporal filter is performed with a past filtered frame to suppress both spatial and temporal noises. The NF performs a memory to memory spatial/temporal noise filter algorithm on a 422 raster input source and produces a 420 tiled output source. Its primary use mode is part of the video input port processing. In this mode, external video source is captured by the Vvideo input port and sent to memory as 422 raster format. It is then brought back into the NF from memory, filtered and sent back to memory as 420 tiled format.

NF can be easily configured to perform spatial-temporal filtering, spatial-only filtering, temporal-only filtering, or at by-pass mode. When the filtering function is enabled, previous NF filtered output is required to use as additional input to perform the noise reduction. Previous noise filter output is not required if NF is in bypass mode, and NF performs YUV422 to YUV420 chroma down-sampling only.

12.8 Scalar (SC)

SC is used to scaling the incoming video stream to other resolutions.

12.8.1 SC Features

SC features include:

- **Input**
 - DEI output, Chroma_up output of VIP output
- **Output**
 - YUV422 YUYV Interleaved

- Horizontal/vertical cropping
- Polyphase filter for horizontal
- Polyphase filter/running average filter for vertical
- Scaling up to maximum 1920 pixels in horizontal direction and 1080 pixels in the vertical direction

12.8.2 SC Functional Description

The scaler takes the data from the upstream module. The input image is resized to the desired output size, and the module sends the output image to the downstream module. It can scale full HD (1080p) and output full HD (1080p). The scaling is performed in following three steps:

1. Trimming
2. Vertical Scaling
3. Horizontal scaling

12.8.2.1 Trimmer

The trimmer can be programmed to re-define a new source image within the input video frame sent from an upstream module before it is sent to the scaling sub-modules. This feature enables small area zoom out, source pan/scan, or removal of unwanted area in the video.

12.8.2.2 Vertical Scaling

The vertical scalar has a poly-phase and a running average filter. While the poly-phase filter can be used for any up-scaling and preferably downscaling to 3/16 scale factor, the running average filter is used only for downscaling to a 1/2 or less size. Selection between these two scalars is based on the user setting of the "use_rav" parameter, according to the user preference of the tradeoff between sharpness preserving and introduced artifacts.

12.8.2.2.1 Polyphase Scaler

The vertical polyphase scalar is mainly implemented using a 32-phase, 5-tap polyphase filter.

12.8.2.2.2 Running Average Filter

When a poly-phase filter is used, it usually has to have many taps in order to achieve acceptable quality for very small downscaling ratio, which requires the use of many line buffers. In HDVPSS, there is a weighted running average filter for downscaling when the scaling factor is small (for example, when the scaling ratio is less than 0.5). This highly optimized design requires only one line buffer for luma and one for chroma, which still achieves acceptable quality. The output of the running average filter is based on weighted average of pixels in the current and previous rows in vertical direction.

12.8.2.3 Horizontal Scaling

The horizontal scalar is implemented using a 32-phase x 7-tap polyphase filter preceded by two sets of 1/2x decimators. The general configuration of the horizontal scalar is performed as follows:

1. For upscaling, the input video is interpolated using the polyphase scalar.
2. For downscaling, input video is decimated by 2 until modified scale factor falls between 1/2 and 1. Then, a polyphase filter is configured with coefficients selected based on the scale factor.

12.9 Standard-Definition Video Encoder (SD-VENC) Module

The stand definition video encoder (SD_VENC) converts digital component YCbCr/RGB video signals to conform to the various TV standard analog video.

12.9.1 SD-VENC Features

The SD-VENC features include:

- Master clock Input - 27 MHz

- Support PAL/NTSC standard
- Composite (CVBS)
- S-Video (Y/C)
- Color space Conversion

12.9.2 SD-VENC Functional Description

SD-VENC operates in synchronization with horizontal/vertical sync signals generated in a built-in sync signal generator. For the analog video output, one of the following TV formats (525i or 625i) must be specified. The format setting specifies the format-dependent timing parameters such as sync rise/fall build-up time, active video rise/fall time, vertical sync and equalizing pulse position and so on.

12.9.2.1 Color Space Converter

The 2x interpolated data comes into a color space converter (CSC) to be converted into the desired color format.

12.9.2.2 Macrovision

The VENC supports analog copy protection Macrovision Rev7.1 to the SDTV CVBS output. Due to strict security control by Macrovision, any information such as the Macrovision register map, usages and so on, are not directly distributed to the customers. This information is supposed to be given by Macrovision upon a certain certification.

12.9.2.3 DAC Output

The VENC has four channel 12-bit digital outputs for DAC input.

12.10 Video Input Parser (VIP) Module

The video input parser (VIP_ module is used to capture the video data into HD-VPSS module.

12.10.1 VIP Features

Features of the VIP include:

- **Input**
 - YUV422 8-bit embedded sync mode (exclude BT. 1120)
 - YUV422 8-bit discrete sync mode
 - YUV422 16-bit embedded sync mode
 - YUV422 16-bit discrete sync mode
 - YUV422 8-bit 2x/4x pixel multiplexed mode
 - YUV422 8-bit 4x line multiplexed mode
 - RGB 24-bit embedded sync mode
 - RGB 24-bit discrete sync mode
 - YUV444 24-bit embedded sync
 - YUV444 24-bit discrete sync mode
- **Output**
 - YUV422 YUYV interleaved format
 - YUV420 Semi-planar format
 - RGB 24-bit interleaved format
 - YUV422 semi-planer format
- Two 165MHz video capture instances of the VIP Subsystem .
- Both VIP instance are 16/24 bit channel

- For each VIP instance, two pixel clock input domains are supported (Port A and Port B)
- Pixel Clock Input Domain Port A supports one input data bus up to 24-bit.
- Pixel Clock Input Domain Port B supports one 8-bit input data bus.
- Each VIP instance can be in dual 8-bit capture channels
- Embedded sync data interface mode supports single or multiplexed sources
- Discrete sync data interface mode supports only single source input
- The two pixel clock input domains can be individually configured in any combination of embedded or discrete sync
- Multiplexed data can only appear in embedded sync mode
- Where possible, blanking pixels that may contain embedded vertical ancillary data will be stored in a dedicated buffer per each video source
- Color space conversion (CSC)
- Chroma down-sampling
- Scaling
- Multiplexed data cannot use CSC, chroma down-sampling and scaling

12.10.2 VIP Functional Description

The video data is captured from the external video source by the VIP Parser sub-block in the VIP block. The VIP Parser then sends the captured data for further processing in the VIP block which can include color space conversion, scaling, chroma down-sampling and finally writes the video data to external DDR memory. Color space conversion, scaling and chroma down-sampling are all optional for the incoming stream.

The scaler and chroma down-sample module inside of the VIP can also be used for the memory-to-memory operation if they are not used in the capture mode.

12.10.2.1 Analog Video

A digital interface stream is based on analog video. The waveform for a line of NTSC analog video is shown in [Figure 12-2](#).

Figure 12-2. NTSC Analog Video Waveform for one Horizontal Line

T is a time constant. For NTSC, $T=1/13.5 \text{ Mhz} = 74\text{ns}$.

12.10.2.2 Digitized Video

Digitized video is based on scan lines in found in analog video. BT.601 uses various sync signals to specify when a new field and a new line starts. BT.656 and BT.1120 uses sync words embedded in the data stream to specify start of field and start of line. An image can be digitized into regions shown in Figure 12-3.

Figure 12-3. Digitized Video

With the capability to encode sync words inside the data stream, there is more flexibility for adding non-video related data, called Ancillary Data. Also, code words embedded in the digital stream can be used as a type of identifier for multiplexing several sources of video into one data stream. Such a multi-camera multiplex is useful in the digital security markets.

Figure 12-4. Code Word Embedded Video Format

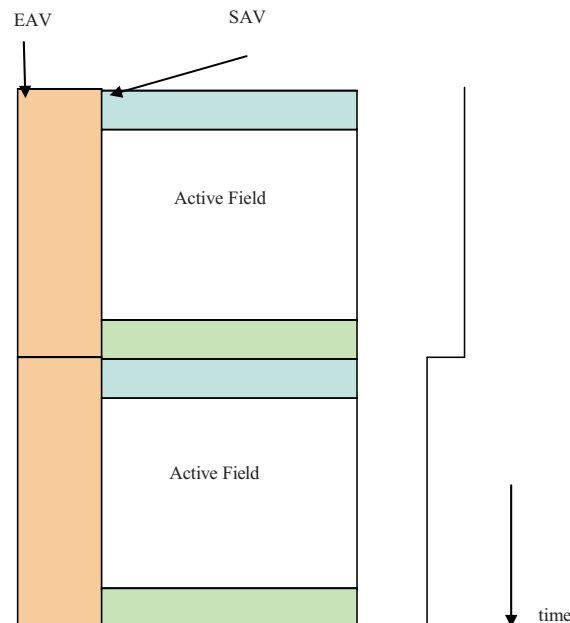

Figure 12-4 shows End-of-Active-Video (EAV) and Start-of-Active-Video (SAV) code words added to a video transmission. The period between the EAV and SAV is equivalent to Horizontal Blanking. The period between the SAV to the next EAV is active video or vertical blanking. In the BT.656 or BT.1120 embedded code word scheme, three bits of the EAV/SAV code word are important: F (field), H (horizontal blanking), and V (vertical blanking).

Figure 12-5. Digitized Video with F, V, and H Flags in EAV/SAV

Figure 12-5 shows the values of F, V, and H flags at different locations in the picture. The Field flag represents the state of the Field ID for the picture. For progressive frames, F is always "0". The V flag specifies vertical blanking areas. The H flag specifies horizontal blanking portions of the picture.

12.10.2.3 Input Data Interface

This section describes how the data (luma and chroma data for YUV422 format capture & R,G and B data for RGB888 format capture) is muxed for the interface modes described below.

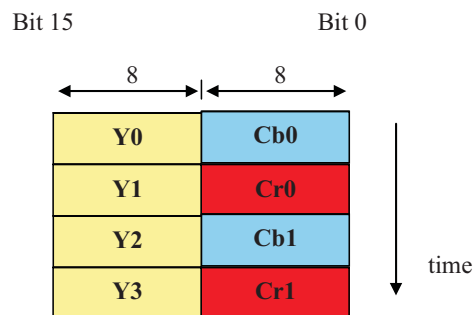

12.10.2.3.1 8b Interface Mode

In 8b data interface mode, the input pixels are multiplexed according to Figure 12-6. The chroma format is 4:2:2. Sites with Cb/Cr pixels are known as chroma sites. Those sites with Y pixels are known as Luma sites.

Figure 12-6. 8b Interface Discrete Sync Pixel Multiplexing

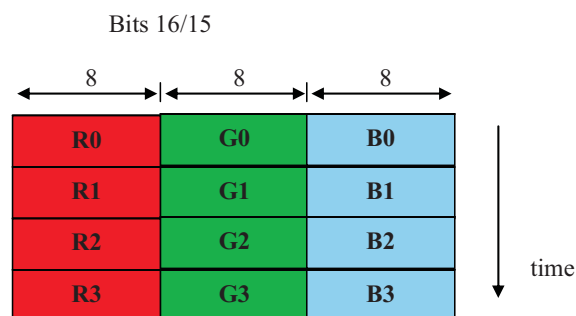

12.10.2.3.2 16b Interface Mode

In 16b interface mode, Luma is on 8 bits of the data bus and Cb/Cr chroma pixels alternate on the other 8 bits of the data bus as shown in Figure 12-7.

Figure 12-7. 16b Interface Discrete Sync Pixel Multiplexing

12.10.2.3.3 24b Interface Mode

RGB data is sent in 24-bit interface mode. The three components are packed into the data bus and sent to the VPDMA. The 24-bit Luma VPI client to the VPDMA carries all three components. This data is saved to the DDR in packed mode; i.e., the three components are not separated by hardware.

Figure 12-8. 24b Interface RGB Discrete Sync

12.10.2.4 Input Ports and Sharing of the 24-bit Data Bus

The VIP Parser supports two independent pixel clock input domains, called Port A and Port B. Port A supports a single up to 24 bit data bus at the instance level and Port B supports a single 8 bit data bus at the instance level. For the device, a single set of 24 device pins are used to drive both Ports A and B.

Two VIP instances are not identical from chip level. VIP instance 0 is a 24-bit interface and VIP instance 1 is a 16-bit interface. The configuration for each device input port is described in [Table 12-7](#).

Table 12-7. Valid Input Port Configurations

PortA	PortB
8 Bit	Off
16 Bit	Off
24 Bit	Off
8 Bit	8 Bit
Off	8 Bit

Each Port can individually be configured as Discrete Sync or Embedded Sync.

12.10.2.5 Frame Buffers

The VIP/VPDMA supports frame buffers in DDR for active video. 4:2:2 data is always saved in packed pixel buffers. The 4:2:0 data is saved in planar luma buffers and planar CbCr pair buffers. A luma frame buffer is a planar storage area. Each line is the width in pixels (1 Byte/pixel) of the output picture size format. The frame buffer contains the number of active video lines in the output picture size format. A chroma pair frame buffer is planar storage of CbCr pixel pairs, with each pixel being a byte. For 4:2:0 storage, N lines in the output picture active video results in N/2 lines of CbCr pairs being stored.

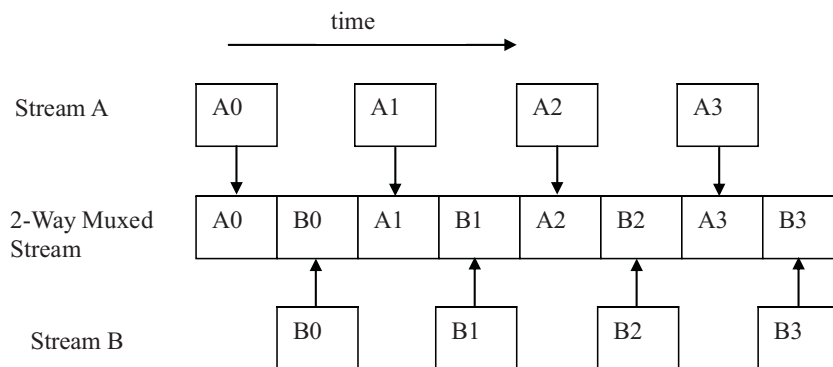

12.10.2.6 Source Multiplexing

Some applications require multiple camera sources to be used at the same time. For example, video surveillance systems can record and display multiple camera sources. Sixteen camera sources are limited to be saved to DDR per pixel clock input domain.

12.10.2.6.1 2-Way Multiplexing

For 2-way multiplexing, two embedded sync streams are interleaved a pixel at a time as shown in [Figure 12-9](#) below. The sync codeword, FF-00-00-XY, is replicated in both source streams. In 2-way multiplexing, the sizes of both camera sources must be the same. Likewise, the vertical ancillary data size for both sources must be identical. However, the two streams are not necessarily sending the same pixel site in adjacent clock cycles.

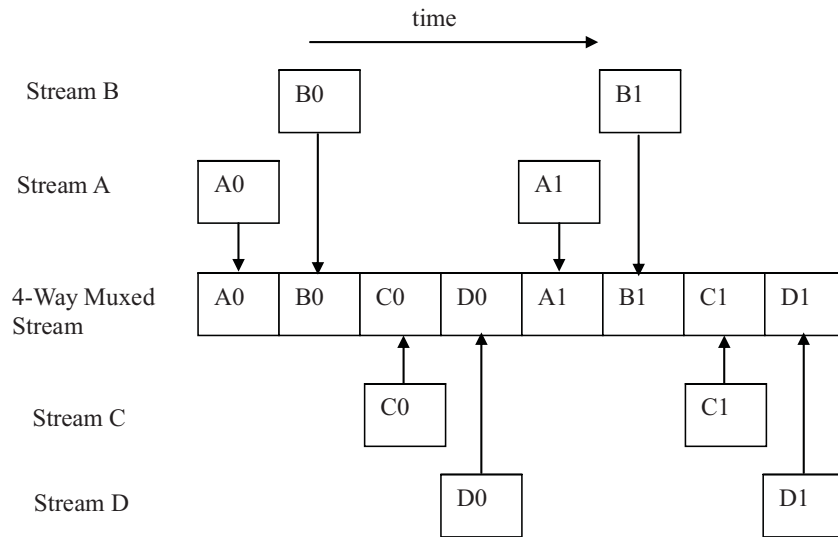

Figure 12-9. 2-Way Multiplexing

12.10.2.6.2 4-Way Multiplexing

For 4-way multiplexing, four embedded sync streams are multiplexed into one as seen in [Figure 12-10](#) below. Again, the sync codeword is in all four sources. Like 2-way multiplexing, the sizes of the four camera sources are the same and the sizes of the vertical ancillary data regions are the same. The four streams are not necessarily sending the same pixel site in adjacent clock cycles.

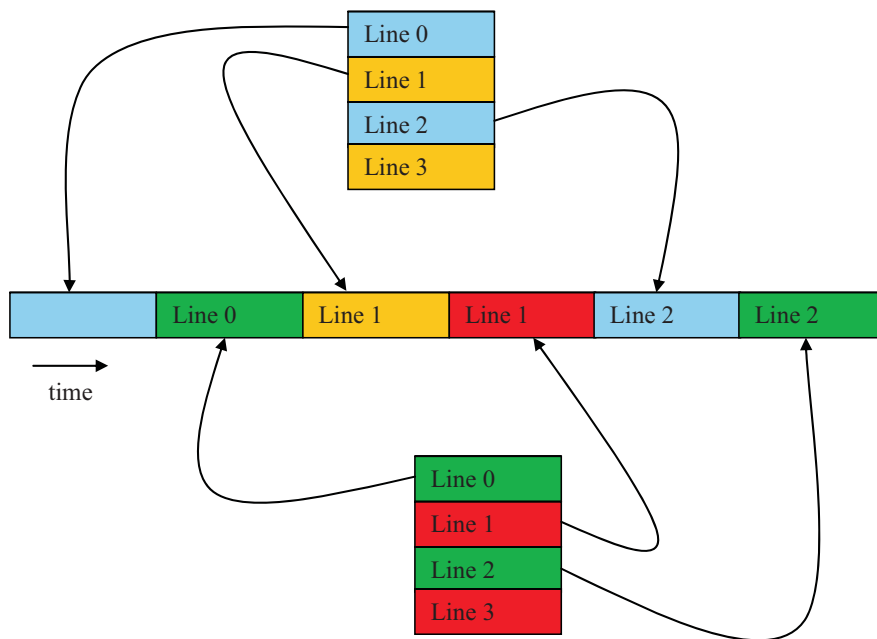

Figure 12-10. 4-Way Multiplexing

12.10.2.6.3 Line Multiplexing

In line multiplexing, n-different sources are sent into the VIP a complete line at a time using a modified version of embedded sync. An example of line multiplexing for two sources is shown in Figure 12-11.

Figure 12-11. Line Multiplexing

12.10.2.7 Embedded Sync Mux Modes and Data Bus Widths

Legal combinations of embedded sync mux modes and data bus widths are described in Table 12-8.

Table 12-8. Valid Embedded Sync Mux Mode and Data Bus Width Combinations

	1x Mux	2x Mux	4x Mux	Line Mux
8 bit	Yes	Yes	Yes	Yes
16 bit	Yes	No	No	No

Table 12-8. Valid Embedded Sync Mux Mode and Data Bus Width Combinations (continued)

	1x Mux	2x Mux	4x Mux	Line Mux
24 bit	Yes	No	No	No

12.11 Other Video Input Ports

12.11.1 Bypass Video Input Ports

12.11.1.1 Features

- **Input**
 - YUV422 YUYV Interleaved non-tiled memory

12.11.1.2 Functional Descriptions

HDVPSS has two independent bypass video input ports: bypass0 and bypass1. Both ports are used for display purposes without any processing.

12.11.2 Secondary Video Input Ports

12.11.2.1 Features

- **Input**
 - YUV420 semi-planar tiled memory
 - YUV422 semi-planar tiled memory
 - YUV420 semi-planar non-tiled memory
 - YUV422 semi-planar non-tiled memory
 - YUV422 YUYV interleaved non-tiled memory
- **Output**
 - YUV422 YUYV interleaved non-tiled memory (memory to memory operations)

12.11.2.2 Functional Description

HDVPSS has two secondary video input ports: secondary0 and secondary1. Secondary0 is used for the memory to memory operations through scaler5 and Secondary1 is used for SD display only through SD VENC.

High-Definition Multimedia Interface (HDMI)

This chapter describes the high-definition multimedia interface (HDMI) module.

Topic	Page
13.1 Introduction	1733
13.2 Architecture	1737
13.3 HDMI Registers.....	1753

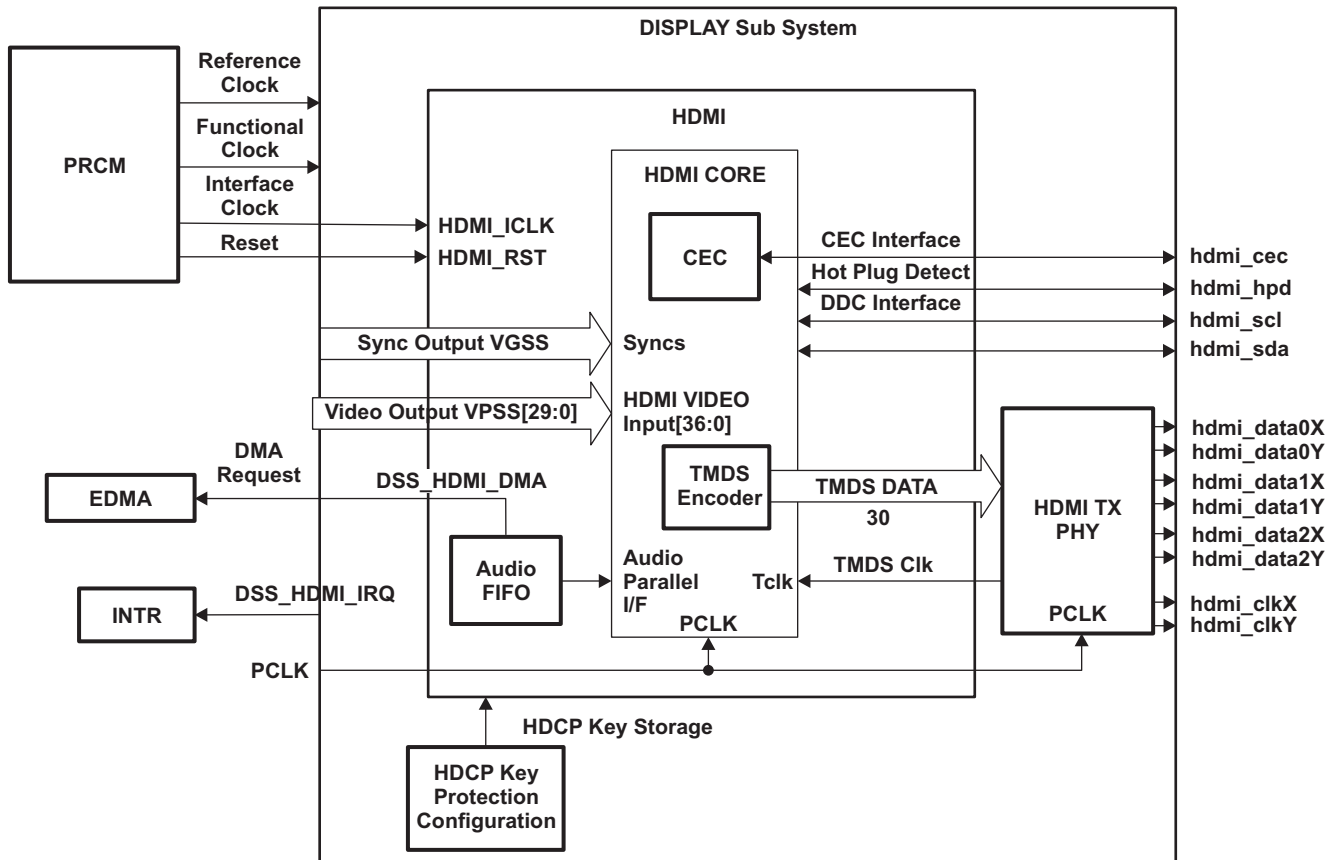

13.1 Introduction

13.1.1 Overview

The high-definition multimedia interface wrapper (HDMI_WP) module is used to encapsulate the HDMI, providing compatibility and interface to the HDMI TXPHY module. The HDMI_WP module contains the support logic for the HDMI IP, including the HDMI core (HDMI_CORE) and CEC core. The major additional parts comprise a slave interface port for configuration and buffering for the audio data streams.

Figure 13-1 is an overview of the HDMI module.

Figure 13-1. HDMI Overview

13.1.2 Main Features

The HDMI module provides the following main features:

- HDMI 1.3, HDCP 1.2, and DVI 1.0 compliant
- EIA/CEA-861-D video format support
- VESA Display Monitor Timing (DMT) video format support
- Support for deep-color mode:
 - 10-bit/component color depth up to 1080p at 60 Hz
 - 12-bit/component color depth up to 720p/1080i at 60 Hz
- Supports up to 165-MHz pixel clock (1920 × 1080p at 60 Hz)
- Video formats: 24-bit RGB
- Uncompressed multichannel (up to eight channels) audio (L-PCM) support
- Master inter-integrated circuit (I2C) interface for display data channel (DDC) connection

- Consumer Electronic Control (CEC) interface
- Integrated High-bandwidth Digital Content Protection (HDCP) encryption engine for transmitting protected audio and video content (authentication performed by software)
- Integrated Transition Minimized Differential Signaling (TMDS) and TER4 encoders for data island support
- Integrated TMDS physical layer (PHY) (three TMDS differential data lanes + TMDS differential clock lane)
 - Up to 1.85625 Gbps per lane at (1080p at 60 Hz at 10 bits/component, lower resolutions at 12 bits/component)
 - 928.125 Mbps per lane at (720p/1080i at 60 Hz 10 bits/component, lower resolutions at 12 bits/component)
 - 337.5 Mbps at (576p at 50 Hz/480p at 60 Hz 10 bits/component)

13.1.3 Functional Block Diagram

Figure 13-2 is a functional block diagram of the HDMI module.

Figure 13-2. HDMI Block Diagram

13.1.4 Video Formats and Timings

Table 13-1 lists the video timings supported by the HDMI module, according to the CEA-861-D standard.

Table 13-2 lists the video timings supported by the HDMI module, according to the VESA DMT standard.

Table 13-1. HDMI Video Timings (CEA-861-D)

Refresh Rate	Resolution
24 Hz (low-field rate)	1920 x 1080p
	1920 x 1080p
	1920 x 1080i
50 Hz	1280 x 720p

13.1.5 Environment

This section describes the HDMI application fields from an environment point of view (external connections). It describes HDMI connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

Figure 13-3 shows the external connections and simplified data path for the HDMI module.

Figure 13-3. HDMI Environment

The following paths are used to transmit video and audio data through the HDMI link:

- Video data path:
 - Video Processing Sub System (VPSS)
 - HDMI module
 - HDMI complex input/output (I/O) (HDMI_TXPHY)

The VPSS module provides synchronization signals to the HDMI and synchronously sends 30 bits of pixel data to the HDMI with these signals. The digital output of the VPSS is always a 30-bit RGB value. For more information about the connection between the VPSS and HDMI, see Section 1.4.7.1, HDMI Video Interface. For more information about the VPSS settings and features, see the Video Processing Sub System chapter in the device TRM. The video data received on the HDMI video slave port is always a 30-bit RGB value. The HDMI module performs pixel processing that allows manipulation of the pixels received on the video interface. The processed data is sent to the HDCP for encryption, or directly to the HDMI_TXPHY module after TDMS encoding, if there is no HDCP encryption enabled.

- Audio data path:
 - Level 3 (L3) interconnect
 - HDMI module
 - HDMI complex I/O (HDMI_TXPHY)

The audio data is received on the buffered HDMI audio port through the L3 Interconnect using a direct memory access (DMA) request to the device system DMA (EDMA) module, or interrupt request (IRQ) to the device microprocessor unit (MPU) interrupt controllers (INTCs). In the HDMI, the data is packed, formatted, and sent to the HDMI_TXPHY module.

Additionally, the HDMI module provides universal remote control capability through the CEC protocol on the `hdmi_cec` pin, which allows common communication between different pieces of consumer electronics when the device is connected to them by HDMI cable.

The HDMI module can drive the display data channel (DDC) bus, which supports a variety of I2C commands, on the `hdmi_ddc_scl` and `hdmi_ddc_sda` pins. This allows the TV-set/monitor to provide information to the host device, such as supported resolutions.

Hot plug detection (HPD) capability is supported by the HDMI module on the `hdmi_hpd` pin. It allows detection of the presence of an attached TV display.

13.2 Architecture

This section describes the HDMI configuration.

13.2.1 Clock Configuration

13.2.1.1 Clock Domains

There are three main clock domains within the HDMI module:

- L3 clock domain: Runs at the frequency of the `DSS_L3_ICLK` clock, generated by the device PRCM module, and is asynchronous with the other clocks
- TCLK clock domain: Runs at the frequency of the TMDS clock (`TMDS_CLK`) generated by the HDMI_TXPHY module
- PCLK clock domain: VPSS to HDMI_WP input runs at PCLK generated by VPSS Venc.

13.2.1.2 CEC Interface Clock Configuration

The clock for the CEC interface module (`CEC_DDC_CLK`) is generated inside the HDMI module from the `DSS_HDMI` clock (48 MHz) by division. The divider value is set through the `HDMI_WP_CLK[5:0]` `CEC_DIV` bit field, as defined in [Table 13-3](#). The clock frequency required by the CEC protocol is 2 MHz, and is achieved by setting the `CEC_DIV` bit field to 18h.

Table 13-3. CEC Clock Generation

Reference Clock	HDMI_WP_CLK[5:0] CEC_DIV Value	CEC Clock
DSS_HDMI	0	Gated
-	1	Free running
-
-	18h	2-MHz clock
-

13.2.1.3 Time-Out Capability

The HDMI module provides time-out capability to the `DSS_HDMI` clock. The `OCP_TIME_OUT_INTR` interrupt is generated, if the `HDMI_WP_CLK[16]` `OCP_TIME_OUT_DIS` bit is cleared to 0 and the `DSS_HDMI` clock is not provided to the HDMI module. For more information about the `OCP_TIME_OUT_INTR` interrupt, see [Section 13.2.6](#). The time-out capability can be disabled by writing 1 to the `HDMI_WP_CLK[16]` `OCP_TIME_OUT_DIS` bit. By default, this option is enabled.

13.2.2 Signals

Table 13-4 describes the HDMI module signals.

Table 13-4. HDMI I/O Signal Description

Signal	I/O ⁽¹⁾	Description	Function
hdmi_data0x hdmi_data0y	O	Transmit data lane 0	TMDS serial data output
hdmi_data1x hdmi_data1y	O	Transmit data lane 1	TMDS serial data output
hdmi_data2x hdmi_data2y	O	Transmit data lane 2	TMDS serial data output
hdmi_clockx hdmi_clocky	O	Transmit clock lane	TMDS clock output
hdmi_cec	I/O	CEC interface line	CEC interface input/output
hdmi_hpd	I	Monitor charge input	Used to connect to the HDMI hot plug pin to detect the presence of an attached monitor
hdmi_ddc_scl	I/O	DDC I2C clock line	DDC clock input/output
hdmi_ddc_sda	I/O	DDC I2C clock line	DDC clock input/output

⁽¹⁾ I = Input; O = Output

13.2.3 Integration

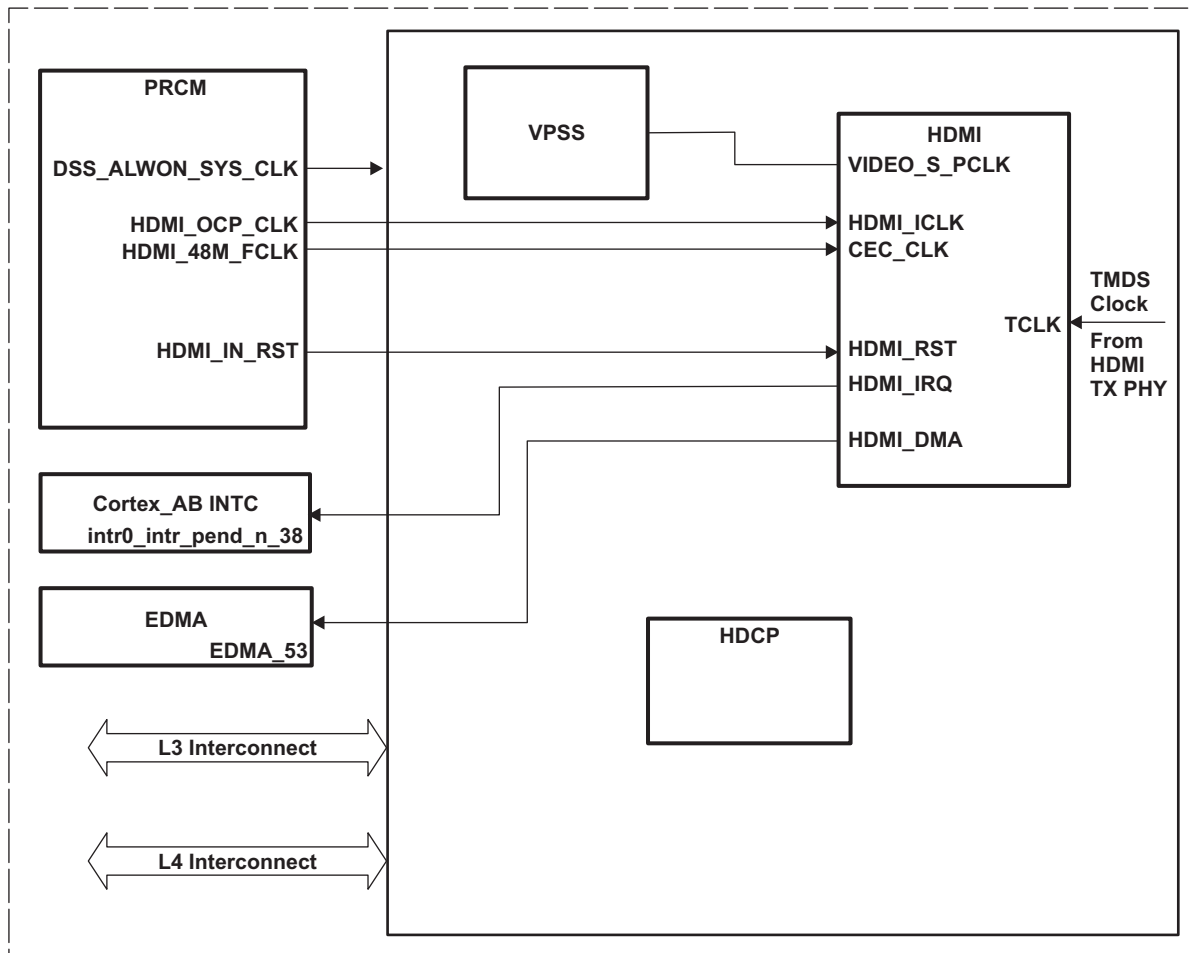

This section describes the module integration in the device (see [Figure 13-4](#)), including information about clocks, resets, and hardware requests.

[Table 13-5](#), [Table 13-6](#), and [Table 13-7](#) summarize the integration of the module in the device.

13.2.4 Software Reset

Global reset of the module is done at the PRCM module level. The HDMI module can be reset by software. This has the same effect as a hardware reset. The HDMI module can be reset by setting the HDMI_WP_SYSCONFIG[0] SOFTRESET bit to 1. Software can monitor this bit to wait for the reset to complete.

Figure 13-4. HDMI Integration

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Sleep (Idle) and Wake-Up Management, in Power, Reset, and Clock Management.

Table 13-5. Integration Attributes

Module Instance	Attributes
HDMI	Power Domain — Interconnect Active Domain —L3 for Data; L4 for Configuration

Table 13-6. Clocks and Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Destination
Clocks				
HDMI	DSS_HDMI	HDMI_PHY_48_S_FCLK	PRCM	The CEC/DDC clock is derived from this clock. Also reference clock for HDMI_TXPHY module.
	HDMI_ICLK	DSS_L3_ICLK	PRCM	Interface clock
	TCLK	TMDS_CLK	HDMI_TXPHY	The TMDS encoded data is sent to the HDMI_TXPHY module on this clock.
VPSS	VIDEO_S_PCLK	HDMI_CLK	VPSS	HDMI
Resets				
HDMI	HDMI_RST	HDMI_IN_RST	PRCM	Nonretention reset

Table 13-7. Hardware Requests

Module Instance	Destination Signal Name	Source Signal Name	Destination	Description
HDMI	DSS_HDMI_IRQ	intr0_intr_pend_n_38	CortexA8	HDMI Interrupt Request
HDMI	DSS_HDMI_DMA	EDMA_53	EDMA	HDMI audio DMA request

13.2.5 Power Management

Table 13-8 describes the power-management features available to the HDMI module.

NOTE: For information about source clock gating and a description of the sleep/wake-up transitions, see the Sleep (Idle) and Wake-Up Management section in the Power, Reset, and Clock Management..

For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see the AutoIDLE Clock Control section in the Power, Reset, and Clock Management.

Table 13-8. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	HDMI_WP_SYSCONFIG[3:2] IDLEMODE bit field	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.

13.2.6 Interrupt Requests

One external interrupt line is generated by the HDMI module: DSS_HDMI_IRQ (for more information, see [Table 13-7](#)). [Table 13-9](#) lists the event flags, and their masks, that can cause internal module interrupts that are mapped to DSS_HDMI_IRQ.

Table 13-9. HDMI Interrupt Events

Event Flag	Event Mask	Map To	Description
HDMI_WP_IRQSTATUS[10] AUDIO_FIFO_SAMPLE_REQ_INTR	HDMI_WP_IRQENABLE_SET[10] ENABLE_SET_AUDIO_FIFO_ SAMPLE_REQ_INTR	AUDIO_FIFO_SAMPLE_ REQ_INTR	Audio FIFO requests some data in IRQ mode
HDMI_WP_IRQSTATUS[9] AUDIO_FIFO_OVERFLOW_INTR	HDMI_WP_IRQENABLE_SET[9] ENABLE_SET_AUDIO_FIFO_ OVERFLOW_INTR	AUDIO_FIFO_ OVERFLOW_INTR	Audio FIFO overflow
HDMI_WP_IRQSTATUS[8] AUDIO_FIFO_UNDERFLOW_INTR	HDMI_WP_IRQENABLE_SET[8] ENABLE_SET_AUDIO_FIFO_ UNDERFLOW_INTR	AUDIO_FIFO_ UNDERFLOW_INTR	Audio FIFO underflow
HDMI_WP_IRQSTATUS[4] OCP_TIME_OUT_INTR	HDMI_WP_IRQENABLE_SET[4] OCP_TIME_OUT_INTR	OCP_TIME_OUT_INTR	Time-out interrupt in case the DSS_HDMI clock is not provided
HDMI_WP_IRQSTATUS[0] CORE_INTR	HDMI_WP_IRQENABLE_ SET[0] ENABLE_SET_CORE_INTR	CORE_INTR	HDMI core has generated internally an interrupt. Software must read the interrupt status register in the HDMI core to identify the interrupt event(s).

NOTE: The HDMI_WP_IRQENABLE_SET register is used to enable the interrupt event(s), by writing 1 in the desired bit field(s). To disable the interrupt event(s), the HDMI_WP_IRQENABLE_CLR register must be used, by writing 1 in the respective bit field(s).

13.2.7 DMA Requests

The HDMI module generates one DMA request for audio data: DSS_HDMI_DMA (for more information, see [Section 13.2.8.2.2.1](#)).

13.2.8 Wrapper Functions

13.2.8.1 Wrapper Video Interface

13.2.8.1.1 Video Interface Features

- Video slave port with 30 bit RGB data format (deep color mode)
- Slave operational mode:
 - Synchronization signals, pixel clock, data-enable and data pixels are provided to the HDMI module
- CEA 861-D video timings support at 50 Hz, 59.94 Hz, and 60 Hz (low field rate 24 Hz included)
- VESA DMT video timings support at 60 Hz (reduced blanking included)
 - 10 bits per color component for 1080p/60fps and 1080p/50fps – 12 bits per color component otherwise
- Support for TCLK up to 185.625 MHz (TCLK derived from PCLK)

13.2.8.1.2 Video Interface Description

NOTE: The signals described in this section are internal and not bounded outside the device.

The HDMI module receives synchronization signals, pixel clock, and 30 bits of pixel data on its video slave port from VPSS module (Table 13-10). The digital output of the VPSS is always a 30-bit RGB value. This is extended to 36 bits by adding LSB zeroes, as listed in Table 13-11.

Table 13-10. Video Port Signals

Signal Name	Width	Direction	Description
VIDEO_S_PCLK	---	IN	Input pixel clock (PCLK)
VIDEO_S_DATA	35:0	IN	Video data input bus
VIDEO_S_DE	---	IN	Data Enable
VIDEO_S_HS	---	IN	Horizontal sync
VIDEO_S_VS	---	IN	Vertical sync
VIDEO_S_FID	---	IN	Field identifier

13.2.8.1.3 Video Interface Configuration

The slave port is connected to the HDMI module. Always clear the HDMI_WP_VIDEO_CFG[1:0] Mode bit field to 0.

According to the video data bus connection and pixel format, packing mode must be selected. The format supported by the HDMI module is 36-bit RGB. The packing can be selected through the HDMI_WP_VIDEO_CFG[10:8] PACKING_MODE bit field:

- HDMI_WP_VIDEO_CFG[10:8] PACKING_MODE = 0: If 10-bit deep-color mode is selected and RGB format is used on the video port data bus:
- HDMI_WP_VIDEO_CFG[10:8] PACKING_MODE = 1: If 8-bit deep-color mode is not selected and RGB format is used on the video port data bus:
- HDMI_WP_VIDEO_CFG[10:8] PACKING_MODE = 7h: If 12-bit deep-color mode is selected and

RGB format is used on the video port data bus. No change on input video data lines. The VIDEO_S_DATA[35:0] data is provided without any change in it.

Video Timing is controlled by VENC module inside VPSS which drives HDMI module. Please refer VPSS PRG for information about timing for different resolutions.

13.2.8.2 Wrapper Audio Interface

13.2.8.2.1 Audio Interface Description

The HDMI module supports parallel interface that is based on a filling of the audio FIFO through the L3 interconnect. The audio data and register configuration is received through the L3 interconnect on a request to the device EDMA module. Each 32-bit access is split into four consecutive accesses to the HDMI Core 8-bit registers of the 32-bit access, starting with the least-significant bit (LSB) to the MSB.

Figure 13-5 is an overview of the audio interface to the HDMI core.

Figure 13-5. HDMI Audio Interface Overview

13.2.8.2.2 Audio FIFO Overview

The audio FIFO provides buffering to ensure that audio samples can always be delivered to the HDMI core exactly when required, despite the L3 interconnect latency.

13.2.8.2.2.1 Audio Data Request

By default, the audio FIFO is filled by the device EDMA using a standard DMA request signal mapped to DSS_HDMI_DMA on the display subsystem level. For additional mapping information, see [Table 13-7](#).

The FIFO can also use an IRQ signal (AUDIO_FIFO_SAMPLE_REQ_INTR) to request audio data, instead of a DMA request, using the same threshold. The IRQ status can be read in the HDMI_WP_IRQSTATUS[10] AUDIO_FIFO_SAMPLE_REQ_INTR bit. For more information about the audio IRQ, see [Table 13-9](#).

The selection between DMA or IRQ request can be done through the HDMI_WP_AUDIO_CTRL[9] DMA_OR_IRQ bit.

The audio data is written in the HDMI_WP_AUDIO_DATA[31:0] FIFO_DAT bit field.

The request is made based on comparison of fullness with register programmable thresholds. The DMA/IRQ is generated when the number of samples (24- or 16-bit) in the FIFO is less than or equal to the threshold value.

- The size of samples is selected through the HDMI_WP_AUDIO_CFG[0] SAMPLE_SIZE bit.
- The valid number of samples can be read from the HDMI_WP_AUDIO_CTRL[25:16].

NUMBER_OF_SAMPLE bit field:

- The threshold value can be set in the HDMI_WP_AUDIO_CTRL[8:0] TRESHOLD_VALUE bit field.

The DSS_HDMI_DMA signal is released (deactivated) when the last transfer of the DMA burst is performed in the FIFO. An internal counter is used to do this. The reset value of this counter is set to 16 and the maximum value is set to 64. In this case, the maximum length of the DMA transfer is 64 (32-bit interface access). The counter can be configured through the HDMI_WP_AUDIO_CFG2[15:8] DMA_TRANSFER bit field.

The threshold value and the DMA burst size must be set to ensure the filling of the FIFO to four samples. The minimum level (otherwise, underflow occurs) is four audio samples, which can be 2×32 -bit data (in case of two samples per word) or 4×32 -bit data (IEC or one sample per word). The interconnect latency must be considered. The number of samples is controlled through the HDMI_WP_AUDIO_CFG[1] SAMPLE_NBR bit.

13.2.8.2.2.2 Audio FIFO Error (Underflow and Overflow)

The underflow and overflow status are required and highlighted by sending interrupt requests IRQs).

The FIFO underflow condition occurs when the HDMI core is requesting data from the FIFO when the FIFO is empty. The status can be read through the HDMI_WP_IRQSTATUS[8] AUDIO_FIFO_UNDERFLOW_INTR bit.

The underflow IRQ may happen during a sequence only if one of the following occurs:

- The audio data path is not set correctly. In this case, the device EDMA cannot fill the FIFO fast enough.
- It is the end of the sequence and the number of samples is not a multiple of two times the value in the HDMI_WP_AUDIO_CFG2[7:0] BLOCK_SIZE bit field (384 samples by default).

The FIFO filling must be ensured by the system before the HDMI core is enabled; this means that in steady state the filling of the FIFO is always four words of 32 bits (except at the end).

The FIFO overflow condition occurs when an audio data is written (by the device EDMA or MPU modules) while the FIFO is full. The status can be read through the HDMI_WP_IRQSTATUS[9] AUDIO_FIFO_OVERFLOW_INTR bit.

The overflow IRQ may happen only if:

- The device EDMA module does not respect the DMA transfer length.
- The threshold is not set to the correct value in the HDMI_WP_AUDIO_CTRL[8:0] THRESHOLD_VALUE bit field.
- The device MPU module does not check the filling of the FIFO when the audio data is requested through an IRQ.

13.2.8.2.2.3 Audio FIFO Reset

The audio sample in the FIFO can be flushed by writing 0 in the HDMI_WP_AUDIO_CTRL[31] WRAPPER_ENABLE bit. As soon as the enable signal is deactivated (set to 0), the following occur: 1. The audio FIFO is reset. 2. The read and write pointers are reset. 3. The DSS_HDMI_DMA signal is deasserted. 4. Only the threshold value in the HDMI_WP_AUDIO_CTRL[8:0] THRESHOLD_VALUE bit field is kept.

13.2.8.2.3 Audio FIFO Data Formats

The format of the audio data in the audio FIFO can be configured through the HDMI_WP_AUDIO_CFG[4] IEC bit field.

- IEC = 0: The audio format is L-PCM.
- IEC = 1: The audio format is IEC 60958/IEC 61937.

13.2.8.2.3.1 L-PCM Format in Audio FIFO

Table 13-12 describes the 16-bit data format in the audio FIFO.

Table 13-12. PCM, 16-Bit Format

Order	Bits [31:16]	Bits [15:0]
---	16 bits, 2 channels (stereo)	---
1	Right - Channel 2	Left - Channel 1
---	16 bits, 4 channels	---
1	Right - Channel 2	Left - Channel 1
2	Right - Channel 4	Left - Channel 3
3	Right - Channel 2	Left - Channel 1
4	Right - Channel 4	Left - Channel 3
---	16 bits, 8 channels	---
1	Right - Channel 2	Left - Channel 1

Table 13-12. PCM, 16-Bit Format (continued)

Order	Bits [31:16]	Bits [15:0]
2	Right - Channel 4	Left - Channel 3
3	Right - Channel 6	Left - Channel 5
4	Right - Channel 8	Left - Channel 7

Table 13-13 describes the 24-bit data format in the audio FIFO. For the following formats, if less than 24 bits are valid, the data can be MSB- or LSB-justified. This is controlled through the HDMI_WP_AUDIO_CFG[3] JUSTIFY bit field.

Table 13-13. PCM, 24-Bit Format

Order	Bits [31:24]	Bits [23:0]
---	24 bits, 2 channels (stereo right - justified)	---
1	Unused	Left - Channel 1
2	Unused	Right - Channel 2
---	24 bits, 2 channels stereo left - justified	---
1	Left - Channel 1	Unused
2	Right - Channel 2	Unused
---	24 bits, 3 channels stereo right - justified	---
1	Unused	Left - Channel 1
2	Unused	Right - Channel 2
3	Unused	Center - Channel 3
4	Unused	Left - Channel 1
5	Unused	Right - Channel 2
6	Unused	Center - Channel 3
---	24 bits, 8 channels (right-justified)	---
1	Unused	Left - Channel 1
2	Unused	Right - Channel 2
3	Unused	Left - Channel 3
4	Unused	Right - Channel 4
5	Unused	Left - Channel 5
6	Unused	Right - Channel 6
7	Unused	Left - Channel 7
8	Unused	Right - Channel 8

NOTE: Left justification for three- and eight-channel data formats is also possible.

13.2.8.2.3.2 Speaker Mapping and Channel Ordering in the Audio FIFO

The speaker mapping in the eight channels is defined by the CEA-861-D specification and is described in Table 13-14. The CEA code is used to program the Packet Byte 4 of the Audio Info FRAME register inside the HDMI core (for more information, see the HDMI standard v1.3).

Table 13-14. Speaker Mapping Versus Channel

CEA Code	8	7	6	5	4	3	2	1
0h	-	-	-	-	-	-	FR	FL
1h	-	-	-	-	-	LFE	FR	FL
2h	-	-	-	-	FC	-	FR	FL

30h	FRW	FLW	RR	RL	FC	-	FR	FL
31h	FRW	FLW	RR	RL	FC	LFE	FR	FL

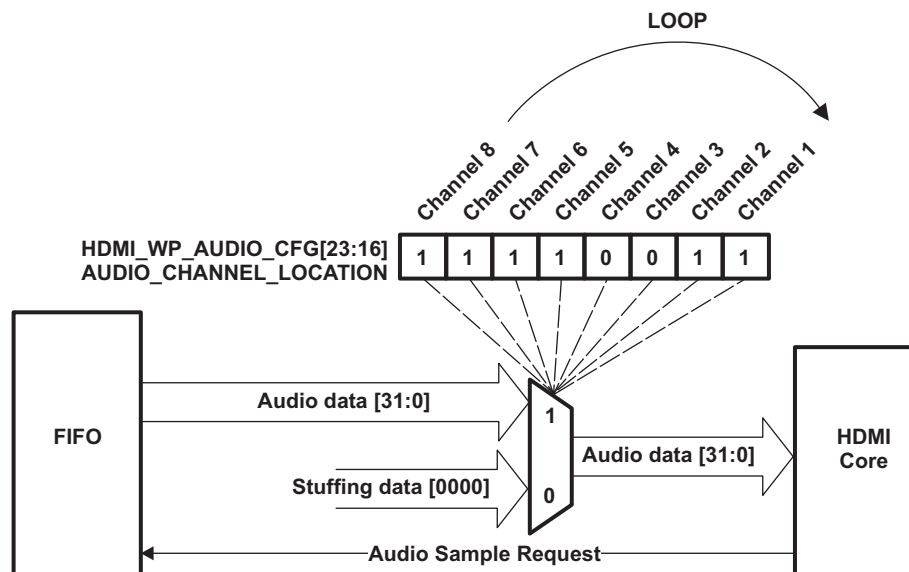

In [Table 13-14](#), the following acronym definitions are used:

- FL: Front left
- FC: Front center
- FR: Front right
- FLC: Front left center
- FRC: Front right center
- RL: Rear left
- RC: Rear center
- RR: Rear right
- RLC: Rear left center
- RRC: Rear right center
- LFE: Low-frequency effect
- FLW: Front left wide
- FRW: Front right wide
- FLH: Front left high
- FCH: Front center high
- FRH: Front right high
- TC: Top center

The audio FIFO can be filled from two to eight channels, but the HDMI core supports only an even number of channels (the missing sample must be filled with 0, depending on the audio format).

The HDMI_WP_AUDIO_CFG[23:16] AUDIO_CHANNEL_LOCATION bit field indicates the location and the active channels. The AUDIO_CHANNEL_LOCATION field contains 8-bit fields, each corresponding to one channel. The HDMI_WP_AUDIO_CFG[26:24] STEREO_CHANNEL_ENABLE bit field indicates the number of stereo channels used. In [Figure 13-6](#), the registers are filled accordingly with the CEA channel/speaker allocation code 10h received from the HDMI core. Upon a data request from the HDMI core, the data coming from the audio FIFO or the stuffing (filling zeros) data are sent.

Figure 13-6. Audio Data Stuffing Behavior

If only three stereo channels are set in the HDMI wrapper, the loop can be optimized and set to 6. If three stereo channels are enabled in the HDMI core module, the function must be set to 3h in the HDMI_WP_AUDIO_CFG[26:24] STEREO_CHANNEL_ENABLE bit field.

Figure 13-7 shows an example with the CEA channel/speaker allocation code 7h and only three stereo channels enabled in the HDMI core. This format is also supported with the four channels enabled, but channel 7/8 must be cleared to 0.

Figure 13-7. Audio Data Stuffing Behavior with Only Three Stereo Channels Active

13.2.8.2.3.3 IEC 61958 Format

In the IEC 61958 format (Table 13-15), the channel status and user data bits are supplied with the audio data.

The valid bits are supplied with the audio data but may be overridden based on the audio FIFO operation (forced to invalid, if FIFO data is invalid). They may also be forced to valid or invalid.

This format supports only two channels (stereo) or two monophonic channels.

The audio FIFO can be filled directly with data aligned with the 60958 format. In this case, the VUCP and the preamble data are available.

Table 13-15. IEC 60958 Sample Format

Order	Bits [31:28]	Bits [27:4]	Bits [3:0]
1	VUCP	Left - Channel 1	Preamble
2	VUCP	Right - Channel 2	Preamble

13.2.8.2.3.4 IEC 61937 Format

The IEC 61937 format (Table 13-16) is similar to the IEC 61958 format, with multichannel supported.

Table 13-16. IEC 60937 Format

Order	Bits [31:28]	Bits [27:4]	Bits [3:0]
1	VUCP	Left - Channel 1	Preamble
2	VUCP	Right - Channel 2	Preamble
3	VUCP	Left - Channel 3	Preamble
4	VUCP	Right - Channel 4	Preamble
5	VUCP	Left - Channel 5	Preamble
6	VUCP	Right - Channel 6	Preamble

Table 13-16. IEC 60937 Format (continued)

Order	Bits [31:28]	Bits [27:4]	Bits [3:0]
7	VUCP	Left - Channel 7	Preamble
8	VUCP	Right - Channel 8	Preamble

NOTE: The compressed formats are supported only if software can stuff the missing data with zeros to reach the bandwidth defined in the IEC 60958 format.

13.2.8.2.4 AUDIO FIFO Data Adaptation

The HDMI core supports only the IEC 60958 format, or similar formats. Between the audio FIFO and the HDMI core, a format adaptation is done to optimize the audio data transfer.

There are three different formats in the audio FIFO:

- Two L-PCM samples on 16 bits in a 32-bit container
- One L-PCM sample on 24 bits in a 32-bit container
- IEC 61937 or IEC 60958 sample format compliant

The audio formats supported include 16- and 24-bit modes for stereo (two channels) and 8-channel modes.

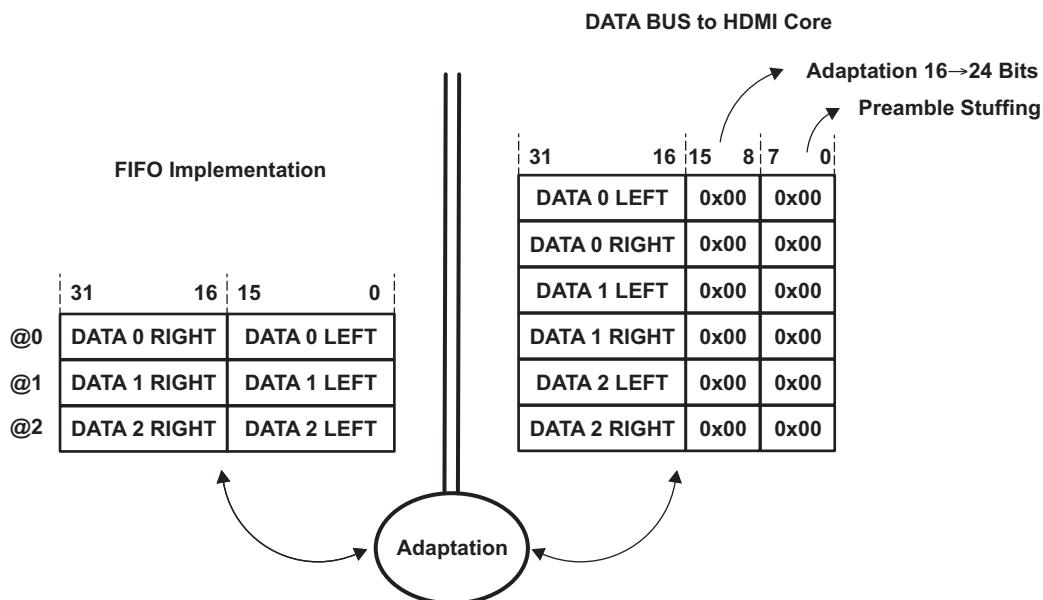

13.2.8.2.4.1 IEC 61937 and IEC 60958 Format Adaptation

The IEC 61937 and IEC 60958 formats are fully compatible with the HDMI core. In this case, data in the FIFO is sent to the HDMI core without adaptation. This is true for 16- and 24-bit modes and it is channel-number independent.

13.2.8.2.4.2 L-PCM 16-Bit Format Adaptation

When the audio FIFO is filled with 16-bit samples on the 32-bit container, the data is adapted to be similar to the IEC 61937/IEC 60958 format, as shown in [Figure 13-8](#).

Figure 13-8. L-PCM 16-Bit Format Adaptation

13.2.8.2.4.3 L-PCM 24-bit Format Adaptation

When the audio FIFO is filled with a 24-bit sample on the 32-bit container, it is already in a format similar to IEC 61937/IEC 60958, left- or right-justified, depending on the FIFO filling (the HDMI_WP_AUDIO_CFG[3] JUSTIFY bit). In this case, the data in the audio FIFO is sent directly to the HDMI core without adaptation. However, the 8 dummy bits (MSB or LSB, depending on the justification) are filled with 0 data.

13.2.9 TXPHY Functions

13.2.9.1 TXPHY Overview

NOTE: The HDMI_TXPHY module must be configured before any transfer on the HDMI link. The HDMI module is fully functional only when the TMDS clock is provided. It has an internal PLL which will take in PCLK as an input and provide the required TCLK based on register configuration.

The HDMI_TXPHY receives 30 bits of TMDS parallel encoded data from the HDMI module and then prepares the data for transmission by serializing it. HDMI_TXPHY is a complex I/O with four unidirectional lane modules. This includes three data lane modules and one clock lane module. Each lane module has two data pads (DX and DY), which form a differential pair. These correspond to the HDMI serial output transmit signals, as described in [Table 13-4](#). The data pads are connected with a complementary lane module on the external HDMI receiver device using a point-to-point interconnect.

The maximum data rate supported is 1.85625 Gbps per data lane. The lane module function and position are configurable. That is, any lane module can be chosen as a clock or a data lane module, and the DX/DY data pad for each lane module can be configured as a positive polarity (DP) or negative polarity (DN) pin.

13.2.9.2 TXPHY Clock Domains

The HDMI_TXPHY module has the following clock domains:

- TMDS clock domain: This is the data interface clock to the HDMI module. The data received on the HDMI_TXPHY inputs are sampled on this clock.
- HFBITCLK clock domain: This is the high frequency clock on which the transmit of the serialized data occurs.
- REFCLK clock domain: This is the 48-MHz free-running clock (DSS_HDMI) that is used as a reference for the switched capacitor circuit.

13.2.9.3 TXPHY RX Connection Detect

The HDMI_TXPHY can detect a pullup to 3.3 V on any clock and data lines. This situation occurs when an external HDMI receiver is connected to the device.

The information can be read by reading TMDS_CNTL2[0], RSEN.

13.2.9.4 TXPHY Data Interface

13.2.9.4.1 Input Interface

The HDMI_TXPHY module receives the 30-bit parallel data on its D0 to D2 inputs. The data is sampled on the rising edge of the TMDS clock.

13.2.9.4.2 Output Interface

The serialized data on differential output lines DX/DY has the order LSB first and MSB last. The TMDS clock on the clock lane has a falling edge at the start of the 10-bit serial data word on the line.

13.2.10 Programming Video Input Mode and Video Output Mode

Specific registers in the HDMI Transmitter must be programmed according to the selection of input video bus mode and output video format. See [Figure 13-9](#).

- The DE parameters need to be programmed only when the DE Generator is enabled. It is not recommended to enable the DE Generator.
- Set RANGE to 1 whenever converting YCbCr data and outputting full-range (0-255) RGB (PC mode) data across HDMI. When outputting limited-range (16-235) RGB (CE mode) data across the link, clear RANGE to 0.
- Set WIDE_BUS to the number of bits per input video channel.
- Set DITHER_MODE to the number of bits per output video channel supported by the Sink. By default, the HDMI Transmitter dithers the input (if DITHER is enabled) or truncates the input (if DITHER is disabled) to 8 bits.
- PB_CTRL1 and PB_CTRL2 should be programmed once the core is powered up only.
- Always clear (set to 0) the DE_ADJ field in IADJUST register when DE is not enabled (Recommended usage).
- DIV_ENC_BYB field in TEST_TXCTRL register should always be programmed to zero.
- ten_bit_bypass in TMDS_CNTL9 register and enc_byb in BIST_CNTL register should always be set to 1.
- Program the HDMI registers and then enable the VENC on VPSS side. All timings are provided by the VENC module in VPSS.

Figure 13-9. Transmitter Video Data Processing Path

13.3 HDMI Registers

13.3.1 HDMI Wrapper Registers

Table 13-17 lists the HDMI wrapper registers.

Table 13-17. HDMI Wrapper Registers

Address Offset	Acronym	Register Name
00h	HDMI_WP_REVISION	IP Revision Identifier
10h	HDMI_WP_SYSCONFIG	Clock management configuration
24h	HDMI_WP_IRQSTATUS_RAW	Raw Interrupt Status
28h	HDMI_WP_IRQSTATUS	Interrupt Status
2Ch	HDMI_WP_IRQENABLE_SET	Interrupt Enable
30h	HDMI_WP_IRQENABLE_CLR	Interrupt Disable
44h	HDMI_WP_DEBOUNCE	Glitch filter
50h	HDMI_WP_VIDEO_CFG	Configuration of HDMI Wrapper video
70h	HDMI_WP_CLK	Configuration of clocks
80h	HDMI_WP_AUDIO_CFG	Audio Configuration in FIFO
84h	HDMI_WP_AUDIO_CFG2	Audio configuration of DMA
88h	HDMI_WP_AUDIO_CTRL	Audio FIFO control
8Ch	HDMI_WP_AUDIO_DATA	TX Data of FIFO

13.3.1.1 IP Revision Identifier Register (HDMI_WP_REVISION)

The IP revision identifier register is shown in Figure 13-10 and described in Table 13-18.

Figure 13-10. IP Revision Identifier Register (HDMI_WP_REVISION)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

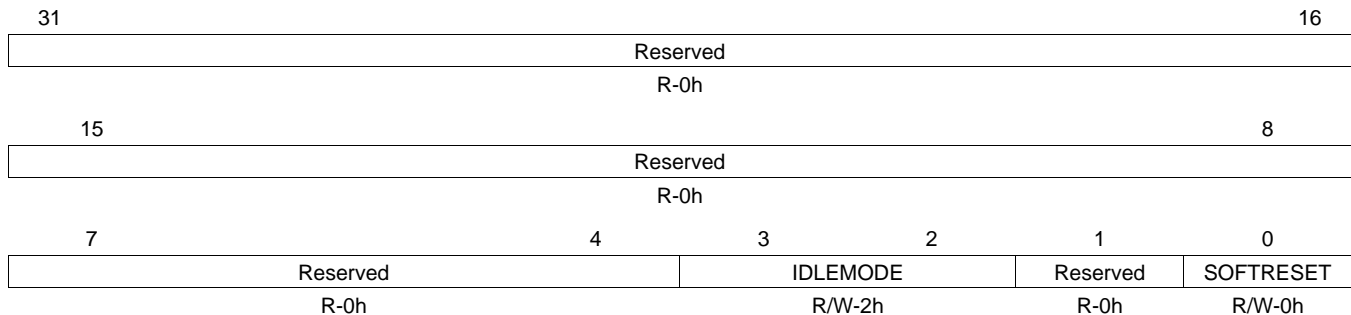

Table 13-18. IP Revision Identifier Register (HDMI_WP_REVISION) Field Descriptions

Bit	Field	Description
31-0	Revision	IP Revision

13.3.1.2 Clock Management Configuration Register (HDMI_WP_SYSCONFIG)

The Clock management configuration register is shown in [Figure 25-24](#) and described in [Table 13-19](#).

Figure 13-11. Clock Management Configuration Register (HDMI_WP_SYSCONFIG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

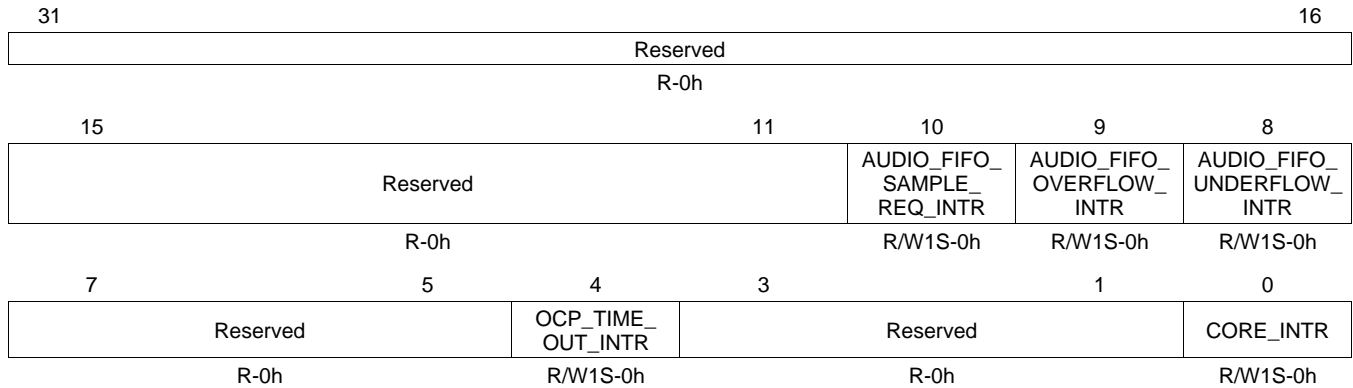

**Table 13-19. Clock Management Configuration Register (HDMI_WP_SYSCONFIG)
Field Descriptions**

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3-2	IDLEMODE	0	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. Default = 2h.
		0	Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, that is regardless of the IP module's internal requirements. Backup mode, for debug only.
		1h	No-idle mode: local target never enters idle state. Used in case Audio is transferred (to avoid DSS_L3_ICLK clock to be shut down)
		2h	Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module should not generate (IRQ- or DMA-request-related) wakeup events. To be used, if only Video is transmitted (since the DSS_L3_ICLK clock is not required)
		3h	Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.
1	Reserved	0	Reserved
0	SOFTRESET	R0	Software reset. (Optional)
		W0	Software reset done, no pending action
		R1	No action
		W1	Software reset ongoing
		W1	Initiate software reset

13.3.1.3 Raw Interrupt Status Register (HDMI_WP_IRQSTATUS_RAW)

The raw interrupt status register is shown in [Figure 13-12](#) and described in [Table 13-20](#).

Figure 13-12. Raw Interrupt Status Register (HDMI_WP_IRQSTATUS_RAW)

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set, write 0 has no effect; -n = value after reset

Table 13-20. Raw Interrupt Status Register (HDMI_WP_IRQSTATUS_RAW) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	Reserved
10	AUDIO_FIFO_SAMPLE_REQ_INTR	R0 W0 R1 W1	Settable raw status for audio events No event pending No action IRQ event pending Set event
9	AUDIO_FIFO_OVERFLOW_INTR	R0 W0 R1 W1	Settable raw status for audio events No event pending No action IRQ event pending Set event
8	AUDIO_FIFO_UNDERFLOW_INTR	R0 W0 R1 W1	Settable raw status for audio events No event pending No action IRQ event pending Set event
7-5	Reserved	0	Reserved
4	OCP_TIME_OUT_INTR	R0 W0 R1 W1	Settable raw status for OCP timeout interrupt No event pending No action IRQ event pending Set event
3-1	Reserved	0	Reserved
0	CORE_INTR	R0 W0 R1 W1	Settable raw status for HDMI Core interrupt Software reset done, no pending action No action Software reset ongoing Set event

13.3.1.4 Interrupt Status Register (HDMI_WP_IRQSTATUS)

The interrupt status register is shown in [Figure 13-13](#) and described in [Table 13-21](#).

Figure 13-13. Interrupt Status Register (HDMI_WP_IRQSTATUS)

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear, write 0 has no effect; -n = value after reset

13.3.1.7 Glitch Filter Register (HDMI_WP_DEBOUNCE)

The glitch filter register is shown in [Figure 13-16](#) and described in [Table 13-24](#).

Figure 13-16. Glitch Filter Register (HDMI_WP_DEBOUNCE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

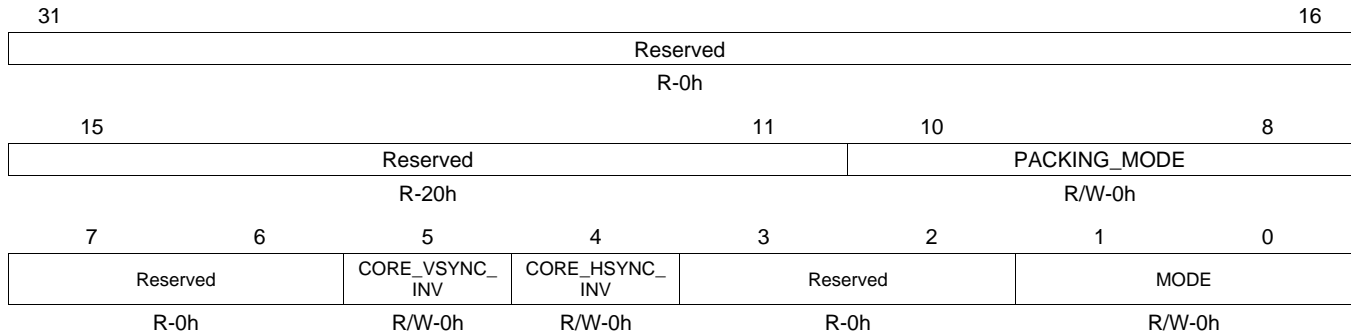

Table 13-24. Glitch Filter Register (HDMI_WP_DEBOUNCE) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved
13-8	RXDET	0 1-3Fh	Glitch Filter for RXDET Input. Disabled From 1–63, size of the glitch filtered based on OCP clock frequency
7-6	Reserved	0	Reserved
5-0	LINE5VSHORT	0 1-3Fh	Glitch filter for line 5v short input. Disabled From 1–63, size of the glitch filtered based on OCP clock frequency

13.3.1.8 Configuration of HDMI Wrapper Video Register (HDMI_WP_VIDEO_CFG)

The configuration of HDMI wrapper video register is shown in [Figure 13-17](#) and described in [Table 13-25](#).

Figure 13-17. Configuration of HDMI Wrapper Video Register (HDMI_WP_VIDEO_CFG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 13-25. Configuration of HDMI Wrapper Video Register (HDMI_WP_VIDEO_CFG)
Field Descriptions**

Bit	Field	Value	Description
31-11	Reserved	20h	Reserved
10-8	PACKING_MODE	0	Used to pack 10-bits RGB or YUV444 input data in case the video input is not already packed. Will pack video_data[35:26] - video_data[23:14] - video_data[11:2]
		1h	Used to pack 24-bits RGB, 24-bit YUV444, 16-bit YUV422 or 24-bit YUV422 input data in case the video input is not already packed. Will pack video_data[35:28] - video_data[23:16] - video_data[11:4]
		2h	Used to pack 20-bits YUV422 input data in case the video input is not already packed. Will pack video_data[35:28] - video_data[23:16] - video_data[11:10] - video_data[7:6]
		3h-6h	Reserved
		7h	No change on input video_data lines. The video_data[35:0] is provided to the core without any change on it.
7-6	Reserved	0	Reserved
5	CORE_VSYNC_INV	0	Enables to invert or not the VSYNC signal provided to the HDMI core VSYNC is unchanged
		1	VSYNC is inverted
4	CORE_HSYNC_INV	0	Enables to invert or not the HSYNC signal provided to the HDMI core HSYNC is unchanged
		1	HSYNC is inverted
3-2	Reserved	0	Reserved
1-0	MODE	0	Always program to 0

13.3.1.9 Configuration of Clocks Register (HDMI_WP_CLK)

The configuration of clocks register is shown in [Figure 13-18](#) and described in [Table 13-26](#).

Figure 13-18. Configuration of Clocks Register (HDMI_WP_CLK)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

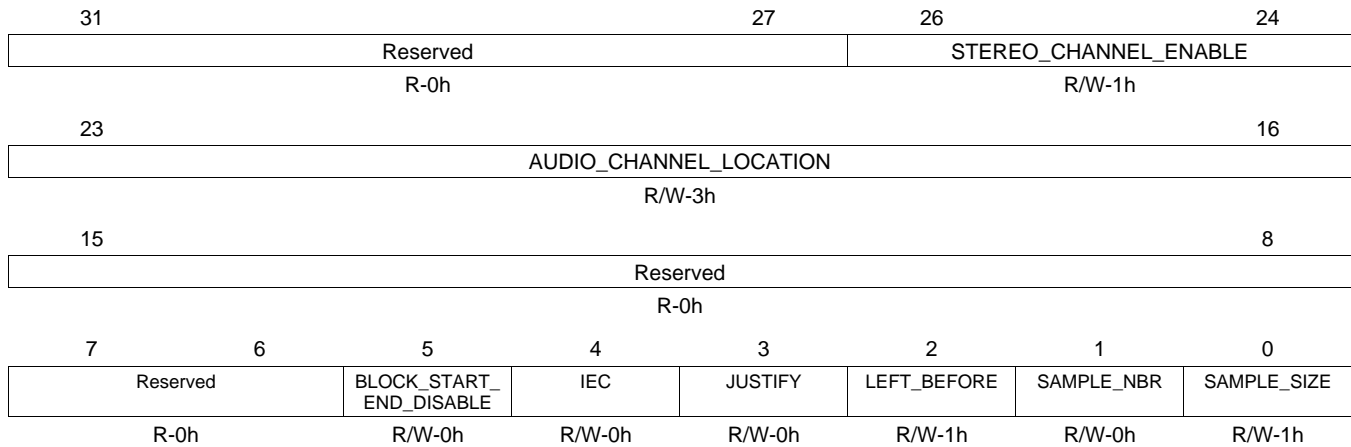

Table 13-26. Configuration of Clocks Register (HDMI_WP_CLK) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	OCP_TIME_OUT_DIS	0	Timeout in case CEC_DDC_CLK not provided. Timeout after 4095 OCP clock cycles after inactivity. HDMI Core register interface (due to CEC_DDC_CLK not provided to HDMI). An interrupt is generated. No error response is provided on the OCP interface.
		1	No timeout capability
15-6	Reserved	0	Reserved
5-0	CEC_DIV		Defines the divisor value to be used for the generation of the CEC clock (1 MHz) from the input CEC_DDC clock (48 MHz). If 48 MHz is provided, the division by 24 is required (18h) to get the expected CEC clock speed (2 MHz) The valid values are from 0 to 63.
		0	Gated
		1	Free-running

13.3.1.10 Audio Configuration in FIFO Register (HDMI_WP_AUDIO_CFG)

The audio configuration in FIFO register is shown in [Figure 13-19](#) and described in [Table 13-27](#).

Figure 13-19. Audio Configuration in FIFO Register (HDMI_WP_AUDIO_CFG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-27. Audio Configuration in FIFO Register (HDMI_WP_AUDIO_CFG) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reserved
26-24	STEREO_CHANNEL_ENABLE	0 1h 2h 3h 4h 5h-7h	This field contains the number of stereo channels enabled in the HDMI_CORE module. Must be set by the software and aligned with the register set in the HDMI_core. No stereo channel enabled in the HDMI_core module 1 stereo channel enabled in the HDMI_core module 2 stereo channels enabled in the HDMI_core module 3 stereo channels enabled in the HDMI_core module 4 stereo channels enabled in the HDMI_core module Reserved
23-16	AUDIO_CHANNEL_LOCATION	3h	This field contains which channels are active. It is used also to define which registers are stuffed with zero.
15-6	Reserved	0	Reserved
5	BLOCK_START_END_DISABLE	0 1	This field disables or not the block end start generation. This field does not affect the pcm format. Block signals are generated. Block signals are not generated; Block start is set to high and block end to low
4	IEC	0 1	Indicate if the format of the FIFO is compliant with the IEC format. Audio format is L-PCM; Format not aligned with IEC Audio format is IEC 60 958/61937; Format is aligned with IEC format
3	JUSTIFY	0 1	This field shows the justification (not applicable if IEC format) Justify left Justify right
2	LEFT_BEFORE	0 1	DO NOT USE—Software always uses LEFT_BEFORE = 1 The first sample is the right The first sample is the left
1	SAMPLE_NBR	0 1	This field indicates the number of sample per word (32 bits) (not applicable if IEC format) 1 sample per word, 32 bit 2 samples per word, 32 bits (only compatible with sample on 16 bits)

Table 13-27. Audio Configuration in FIFO Register (HDMI_WP_AUDIO_CFG) Field Descriptions (continued)

Bit	Field	Value	Description
0	SAMPLE_SIZE		Audio sample size, 16 bits or 24 bits (not applicable if IEC format)
		0	Sample is on 16 bits
		1	Sample is on 24 bits

13.3.1.11 Audio Configuration of DMA Register (HDMI_WP_AUDIO_CFG2)

The audio configuration of DMA register is shown in [Figure 13-20](#) and described in [Table 13-28](#).

Figure 13-20. Audio Configuration of DMA Register (HDMI_WP_AUDIO_CFG2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-28. Audio Configuration of DMA Register (HDMI_WP_AUDIO_CFG2) Field Descriptions

Bit	Field	Description
31-16	Reserved	Reserved
15-8	DMA_TRANSFER	Use to control the dma request. When the number of OCP dma access is performed, the DMA request signal is de-asserted (set to low) All dma access are performed on 32 bit in HDMI_WP_AUDIO_DATA register Encoded value (from 0 to 255). The value 0 is invalid.
7-0	BLOCK_SIZE	Define the block size if audio sample are compressed default value is 192 to match the IEC 60958 standard.

13.3.1.12 Audio FIFO Control Register (HDMI_WP_AUDIO_CTRL)

The audio FIFO control register is shown in [Figure 13-21](#) and described in [Table 13-29](#).

Figure 13-21. Audio FIFO Control Register (HDMI_WP_AUDIO_CTRL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-29. Audio FIFO Control Register (HDMI_WP_AUDIO_CTRL) Field Descriptions

Bit	Field	Value	Description
31	WRAPPER_ENABLE	0 1	This field enable the audio wrapper. When disable the audio path is under reset Register setting are not affected by the enable. Wrapper is disabled Wrapper is enabled
30	CORE_REQ_ENABLE	0	Enables the Audio data request generated by the core. This is used to start the audio data transmission from the wrapper to the core. This must be enabled only after the 5th VSYNC is generated to ensure that the Audio and Video are in Sync.
29-26	Reserved	0	Reserved
25-16	NUMBER_OF_SAMPLE	0	Shows the number of valid sample (16 or 24 bits) in the FIFO (depends of the FIFO format setting)
15-10	Reserved	0	Reserved
9	DMA_OR_IRQ	0 1	Indicated if the threshold generates a DMA or an IRQ When the threshold is reached a DMA req will be generated When the threshold is reached an IRQ will be generated
8-0	THRESHOLD_VALUE	10h	The DMA/IRQ is generated if the number of sample (24 or 16 bit) in the FIFO is less or equal to the threshold value. The maximum threshold is 511 and the minimum is 0.

13.3.1.13 TX Data of FIFO Register (HDMI_WP_AUDIO_DATA)

The TX data of FIFO register is shown in [Figure 13-22](#) and described in [Table 13-30](#).

Figure 13-22. TX Data of FIFO Register (HDMI_WP_AUDIO_DATA)

LEGEND: W = Write only; -n = value after reset

Table 13-30. TX Data of FIFO Register (HDMI_WP_AUDIO_DATA) Field Descriptions

Bit	Field	Description
31-0	FIFO_DATA	Audio TX DATA. Can be accessed in 32-bit mode only. Read returns 0.

13.3.2 HDMI Core System Registers

Table 13-31 lists the HDMI core system registers.

Table 13-31. HDMI Core System Registers

Address Offset	Acronym	Register Name
00h	VND_IDL	Vendor ID Register
04h	VND_IDH	Vendor ID Register
08h	DEV_IDL	Device ID Register

3CCh	DDC_CMD	DDC I2C Command Register
3D0h	DDC_DATA	DDC I2C Data Register
3D4h	DDC_FIFOCNT	DDC I2C FIFO Count Register
3E4h	EPST	ROM Status Register
3E8h	EPCM	ROM Command Register

13.3.2.1 Vendor IDL Register (VND_IDL)

The vendor IDL register is shown in [Figure 13-23](#) and described in [Table 13-32](#).

Figure 13-23. Vendor ID Register (VND_IDL)

LEGEND: R = Read only; -n = value after reset

Table 13-32. Vendor ID Register (VND_IDL) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	VND_IDL	Vendor ID low byte. Provides unique vendor identification through I2C.

13.3.2.2 Vendor IDH Register (VND_IDH)

The vendor IDH register is shown in [Figure 13-24](#) and described in [Table 13-33](#).

Figure 13-24. Vendor ID Register (VND_IDH)

LEGEND: R = Read only; -n = value after reset

Table 13-33. Vendor ID Register (VND_IDH) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	VND_IDH	Vendor ID high byte. Provides unique vendor identification through I2C.

13.3.2.3 Device IDL Register (DEV_IDL)

The device IDL register is shown in [Figure 13-25](#) and described in [Table 13-34](#).

Figure 13-25. Device IDL Register (DEV_IDL)

LEGEND: R = Read only; -n = value after reset

Table 13-34. Device IDL Register (DEV_IDL) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DEV_ID	Device ID low byte. Provides unique vendor identification through I2C.

13.3.2.4 Device IDH Register (DEV_IDH)

The device IDH register is shown in [Figure 13-26](#) and described in [Table 13-35](#).

Figure 13-26. Device IDH Register (DEV_IDH)

LEGEND: R = Read only; -n = value after reset

Table 13-35. Device IDH Register (DEV_IDH) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DEV_ID	Device ID high byte. Provides unique vendor identification through I2C.

13.3.2.5 Device Revision Register (DEV_REV)

The device revision register is shown in [Figure 13-27](#) and described in [Table 13-36](#).

Figure 13-27. Device Revision Register (DEV_REV)

LEGEND: R = Read only; -n = value after reset

Table 13-36. Device Revision Register (DEV_REV) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DEV_REV	Allows distinction between revisions of same device.

13.3.2.6 Software Reset Register (SRST)

The software reset register (SRST) is shown in [Figure 13-28](#) and described in [Table 13-37](#).

Figure 13-28. Software Reset Register (SRST)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

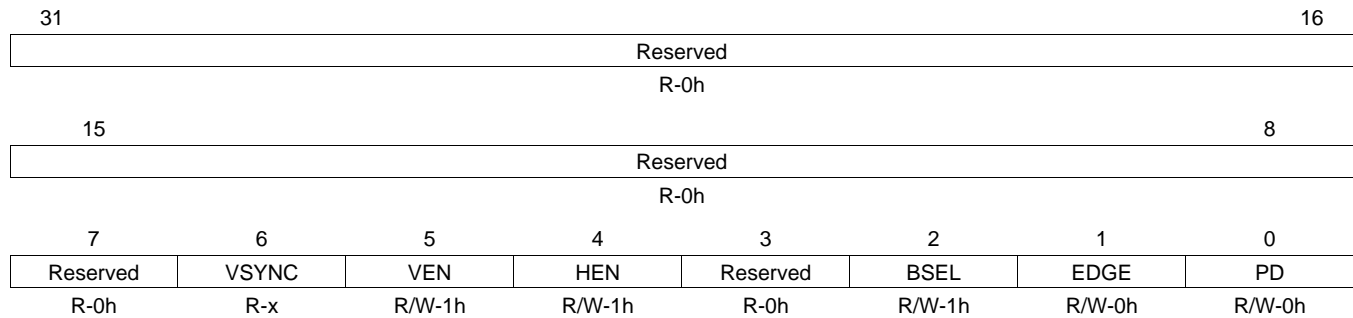

Table 13-37. Software Reset Register (SRST) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	FIFORST		Audio FIFO reset
		0	Normal operation
		1	Reset (flush) audio FIFO
0	SWRST		Software reset
		0	Normal operation
		1	Reset all sections, including audio FIFO but not writable registers or HDCP

13.3.2.7 System Control Register 1 (SYS_CTRL1)

The system control register 1 is shown in [Figure 13-29](#) and described in [Table 13-38](#).

Figure 13-29. System Control Register 1 (SYS_CTRL1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; x = value is indeterminate

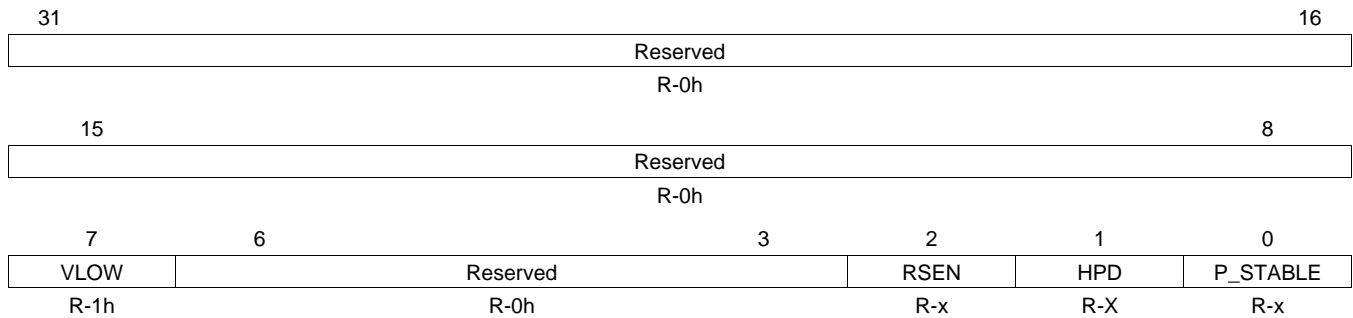

Table 13-38. System Control Register 1 (SYS_CTRL1) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	VSYNC	x	The current status of the VSYNC input pin. Refer to the INTR2 register for an interrupt tied to VSYNC active edge.
5	VEN	0 1	VSYNC enable Fixed LOW Follow VSYNC input
4	HEN	0 1	HSYNC enable Fixed LOW Follow HSYNC input
3	Reserved	0	Reserved
2	BSEL	0 1	Input bus select 12-bit Data Bus 24-bit Data Bus
1	EDGE	0 1	Edge select Latch Input on Falling Edge Latch Input on Rising Edge
0	PD	0 1	Power down mode. Most other register values are not affected by assertion of the PD bit. Interrupts are in power-down mode Normal operation

13.3.2.8 System Status Register (SYS_STAT)

The system status register is shown in [Figure 13-30](#) and described in [Table 13-39](#).

Figure 13-30. System Status Register (SYS_STAT)

LEGEND: R = Read only; -n = value after reset; x = value is indeterminate

Table 13-39. System Status Register (SYS_STAT) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	VLOW	1	VREF mode. Always HIGH.
6-4	Reserved	0	Reserved
2	RSEN	0 1	Receiver sense (works in DC-coupled systems only) RSEN is active when the TMDS link is terminated, usually into a powered-on TMDS receiver chip. An active RSEN implies an active Hot Plug Detect; as the link must also be physically connected. 0 No receiver is connected 1 Receiver is connected and powered on
1	HPD	x	Hot plug detect. The state of the hot plug detect pin can be read here.
0	P_STABLE	x	IDCK (io_pclkpin) to TMDS clock (v_ck2x) is stable and the Transmitter can send reliable data on the TMDS link. A change to the IDCK sets this bit LOW. After a subsequent LOW to HIGH transition, indicating a stable input clock, a software reset is recommended.

13.3.2.9 System Control Register 3 (SYS_CTRL3)

The system control register 3 is shown in [Figure 13-31](#) and shown in [Table 13-40](#).

Figure 13-31. System Control Register 3 (SYS_CTRL3)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-40. System Control Register 3 (SYS_CTRL3) Field Descriptions

Bit	Field	Description
31-3	Reserved	Reserved
2-1	CTL	The states of these control bits are transmitted across the TMDS link during blanking times for DVI 1.0 mode only.
0	Reserved	Reserved

13.3.2.10 Data Control Register (DCTL)

The data control register is shown in [Figure 13-32](#) and described in [Table 13-41](#).

Figure 13-32. Data Control Register (DCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-41. Data Control Register (DCTL) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2	VID_BLANK	0	Normal operation (video output is not blanked)
		1	Video output is blanked and the colors sent are those specified in registers VID_BLANK1, VID_BLANK2, and VID_BLANK3.
1	AUD_MUTE	0	Do not send zeroes in audio pocket
		1	Send zeroes in audio pocket
0	HDCP_SEL	0	This register gets the value of the pin io_hdcp_sel. When connected to 1 b0; enables firmware to take the decision whether to send unencrypted data or not. By connecting to 1 b1; HDMI Tx will be able to send ONLY encrypted data.

13.3.2.11 HDCP Control Register (HDCP_CTRL)

The HDCP control register is shown in [Figure 13-33](#) and described in [Table 13-42](#).

Figure 13-33. HDCP Control Register (HDCP_CTRL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-42. HDCP Control Register (HDCP_CTRL) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	ENC_ON	0	Encryption disabled or not in progress
		1	Encryption enabled and in progress
5	BKSV_ERR	0	BKSV error. To clear BKSV_ERR; the firmware must first set the TX_ANSTOP bit; then perform an authentication twice with a valid BKSV value.
		1	No error in BKSV format
		1	Error in BKSV format
4	RX_RPTR	0	Repeater. If the HDMI Receiver is in a Repeater, write bit 4 (RX_RPTR) to 1 before beginning the authentication process. Note: This bit is written when the Source device detects an attached HDCP Repeater device. This is a necessary step in the computation of shared values in the HDCP protocol. For more information, see section 2.2 in the HDCP 1.0 Specification.
		1	Single HDMI Receiver
		1	HDMI Receiver is a Repeater
3	TX_ANSTOP	0	AN control. When cleared; the cipher engine is allowed to free run and the AN registers cycle through pseudo-random values. When set; the cipher engines stops and the AN register may be read and initialized in the HDCP-capable Receiver. To clear this bit; toggle the RX_RPTR bit. This bit is also cleared when the hardware is reset or BKSV_ERR is set.
2	CP_RESTN	0	Content protection reset
		1	Reset
		1	Normal operation
1	RI_RDY	0	Ri Ready
		1	Ri first value is not ready
		1	Ri first value is ready in the HDMI Transmitter. Cleared by a hardware reset. This bit is also cleared when the first byte of BKSV is written into the HDMI Transmitter (performed at the beginning of the next authentication process).
0	ENC_EN	0	Encryption enable
		1	Encryption is disabled
		1	Encryption is enabled. See description of HDCP_SEL bit in register DCTL (see Section 13.3.2.10).

13.3.2.12 HDCP BKS_V Register (BKS_V__0-BKS_V__4)

The HDCP BKS_V register is shown in [Figure 13-34](#) and described in [Table 13-43](#).

Figure 13-34. HDCP BKS_V Register (BKS_V__0-BKS_V__4)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-43. HDCP BKS_V Register (BKS_V__0-BKS_V__4) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	BKS _V	Write : Written with the HDCP receiver key selection vector register value. Writing 5th BKS _V byte triggers the authentication logic in the HDMI Transmitter. Write this byte last.

13.3.2.13 HDCP AN Register (AN__0-AN__7)

The HDCP AN register is shown in [Figure 13-35](#) and described in [Table 13-44](#).

Figure 13-35. HDCP AN Register (AN__0-AN__7)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-44. HDCP AN Register (AN__0-AN__7) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	AN	AN value is an HDCP 64-Bit pseudo-random value.

13.3.2.14 HDCP AKS_V Register (AKS_V__0-AKS_V__4)

The HDCP AKS_V register is shown in [Figure 13-36](#) and described in [Table 13-45](#).

Figure 13-36. HDCP AKS_V Register (AKS_V__0-AKS_V__4)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; x = value is indeterminate

Table 13-45. HDCP AKS_V Register (AKS_V__0-AKS_V__4) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	AKS _V	HDCP-capable transmitter s key selection vector. Fifth AKS _V byte triggers the authentication logic in the receiver. Write this byte last.

13.3.2.15 HDCP Ri1 Register (Ri1)

The HDCP Ri1 register is shown in [Figure 13-37](#) and described in [Table 13-46](#).

Figure 13-37. HDCP Ri1 Register (RI1)

31	Reserved	8 7	0
	R-0h		RI R-0h

LEGEND: R = Read only; -n = value after reset

Table 13-46. HDCP Ri Register (RI1) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	RI1	RI1 register. The value of this register should be read and compared with the HDMI Receiver's Ri value.

13.3.2.16 HDCP Ri2 Register (RI2)

The HDCP Ri2 register is shown in [Figure 13-38](#) and described in [Table 13-47](#).

Figure 13-38. HDCP Ri2 Register (RI2)

31	Reserved	8 7	0
	R-0h		RI2 R-0h

LEGEND: R = Read only; -n = value after reset

Table 13-47. HDCP Ri2 Register (RI2) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	RI2	RI2 register. The value of this register should be read and compared with the HDMI Receiver's Ri value.

13.3.2.17 HDCP Ri 128 Compare Register (RI_128_COMP)

The HDCP Ri 128 compare register is shown in [Figure 13-39](#) and described in [Table 13-48](#).

Figure 13-39. HDCP Ri 128 Compare Register (RI_128_COMP)

31	Reserved	7 6	0
	R-0h		RI_128_COMP R/W-0h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-48. HDCP Ri 128 Compare Register (RI_128_COMP) Field Descriptions

Bit	Field	Description
31-7	Reserved	Reserved
6-0	RI_128_COMP	Limit counter for Ri comparison. When the frame counter (I_CNT) reaches the index set in this register an RI_128 interrupt is generated.

13.3.2.18 HDCP I Counter Register (I_CNT)

The HDCP I counter register is shown in [Figure 13-40](#) and described in [Table 13-49](#).

Figure 13-40. HDCP I Counter Register (I_CNT)

LEGEND: R = Read only; -n = value after reset

Table 13-49. HDCP I Counter Register (I_CNT) Field Descriptions

Bit	Field	Description
31-7	Reserved	Reserved
6-0	I_CNT	Current value of I counter. This register counts frames from 0 to 127, then rolls over to zero.

13.3.2.19 Ri Status Register (RI_STAT)

The Ri status register is shown in [Figure 13-41](#) and described in [Table 13-50](#).

Figure 13-41. Ri Status Register (RI_STAT)

LEGEND: R = Read only; -n = value after reset

Table 13-50. Ri Status Register (RI_STAT) Field Descriptions

Bit	Field	Description
31-1	Reserved	Reserved
0	RI_STARTED	Ri check started status. This signal is used for handshaking between the firmware and the hardware. After the Ri check is enabled, the hardware waits for the DDC master to finish the current transaction before taking control. After this bit is set, the firmware loses the ability to use the DDC Master, unless it disables Ri Check and resets to 0.

13.3.2.20 Ri Command Register (RI_CMD)

The Ri command register is shown in [Figure 13-42](#) and described in [Table 13-51](#).

Figure 13-42. Ri Command Register (RI_CMD)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-51. Ri Command Register (RI_CMD) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	BCAP_EN	0 1	Enable polling of the BCAP_DONE bit (in the register INTR2). Note: To poll the BCAP_DONE bit; the ENC_EN (in HDPC_CTRL register) bit and the Ri_EN (in RI_CMD register) bit must be enabled on the HDMI Transmitter. Disable Enable
0	RI_EN	0 1	Enable Ri check. Check bit RI_STARTED of the Ri_STAT register for firmware and hardware DDC control handshaking. Disable Enable

13.3.2.21 Ri Line Start Register (RI_START)

The Ri line start register is shown in [Figure 13-43](#) and described in [Table 13-52](#).

Figure 13-43. Ri Line Start Register (RI_START)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-52. Ri Line Start Register (RI_START) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	RI_LINE_START	Indicates at what line within frame 127 or 0 to start the Ri Check. Note that the value for this register bit represents the power of 2; the 2 LSBs are 0.

13.3.2.22 Ri From RX Registers (Low) (RI_RX_L)

The Ri from RX registers (low) are shown in [Figure 13-44](#) and described in [Table 13-53](#).

Figure 13-44. Ri From RX Registers (Low) (RI_RX_L)

LEGEND: R = Read only; -n = value after reset

Table 13-53. Ri From RX Register (Low) (RI_RX_L) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	RI_RX	Ri_RX[15:8] and Ri_RX[7:0]. This value represents the HDMI Receiver s Ri value if any of the Ri Check errors occurred.

13.3.2.23 Ri From RX Registers (High) (RI_RX_H)

The Ri from RX registers (high) are shown in [Figure 13-45](#) and described in [Table 13-54](#).

Figure 13-45. Ri From RX Registers (High) (RI_RX_H)

LEGEND: R = Read only; -n = value after reset

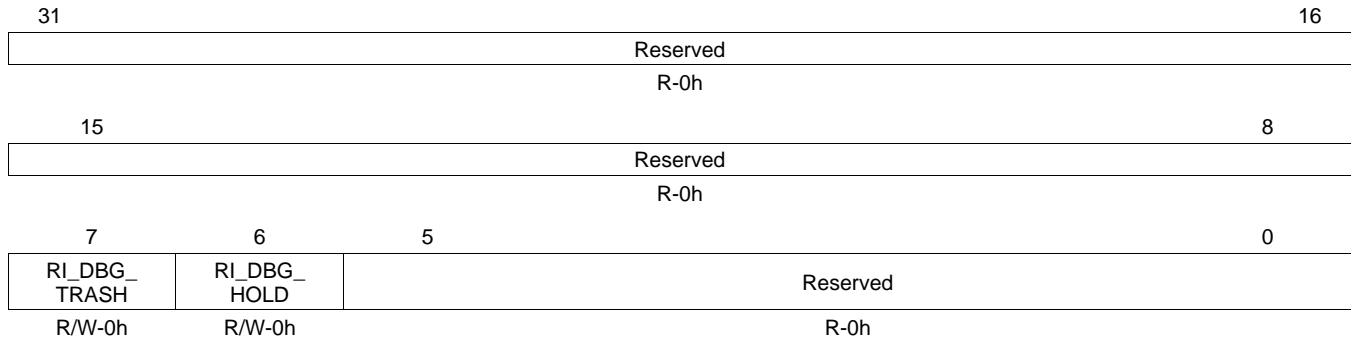

Table 13-54. Ri From RX Registers (High) (RI_RX_H) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	RI_RX	Ri_RX[15:8] and Ri_RX[7:0]. This value represents the HDMI Receiver s Ri value if any of the Ri Check errors occurred.

13.3.2.24 Ri Debug Registers (RI_DEBUG)

The Ri debug registers are shown in [Figure 13-46](#) and described in [Table 13-55](#).

Figure 13-46. Ri Debug Registers (RI_DEBUG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-55. Ri Debug Registers (RI_DEBUG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	RI_DBG_TRASH	0	Ri value trash
		1	Force a corruption of the Ri values
6	RI_DBG_HOLD	0	Ri value hold
		1	Hold the Ri value steady; stop updating
5-0	Reserved	0	Reserved

13.3.2.25 VIDEO DE Delay Register (DE_DLY)

The VIDEO DE delay register is shown in [Figure 13-47](#) and described in [Table 13-56](#).

Figure 13-47. VIDEO DE Delay Register (DE_DLY)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-56. VIDEO DE Delay Register (DE_DLY) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DE_DLY	Width of the area to the left of the active display. The unit of measure is pixels. This register should be set to the sum of (HSYNC width) + (horizontal back porch) + (horizontal left border), and is used only for DE generation. Note that this 12-bit value includes four bits from register DE_CTRL (see Section 13.3.2.26). The valid range is 1-4095. 0 is invalid.

13.3.2.26 VIDEO DE Control Register (DE_CTRL)

The VIDEO DE control register is shown in [Figure 13-48](#) and described in [Table 13-57](#).

Figure 13-48. VIDEO DE Control Register (DE_CTRL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-57. VIDEO DE Control Register (DE_CTRL) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	DE_GEN	0 1	Generate DE signal Disabled Enabled
5	VS_POL	0 1	VSYNC polarity 0 Positive polarity (leading edge rises) 1 Negative polarity (leading edge falls) Set this bit to the input VSYNC polarity for the source that provides VSYNC. For embedded syncs, set this bit to the desired VSYNC polarity that is generated from the embedded sync codes.
4	HS_POL	0 1	HSYNC polarity 0 Positive polarity (leading edge rises) 1 Negative polarity (leading edge falls) Set this bit to the input HSYNC polarity for the source that provides HSYNC. For embedded syncs, set this bit to the desired HSYNC polarity that is generated from the embedded sync codes.
3-0	DE_DLY	0	Width of the area to the left of the active display. The unit of measure is pixels. This register should be set to the sum of (HSYNC width) + (horizontal back porch) + (horizontal left border), and is used only for DE generation. Note that this 12-bit value includes eight bits from register DE_DLY (see Section 13.3.2.25).

13.3.2.27 VIDEO DE Top Register (DE_TOP)

The VIDEO DE top register is shown in [Figure 13-49](#) and described in [Table 13-58](#).

Figure 13-49. VIDEO DE Top Register (DE_TOP)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-58. VIDEO DE Top Register (DE_TOP) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DE_TOP	Defines the height of the area above the active display. The unit of measure is lines (HSYNC pulses). This register should be set to the sum of (VSYNC width) + (vertical back porch) + (vertical top border). The valid range is 1-127. 0 is invalid.

13.3.2.28 VIDEO DE Count Register (DE_CNTL)

Figure 13-50. VIDEO DE Count Register (DE_CNTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

The VIDEO DE count register is shown in [Figure 13-50](#) and described in [Table 13-59](#).

Table 13-59. VIDEO DE Count Register (DE_CNTL) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DE_CNT	Defines the width of the active display. The unit of measure is pixels. This register should be set to the desired horizontal resolution. Note that this 12-bit value includes four bits from register DE_CNTH (see Section 13.3.2.29). The valid range is 1-4095. 0 is invalid.

13.3.2.29 VIDEO DE Count Register (DE_CNTH)

The VIDEO DE count register is shown in [Figure 13-51](#) and described in [Table 13-60](#).

Figure 13-51. VIDEO DE Count Register (DE_CNTH)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-60. VIDEO DE Count Register (DE_CNTH) Field Descriptions

Bit	Field	Description
31-4	Reserved	Reserved
3-0	DE_CNT	Defines the width of the active display. The unit of measure is pixels. This register should be set to the desired horizontal resolution. Note that this 12-bit value includes eight bits from register DE_CNTL (see Section 13.3.2.28). The valid range is 1-4095. 0 is invalid.

13.3.2.30 VIDEO DE Line Register (DE_LINL)

The VIDEO DE line register is shown in [Figure 13-52](#) and described in [Table 13-61](#).

Figure 13-52. VIDEO DE Line Register (DE_LINL)

31	Reserved	8 7	0
	R-0h		DE_LIN[7:0] R/W-0h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-61. VIDEO DE Line Register (DE_LINL) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DE_LIN	Defines the height of the active display. The unit of measure is lines (HSYNC pulses). Set this register to the desired vertical resolution. For interlaced modes; set this register to the number of lines per field; which is half the overall vertical resolution. Note that this 11-bit value includes three bits from register DE_LINH_1 (see Section 13.3.2.31). The valid range is 1-2047. 0 is invalid.

13.3.2.31 VIDEO DE Line Register (DE_LINH_1)

The VIDEO DE line register is shown in [Figure 13-53](#) and described in [Table 13-62](#).

Figure 13-53. VIDEO DE Line Register (DE_LINH_1)

31	Reserved	3 2	0
	R-0h		DE_LIN[10:8] R/W-0h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-62. VIDEO DE Line Register (DE_LINH_1) Field Descriptions

Bit	Field	Description
31-3	Reserved	Reserved
2-0	DE_LIN	Defines the height of the active display. The unit of measure is lines (HSYNC pulses). Set this register to the desired vertical resolution. For interlaced modes; set this register to the number of lines per field; which is half the overall vertical resolution. Note that this 11-bit value includes eight bits from register DE_LINL (see Section 13.3.2.30). The valid range is 1-2047. 0 is invalid.

13.3.2.32 Video H Resolution Register (HRES_L)

The video H resolution register is shown in [Figure 13-54](#) and described in [Table 13-63](#).

Figure 13-54. Video H Resolution Register (HRES_L)

LEGEND: R = Read only; -n = value after reset

Table 13-63. Video H Resolution Register (HRES_L) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	H_RES	Measures the time between two HSYNC active edges. The unit of measure is pixels. Note that this 13-bit value includes five bits from register HRES_H (see Section 13.3.2.33).

13.3.2.33 Video H Resolution Register (HRES_H)

The video H resolution register is shown in [Figure 13-55](#) and described in [Table 13-64](#).

Figure 13-55. Video H Resolution Register (HRES_H)

LEGEND: R = Read only; -n = value after reset

Table 13-64. Video H Resolution Register (HRES_H) Field Descriptions

Bit	Field	Description
31-5	Reserved	Reserved
4-0	H_RES	Measures the time between two HSYNC active edges. The unit of measure is pixels. Note that this 13-bit value includes eight bits from register HRES_L (see Section 13.3.2.32).

13.3.2.34 Video V Resolution Register (VRES_L)

The video V resolution register is shown in [Figure 13-56](#) and described in [Table 13-65](#).

Figure 13-56. Video V Resolution Register (VRES_L)

LEGEND: R = Read only; -n = value after reset

Table 13-65. Video V Resolution Low Register (VRES_L) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	V_RES	Measures the time between two VSYNC active edges. The unit of measure is lines. Note that this 11-bit value includes three bits from register VRES_H (see Section 13.3.2.35).

13.3.2.35 Video V Resolution Register (VRES_H)

The video V resolution register is shown in [Figure 13-57](#) and described in [Table 13-66](#).

Figure 13-57. Video V Resolution Register (VRES_H)

LEGEND: R = Read only; -n = value after reset

Table 13-66. Video V Resolution Register (VRES_H) Field Descriptions

Bit	Field	Description
31-3	Reserved	Reserved
2-0	V_RES	Measures the time between two VSYNC active edges. The unit of measure is lines. Note that this 11-bit value includes eight bits from register VRES_L (see Section 13.3.2.34).

13.3.2.36 Video Interlace Adjustment Register (IADJUST)

The video interlace adjustment register is shown in [Figure 13-58](#) and described in [Table 13-67](#).

Figure 13-58. Video Interlace Adjustment Register (IADJUST)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-67. Video Interlace Adjustment Register (IADJUST) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2	DE_ADJ	0 1	Setting this bit HIGH disables VSYNC adjustments and sets the DE generator to be more compatible with the existing transmitters. Clearing this bit enables detection circuits to locate the position of VSYNC relative to HSYNC and only include HSYNC edges that are greater than 3/4 lines from VSYNC in the line count for DE_TOP. Enable VSYNC detection when not using DE generator. 0 Enable VSYNC 1 Disable VSYNC.
1	F2VADJ	0 1	VBIT_TO_VSYNC value (in register VBIT_TO_VSYNC) adjust enable 0 The VBIT_TO_VSYNC value is not adjusted. 1 The VBIT_TO_VSYNC value is adjusted during field 2 of an interlace frame according to the setting of the F2VOFST bit.
0	F2VOFST	0 1	VBIT_TO_VSYNC value (in register VBIT_TO_VSYNC) offset 0 If F2VADJ is set, VBIT_TO_VSYNC is decremented by one during field 2 of an interlace frame. 1 If F2VADJ is set, VBIT_TO_VSYNC is incremented by one during field 2 of an interlace frame.

13.3.2.37 Video SYNC Polarity Detection Register (POL_DETECT)

The video SYNCH polarity detection register is shown in [Figure 13-59](#) and described in [Table 13-68](#).

Figure 13-59. Video SYNC Polarity Detection Register (POL_DETECT)

LEGEND: R = Read only; -n = value after reset

Table 13-68. Video SYNC Polarity Detection Register (POL_DETECT) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2	I_DET	0	Non-interlaced video
		1	Interlaced video. This bit is set by checking for a varying VSYNC timing characteristic of interlaced modes.
1	VPOL_DET	0	Detected input VSYNC polarity using internal circuit Active high (leading edge rises)
		1	Active low (leading edge falls)
0	HPOL_DET	0	Detected input HSYNC polarity using internal circuit Active high (leading edge rises)
		1	Active low (leading edge falls)

13.3.2.38 Video Hbit to HSYNC Register (HBIT_2HSYNC1)

The video Hbit to HSYNC register is shown in [Figure 13-60](#) and described in [Table 13-69](#).

Figure 13-60. Video Hbit to HSYNC Register (HBIT_2HSYNC1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-69. Video Hbit to HSYNC Register (HBIT_2HSYNC1) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	HBIT_TO_HSYNC	Creates HSYNC pulses. Set this register to the delay from the detection of an EAV sequence (H bit change from 1 to 0) to the active edge of HSYNC. The unit of measure is pixels. Note that this 10-bit value includes two bits from register HBIT_2HSYNC2 (see Section 13.3.2.39). The valid range is 1-1023. 0 is invalid.

13.3.2.39 Video Hbit to HSYNC Register (HBIT_2HSYNC2)

The video Hbit to HSYNC register is shown in [Figure 13-61](#) and described in [Table 13-70](#).

Figure 13-61. Video Hbit to HSYNC Register (HBIT_2HSYNC2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-70. Video Hbit to HSYNC Register (HBIT_2HSYNC2) Field Descriptions

Bit	Field	Description
31-2	Reserved	Reserved
1-0	HBIT_TO_HSYNC	Creates HSYNC pulses. Set this register to the delay from the detection of an EAV sequence (H bit change from 1 to 0) to the active edge of HSYNC. The unit of measure is pixels. Note that this 10-bit value includes eight bits from register HBIT_2HSYNC1 (see Section 13.3.2.38). The valid range is 1-1023. 0 is invalid.

13.3.2.40 Video Field2 HSYNC Offset Register (FLD2_HS_OFSTL)

The video field2 HSYNC offset register is shown in [Figure 13-62](#) and described in [Table 13-71](#).

Figure 13-62. Video Field2 HSYNC Offset Register (FLD2_HS_OFSTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-71. Video Field2 HSYNC Offset Register (FLD2_HS_OFSTL) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	FIELD2_OFST	Determines VSYNC pixel offset for the odd field of an interlaced source. Set this to half the number of pixels/line. Note that this 12-bit value includes four bits from register FLD2_HS_OFSTH (see Section 13.3.2.41). The valid range is 1-4095. 0 is invalid.

13.3.2.41 Video Field2 HSYNC Offset Register (FLD2_HS_OFSTH)

Figure 13-63. Video Field2 HSYNC Offset Register (FLD2_HS_OFSTH)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

The video field2 HSYNC offset register is shown in [Figure 13-63](#) and described in [Table 13-72](#).

Table 13-72. Video Field2 HSYNC Offset Register (FLD2_HS_OFSTH) Field Descriptions

Bit	Field	Description
31-4	Reserved	Reserved
3-0	FIELD2_OFST	Determines VSYNC pixel offset for the odd field of an interlaced source. Set this to half the number of pixels/line. Note that this 12-bit value includes eight bits from register FLD2_HS_OFSTL (see Section 13.3.2.40). The valid range is 1-4095. 0 is invalid.

13.3.2.42 Video HSYNC Length Register (HWIDTH1)

The video HSYNC length register is shown in [Figure 13-64](#) and described in [Table 13-73](#).

Figure 13-64. Video HSYNC Length Register (HWIDTH1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-73. Video HSYNC Length Register (HWIDTH1) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	HWIDTH	Sets the width of the HSYNC pulses. Set this register to the desired HSYNC pulse width. The unit of measure is pixels. Note that this 10-bit value includes two bits from register HWIDTH2 (see Section 13.3.2.43). The valid range is 1-1023. 0 is invalid.

13.3.2.43 Video HSYNC Length Register (HWIDTH2)

The video HSYNC length register is shown in [Figure 13-65](#) and described in [Table 13-74](#).

Figure 13-65. Video HSYNC Length Register (HWIDTH2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-74. Video HSYNC Length Register (HWIDTH2) Field Descriptions

Bit	Field	Description
31-2	Reserved	Reserved
1-0	HWIDTH	Sets the width of the HSYNC pulses. Set this register to the desired HSYNC pulse width. The unit of measure is pixels. Note that this 10-bit value includes eight bits from register HWIDTH1 (see Section 13.3.2.42). The valid range is 1-1023. 0 is invalid.

13.3.2.44 Video Vbit to VSYNC Register (VBIT_TO_VSYNC)

The video Vbit to VSYNC register is shown in [Figure 13-66](#) and described in [Table 13-75](#).

Figure 13-66. Video Vbit to VSYNC Register (VBIT_TO_VSYNC)

31	6	5	0
Reserved		VBIT_TO_VSYNC	
R-0h		R/W-0h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-75. Video Vbit to VSYNC Register (VBIT_TO_VSYNC) Field Descriptions

Bit	Field	Description
31-6	Reserved	Reserved
5-0	VBIT_TO_VSYNC	Sets the delay from the detection of V bit changing from 1 to 0 in an EAV sequence; to the asserting edge of VSYNC. The unit of measure is lines. The valid range is 1-63. 0 is invalid.

13.3.2.45 Video VSYNC Length Register (VWIDTH)

The video VSYNC length register is shown in [Figure 13-67](#) and described in [Table 13-76](#).

Figure 13-67. Video VSYNC Length Register (VWIDTH)

31	6	5	0
Reserved		VWIDTH	
R-0h		R/W-0h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-76. Video VSYNC Length Register (VWIDTH) Field Descriptions

Bit	Field	Description
31-6	Reserved	Reserved
5-0	VWIDTH	Sets the width of VSYNC pulse. The unit of measure is lines. The valid range is 1-63. 0 is invalid.

13.3.2.46 Video Control Register (VID_CTRL)

The video control register is shown in [Figure 13-68](#) and described in [Table 13-77](#).

Figure 13-68. Video Control Register (VID_CTRL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-77. Video Control Register (VID_CTRL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	IFPOL	0 1	Invert field polarity. This bit is used when the 656 Flag bit is opposite the standard polarity for Field1 and Field2. Inverting the field polarity causes the sync extraction to format HSYNC and VSYNC properly based on the F bit. In embedded sync mode, the HDMI Transmitter does not detect even from odd field, except based on the setting of the F bit. With explicit syncs, the HDMI transmitter encodes HSYNC and VSYNC across the HDMI/TMDS link regardless of field sequence. Do not invert field bit Invert field bit
6	Reserved	0	Reserved
5	EXTN	0 1	Extended bit mode 0 All 8-bit input modes 1 All 12-bit 4:2:2 input modes. For 4:2:2 inputs wider than 8 bits but less than 12 bits; the unused bits should be cleared to 0.
4	CSCSEL	0 1	Color space conversion standard select 0 BT.601 conversion 1 BT.709 conversion
3-2	Reserved	0	Reserved
1-0	ICLK	0 1h 2h 3h	Clock mode If the DEMUX bit in the VID_MODE register is cleared to 0, set the ICLK bit and the pixel replication field of the AVI v2 data byte 5 to the same value. If the DEMUX bit in the VID_MODE register is set to 1, set the pixel replication field of the AVI v2 data byte 5 to the next higher pixel replication rate. For example, if DEMUX = 1 and ICLK = 1, set the pixel replication field of AVI v2 data byte 5 to 3h. 0 Pixel data is not replicated 1h Pixels are replicated once (each sent twice) 2h Reserved 3h Pixels are replicated 4 times (each sent four times)

13.3.2.47 Video Action Enable Register (VID_ACEN)

The video action enable register is shown in [Figure 13-69](#) and described in [Table 13-78](#).

Figure 13-69. Video Action Enable Register (VID_ACEN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-78. Video Action Enable Register (VID_ACEN) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-6	WIDE_BUS	0 1h 2h 3h	Identifies the number of bits per input video channel 8 bits per channel or 24-bit bus mode 10 bits per channel or 30-bit bus mode 12 bits per channel or 36-bit bus mode Reserved
5	Reserved	0	Reserved
4	CLIP_CS_ID	0 1	Identifies the output color space on the link - used by the Clipper block to determine which way to clip Output color space is RGB 1 Output color space is YCbCr
3	RANGE_CLIP	0 1	Enable range clip from 16 to 235 (RGB and Y)/ 240 (CbCr) Disable Enable
2	RGB_2_YCBCR	0 1	Enable RGB to YCbCr color-space converter Disable Enable
1	RANGE_CMPS	0 1	Enable range compress 0-255 to 16-234 Disable Enable
0	DOWN_SMPL	0 1	Enable down sampler 4:4:4 to 4:2:2 Disable Enable

13.3.2.48 Video Mode1 Register (VID_MODE)

The video mode1 register is shown in [Figure 13-70](#) and described in [Table 13-79](#).

Figure 13-70. Video Mode1 Register (VID_MODE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-79. Video Mode1 Register (VID_MODE) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-6	DITHER_MODE	0 1h 2h 3h	Identifies the number of bits per output video channel Dither to 8 bits Dither to 10 bits Dither to 12 bits Reserved
5	DITHER	0 1	Dither enable 0 Dither disabled; the video output is truncated to the output width specified in the DITHER_MODE bit. 1 Dither enabled; the video output is dithered to the output width specified in the DITHER_MODE bit.
4	RANGE	0 1	Data range 16–235 to 0–255 expansion When this bit is set, the HDMI transmitter expands the range of pixel data values from 16-235 into the full 8-bit range of 0-255. This is suitable for translating input YCbCr data into output RGB data in PC modes that use the complete range. The HDMI Specification allows one non-CEA-861D mode in the first and only 18-byte descriptor of the Sink's EDID 1.3. This is the native resolution of the Sink, which may be RGB. It may be a standard PC resolution (XGA, SXGA, WXGA, and so on), or a specific native resolution. In these cases (or for a Sink with the Type B HDMI connector, which allows multiple PC modes), when the HDMI transmitter receives YCbCr data, the data must be expanded to full range for outputting RGB full-range modes.
3	CSC	0 1	YcbCr to RGB color space conversion 0 Disable 1 Enable
2	UPSMP	0 1	Upsampling 4:2:2 to 4:4:4 0 Disable 1 Enable
1	DEMUX	0 1	One- to two-data-channel demux 0 Disable 1 Enable
0	SYNCEX	0 1	Embedded sync extraction 0 Disable 1 Enable

13.3.2.49 Video Blanking Register (VID_BLANK1)

The video blanking register is shown in [Figure 13-71](#) and described in [Table 13-80](#).

Figure 13-71. Video Blanking Register (VID_BLANK1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

LEGEND: R = Read only; -n = value after reset

Table 13-111. Interrupt Source Register (INTR1) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7	SOFT	Software Induced Interrupt. Allows the firmware to generate an interrupt directly.
6	HPD	Monitor detect interrupt. Asserted if hot plug detect has changed state. The HDMI transmitter signals a change in the connectivity to a Sink, either unplug or plug. HDMI specifies that hot plug be active only when the Sink s EDID is ready to be read and that hot plug be toggled any time there is a change in connectivity downstream of an attached repeater.
5	RSEN	Receiver sense interrupt asserted if RSEN has changed. This interrupt is set whenever V _{CC} is applied to or removed from the attached HDMI receiver chip. A receiver with multiple input ports can also disconnect the TMDS termination to the unused port, which triggers this RSEN interrupt.
4	DROP_SAMPLE	New preamble forced to drop sample (S/PDIF input only). If the HDMI transmitter detects an 8-bit preamble in the S/PDIF input stream before the subframe has been captured, this interrupt is set. A S/PDIF input that stops signaling or a flat line condition can create such a premature preamble.
3	BIP_HASE_ERR	Input S/PDIF stream has bi-phase error. This can occur when there is noise or an Fs rate change on the S/PDIF input.
2	RI_128	Input counted past frame count threshold set in RI_128_COMP register. This interrupt occurs when the count written to register RI_128_COMP is matched by the VSYNC (frame) counter in the HDMI transmitter. It should trigger the firmware to perform a link integrity check. Such a match occurs every 128 frames.
1	OVER_RUN	Audio FIFO overflow. This interrupt occurs if the audio FIFO overflows when more samples are written into it than are drawn out across the HDMI link. Such a condition can occur from a transient change in the Fs or pixel clock rate.
0	UNDER_RUN	Audio FIFO underflow. Similar to OVER_RUN, this interrupt occurs when the audio FIFO empties.

13.3.2.81 Interrupt Source Register (INTR2)

The interrupt source register is shown in [Figure 13-103](#) and described in [Table 13-112](#).

Figure 13-103. Interrupt Source Register (INTR2)

LEGEND: R = Read only; -n = value after reset; x = value is indeterminate

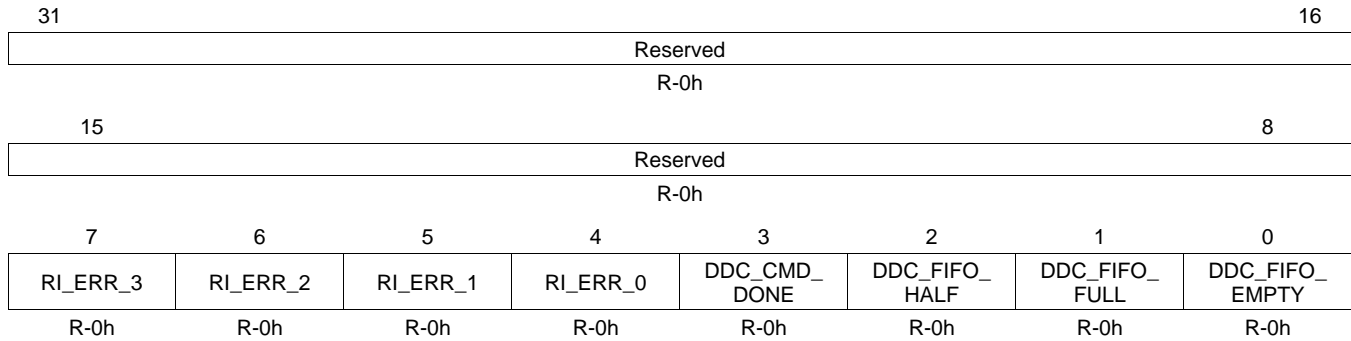

Table 13-112. Interrupt Source Register (INTR2) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7	BCAP_DONE	If set, this interrupt detected that the FIFORDY bit is set to 1.
6	SPDIF_PAR	S/PDIF parity error. The S/PDIF stream includes a parity (P) bit at the end of each sub-frame. An interrupt occurs if the calculated parity does not match the state of this bit.
5	ENC_DIS	The ENC_EN bit (in register HDCP_CTRL) changed from 1 to 0. This interrupt occurs if encryption is turned off.
4	PREAM_ERR	This condition is the opposite of the condition that causes DROP_SAMPLE (in register INTR1). This interrupt occurs if a preamble is expected but not found when decoding the S/PDIF stream.
3	CTS_CHG	Change in ACR CTS value. This interrupt occurs when the change is of an unexpected magnitude. Such an interrupt should be expected when changing Fs or pixel clock frequency.
2	ACR_OVR	ACR packet overwrite. This interrupt occurs if the HDMI transmitter puts a NCTS packet into the queue before the previous NCTS packet has been sent. This can happen if very long active data times do not allow for sufficient NCTS packet bandwidth. For all CEA- 861D modes, no ACR_OVR interrupt should occur.
1	TCLK_STBL	Whenever IDCK changes, there is a temporary instability in the internal clocking. This interrupt is set when the internal clocking has stabilized.
0	VSYNC_REC	Asserted when VSYNC active edge is recognized. It is useful for triggering firmware actions that occur during vertical blanking.

13.3.2.82 Interrupt Source Register (INTR3)

The interrupt source register is shown in [Figure 13-104](#) and described in [Table 13-113](#).

Figure 13-104. Interrupt Source Register (INTR3)

LEGEND: R = Read only; -n = value after reset

Table 13-113. Interrupt Source Register (INTR3) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7	RI_ERR_3	Ri and Ri do not match during frame 127 (ICNT .1).
6	RI_ERR_2	Ri and Ri do not match during frame 0 (ICNT).
5	RI_ERR_1	Ri did not change between frame 127 and 0.
4	RI_ERR_0	Ri not read within one frame.
3	DDC_CMD_DONE	DDC command is complete.
2	DDC_FIFO_HALF	DDC FIFO is half full.
1	DDC_FIFO_FULL	DDC FIFO is full.
0	DDC_FIFO_EMPTY	DDC FIFO is empty. Reset value is 0, but can be set after reset since the FIFO is empty.

13.3.2.83 Interrupt Source Register (INTR4)

The interrupt source register is shown in [Figure 13-105](#) and described in [Table 13-114](#).

Figure 13-105. Interrupt Source Register (INTR4)

5	ENC_DIS	The ENC_EN bit (in register HDCP_CTRL) changed from 1 to 0. This interrupt occurs if encryption is turned off.
4	PREAM_ERR	This condition is the opposite of the condition that causes DROP_SAMPLE (in register INTR1). This interrupt occurs if a preamble is expected but not found when decoding the S/PDIF stream.
3	CTS_CHG	Change in ACR CTS value. This interrupt occurs when the change is of an unexpected magnitude. Such an interrupt should be expected when changing Fs or pixel clock frequency.
2	ACR_OVR	ACR packet overwrite. This interrupt occurs if the HDMI transmitter puts a NCTS packet into the queue before the previous NCTS packet has been sent. This can happen if very long active data times do not allow for sufficient NCTS packet bandwidth. For all CEA- 861D modes, no ACR_OVR interrupt should occur.
1	TCLK_STBL	TCLK_STABLE. Whenever IDCK changes, there is a temporary instability in the internal clocking. This interrupt is set when the internal clocking has stabilized.
0	VSYNC_REC	Asserted when VSYNC active edge is recognized, it is useful for triggering firmware actions that occur during vertical blanking.

13.3.2.86 Interrupt Unmask Register (INT_UNMASK3)

The interrupt unmask register is shown in [Figure 13-108](#) and described in [Table 13-117](#).

Figure 13-108. Interrupt Unmask Register (INT_UNMASK3)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

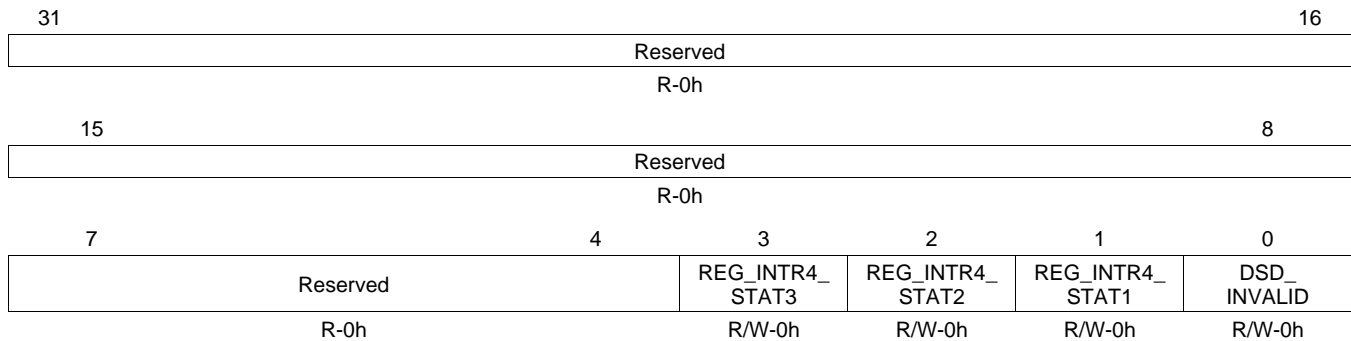

Table 13-117. Interrupt Unmask Register (INT_UNMASK3) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7	RI_ERR_3	Ri and Ri do not match during frame 127 (ICNT .1).
6	RI_ERR_2	Ri and Ri do not match during frame 0 (ICNT).
5	RI_ERR_1	Ri did not change between frame 127 and 0.
4	RI_ERR_0	Ri not read within one frame.
3	DDC_CMD_DONE	DDC command is complete.
2	DDC_FIFO_HALF	DDC FIFO is half full.
1	DDC_FIFO_FULL	DDC FIFO is full.
0	DDC_FIFO_EMPTY	DDC FIFO is empty. Reset value is 0, but can be set after reset since the FIFO is empty.

13.3.2.87 Interrupt Unmask Register (INT_UNMASK4)

The interrupt unmask register is shown in [Figure 13-109](#) and described in [Table 13-118](#).

Figure 13-109. Interrupt Unmask Register (INT_UNMASK4)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-118. Interrupt Unmask Register (INT_UNMASK4) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	REG_INTR4_STAT3	0 1	CEC interrupt No interrupt occurred Interrupt asserted
2	REG_INTR4_STAT2	0 1	For each interrupt bit: No interrupt occurred Interrupt asserted
1	REG_INTR4_STAT1	0 1	For each interrupt bit: No interrupt occurred Interrupt asserted
0	DSD_INVALID	0	DSD stream got invalid sequence: more than 24 bits of the same value. Asserted if set to 1.

13.3.2.88 Interrupt Control Register (INT_CTRL)

The interrupt control register is shown in [Figure 13-110](#) and described in [Table 13-119](#).

Figure 13-110. Interrupt Control Register (INT_CTRL)

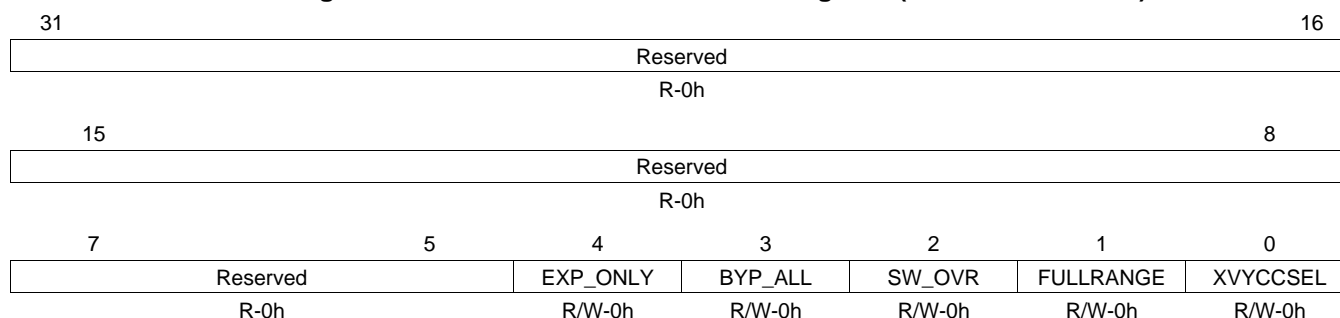

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-119. Interrupt Control Register (INT_CTRL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	SOFT_INTR		Set software interrupt
		0	Clear interrupt
		1	Set interrupt
2	OPEN_DRAIN		INT pin output type
		0	Push/Pull
		1	Open Drain pin
1	POLARITY		INT pin assertion level
		0	Assert HIGH
		1	Assert LOW
0	Reserved	0	Reserved

13.3.2.89 xvYCC_2_RGB Control Register (XVYCC2RGB_CTL)

The xvYCC_2_RGB control register is shown in [Figure 13-111](#) and described in [Table 13-120](#).

Figure 13-111. xvYCC_2_RGB Control Register (XVYCC2RGB_CTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-120. xvYCC_2_RGB Control Register (XVYCC2RGB_CTL) Field Descriptions

Bit	Field	Description
31-5	Reserved	Reserved
4	EXP_ONLY	When set to 1, indicates the internal CSC will be bypassed and only range expansion is on.
3	BYP_ALL	When set to 1, indicates all the functions will be bypassed.
2	SW_OVR	Software over ride. When turned on, all coefficients and offsets are coming from registers not internal hardware decision.
1	FULLRANGE	xvYCC full-range expansion enable
0	XVYCCSEL	Indicates the source. When set to 1, is xvYCC; when cleared to 0, is YcbCr. It can be configured by firmware. Under auto video configure (AVC) mode, this control comes from HDMI packet decoding.

13.3.2.90 xvYCC_2_RGB Conversion Y_2_R Register (Y2R_COEFF_LOW)

The xvYCC_2_RGB conversion Y_2_R register is shown in [Figure 13-112](#) and described in [Table 13-121](#).

Figure 13-112. xvYCC_2_RGB Conversion Y_2_R Register (Y2R_COEFF_LOW)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-121. xvYCC_2_RGB Conversion Y_2_R Register (Y2R_COEFF_LOW) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	Y2RCOEFF_L	xvYCC to RGB conversion. Y to R coefficient lower byte (override internal CSC value when SW_OVR = 1 in register XvYCC2RGB_CTL)

13.3.2.91 xvYCC_2_RGB Conversion Y_2_R Register (Y2R_COEFF_UP)

The xvYCC_2_RGB conversion Y_2_R register is shown in [Figure 13-113](#) and described in [Table 13-122](#).

Figure 13-113. xvYCC_2_RGB Conversion Y_2_R Register (Y2R_COEFF_UP)

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	DDC_FLT_EN	0 1	Enable the DCC delay. A DDC delay is inserted into the SDA line to create a 300 ns delay for the falling edge of the DDC SDA signal to avoid an erroneous I2C START condition. The real start condition must have a setup time of 600 ns so that this delay of 300 ns does not remove the real START condition. Filtering is done using a ring oscillator. 0 Enable 1 Disable
4	SDA_DEL_EN	0 1	Enable 3 ns glitch filtering on the DDC clock and data line. Filtering is done using a ring oscillator. 0 Enable 1 Disable
3-0	DDC_CMD	0 2h 4h 6h 7h 9h Ah Fh	DDC command Writing to this register immediately initiates the I2C transaction on the DDC bus. Note: The clear FIFO command resets the FIFO read and write pointers to zero. Data formerly loaded into the FIFO cannot be re-read after a clear FIFO, as the FIFO will be empty. Other command codes are reserved and may cause the DDC bus to hang if used. The clock SCL command resets any I2C devices on the DDC lines. This should be initiated once before initiating the DDC commands. 0 Current address read with no ACK on last byte 2h Sequential read with no ACK on last byte 4h Enhanced DDC read with no ACK on last byte 6h Sequential write ignoring ACK on last byte 7h Sequential write requiring ACK on last byte 9h Clear FIFO Ah Clock SCL Fh Abort transaction All other values are reserved.

13.3.2.117 DDC I2C Data Register (DDC_DATA)

The DDC I2C data register is shown in [Figure 13-139](#) and described in [Table 13-148](#).

Figure 13-139. DDC I2C Data Register (DDC_DATA)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-148. DDC I2C Data Register (DDC_DATA) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	DDC_DATA	DDC data input

13.3.2.118 DDC I2C FIFO Count Register (DDC_FIFOCNT)

The DDC I2C FIFO count register is shown in [Figure 13-140](#) and described in [Table 13-149](#).

Figure 13-140. DDC I2C FIFO Count Register (DDC_FIFOCNT)

LEGEND: R = Read only; -n = value after reset

Table 13-149. DDC I2C FIFO Count Register (DDC_FIFOCNT) Field Descriptions

Bit	Field	Description
31-5	Reserved	Reserved
4-0	DDC_FIFOCNT	FIFO data byte count (the number of bytes in the FIFO). The DDC FIFO size is 16. The maximum value for DDC_FIFOCNT is 10h.

13.3.2.119 ROM Status Register (EPST)

The ROM status register is shown in [Figure 13-141](#) and described in [Table 13-150](#).

Figure 13-141. ROM Status Register (EPST)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

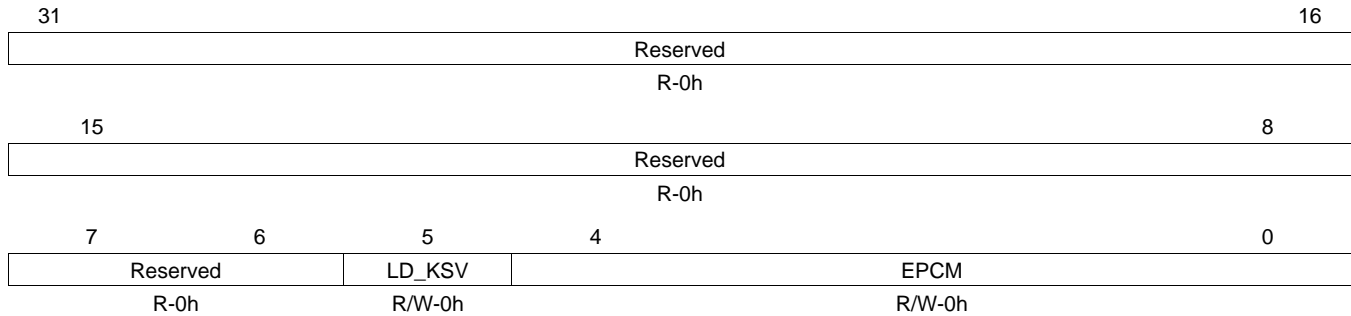

Table 13-150. ROM Status Register (EPST) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	BIST2_ERR	0	BIST self-authentication test 2 error No error
		1	BIST self-authentication test 2 error
5	BIST1_ERR	0	BIST self-authentication test 1 error No error
		1	BIST self-authentication test 1 error
4-2	Reserved	0	Reserved
1	CRC_ERR	0	CRC error No error
		1	CRC error
0	CMDD	0	Command done After reset. Set to 1 once the KSV keys are read (when osclk is running).
		1	Command done (last operation completed successfully).

13.3.2.120 ROM Command Register (EPCM)

The ROM command register is shown in [Figure 13-142](#) and described in [Table 13-151](#).

Figure 13-142. ROM Command Register (EPCM)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-151. ROM Command Register (EPCM) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	LD_KSV	0	Load KSV enable Write 0 before enabling again
		1	Enable loading of KSV from OTP
4-0	EPCM	3h	Run all BIST tests
		4h	Run only CRC test
		8h	Run only BIST self authentication test 1 (16-bit CRC to verify OTP contents)
		10h	Run only BIST self authentication test 2 (2 pass authentication to verify the HDCP cipher engine)
			All other values are reserved.

13.3.3 HDMI IP Core Gamut Registers

Table 13-152 lists the HDMI IP core gamut registers.

Table 13-152. HDMI IP Core Gamut Registers

Address Offset	Acronym	Register Name
00h	GAMUT_HEADER1	Gamut Metadata Register
04h	GAMUT_HEADER2	Gamut Metadata Register
08h	GAMUT_HEADER3	Gamut Metadata Register
0Ch-78h	GAMUT_DBYTE__0 - GAMUT_DBYTE__27	Gamut Metadata Registers

13.3.3.1 Gamut Metadata Register (GAMUT_HEADER1)

The gamut metadata register is shown in Figure 13-143 and described in Table 13-153.

Figure 13-143. Gamut Metadata Register (GAMUT_HEADER1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-153. Gamut Metadata Register (GAMUT_HEADER1) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	HEADER1	Gamut metadata header information

13.3.3.2 Gamut Metadata Register (GAMUT_HEADER2)

The gamut metadata register is shown in [Figure 13-144](#) and described in [Table 13-154](#).

Figure 13-144. Gamut Metadata Register (GAMUT_HEADER2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-154. Gamut Metadata Register (GAMUT_HEADER2) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	NEXT_FIELD	0	Indicates that the GBD will be effective on the next video field. NEXT_FIELD should be set even if the GBD is already effective (for example, Current = Affected)
6-4	GBD_PROFILE	0 1h 2h 3h	Transmission profile number. Values from 4h-7h are reserved. P0 P1 P2 P3
3-0	AFF_GAM_SEQ_NUM	0	Indicates which video fields are relevant for this metadata.

13.3.3.3 Gamut Metadata Register (GAMUT_HEADER3)

The gamut metadata register is shown in [Figure 13-145](#) and described in [Table 13-155](#).

Figure 13-145. Gamut Metadata Register (GAMUT_HEADER3)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-155. Gamut Metadata Register (GAMUT_HEADER3) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	NO_CRNT_GBD	0	Indicates no gamut metadata available for currently transmitted video. When set to 1, CUR_GAM_SEQ_NUM shall be ignored by the sink.
6	Reserved	0	Reserved
5-4	PACKET_SEQ	0	Indicates the position of current packet.
		0	Intermediate packet
		1h	First packet
		2h	Last packet
		3h	Only packet in sequence
3-0	CUR_GAM_SEQ_NUM	0	Indicates the gamut number of the currently transmitted video stream.

13.3.3.4 Gamut Metadata Registers (GAMUT_DBYTE__0-GAMUT_DBYTE__27)

The gamut metadata registers are shown in [Figure 13-146](#) and described in [Table 13-156](#).

Figure 13-146. Gamut Metadata Registers (GAMUT_DBYTE__0-GAMUT_DBYTE__27)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-156. Gamut Metadata Registers (GAMUT_DBYTE__0-GAMUT_DBYTE__27) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	GAM_MDATA	Gamut metadata data bytes

13.3.4 HDMI IP Core Audio Video Registers

Table 13-157 lists the HDMI IP core audio video registers.

Table 13-157. HDMI IP Core Audio Video Registers

Address Offset	Acronym	Register Name
04h	ACR_CTRL	ACR Control Register
08h	FREQ_SVAL	ACR Audio Frequency Register
0Ch	N_SVAL1	ACR N Software Value Register
10h	N_SVAL2	ACR N Software Value Register
14h	N_SVAL3	ACR N Software Value Register
18h	CTS_SVAL1	ACR CTS Software Value Register
1Ch	CTS_SVAL2	ACR CTS Software Value Register
20h	CTS_SVAL3	ACR CTS Software Value Register
24h	CTS_HVAL1	ACR CTS Hardware Value Register
28h	CTS_HVAL2	ACR CTS Hardware Value Register
2Ch	CTS_HVAL3	ACR CTS Hardware Value Register
50h	AUD_MODE	Audio In Mode Register
54h	SPDIF_CTRL	Audio In S/PDIF Control Register
60h	HW_SPDIF_FS	Audio In S/PDIF Extracted Fs and Length Register
64h	SWAP_I2S	Audio In I2S Channel Swap Register
6Ch	SPDIF_ERTH	Audio Error Threshold Register
70h	I2S_IN_MAP	Audio In I2S Data In Map Register
74h	I2S_IN_CTRL	Audio In I2S Control Register
78h	I2S_CHST0	Audio In I2S Channel Status Registers
7Ch	I2S_CHST1	Audio In I2S Channel Status Registers
80h	I2S_CHST2	Audio In I2S Channel Status Registers
84h	I2S_CHST4	Audio In I2S Channel Status Registers
88h	I2S_CHST5	Audio In I2S Channel Status Registers
8Ch	ASRC	Audio Sample Rate Conversion Register
90h	I2S_IN_LEN	Audio I2S Input Length Register
BCh	HDMI_CTRL	HDMI Control Register
C0h	AUDO_TXSTAT	Audio Path Status Register
CCh	AUD_PAR_BUSCLK_1	Audio Input Data Rate Adjustment Register
D0h	AUD_PAR_BUSCLK_2	Audio Input Data Rate Adjustment Register
D4h	AUD_PAR_BUSCLK_3	Audio Input Data Rate Adjustment Register
F0h	TEST_TXCTRL	Test Control Register
F4h	DPD	Diagnostic Power Down Register
F8h	PB_CTRL1	Packet Buffer Control 1 Register
FCh	PB_CTRL2	Packet Buffer Control 2 Register
100h	AVI_TYPE	Packet Registers
104h	AVI_VERS	Packet Registers
108h	AVI_LEN	Packet Registers
10Ch	AVI_CHSUM	Packet Registers
110h-148h	AVI_DBYTE_0 - AVI_DBYTE_14	Packet Registers
180h	SPD_TYPE	SPD InfoFrame Registers
184h	SPD_VERS	SPD InfoFrame Registers
188h	SPD_LEN	SPD InfoFrame Registers
18Ch	SPD_CHSUM	SPD InfoFrame Registers
190h-1F8h	SPD_DBYTE_0 - SPD_DBYTE_26	SPD InfoFrame Registers
200h	AUDIO_TYPE	Audio InfoFrame Registers

Table 13-157. HDMI IP Core Audio Video Registers (continued)

Address Offset	Acronym	Register Name
204h	AUDIO_VERS	Audio InfoFrame Registers
208h	AUDIO_LEN	Audio InfoFrame Registers
20Ch	AUDIO_CHSUM	Audio InfoFrame Registers
210h-234h	AUDIO_DBYTE_0 - AUDIO_DBYTE_9	Audio InfoFrame Registers
280h	MPEG_TYPE	MPEG InfoFrame Registers
284h	MPEG_VERS	MPEG InfoFrame Registers
288h	MPEG_LEN	MPEG InfoFrame Registers
28Ch	MPEG_CHSUM	MPEG InfoFrame Registers
290h-2F8h	MPEG_DBYTE_0 - MPEG_DBYTE_26	MPEG InfoFrame Registers
300h-378h	GEN_DBYTE_0 - GEN_DBYTE_30	Generic Packet Registers
37Ch	CP_BYTE1	General Control Packet Register
380h-3F8h	GEN2_DBYTE_0 - GEN2_DBYTE_30	Generic Packet 2 Registers
3FCh	CEC_ADDR_ID	CEC Slave ID Register

13.3.4.1 ACR Control Register (ACR_CTRL)

The ACR control register is shown in [Figure 13-147](#) and described in [Table 13-158](#).

Figure 13-147. ACR Control Register (ACR_CTRL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-158. ACR Control Register (ACR_CTRL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	NCTSPKT_EN		CTS request enable
		0	N/CTS packet is disabled
		1	N/CTS packet is enabled
0	CTS_SEL		CTS source select
		0	Send hardware-updated CTS value in N/CTS packet (recommended)
		1	Send software-updated CTS value in N/CTS packet (for diagnostic use)

13.3.4.2 ACR Audio Frequency Register (FREQ_SVAL)

The ACR audio frequency register is shown in [Figure 13-148](#) and described in [Table 13-159](#).

Figure 13-148. ACR Audio Frequency Register (FREQ_SVAL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-159. ACR Audio Frequency Register (FREQ_SVAL) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	MCLK_CONF	0	MCLK input mode. The HDMI transmitter uses these bits to divide the MCLK input to produce CTS values according to the $128 \times F_s$ formula. The MCLK to F_s ratio is for the input F_s , not the down-sampled output F_s (see Section 13.3.4.25).
		0	MCLK is $128 \times F_s$
		1h	MCLK is $256 \times F_s$
		2h	MCLK is $384 \times F_s$
		3h	MCLK is $512 \times F_s$
		4h	MCLK is $768 \times F_s$
		5h	MCLK is $1024 \times F_s$
		6h	MCLK is $1152 \times F_s$
		7h	MCLK is $192 \times F_s$

13.3.4.3 ACR N Software Value Register 1 (N_SVAL1)

The ACR N software value register is shown in [Figure 13-149](#) and described in [Table 13-160](#).

Figure 13-149. ACR N Software Value Register 1 (N_SVAL1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-160. ACR N Software Value Register 1 (N_SVAL1) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	N_SVAL	N value for audio clock regeneration method, a 20-bit value. This must be written to the registers to create the correct divisor for audio clock regeneration. Only values greater than 0 are valid. This register must be written after a hardware reset.

13.3.4.4 ACR N Software Value Register 2 (N_SVAL2)

The ACR N software value register is shown in [Figure 13-150](#) and described in [Table 13-161](#).

Figure 13-150. ACR N Software Value Register 2 (N_SVAL2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-161. ACR N Software Value Register 2 (N_SVAL2) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	N_SVAL	N value for audio clock regeneration method, a 20-bit value. This must be written to the registers to create the correct divisor for audio clock regeneration. Only values greater than 0 are valid. This register must be written after a hardware reset.

13.3.4.5 ACR N Software Value Register 3 (N_SVAL3)

Figure 13-151. ACR N Software Value Register 3 (N_SVAL3)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-162. ACR N Software Value Register 3 (N_SVAL3) Field Descriptions

Bit	Field	Description
31-4	Reserved	Reserved
3-0	N_SVAL	N Value for audio clock regeneration method; a 20-bit value. This must be written to the registers to create the correct divisor for audio clock regeneration. Only values greater than 0 are valid. This register must be written after a hardware reset.

13.3.4.6 ACR CTS Software Value Register 1 (CTS_SVAL1)

Figure 13-152. ACR CTS Software Value Register 1 (CTS_SVAL1)

31	Reserved	8 7	0
	R-0h		CTS_SVAL R/W-0h

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-163. ACR CTS Software Value Register 1 (CTS_SVAL1) Field Descriptions

Bit	Field	Description
31-8	Reserved	Reserved
7-0	CTS_SVAL	CTS Value for audio clock regeneration method; a 20-bit value. Diagnostic use and applied only when the CTS_SEL bit (in register ACR_CTRL) is set to 1.

13.3.4.7 ACR CTS Software Value Register 2 (CTS_SVAL2)

Figure 13-153. ACR CTS Software Value Register 2 (CTS_SVAL2)

Table 13-175. Audio In I2S Control Register (I2S_IN_CTRL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	HBRA_ON	0 1	High Bit Rate Audio On. All of the I2S control bits will apply to the control of the High Bit Rate Audio. Input stream is not high bit rate Input stream is high bit rate
6	SCK_EDGE	0 1	SCK sample edge Sample edge is falling; SD3-SD0 and WS source should change state on the rising edge of SCK Sample clock is rising; SD3-SD0 and WS source should change state on the falling edge of SCK
5	CBIT_ORDER	0	This bit should be set to 1 for High Bit Rate Audio.
4	VBIT	0 1	V bit value PCM Compressed
3	I2S_WS	0 1	WS polarity Left polarity when WS is LOW Left polarity when WS is HIGH
2	I2S_JUST	0 1	SD justify Data is left-justified Data is right-justified
1	I2S_DIR	0 1	SD direction MSB shifted first LSB shifted first
0	I2S_SHIFT	0 1	WS to SD first bit shift First bit shift (refer to the Philips Specification) No shift

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-4	FS_ORIG	0	Original Fs
3-1	I2S_LEN		Audio sample word length. Defined in bits with I2S_MAXLEN. When I2S_MAXLEN = 0 (20 bits):
		0	Reserved
		1h	16 bits
		2h	18 bits
		3h	Reserved
		4h	19 bits
		5h	20 bits
		6h	17 bits
		7h	Reserved
			When I2S_MAXLEN = 1 (24 bits):
		0	Reserved
		1h	20 bits
		2h	22 bits
		3h	Reserved
		4h	23 bits
		5h	24 bits
		6h	21 bits
		7h	Reserved
0	I2S_MAXLEN		Maximum audio sample word length.
		0	20 bits
		1	24 bits

13.3.4.25 Audio Sample Rate Conversion Register (ASRC)
Figure 13-171. Audio Sample Rate Conversion Register (ASRC)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-182. Audio Sample Rate Conversion Register (ASRC) Field Descriptions

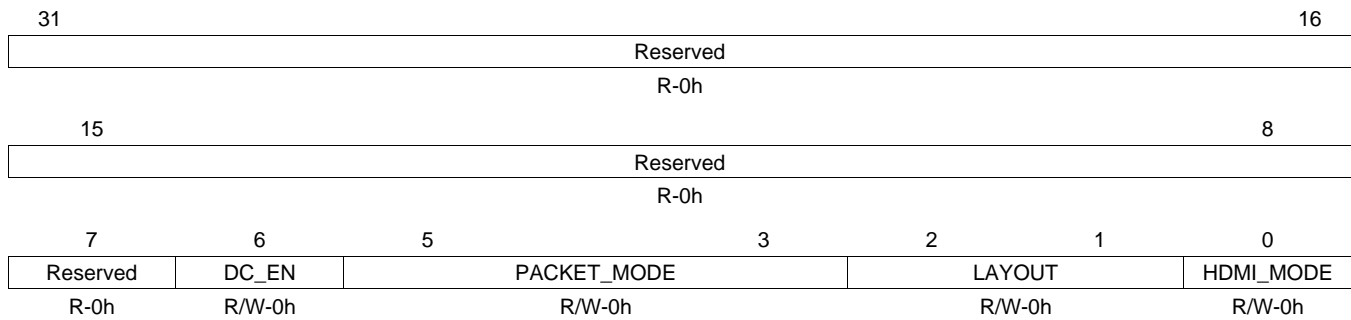

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-4	HBR_SPR_MASK	0	Mask for the sample present and flat bit of the High Bit Rate Audio header. Each bit masks out one of the subpacket sample present bits.
		0	Mask out
		1	Unmask bits 7-4 must be programmed to 0 when HBRA mode is selected
3-2	Reserved	0	Reserved
1	RATIO	0	Sample rate down-conversion ratio when the SRC_EN bit is set to 1.
		0	Down-sample is 2-to-1
		1	Down-sample is 4-to-1
0	SRC_EN	0	Audio sample rate conversion
		0	Disable
		1	Enable

13.3.4.26 Audio I2S Input Length Register (I2S_IN_LEN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-183. Audio I2S Input Length Register (I2S_IN_LEN) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-4	HDR_PKT_ID	9h	The ID of the High Bit Rate Audio packet header
3-0	IN_LENGTH		Number of valid bits in the input I2S stream. Used for the extraction of the I2S data from the input stream.
		0-1h	Reserved
		2h	16 bits
		3h	Reserved
		4h	18 bits
		5h	22 bits
		6h-7h	Reserved
		8h	19 bits
		9h	23 bits
		Ah	20 bits
		Bh	24 bits
		Ch	17 bits
		Dh	21 bits
		Eh-Fh	Reserved

13.3.4.27 HDMI Control Register (HDMI_CTRL)
Figure 13-173. HDMI Control Register (HDMI_CTRL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

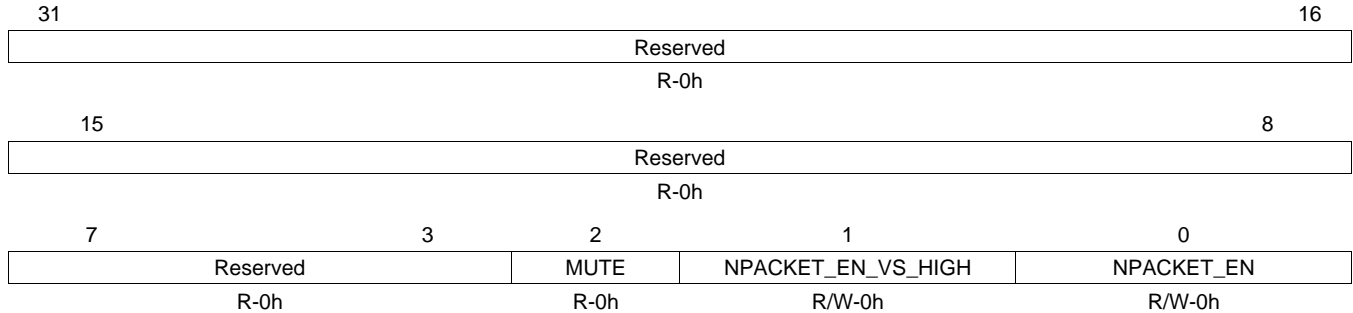

Table 13-184. HDMI Control Register (HDMI_CTRL) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	DC_EN	0 1	<p>Deep-color packet enable.</p> <p>The following data is sent in data byte 1 of the packet: 7 = Reserved, 6 = PP2, 5 = PP1, 4 = PP0, 3 = PP_valid, 2 = CD2, 1 = CD1, 0 = CD0. The CD bits indicate deep-color mode (defined in the same register bits 5:3). The PP bits indicate the fragment s phase related information that comes from the hardware state machine.</p> <p>0 Do not send deep-color related information in the packet to the HDMI Receiver.</p> <p>1 Send deep-color related information in the packet to the HDMI Receiver.</p>
5-3	PACKET_MODE	0-3h 4h 5h 6h 7h	<p>Specifies the number of bits per pixel sent to the paketizer. The firmware must program 24 bits per pixel (8 bits per pixel; no packing) for initialization.</p> <p>0-3h Reserved</p> <p>4h 24 bits per pixel (8 bits per pixel; no packing)</p> <p>5h 30 bits per pixel (10 bits per pixel pack to 8 bits)</p> <p>6h 36 bits per pixel (12 bits per pixel pack to 8 bits)</p> <p>7h 48 bits per pixel (16 bits per pixel; no packing)</p>
2-1	LAYOUT	0 1h 2h-3h	<p>Audio packet header layout indicator.</p> <p>0 Layout 0 (2-channel)</p> <p>1h Layout 1 (up to 8 channels)</p> <p>2h-3h Reserved</p>
0	HDMI_MODE	0 1	<p>HDMI Mode</p> <p>0 Disable</p> <p>1 Enable</p>

13.3.4.28 Audio Path Status Register (AUDIO_TXSTAT)

NOTE: MUTE is not set immediately when the SETAVM bit in register CP_BYTE1 is written. After writing SETAVM to 1, MUTE is set after the Control Packet is transmitted in HDMI mode. In DVI mode, MUTE is set at the start of VSYNC. MUTE is cleared when a Control Packet with CLRAVM = 1 is sent, or (in DVI mode) at the start of VSYNC after CLRAVM has been written to 1. Note that the combinations {SETAVM, CLRAVM} = {0,0} and {1,1} are not supported by HDMI. Such a packet is not compliant.

Figure 13-174. Audio Path Status Register (AUDIO_TXSTAT)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-185. Audio Path Status Register (AUDIO_TXSTAT) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2	MUTE	0	General Control Packet mute status
		0	No packet with SETAVM = 1 has been sent
		1	A packet with SETAVM = 1 has been sent
1	NPACKET_EN_VS_HIGH	0	Enables null packet flooding only when VSync is high.
0	NPACKET_EN	0	Enables null packet flooding all the time.

13.3.4.29 Audio Input Data Rate Adjustment Register 1 (AUD_PAR_BUSCLK_1)

Figure 13-175. Audio Input Data Rate Adjustment Register 1 (AUD_PAR_BUSCLK_1)

31-5	Reserved	Reserved
4	CLRAVM	Clear AV Mute flag
3-1	Reserved	Reserved
0	SETAVM	Set AV Mute flag. When the AVMUTE flag is set, the HDMI Transmitter sends a General Control Packet on the TMDS link to inform the Sink that the data may be incorrect. The HDMI Transmitter sends blanklevel data for all video packets and 00 for all audio packet data. When the AVMUTE flag is set, the Sink assumes that no valid data is being received. Optionally, the Sink can apply a mute function to the audio data and/or a blank function to the video data.

13.3.4.58 Generic Packet 2 Registers (GEN2_DBYTE_0-GEN2_DBYTE_30)

Figure 13-204. Generic Packet 2 Registers (GEN2_DBYTE_0-GEN2_DBYTE_30)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

ARM Interrupt Controller (AINTC)

This chapter discusses the ARM interrupt controller.

Topic	Page
14.1 Introduction	1897
14.2 Architecture	1900
14.3 Basic Programming Model	1903
14.4 Registers	1912

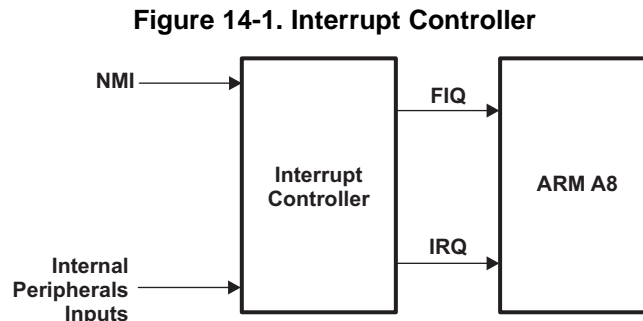

14.1 Introduction

14.1.1 Overview

The Host ARM Interrupt Controller (AINTC) is responsible for prioritizing all service requests from the system peripherals and generating either nIRQ or nFIQ to the host. The type of the interrupt (nIRQ or nFIQ) and the priority of the interrupt inputs are programmable. However, FIQ can only be used on secure devices, and is not available on GP devices. It has the capability to handle up to 128 requests which can be steered/prioritized as ARM Cortex-A8 nFIQ or nIRQ interrupt requests. The general features of the AINTC are:

- Up to 128 level sensitive interrupts inputs
- Individual priority for each interrupt input
- Each interrupt can be steered to nFIQ or nIRQ
- Independent priority sorting for nFIQ and nIRQ

Figure 14-1 shows the internal interrupt scheme.

14.1.2 Limitations

FIQ is only available on secure devices, and cannot be used on GP devices.

14.1.3 Functional Block Diagram

The interrupt controller processes incoming interrupts by masking and priority sorting to produce the interrupt signals for the processor to which it is attached. Figure 14-2 shows the top-level view of interrupt processing.

14.1.4 Environment

The sources of interrupt for AINTC are:

- External interrupts through NMI pin. Note that interrupts from external peripherals of SOC need to be routed through GPIO.
 - NMI is treated like other interrupts and can be masked. In general, software should configure the NMI input as the highest priority interrupt
- Interrupt from peripherals inside the SOC and ARM Cortex-A8.

All the unmasked interrupts can generate a wake up to the interrupt controller.

Figure 14-2. Interrupt Controller Block Diagram

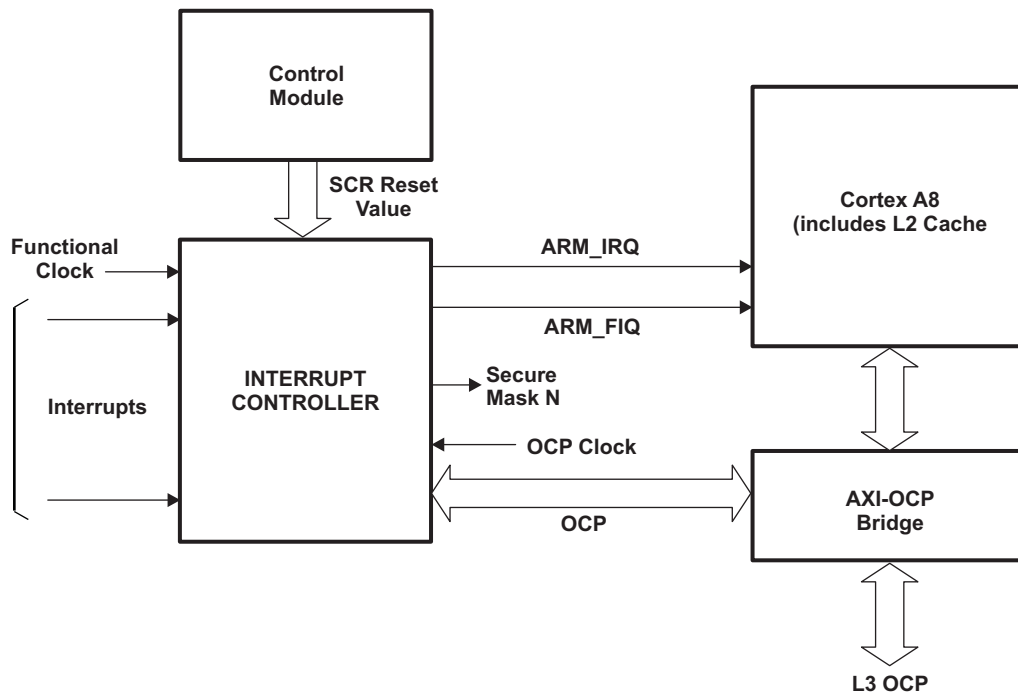

14.1.5 ARM A8—Interrupt Controller Integration

The interrupt controller (INTC) is the interface between the many incoming interrupts and the two interrupt inputs of the ARM Cortex-A8. The two interrupts inputs to ARM are FIQ and IRQ. Figure 14-3 shows the integration of the interrupt controller in the ARM Cortex-A8 subsystem.

The ARM Cortex-A8 subsystem INTC is directly connected to the ARM Cortex-A8 by an ARM peripheral port. Consequently, the ARM Cortex-A8 subsystem INTC is accessible and visible only by the ARM Cortex-A8.

Figure 14-3. ARM A8 Subsystem INTC Integration

14.2 Architecture

This section discusses the architecture of the interrupt controller.

14.2.1 Clocking and Reset

14.2.1.1 ARM A8 INTC Clocks

The interrupt controller runs at half the rate of the ARM Cortex-A8 functional clock. The interface clock, used for register access, runs at the rate of the interconnect bus clock (equal to the rate of the ARM Cortex-A8 interface clock).

14.2.1.2 Hardware and Software Reset

[Table 14-1](#) lists the ARM Cortex-A8 subsystem INTC resets.

Table 14-1. Interrupt Controller Resets

Type	Name	Source	Activation
Hardware	ARM Cortex-A8 top-level Reset	PRCM	Active low
Software	SOFTRESET	INTCPS_SYSCONFIG[1]SOFTRESET bit, write 1 to clear. Read returns 0.	Active high

14.2.2 Interrupt Request Lines

[Table 14-2](#) lists the incoming and outgoing interrupt lines of the ARM Cortex-A8 INTC.

For mapping of interrupt from various modules to the ARM Cortex-A8 INTC, refer to your device-specific data manual. Check availability of modules and features in a particular device. Ensure that interrupts of unavailable modules and features are masked in ARM Cortex-A8 subsystem.

Table 14-2. Interrupt Controller Interrupt Inputs and Outputs

Type	Number	Name	Mapping	Comment
Interrupt request inputs	Up to 128	Refer to data manual	Refer to data manual	Inputs to ARM Cortex-A8 INTC module, source from various modules.
Interrupt request outputs	2	INTC_FIQ INTC_IRQ	INTC_FIQ INTC_IRQ	FIQ is fast interrupt to ARM IRQ is normal input to ARM Cortex-A8

14.2.3 Interrupt Processing

14.2.3.1 Input Selection

The INTC supports only level-sensitive incoming interrupt detection. A peripheral asserting an interrupt maintains it until software has handled the interrupt and instructed the peripheral to deassert the interrupt. A software interrupt is generated if the corresponding bit in the INTCPS_ISR_SETn register is set (register bank number: n = [0,1,2,3] for the MPU subsystem INTC, 128 incoming interrupt lines are supported). The software interrupt clears when the corresponding bit in the INTCPS_ISR_CLEARn register is written. Typical use of this feature is software debugging.

14.2.3.2 Masking

14.2.3.2.1 Individual Masking

Detection of interrupts on each incoming interrupt line can be enabled or disabled independently by the INTCPS_MIRn interrupt mask register. In response to an unmasked incoming interrupt, the INTC can generate one of two types of interrupt requests to the processor:

- IRQ: normal interrupt request
- FIQ: fast interrupt request

The type of interrupt request is determined by the INTCPS_ILRm[0] FIQNIRQ bit (m= [0,127]). The current incoming interrupt status before masking is readable from the INTCPS_ITRn register. After masking and IRQ/FIQ selection, and before priority sorting is done, the interrupt status is readable from the INTCPS_PENDING_IRQn and INTCPS_PENDING_FIQn registers.

14.2.3.2.2 Priority Masking

To enable faster processing of high-priority interrupts, a programmable priority masking threshold is provided (the INTCPS_THRESHOLD[7:0] PRIORITYTHRESHOLD field). This priority threshold allows preemption by higher priority interrupts; all interrupts of lower or equal priority than the threshold are masked. However, priority 0 can never be masked by this threshold; a priority threshold of 0 is treated the same way as priority 1. PRIORITY and PRIORITYTHRESHOLD fields values can be set between 0 and 7Fh; 0 is the highest priority and 7Fh is the lowest priority. When priority masking is not necessary, a priority threshold value of FFh disables the priority threshold mechanism. This value is also the reset default for backward compatibility with previous versions of the INTC.

14.2.3.3 Priority Sorting

A priority level (0 being the highest) is assigned to each incoming interrupt line. Both the priority level and the interrupt request type are configured by the INTCPS_ILRm register. If more than one incoming interrupt with the same priority level and interrupt request type occur simultaneously, the highest-numbered interrupt is serviced first. When one or more unmasked incoming interrupts are detected, the INTC separates between IRQ and FIQ using the corresponding INTCPS_ILRm[0] FIQNIRQ bit. The result is placed in INTCPS_PENDING_IRQn or INTCPS_PENDING_FIQn. If no other interrupts are currently being processed, INTC asserts IRQ/FIQ and starts the priority computation. Priority sorting for IRQ and FIQ can execute in parallel. Each IRQ/FIQ priority sorter determines the highest priority interrupt number. Each priority number is placed in the corresponding INTCPS_SIR_IRQ[6:0] ACTIVEIRQ field or INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field. The value is preserved until the corresponding INTCPS_CONTROL NEWIRQAGR or NEWFIQAGR bit is set. Once the interrupting peripheral device has been serviced and the incoming interrupt deasserted, you must write to the appropriate NEWIRQAGR or NEWFIQAGR bit to indicate to the INTC the interrupt has been handled. If there are any pending unmasked incoming interrupts for this interrupt request type, the INTC restarts the appropriate priority sorter; otherwise, the IRQ or FIQ interrupt line is deasserted.

14.2.4 Module Power Saving

The INTC provides an auto-idle function in its three clock domains:

- Interface clock
- Functional clock
- Synchronizer clock

The interface clock auto-idle power-saving mode is enabled if the `INTCPS_SYSCONFIG[0] AUTOIDLE` bit is set to 1. When this mode is enabled and there is no activity on the bus interface, the interface clock is disabled internally to the module, thus reducing power consumption. When there is new activity on the bus interface, the interface clock restarts without any latency penalty. After reset, this mode is disabled, by default.

The functional clock auto-idle power-saving mode is enabled if the `INTCPS_IDLE[0] FUNCIDLE` bit is cleared to 0. When this mode is enabled and there is no active interrupt (IRQ or FIQ interrupt being processed or generated) or no pending incoming interrupt, the functional clock is disabled internally to the module, thus reducing power consumption. When a new unmasked incoming interrupt is detected, the functional clock restarts and the INTC processes the interrupt. If this mode is disabled, the interrupt latency is reduced by one cycle. After reset, this mode is enabled, by default.

The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked. The synchronizer input clock has an auto-idle power-saving mode enabled if the `INTCPS_IDLE[1] TURBO` bit is set to 1. If the auto-idle mode is enabled, the standby power is reduced, but the IRQ or FIQ interrupt latency increases from four to six functional clock cycles. This feature can be enabled dynamically according to the requirements of the device. After reset, this mode is disabled, by default.

14.2.5 Error Handling

The following accesses will cause error:

- Privilege violation (attempt to access PROTECTION register in user mode or any register in user mode if Protection bit is set).
- Unsupported commands.

The following will NOT cause any error response:

- Access to a non-decoded address.
- Write to a read-only register.

14.2.6 Interrupt Latency

The IRQ/FIQ interrupt generation takes four INTC functional clock cycles (plus or minus one cycle) if the `INTCPS_IDLE[1] TURBO` bit is cleared to 0. If the TURBO bit is set to 1, the interrupt generation takes six cycles, but power consumption is reduced while waiting for an interrupt. These latencies can be reduced by one cycle by disabling functional clock auto-idle (`INTCPS_IDLE[0] FUNCIDLE` bit set to 1), but power consumption is increased, so the benefit is minimal. To minimize interrupt latency when an unmasked interrupt occurs, the IRQ or FIQ interrupt is generated before priority sorting completion. The priority sorting takes 10 functional clock cycles, which is less than the minimum number of cycles required for the MPU to switch to the interrupt context after reception of the IRQ or FIQ event.

Any read of the `INTCPS_SIR_IRQ` or `INTCPS_SIR_FIQ` register during the priority sorting process stalls until priority sorting is complete and the relevant register is updated. However, the delay between the interrupt request being generated and the interrupt service routine being executed is such that priority sorting always completes before the `INTCPS_SIR_IRQ` or `INTCPS_SIR_FIQ` register is read.

14.3 Basic Programming Model

14.3.1 Initialization Sequence

1. Program the INTCPS_SYSCONFIG register: If necessary, enable the interface clock autogating by setting the AUTOIDLE bit.
2. Program the INTCPS_IDLE register: If necessary, disable functional clock autogating or enable synchronizer autogating by setting the FUNCIDLE bit or TURBO bit accordingly.
3. Program the INTCPS_ILRm register for each interrupt line: Assign a priority level and set the FIQNIRQ bit for an FIQ interrupt (by default, interrupts are mapped to IRQ and priority is 0 [highest]).
4. Program the INTCPS_MIRn register: Enable interrupts (by default, all interrupt lines are masked).
To program the INTCPS_MIRn register, the INTCPS_MIR_SETn and INTCPS_MIR_CLEARn registers are provided to facilitate the masking, even if it is possible for backward-compatibility to write directly to the INTCPS_MIRn register.

14.3.2 INTC Processing Sequence

After the INTCPS_MIRn and INTCPS_ILRm registers are configured to enable and assign priorities to incoming interrupts, the interrupt is processed as explained in the following subsections. IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in the code below.

1. One or more unmasked incoming interrupts (M_IRQ_n signals) are received and IRQ or FIQ outputs (IRQ/FIQ) are not currently asserted.
2. If the INTCPS_ILRm[0] FIQNIRQ bit is cleared to 0, the MPU_INTC_IRQ output signal is generated. If the FIQNIRQ bit is set to 1, the MPU_INTC_FIQ output signal is generated.
3. The INTC performs the priority sorting and updates the INTCPS_SIR_IRQ[6:0] ACTIVEIRQ /INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field with the current interrupt number.
4. During priority sorting, if the IRQ/FIQ is enabled at the host processor side, the host processor automatically saves the current context and executes the ISR as follows.

The ARM host processor automatically performs the following actions in pseudo code:

```

LR = PC + 4                /* return link */
SPSR = CPSR                /* Save CPSR before execution */
CPSR[5] = 0                /* Execute in ARM state */
CPSR[7] = 1                /* Disable IRQ */
CPSR[8] = 1                /* Disable Imprecise Data Aborts */
CPSR[9] = CP15_reg1_EEbit /* Endianness on exception entry */
if interrupt == IRQ then
CPSR[4:0] = 0b10010       /* Enter IRQ mode */
if high vectors configured then
PC = 0xFFFF0018
else
PC = 0x00000018          /* execute interrupt vector */
else if interrupt == FIQ then
CPSR[4:0] = 0b10001       /* Enter FIQ mode */
CPSR[6] = 1                /* Disable FIQ */
if high vectors configured then
PC = 0xFFFF001C
else
PC = 0x0000001C          /* execute interrupt vector */
endif

```

- The ISR saves the remaining context, identifies the interrupt source by reading the ACTIVEIRQ/ACTIVEFIQ field, and jumps to the relevant subroutine handler as follows:

CAUTION

The code in steps 5 and 7 is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```

;INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register address
INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR .word 0x48200040/0x48200044
; ACTIVEIRQ bit field mask to get only the bit field
ACTIVEIRQ_MASK .equ 0x7F
_IRQ_ISR/_FIQ_ISR:
; Save the critical context
STMFDP SP!, {R0-R12, LR} ; Save working registers and the Link register
MRS R11, SPSR ; Save the SPSR into R11
; Get the number of the highest priority active IRQ/FIQ
LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
LDR R10, [R10] ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
AND R10, R10, #ACTIVEIRQ_MASK ; Apply the mask to get the active IRQ number
; Jump to relevant subroutine handler

.word IRQ0handler ;For IRQ0 of BANK0
.word IRQ1handler
.word IRQ2handler

```

- The subroutine handler executes code specific to the peripheral generating the interrupt by handling the event and deasserting the interrupt condition at the peripheral side.

```

; IRQ0 subroutine
IRQ0handler:
; Save working registers
STMFDP SP!, {R0-R1}
; Now read-modify-write the peripheral module status register
; to de-assert the M_IRQ_0 interrupt signal
; De-Assert the peripheral interrupt
MOV R0, #0x7 ; Mask for 3 flags
LDR R1, MODULE0_STATUS_REG_ADDR ; Get the address of the module Status Register
STR R0, [R1] ; Clear the 3 flags
; Restore working registers LDMFDP SP!, {R0-R1}
; Jump to the end part of the ISR
B IRQ_ISR_end/FIQ_ISR_end

```

7. After the return of the subroutine, the ISR sets the NEWIRQAGR/NEWFIQAGR bit to enable the processing of subsequent pending IRQs/FIQs and to restore ARM context in the following code. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/FIQs, a Data Synchronization Barrier is used. This operation ensure that the IRQ/FIQ line is de-asserted before IRQ/FIQ enabling. After that, the INTC processes any other pending interrupts or deasserts the IRQ/FIQ signal if there is no interrupt.

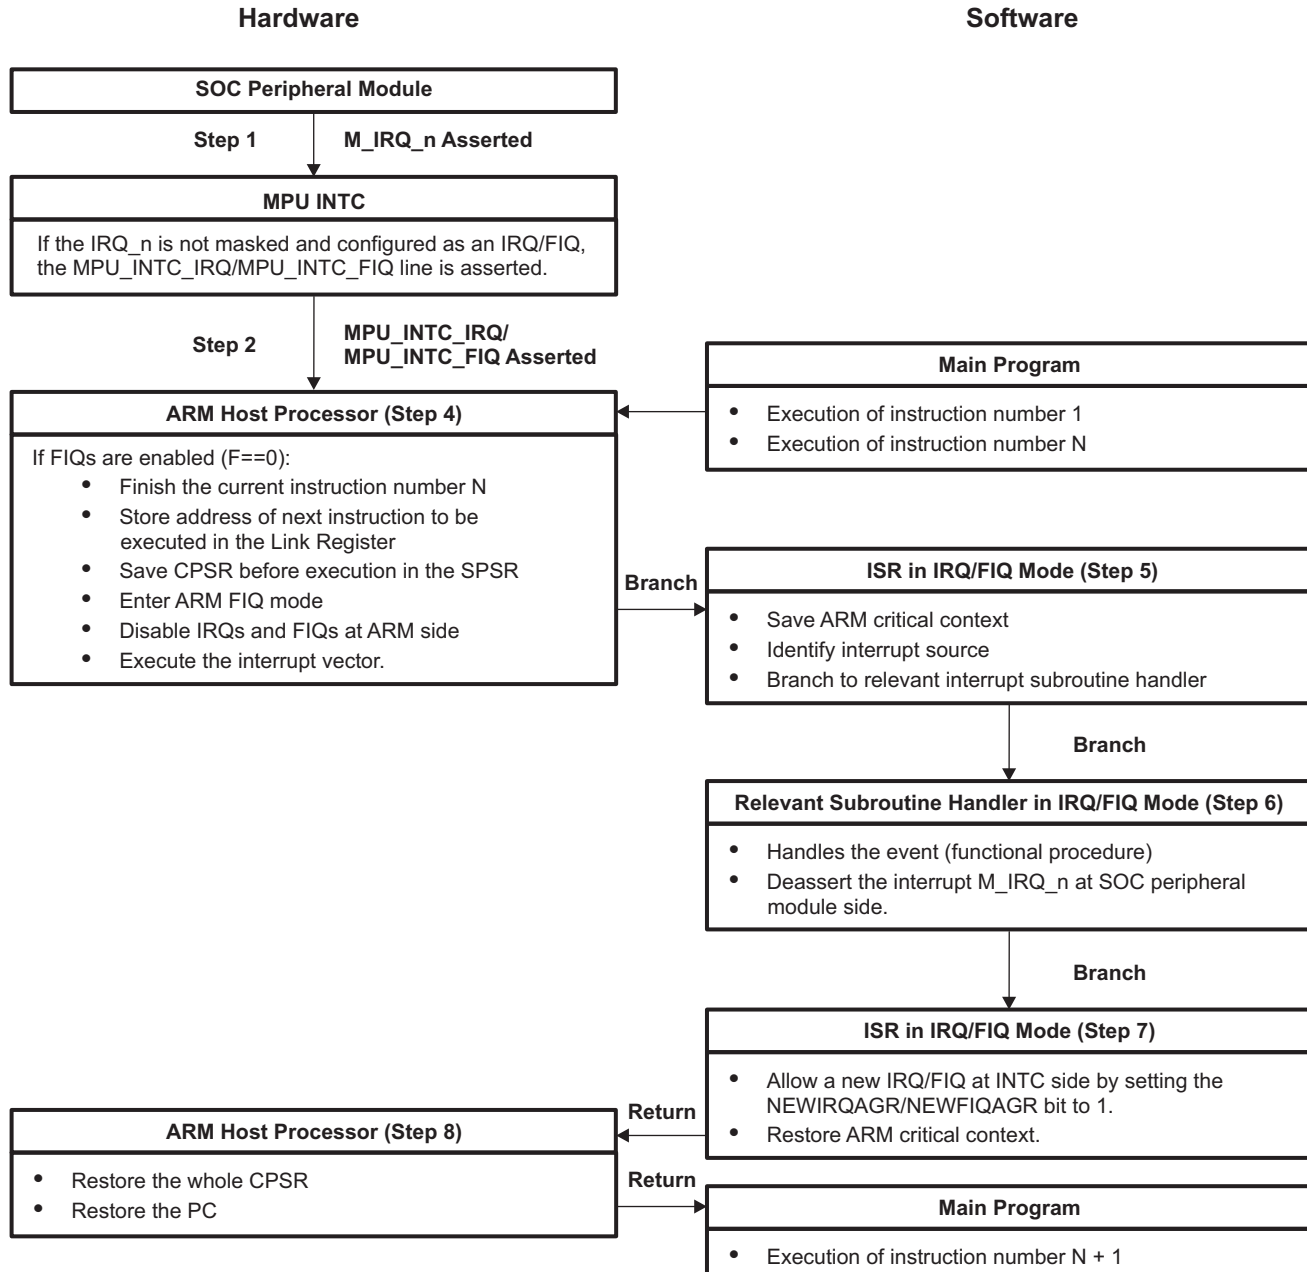

```

; INTCPS_CONTROL register address
INTCPS_CONTROL_ADDR .word 0x48200048;
NEWIRQAGR/NEWFIQAGR bit mask to set only the NEWIRQAGR/NEWFIQAGR bit
NEWIRQAGR_MASK/NEWFIQAGR_MASK .equ 0x01/0x02
IRQ_ISR_end/FIQ_ISR_end:
; Allow new IRQs/FIQs at INTC side
; The INTCPS_CONTROL register is a write only register so no need to write back others bits
MOV R0, #NEWIRQAGR_MASK/NEWFIQAGR_MASK ; Get the NEWIRQAGR/NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR/NEWFIQAGR bit to allow new IRQs/FIQ

; restore critical context
MSR SPSR, R11 ; Restore the SPSR from R11
LDMFD SP!, {R0-R12, LR} ; Restore working registers and Link register
; Return after handling the interrupt
SUBS PC, LR, #4
8. After the ISR return, the ARM automatically restores its context as follows:
CPSR = SPSR
PC = LR

```

Figure 14-4 shows the IRQ/FIQ processing sequence from the originating device peripheral module to the main program interruption.

The priority sorting mechanism is frozen during an interrupt processing sequence. If an interrupt condition occurs during this time, the interrupt is not lost. It is sorted when the NEWIRQAGR/NEWFIQAGR bit is set (priority sorting is reactivated).

Figure 14-4. IRQ/FIQ Processing Sequence

14.3.3 INTC Preemptive Processing Sequence

Preemptive interrupts, also called nested interrupts, can reduce the latencies for higher priority interrupts. A preemptive ISR can be suspended by a higher priority interrupt. Thus, the higher priority interrupt can be served immediately. Nested interrupts must be used carefully to avoid using corrupted data. Programmers must save corruptible registers and enable IRQ or FIQ at ARM side. IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in the code below.

To enable IRQ/FIQ preemption by higher priority IRQs/FIQs, programers can follow this procedure to write the ISR.

At the beginning of an IRQ/FIQ ISR:

1. Save the ARM critical context registers.
2. Save the INTCPS_THRESHOLD PRIORITYTHRESHOLD field before modifying it.
3. Read the active interrupt priority in the INTCPS_IRQ_PRIORITY IRQPRIORITY/INTCPS_FIQ_PRIORITY FIQPRIORITY field and write it to the PRIORITYTHRESHOLD(1) field.
4. Read the active interrupt number in the INTCPS_SIR_IRQ[6:0] ACTIVEIRQ/INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field to identify the interrupt source.
5. Write 1 to the appropriate INTCPS_CONTROL NEWIRQAGR and (2) NEWFIQAGR bit while an interrupt is still processing to allow only higher priority interrupts to preempt.
6. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/FIQs, a Data Synchronization Barrier is used. This operation ensure that the IRQ line is de-asserted before IRQ/FIQ enabling.
7. Enable IRQ/FIQ at ARM side.
8. Jump to the relevant subroutine handler.

The following sample code shows the previous steps:

CAUTION

The following code is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```

; bit field mask to get only the bit field
ACTIVEPRIO_MASK .equ 0x7F
_IRQ_ISR:
; Step 1 : Save the critical context
STMFD SP!, {R0-R12, LR} ; Save working registers
MRS R11, SPSR ; Save the SPSR into R11
; Step 2 : Save the INTCPS_THRESHOLD register into R12
LDR R0, INTCPS_THRESHOLD_ADDR
LDR R12, [R0]
(1) The priority-
threshold mechanism is enabled automatically when writing a priority in the range of 0x00 to
0x7F. Writing a value of 0xFF (reset default) disables the priority-
threshold mechanism. Values between 0x3F and 0xFF must not be used. When the hardware-
priority threshold is in use, the priorities of interrupts selected as FIQ or IRQ become linked
otherwise, they are independent. When they are linked, all FIQ priorities must be set higher than
all IRQ priorities to maintain the relative priority of FIQ over IRQ.
(2) When handling FIQs using the priority-
threshold mechanism, both NEWFIQAGR and NEWIRQAGR bits must be written at the same time to ensure
that the new priority threshold is applied while an IRQ sort is in progress. This IRQ will not
have been seen by the ARM, as it will have been masked on entry to the FIQ ISR. However, the
source of the IRQ remains active and it is finally processed when the priority threshold falls to
a priority sufficiently low to allow it to be processed. The precaution of writing to New FIQ
Agreement is not required during an IRQ ISR, as FIQ sorting is not affected (provided all FIQ
priorities are higher than all IRQ priorities).
; Step 3 : Get the priority of the highest priority active IRQ
LDR R1, INTCPS_IRQ_PRIORITY_ADDR/INTCPS_FIQ_PRIORITY_ADDR
LDR R1, [R1] ; Get the INTCPS_IRQ_PRIORITY/INTCPS_FIQ_PRIORITY register
AND R1, R1, #ACTIVEPRIO_MASK ; Apply the mask to get the priority of the IRQ
STR R1, [R0] ; Write it to the INTCPS_THRESHOLD register
; Step 4 : Get the number of the highest priority active IRQ
LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
LDR R10, [R10] ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
AND R10, R10, #ACTIVEIRQ_MASK ; Apply the mask to get the active IRQ number
; Step 5 : Allow new IRQs and FIQs at INTC side
MOV R0, #0x1/0x3 ; Get the NEWIRQAGR and NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR and NEWFIQAGR bit
; Step 6 : Data Synchronization Barrier
MOV R0, #0 MCR P15, #0, R0, C7, C10, #4
; Step 7 : Read-modify-write the CPSR to enable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the status register
BIC R0, R0, #0x80/0x40 ; Clear the I/F bit
MSR CPSR, R0 ; Write it back to enable IRQs
; Step 8 : Jump to relevant subroutine handler
LDR PC, [PC, R10, lsl #2] ; PC base address points this instruction + 8
NOP ; To index the table by the PC
; Table of handler start addresses
.word IRQ0handler ;IRQ0 BANK0
.word IRQ1handler
.word IRQ2handler

```

After the return of the relevant IRQ/FIQ subroutine handle:

1. Disable IRQs/FIQs at ARM side.
2. Restore the INTCPS_THRESHOLD PRIORITYTHRESHOLD field.
3. Restore the ARM critical context registers.

The following sample code shows the three previous steps:

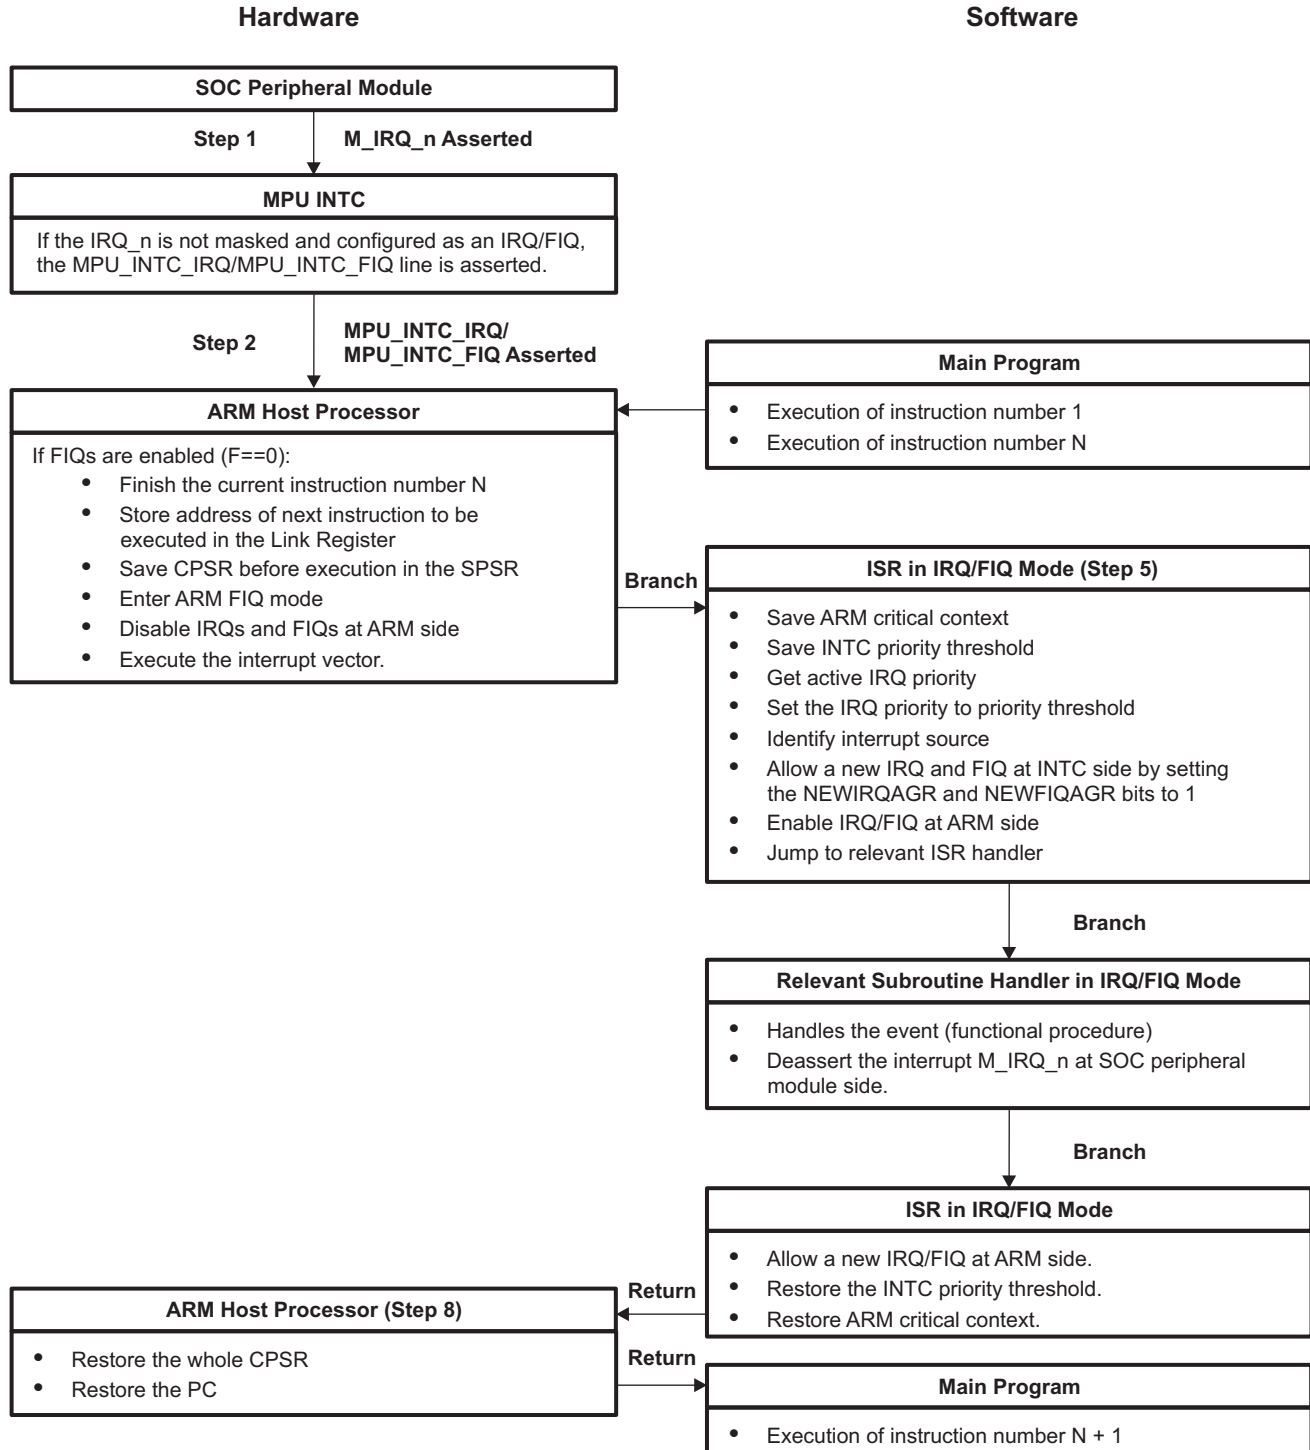

CAUTION

The following code is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```

IRQ_ISR_end:
    ; Step 1 : Read-modify-write the CPSR to disable IRQs/FIQs at ARM side
    MRS R0, CPSR ; Read the CPSR
    ORR R0, R0, #0x80/0x40 ; Set the I/F bit
    MSR CPSR, R0 ; Write it back to disable IRQs
    ; Step 2 : Restore the INTCPS_THRESHOLD register from R12
    LDR R0, INTCPS_THRESHOLD_ADDR
    STR R12, [R0]
    ; Step 3 : Restore critical context
    MSR SPSR, R11 ; Restore the SPSR from R11
    LDMFD SP!, {R0-R12, LR} ; Restore working registers and Link register
    ; Return after handling the interrupt
    SUBS PC, LR, #4
    
```

Figure 14-5 shows the nested IRQ/FIQ processing sequence from the originating device peripheral module to the main program interruption.

Figure 14-5. Nested IRQ/FIQ Processing Sequence

14.3.4 Interrupt Preemption

If wanting to enable pre-emption by higher priority interrupts, the ISR should read the active interrupt priority and write it to the priority threshold register. Writing a '1' to the appropriate NEW_IRQ_AGR or NEW_FIQ_AGR bits of the CONTROL register while still processing the interrupt will now allow only higher priority interrupts to pre-empt.

For each level of pre-emption, the programmer must save the threshold value before modifying it and restore it at the end of that ISR level.

The priority threshold mechanism is enabled automatically when writing a priority in the range of 0 to 7Fh as will be read from the IRQ_PRIORITY and FIQ_PRIORITY registers. Writing a value of FFh (reset default) disables the priority threshold mechanism.

When the hardware priority threshold is in use the priorities of interrupts selected as FIQ or IRQ become linked, otherwise they are independent. When linked, it is required that all FIQ priorities be set higher than all IRQ priorities to maintain the relative priority of FIQ over IRQ.

When handling FIQs using the priority threshold mechanism, it is required to write both New FIQ Agreement and New IRQ Agreement bits at the same time to cover the case that the new priority threshold is applied while an IRQ sorting is in progress. This IRQ will not have been seen by the ARM as it will have been masked on entry to the FIQ ISR. However, the source of the IRQ will remain active and it will be finally processed when the priority threshold falls to a low enough priority. The precaution of writing to New FIQ Agreement (as well as New IRQ Agreement) is not required during an IRQ ISR as FIQ sorting will not be affected (provided all FIQ priorities are higher than all IRQ priorities).

14.3.5 ARM A8 INTC Spurious Interrupt Handling

The spurious flag indicates whether the result of the sorting (a window of 10 INTC functional clock cycles after the interrupt assertion) is invalid. The sorting is invalid if:

- The interrupt that triggered the sorting is no longer active during the sorting.
- A change in the mask has affected the result during the sorting time.

As a result, the values in the INTCPS_MIRn, INTCPS_ILRm, or INTCPS_MIR_SETn registers must not be changed while the corresponding interrupt is asserted. Only the active interrupt input that triggered the sort can be masked before it turns on the sort. If these registers are changed within the 10-cycle window after the interrupt assertion, the resulting values of the following registers become invalid:

- INTCPS_SIR_IRQ
- INTCPS_SIR_FIQ
- INTCPS_IRQ_PRIORITY
- INTCPS_FIQ_PRIORITY

This condition is detected for both IRQ and FIQ, and the invalid status is flagged across the SPURIOUSIRQFLAG (see NOTE 1) and SPURIOUSFIQFLAG (see NOTE 2) bit fields in the SIR and PRIORITY registers. A 0 indicates valid and a 1 indicates invalid interrupt number and priority. The invalid indication can be tested in software as a false register value.

NOTE:

1. The INTCPS_SIR_IRQ[31:7] SPURIOUSIRQFLAG bit field is a copy of the INTCPS_IRQ_PRIORITY[31:7] SPURIOUSIRQFLAG bit field.
 2. The INTCPS_SIR_FIQ[31:7] SPURIOUSFIQFLAG bit field is a copy of the INTCPS_FIQ_PRIORITY[31:7] SPURIOUSFIQFLAG bit field.
-

14.4 Registers

If the `INTCPS_PROTECTION[0]` `PROTECTION` bit is set, access to the INTC registers is restricted to the supervisor mode. Access to the `INTCPS_PROTECTION` register is always restricted to privileged mode.

Each register from `INTCPS_ITRn` to `INTCPS_PENDING_FIQn` contains 32 bits, 1 bit for each interrupt (in ascending order: bit 0 of the `INTCPS_ITR0` register applies to interrupt line 0; bit 0 of the `INTCPS_ITR1` register applies to interrupt line 32).

CAUTION

The INTC registers are limited to 32-bit and 16-bit data accesses; 8-bit data access is not allowed and can corrupt the register content.

Table 14-3 lists the memory-mapped registers for the INTC.

14.4.6 INTCPS_CONTROL Register

This register contains the new interrupt agreement bits.

Figure 14-11. INTCPS_CONTROL Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-9. INTCPS_CONTROL Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Write 0s for future compatibility. Read returns reset value.
1	NEWFIQAGR	W0	Reset FIQ output and enable new FIQ generation. No effect
		W1	Reset FIQ output and enable new FIQ generation.
0	NEWIRQAGR	W0	New IRQ generation No effect
		W1	Reset IRQ output and enable new IRQ generation.

14.4.7 INTCPS_PROTECTION Register

This register controls protection of the other registers. It can be accessed only in supervisor mode, regardless of the current value of the protection bit.

Figure 14-12. INTCPS_PROTECTION Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-10. INTCPS_PROTECTION Register Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Write 0s for future compatibility. Read returns reset value.
0	PROTECTION	0	Protection mode is disabled.
		1	Protection mode is enabled. When enabled, all the INTC registers are accessible only in privileged mode.

14.4.8 INTCPS_IDLE Register

This register controls the functional clock auto-idle and the synchronizer clock auto-gating.

Figure 14-13. INTCPS_IDLE Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-11. INTCPS_IDLE Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Write 0s for future compatibility. Read returns reset value.
1	TURBO	0	Input synchronizer clock is free-running.
		1	Input synchronizer clock is auto-gated based on interrupt input activity.
0	FUNCIDLE	0	Functional clock gating strategy is applied.
		1	Functional clock is free-running.

14.4.9 INTCS_IRQ_PRIORITY Register

This register supplies the currently active IRQ priority level.

Figure 14-14. INTCS_IRQ_PRIORITY Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-12. INTCS_IRQ_PRIORITY Register Field Descriptions

Bit	Field	Value	Description
31-6	SPURIOUSIRQFLAG	0-3FF FFFFh	Spurious IRQ flag
5-0	IRQPRIORITY	0-3Fh	Current IRQ priority

14.4.10 INTCS_FIQ_PRIORITY Register

This register supplies the currently active FIQ priority level.

Figure 14-15. INTCS_FIQ_PRIORITY Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-13. INTCS_FIQ_PRIORITY Register Field Descriptions

7-2	PRIORITY	0-3Fh	Interrupt priority
1	Reserved	0	Write 0 for future compatibility. Read returns reset value.
0	FIQNIRQ	W0	Interrupt IRQ/FIQ mapping. Read returns reset value. Interrupt is routed to IRQ.
		W1	Interrupt is routed to FIQ.

Inter-Integrated Circuit (I2C) Controller Module

This chapter describes the multi-master inter-integrated circuit (I2C) controller module which provides an interface between a CPU and any I2C-bus-compatible device that connects via the I2C serial bus. External components attached to the I2C bus can serially transmit/receive up to 8-bit data to/from the CPU device through the two-wire I2C interface.

Topic	Page
15.1 Introduction	1923
15.2 Architecture	1924
15.3 I2C Registers	1936

15.1 Introduction

15.1.1 Overview

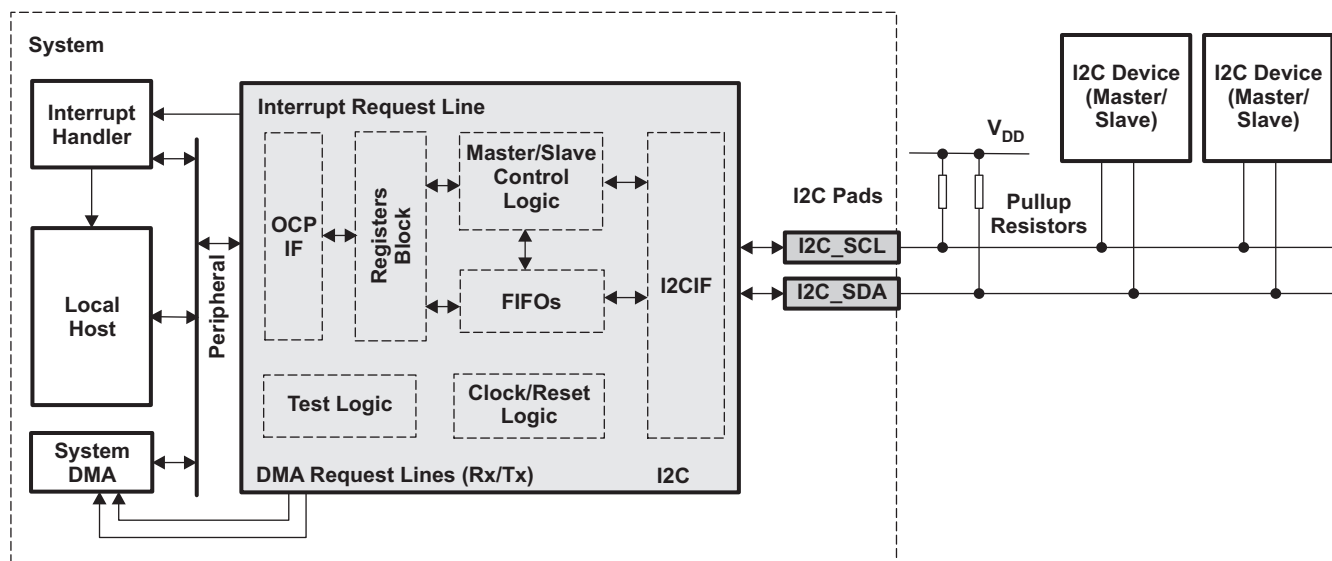

The multi-master I2C peripheral provides an interface between a CPU and any I2C-bus-compatible device that connects via the I2C serial bus. External components attached to the I2C bus can serially transmit/receive up to 8-bit data to/from the CPU device through the two-wire I2C interface.

The I2C bus is a multi-master bus. The I2C controller does support the multi-master mode that allows more than one device capable of controlling the bus to be connected to it. Each I2C device is recognized by a unique address and can operate as either transmitter or receiver, according to the function of the device. In addition to being a transmitter or receiver, a device connected to the I2C bus can also be considered as master or slave when performing data transfers. Note that a master device is the device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave.

15.1.2 Functional Block Diagram

Figure 15-1 shows an example of a system with multiple I2C compatible devices in which the I2C serial ports are all connected together for a two-way transfer from one device to other devices.

Figure 15-1. I2C Functional Block Diagram

15.1.3 Features

The multimaster I2C controller has the following features:

- Compliance with Philips I2C specification version 2.1
- Support for standard mode (up to 100K bits/s) and fast mode (up to 400K bits/s)
- 7-bit and 10-bit device addressing modes
- General call
- Start/restart/stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFO size of 32 bytes for buffered read or write
- Module enable/disable capability

- Programmable clock generation
- 8-bit-wide data access
- Designed for low-power consumption design
- Two DMA channels
- Wide interrupt capability

15.2 Architecture

The I2C peripheral consists of the following primary blocks:

- A serial interface: one data pin (I2C_SDA) and one clock pin (I2C_SCL).
- Data registers to temporarily hold receive data and transmit data traveling between the I2C_SDA pin and the CPU or the DMA controller.
- Control and status registers
- A peripheral data bus interface to enable the CPU and the DMA controller to access the I2C peripheral registers.
- A clock synchronizer to synchronize the I2C input clock (from the processor clock generator) and the clock on the I2C_SCL pin, and to synchronize data transfers with masters of different clock speeds.
- A prescaler to divide down the input clock that is driven to the I2C peripheral
- A noise filter on each of the two pins, I2C_SDA and I2C_SCL
- An arbitrator to handle arbitration between the I2C peripheral (when it is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- DMA event generation logic to send an interrupt to the CPU upon reception or transmission of data.

15.2.1 I2C Master/Slave Controller Signals

Data is communicated to devices interfacing with the I2C via the serial data line (SDA) and the serial clock line (SCL). These two wires can carry information between a device and others connected to the I2C bus. Both SDA and SCL are bi-directional pins. They must be connected to a positive supply voltage via a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open drain to perform the required wired-AND function.

An example of multiple I2C modules that are connected for a two-way transfer from one device to other devices is shown in [Figure 15-2](#).

Figure 15-2. Multiple I2C Modules Connected

Table 15-1. Signal Pads

Name	Default Operating Mode	I2C Mode
		Description
I2C_SCL	In/ Out	I2C serial CLK line Open-drain output buffer. Requires external pull-up resistor (Rp).
I2C_SDA	In/ Out	I2C serial data line Open-drain output buffer. Requires external pull-up resistor (Rp).

15.2.2 I2C Reset

The I2C module can be reset in the following three ways:

- A device reset causes all registers to be reset to their default values.
- A software reset by setting the SRST bit in the I2C_SYSC register. This bit has exactly the same action on the module logic as the device reset. All registers are reset to power up reset values.
- The I2C_EN bit in the I2C_CON register can be used to hold the I2C module in reset. When the device reset is removed, I2C_EN = 0 keeps the functional part of I2C module in reset state and all configuration registers can be accessed. I2C_EN = 0 does not reset the registers to power up reset values.

Table 15-2. Reset State of I2C Signals

Pin	I/O/Z ⁽¹⁾	System Reset	I2C Reset
			(I2C_EN = 0)
SDA	I/O/Z	High impedance	High impedance
SCL	I/O/Z	High impedance	High impedance

⁽¹⁾ I = Input, O = Output, Z = High impedance

15.2.3 Data Validity

The data on the SDA line must be stable during the high period of the clock. The high and low states of the data line can only change when the clock signal on the SCL line is LOW.

Figure 15-3. Bit Transfer on the I2C Bus

15.2.4 START & STOP Conditions

The I2C module generates START and STOP conditions when it is configured as a master.

- START condition is a high-to-low transition on the SDA line while SCL is high.
- STOP condition is a low-to-high transition on the SDA line while SCL is high.
- The bus is considered to be busy after the START condition (BB = 1) and free after the STOP condition (BB = 0).

Figure 15-4. Start and Stop Condition Events

15.2.5 I2C Operation

15.2.5.1 Serial Data Formats

The I2C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte put on the SDA line is 8 bits long. The number of bytes that can be transmitted or received is restricted by the value programmed in the DCOUNT register. The data is transferred with the most significant bit (MSB) first. Each byte is followed by an acknowledge bit from the I2C module if it is in receiver mode.

Figure 15-5. I2C Data Transfer

The I2C module supports two data formats, as shown in [Figure 15-6](#):

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start condition

The first byte after a start condition (S) always consists of 8 bits. In the acknowledge mode, an extra bit dedicated for acknowledgment is inserted after each byte. In the addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 LSB R/W bit. In the addressing formats with 10-bit addresses, the first byte is composed of 7 MSB slave address bits, such as 11110XX, where XX is the two MSB of the 10-bit addresses, and 1 LSB R/W bit, which is 0 in this case.

The least significant R/\overline{W} of the address byte indicates the direction of transmission of the following data bytes. If R/\overline{W} is 0, the master writes data into the selected slave; if it is 1, the master reads data out of the slave.

Figure 15-6. I2C Data Transfer Formats

7-Bit Addressing Format

10-Bit Addressing Format

7-Bit Addressing Format With Repeated START Condition

15.2.5.2 Master Transmitter

In this mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in synch with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL held low when the intervention of the processor is required (XUDF) after a byte has been transmitted.

15.2.5.3 Master Receiver

This mode can only be entered from the master transmitter mode. With either of the address formats (Figure 6 (a), (b), and (c)), the master receiver is entered after the slave address byte and bit R/\overline{W} has been transmitted, if R/\overline{W} is high. Serial data bits received on bus line SDA are shifted in synch with the self-generated clock pulses on SCL. The clock pulses are inhibited and SCL held low when the intervention of the processor is required (ROVR) after a byte has been received. At the end of a transfer, it generates the stop condition.

15.2.5.4 Slave Transmitter

This mode can only be entered from the slave receiver mode. With either of the address formats (Figure 6 (a), (b), and (c)), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/\overline{W} has been transmitted, if R/\overline{W} is high. The slave transmitter shifts the serial data out on the data line SDA in synch with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the CPU is required (XUDF).

15.2.5.5 Slave Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in synch with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the CPU is required (ROVR) following the reception of a byte.

15.2.6 Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 15-7 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 15-7. Arbitration Procedure Between Two Master Transmitters

15.2.7 I2C Clock Generation and I2C Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or to prepare a byte to be transmitted. Figure 15-8 illustrates the clock synchronization.

Figure 15-8. Synchronization of Two I2C Clock Generators

15.2.8 Prescaler (SCLK/ICLK)

The I2C module is operated with a functional clock (SCLK) frequency that can be in a range of 12-100 MHz, according to I2C mode that must be used (an internal ~24 MHz clock (ICLK) is recommended in case of F/S operation mode). Note that the frequency of the functional clock influences directly the I2C bus performance and timings.

The internal clock used for I2C logic - ICLK - is generated via the I2C prescaler block. The prescaler consists of a 4-bit register - I2C_PSC, and is used to divide the system clock (SCLK) to obtain the internal required clock for the I2C module.

15.2.9 Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less, in the case of F/S mode of operation. It is designed to suppress noise with one ICLK. The noise filter is always one ICLK cycle, regardless of the bus speed. For FS mode (prescaler = 4, ICLK = 24 MHz), the maximum width of the suppressed spikes is 41.6 ns. To ensure a correct filtering, the prescaler must be programmed accordingly.

15.2.10 I2C Interrupts

The I2C module generates 12 types of interrupt: addressed as slave, bus free (stop condition detected), access error, start condition, arbitration-lost, no acknowledge, general call, registers-ready-for-access, receive and transmit data, receive and transmit draining. These 12 interrupts are accompanied with 12 interrupt masks and flags defined in the I2C_IRQENABLE_SET and respectively I2C_IRQSTATUS_RAW registers. Note that all these 12 interrupt events are sharing the same hardware interrupt line.

- Addressed As Slave interrupt (AAS) is generated to inform the Local Host that an external master addressed the module as a slave. When this interrupt occurs, the CPU can check the I2C_ACTOA status register to check which of the 4 own addresses was used by the external master to access the module.
- Bus Free interrupt (BF) is generated to inform the Local Host that the I2C bus became free (when a Stop Condition is detected on the bus) and the module can initiate his own I2C transaction.
- Start Condition interrupt (STC) is generated after the module being in idle mode have detected (synchronously or asynchronously) a possible Start Condition on the bus (signalized with WakeUp).
- Access Error interrupt (AERR) is generated if a Data read access is performed while RX FIFO is empty or a Data write access is performed while TX FIFO is full.
- Arbitration lost interrupt (AL) is generated when the I2C arbitration procedure is lost.
- No-acknowledge interrupt (NACK) is generated when the master I2C does not receive acknowledge from the receiver.
- General call interrupt (GC) is generated when the device detects the address of all zeros (8 bits).
- Registers-ready-for-access interrupt (ARDY) is generated by the I2C when the previously programmed address, data, and command have been performed and the status bits have been updated. This interrupt is used to let the CPU know that the I2C registers are ready for access.
- Receive interrupt/status (RRDY) is generated when there is received data ready to be read by the CPU from the I2C_DATA register (see the FIFO Management subsection ([Section 15.2.13](#)) for a complete description of required conditions for interrupt generation). The CPU can alternatively poll this bit to read the received data from the I2C_DATA register.
- Transmit interrupt/status (XRDY) is generated when the CPU needs to put more data in the I2C_DATA register after the transmitted data has been shifted out on the SDA pin (see the FIFO Management subsection ([Section 15.2.13](#)) for a complete description of required conditions for interrupt generation). The CPU can alternatively poll this bit to write the next transmitted data into the I2C_DATA register.
- Receive draining interrupt (RDR) is generated when the transfer length is not a multiple of threshold value, to inform the CPU that it can read the amount of data left to be transferred and to enable the draining mechanism. (see the Draining Feature subsection ([Section 15.2.13.4](#)) for additional details).
- Transmit draining interrupt (XDR) is generated when the transfer length is not a multiple of threshold value, to inform the CPU that it can write the amount of data left to be written and to enable the draining mechanism. (see the Draining Feature subsection ([Section 15.2.13.4](#)) for additional details).

When the interrupt signal is activated, the Local Host must read the I2C_IRQSTATUS_RAW register to define the type of the interrupt, process the request, and then write into these registers the correct value to clear the interrupt flag.

15.2.11 DMA Events

The I2C module can generate two DMA requests events, read (I2C_DMA_RX) and write (I2C_DMA_TX) that can be used by the DMA controller to synchronously read received data from the I2C_DATA or write transmitted data to the I2C_DATA register. The DMA read and write requests are generated in a similar manner as RRDY and XRDY, respectively.

The I2C DMA request signals (I2C_DMA_TX and I2C_DMA_RX) are activated according to the FIFO Management subsection ([Section 15.2.13](#)).

15.2.12 Interrupt and DMA Events

I2C has two DMA channels (Tx and Rx). For event numbers, see the *Device Interrupts and EDMA Events* chapter.

I2C has one interrupt line for all the interrupt requests. For the interrupt number, see the *Device Interrupts and EDMA Events* chapter.

15.2.13 FIFO Management

The I2C module implements two internal 32-bytes FIFOs with dual clock for RX and TX modes. The depth of the FIFOs is reflected in I2C_BUFSTAT.FIFODEPTH register.

15.2.13.1 FIFO Interrupt Mode Operation

In FIFO interrupt mode (relevant interrupts enabled via I2C_IRQENABLE_SET register), the processor is informed of the status of the receiver and transmitter by an interrupt signal. These interrupts are raised when receive/transmit FIFO threshold (defined by I2C_BUF.TXTRSH or I2C_BUF.RXTRSH) is reached; the interrupt signals instruct the Local Host to transfer data to the destination (from the I2C module in receive mode and/or from any source to the I2C FIFO in transmit mode).

[Figure 15-9](#) and [Figure 15-10](#), respectively, illustrate receive and transmit operations from FIFO management point of view.

Figure 15-9. Receive FIFO Interrupt Request Generation

Note that in [Figure 15-9](#), the RRDY Condition illustrates that the condition for generating a RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the CPU by writing a 1 in the corresponding interrupt flag. If the condition is still present after clearing the previous interrupt, another interrupt request will be generated.

In receive mode, RRDY interrupt is not generated until the FIFO reaches its receive threshold. Once low, the interrupt can only be de-asserted when the Local Host has handled enough bytes to make the FIFO level below threshold. For each interrupt, the Local Host can be configured to read an amount of bytes equal with the value of the RX FIFO threshold + 1.

Figure 15-10. Transmit FIFO Interrupt Request Generation

Note that in the figure above, the XRDY Condition illustrates that the condition for generating a XRDY interrupt is achieved. The interrupt request is generated when this condition is achieved (when TX FIFO is empty, or the TX FIFO threshold is not reached and there are still data bytes to be transferred in the TX FIFO), and it can be cleared only by the CPU by writing a 1 in the corresponding interrupt flag after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request will be generated.

Note that in interrupt mode, the module offers two options for the CPU application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the CPU can write/read one data byte to/from the FIFO and then clear the interrupt. The module will not reassert the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the CPU can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold ($I2C_BUF.TXTRSH + 1$ or $I2C_BUF.RXTRSH + 1$). In this case, the interrupt condition will be cleared and the next interrupt will be asserted again when the XRDY or RRDY condition is met again.

If the second interrupt serving approach is used, an additional mechanism (draining feature) is implemented for the case when the transfer length is not a multiple of FIFO threshold (see the Draining Feature subsection ([Section 15.2.13.4](#))).

In slave TX mode, the draining feature cannot be used, since the transfer length is not known at the configuration time, and the external master can end the transfer at any point by not acknowledging one data byte.

15.2.13.2 FIFO Polling Mode Operation

In FIFO polled mode ($I2C_IRQENABLE_SET.XRDY_IE$ and $I2C_IRQENABLE_SET.RRDY_IE$ disabled and DMA disabled), the status of the module (receiver or transmitter) can be checked by polling the XRDY and RRDY status registers ($I2C_IRQSTATUS_RAW$) (RDR and XDR can also be polled if draining feature is used). The XRDY and RRDY flags are accurately reflecting the interrupt conditions mentioned in Interrupt Mode. This mode is an alternative to the FIFO interrupt mode of operation, where the status of the receiver and transmitter is automatically known by means of interrupts sent to the CPU.

15.2.13.3 FIFO DMA Mode Operation

In receive mode, a DMA request is generated as soon as the receive FIFO exceeds its threshold level defined in the threshold level register ($I2C_BUF.RXTRSH + 1$). This request should be de-asserted when the number of bytes defined by the threshold level has been read by the DMA, by setting the $I2C_DMARXENABLE_CLR.DMARX_ENABLE_CLEAR$ field.

Figure 15-11. Receive FIFO DMA Request Generation

In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request should be de-asserted when the number of bytes defined by the number in the threshold register ($I2C_BUF.TXTHRS+1$) has been written in the FIFO by the DMA, by setting the $I2C_DMATXENABLE_CLR.DMATX_ENABLE_CLEAR$ field. If an insufficient number of characters are written, then the DMA request will remain active. [Figure 15-12](#) and [Figure 15-13](#) illustrate DMA TX transfers with different values for TXTRSH.

Figure 15-12. Transmit FIFO DMA Request Generation (High Threshold)

Figure 15-13. Transmit FIFO DMA Request Generation (Low Threshold)

Note that also in DMA mode it is possible to have a transfer whose length is not multiple of the configured FIFO threshold. In this case, the DMA draining feature is also used for transferring the additional bytes of the transfer (see the Draining Feature subsection ([Section 15.2.13.4](#)) for additional details).

In I2C Slave RX Mode, the Local Host can program the RX threshold with the desired value, and use the FIFO draining feature at the end of the I2C transfer to extract from the FIFO the remaining bytes if the threshold is not reached (see the Draining Feature subsection ([Section 15.2.13.4](#)) for additional details).

Note that in I2C Slave TX Mode, the TX FIFO threshold should be set to 1 (I2C_BUF.TXTRSH=0, default value), since the length of the transfer may not be known at configuration time. In this way, the interrupt (or accordingly, DMA) requests will be generated for each byte requested by the remote I2C master to be transferred over the I2C bus. This configuration will prevent the I2C core to request additional data from the CPU or from the DMA controller (using IRQ or DMA), data that will eventually not be extracted from the FIFO by the external master (which can use not acknowledge at any time to end the transfer). If the TX threshold is not set to 1, the module will generate an interrupt or assert a DMA only when the external master requests a byte and the FIFO is empty. However, in this case the TX FIFO will require to be cleared at the end of the transfer.

The I2C module offers the possibility to the user to clear the RX or TX FIFO. This is achieved through I2C_BUF.RXFIFO_CLR and I2C_BUF.TXFIFO_CLR registers, which act like software reset for the FIFOs. In DMA mode, these bits will also reset the DMA state machines.

The FIFO clearing feature can be used when the module is configured as a transmitter, the external receiver responds with a NACK in the middle of the transfer, and there is still data in TX FIFO waiting to be transferred.

On the Functional (I2C) domain, the thresholds can always be considered equal to 1. This means that the I2C Core can start transferring data on the I2C bus whenever it has data in the FIFOs (FIFO is not empty).

15.2.13.4 Draining Feature

The Draining Feature is implemented by the I2C core for handling the end of the transfers whose length is not a multiple of FIFO threshold value, and offers the possibility to transfer the remaining amount of bytes (since the threshold is not reached).

Note that this feature prevents the CPU or the DMA controller to attempt more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having in the FIFO less bytes than the configured DMA transfer length). Otherwise, an Access Error interrupt will be generated (see I2C_IRQSTATUS_RAW.AERR interrupt).

The Draining mechanism will generate an interrupt (I2C_IRQSTATUS_RAW.RDR or I2C_IRQSTATUS_RAW.XDR) at the end of the transfer informing the CPU that it needs to check the amount of data left to be transferred (I2C_BUFSTAT.TXSTAT or RXSTAT) and to enable the Draining Feature of the DMA controller if DMA mode is enabled (by re-configuring the DMA transfer length according to this value), or perform only the required number of data accesses, if DMA mode is disabled.

In receiving mode (master or slave), if the RX FIFO threshold is not reached but the transfer was ended on the I2C bus and there is still data left in the FIFO (less than the threshold), the receive draining interrupt (I2C_IRQSTATUS_RAW.RDR) will be asserted to inform the local host that it can read the amount of data in the FIFO (I2C_BUFSTAT.RXSTAT). The CPU will perform a number of data read accesses equal with RXSTAT value (if interrupt or polling mode) or re-configure the DMA controller with the required value in order to drain the FIFO.

In master transmit mode, if the TX FIFO threshold is not reached but the amount of data remained to be written in the FIFO is less than TXTRSH, the transmit draining interrupt (I2C_IRQSTATUS_RAW.XDR) will be asserted to inform the local host that it can write the amount of data remained to be written in the TX FIFO (I2C_BUFSTAT.TXSTAT). The CPU will need to write the required number of data bytes (specified by TXSTAT value) or re-configure the DMA controller with the required value in order to transfer the last bytes to the FIFO.

Note that in master mode, the CPU can alternatively skip the checking of TXSTAT and RXSTAT values since it can obtain internally this information (by computing DCOUNT modulo TX/RXTRSH).

The draining feature is default disabled, and it can be enabled using I2C_IRQENABLE_SET.XDR_IE or I2C_IRQENABLE_SET.RDR_IE registers (default disabled) only for the transfers with length not equal with the threshold value.

15.2.14 How to Program I2C

15.2.14.1 Module Configuration Before Enabling the Module

1. Program the prescaler to obtain an approximately 12-MHz I2C module clock (I2C_PSC = x; this value is to be calculated and is dependent on the System clock frequency).
2. Program the I2C clock to obtain 100 Kbps or 400 Kbps (SCLL = x and SCLH = x; these values are to be calculated and are dependent on the System clock frequency).
3. Configure its own address (I2C_OA = x) - only in case of I2C operating mode (F/S mode).
4. Take the I2C module out of reset (I2C_CON:I2C_EN = 1).

15.2.14.2 Initialization Procedure

1. Configure the I2C mode register (I2C_CON) bits.
2. Enable interrupt masks (I2C_IRQENABLE_SET), if using interrupt for transmit/receive data.
3. Enable the DMA (I2C_BUF and I2C_DMA/RX/TX/ENABLE_SET) and program the DMA controller - only in case of I2C operating mode (F/S mode), if using DMA for transmit/receive data.

15.2.14.3 Configure Slave Address and DATA Counter Registers

In master mode, configure the slave address (I2C_SA = x) and the number of bytes associated with the transfer (I2C_CNT = x).

15.2.14.4 Initiate a Transfer

Poll the bus busy (BB) bit in the I2C status register (I2C_IRQSTATUS_RAW). If it is cleared to 0 (bus not busy), configure START/STOP (I2C_CON: STT / I2C_CON: STP condition to initiate a transfer) - only in case of I2C operating mode (F/S mode).

15.2.14.5 Receive Data

Poll the receive data ready interrupt flag bit (RRDY) in the I2C status register (I2C_IRQSTATUS_RAW), use the RRDY interrupt (I2C_IRQENABLE_SET.RRDY_IE set) or use the DMA RX (I2C_BUF.RDMA_EN set together with I2C_DMARXENABLE_SET) to read the receive data in the data receive register (I2C_DATA). Use draining feature (I2C_IRQSTATUS_RAW.RDR enabled by I2C_IRQENABLE_SET.RDR_IE)) if the transfer length is not equal with FIFO threshold.

15.2.14.6 Transmit Data

Poll the transmit data ready interrupt flag bit (XRDY) in the I2C status register (I2C_IRQSTATUS_RAW), use the XRDY interrupt (I2C_IRQENABLE_SET.XRDY_IE set) or use the DMA TX (I2C_BUF.XDMA_EN set together with I2C_DMATXENABLE_SET) to write data into the data transmit register (I2C_DATA). Use draining feature (I2C_IRQSTATUS_RAW.XDR enabled by I2C_IRQENABLE_SET.XDR_IE)) if the transfer length is not equal with FIFO threshold.

15.3 I2C Registers

Table 15-3 lists the registers for the I2C module.

NOTE: All bits defined as reserved must be written by software with 0s, for preserving future compatibility. When read, any reserved bit returns 0. Also, note that it is good software practice to use complete mask patterns for setting or testing individually bit fields within a register.

Table 15-3. I2C Registers

Address Offset	Acronym	Register Name	Section
00h	I2C_REVNB_LO	Module Revision Register (low bytes)	Section 15.3.1

15.3.1 I2C_REVNB_LO Register (Module Revision LOW BYTES)

This read-only register contains the hard-coded revision number of the module. A write to this register has no effect.

NOTE:

- I2C controller with interrupt using interrupt vector register (I2C_IV) is revision 1.x.
- I2C controller with interrupt using status register bits (I2C_IRQSTATUS_RAW) is revision 2.x.

Figure 15-14. I2C_REVNB_LO Register (Module Revision) (LOW BYTES)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-4. I2C_REVNB_LO Register (Module Revision) (LOW BYTES) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-11	RTL	0-1Fh	RTL version.
10-8	MAJOR	0-7h	Major Revision. This field changes when there is a major feature change. This field does not change due to bug fix, or minor feature change.
7-6	CUSTOM	0-3h	Indicates a special version for a particular device. Consequence of use may avoid use of standard Chip Support Library (CSL) / Drivers. 0 if non-custom.
5-0	MINOR	0-3Fh	Minor Revision This field changes when features are scaled up or down. This field does not change due to bug fix, or major feature change.

15.3.2 I2C_REVNB_HI Register (HIGH BYTES) (Module Revision)

A reset has no effect on the value returned.

Figure 15-15. I2C_REVNB_HI Register (HIGH BYTES) (Module Revision)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-5. I2C_REVNB_HI Register (HIGH BYTES) (Module Revision) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-14	SCHEME	0-3h	Used to distinguish between old Scheme and current. Spare bit to encode future schemes.
13-12	Reserved	0-3h	Reads return 1h
11-0	FUNC	0-FFFh	Function: Indicates a software compatible module family

15.3.3 I2C_SYSC Register (System Configuration)

This register allows controlling various parameters of the peripheral interface.

Figure 15-16. I2C_SYSC Register (System Configuration)

R-0		R/W-0		R-0		R/W-0		R/W-0		R/W-0		R/W-0		R/W-1							

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-6. I2C_SYSC Register (System Configuration) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-8	CLKACTIVITY	0h Both clocks can be cut off 1h Only Interface/OCP clock must be kept active; system clock can be cut off 2h Only system clock must be kept active; Interface/OCP clock can be cut off 3h Both clocks must be kept active Values after reset are low (for both 2 bits).	Clock Activity selection bits. Those bits (one bit for each clock signal present on the boundary of the module) are set to 1 to disable external clock gating mechanism in Idle Mode. Note: If the System (functional) Clock is cut-off, the module will assert a WakeUp event when it will asynchronously detect a Start Condition on the I2C Bus. Note that in this case the first transfer will not be taken into account by the module (NACK will be detected by the external master).
7-5	Reserved	0	Reads return 0h.
4-3	IDLEMODE	0h Force Idle mode 1h No Idle mode 2h Smart Idle mode 3h smartidle_wakeup Value after reset is 00 (Force Idle).	Idle Mode selection bits. These two bits are used to select one of the idle mode operation mechanisms.
2	ENAWAKEUP	0 Wakeup mechanism is disabled 1 Wakeup mechanism is enabled Value after reset is low.	Enable Wakeup control bit. When this bit is set to 1, the module enables its own wakeup mechanism.
1	SRST	0 Normal mode 1 The module is reset Value after reset is low.	SoftReset bit. When this bit is set to 1, entire module is reset as for the hardware reset. This bit is automatically cleared to 0 by the core and it is only reset by the hardware reset. During reads, it always returns 0.
0	AUTOIDLE	0 Auto Idle mechanism is disabled 1 Auto Idle mechanism is enabled Value after reset is high.	Autoidle bit. When this bit is set to 1, the module activates its own idle mode mechanism. By evaluating its internal state, the module can decide to gate part of his internal clock tree in order to improve the overall power consumption.

15.3.4 I2C_EOI Register (I2C End of Interrupt)

Software End-Of-Interrupt: Allows the generation of further pulses on the interrupt line, if an new interrupt event is pending, when using the pulsed output. Unused when using the level interrupt line (depending on module integration).

Figure 15-17. I2C_EOI Register (I2C End of Interrupt)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-7. I2C_EOI Register (I2C End of Interrupt) Field Descriptions

Bit	Field	Description
31-1	Reserved	Reserved
0	LINE_NUMBER	Software End Of Interrupt (EOI) control. Write number of interrupt output.

15.3.5 I2C_IRQSTATUS_RAW Register (I2C Status Raw)

This register provides core status information for interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit will set it to 1, that is, trigger the IRQ (mostly for debug). Writing a 0 will have no effect, that is, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

Table 15-8. I2C_IRQSTATUS_RAW Register (I2C Status Raw) Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Write 0s for future compatibility. Read returns 0.
14	XDR	0 1	<p>Transmit draining IRQ status. I2C Master Transmit mode only.</p> <p>This read/clear only bit is set to 1 when the module is configured as a master transmitter, the TX FIFO level is below the configured threshold (TXTRSH) and the amount of data still to be transferred is less than TXTRSH. When this bit is set to 1 by the core, CPU must read the I2C_BUFSTAT.TXSTAT register in order to check the amount of data that need to be written in the TX FIFO. Then, according to the mode set (DMA or interrupt), the CPU can enable the DMA draining feature of the DMA controller with the number of data bytes to be transferred (I2C_BUFSTAT.TXSTAT), or generate write data accesses according to this value (IRQ mode). The interrupt needs to be cleared after the DMA controller was reconfigured (if DMA mode enabled), or before generating data accesses to the FIFO (if IRQ mode enabled).</p> <p>If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU can also poll this bit. For more details about TDR generation, refer to the FIFO Management subsection.</p> <p>The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect.</p> <p>0 Transmit draining inactive 1 Transmit draining enabled Value after reset is low.</p>
13	RDR	0 1	<p>Receive draining IRQ status. I2C Receive mode only.</p> <p>This read/clear only bit is set to 1 when the module is configured as a receiver, a stop condition was received on the bus and the RX FIFO level is below the configured threshold (RXTRSH). When this bit is set to 1 by the core, CPU must read the I2C_BUFSTAT.RXSTAT register in order to check the amount of data left to be transferred from the FIFO. Then, according to the mode set (DMA or interrupt), the CPU needs to enable the draining feature of the DMA controller with the number of data bytes to be transferred (I2C_BUFSTAT.RXSTAT), or generate read data accesses according to this value (IRQ mode). The interrupt needs to be cleared after the DMA controller was reconfigured (if DMA mode enabled), or before generating data accesses to the FIFO (if IRQ mode enabled).</p> <p>If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU can also poll this bit. For more details about RDR generation, refer to the FIFO Management subsection.</p> <p>The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect.</p> <p>0 Receive draining inactive 1 Receive draining enabled Value after reset is low.</p>

Table 15-8. I2C_IRQSTATUS_RAW Register (I2C Status Raw) Field Descriptions (continued)

Bit	Field	Value	Description
12	BB	0 1	<p>This read-only bit indicates the state of the serial bus.</p> <p>In slave mode, on reception of a start condition, the device sets BB to 1. BB is cleared to 0 after reception of a stop condition.</p> <p>In master mode, the software controls BB. To start a transmission with a start condition, MST, TRX, and STT must be set to 1 in the I2C_CON register. To end a transmission with a stop condition, STP must be set to 1 in the I2C_CON register. When BB = 1 and STT = 1, a restart condition is generated.</p> <p>0 Bus is free 1 Bus is occupied Value after reset is low.</p>
11	ROVR	0 1	<p>Receive overrun status. Writing into this bit has no effect. I2C receive mode only.</p> <p>This read-only bit indicates whether the receiver has experienced overrun. Overrun occurs when the shift register is full and the receive FIFO is full. An overrun condition does not result in a data loss; the peripheral is just holding the bus (low on SCL) and prevents other bytes from being received.</p> <p>ROVR is set to 1 when the I2C has recognized an overrun. ROVR is clear when reading I2C_DATA register, or when resetting the I2C (I2C_CON:I2C_EN = 0).</p> <p>0 Normal operation 1 Receiver overrun Value after reset is low.</p>
10	XUDF	0 1	<p>Transmit underflow status. Writing into this bit has no effect. I2C transmit mode only.</p> <p>This read-only bit indicates whether the transmitter has experienced underflow. In master transmit mode, underflow occurs when the shift register is empty, the transmit FIFO is empty, and there are still some bytes to transmit (DCOUNT M 0).</p> <p>In slave transmit mode, underflow occurs when the shift register is empty, the transmit FIFO is empty, and there are still some bytes to transmit (read request from external I2C master).</p> <p>XUDF is set to 1 when the I2C has recognized an underflow. The core holds the line till the underflow cause has disappeared.</p> <p>XUDF is clear when writing I2C_DATA register or resetting the I2C (I2C_CON:I2C_EN = 0).</p> <p>0 Normal operation 1 Transmit underflow Value after reset is low.</p>
9	AAS	0 1	<p>Address recognized as slave IRQ status. I2C mode only.</p> <p>This read only bit is set to 1 by the device when it has recognized its own slave address (or one of the alternative own addresses), or an address of all zeros (8 bits). When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled.</p> <p>This bit can be cleared in 2 ways:</p> <ul style="list-style-type: none"> • If the interrupt was enabled, it will be cleared by writing 1 into this register (writing 0 has no effect) • If the interrupt was not enabled, the AAS bit is reset to 0 by restart or stop <p>0 No action 1 Address recognized Value after reset is low.</p>
8	BF	0 1	<p>I2C mode only.</p> <p>This read only bit is set to 1 by the device when the I2C bus became free (after a transfer is ended on the bus – stop condition detected). This interrupt informs the Local Host that it can initiate its own I2C transfer on the bus.</p> <p>When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.</p> <p>0 No action 1 Bus Free Value after reset is low.</p>

Table 15-8. I2C_IRQSTATUS_RAW Register (I2C Status Raw) Field Descriptions (continued)

Bit	Field	Value	Description
7	AERR	0 1	<p>Access Error IRQ status. I2C mode only.</p> <p>This read/clear only bit is set to 1 by the device if an Interface/OCF write access is performed to I2C_DATA while the TX FIFO is full or if an Interface/OCF read access is performed to the I2C_DATA while the RX FIFO is empty.</p> <p>Note that, when the RX FIFO is empty, a read access will return to the previous read data value. When the TX FIFO is full, a write access is ignored. In both events, the FIFO pointers will not be updated.</p> <p>When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.</p> <p>0 No action 1 Access Error</p> <p>Value after reset is low.</p>
6	STC	0 1	<p>Start Condition IRQ status. I2C mode only.</p> <p>This read/clear only bit is set to 1 by the device if previously the module was in idle mode and a start condition was asynchronously detected on the I2C Bus and signaled with an Wakeup (if the I2C_SYSC.ClockActivity allows the system clock to be cut-off). When the Active Mode will be restored and the interrupt generated, this bit will indicate the reason of the wakeup.</p> <p>Note 1: The corresponding interrupt for this bit should be enabled only if the module was configured to allow the possibility of cutting-off the system clock while in Idle State (I2C_SYSC.ClockActivity = 00 or 01).</p> <p>Note 2: The first transfer (corresponding to the detected start condition) will be lost (not taken into account by the module) and it will be used only for generating the WakeUp enable for restoring the Active Mode of the module. On the I2C line, the external master which generated the transfer will detect this behavior as a not acknowledge to the address phase and will possibly restart the transfer.</p> <p>The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.</p> <p>0 No action 1 Start Condition detected</p> <p>Value after reset is low.</p>
5	GC	0 1	<p>General call IRQ status. Set to '1' by core when General call address detected and interrupt signaled to MPUSS. Write '1' to clear. I2C mode only.</p> <p>This read/clear only bit is set to 1 by the device if it detects the address of all zeros (8 bits) (general call). When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.</p> <p>Note: When this bit is set to 1, AAS also reads as 1.</p> <p>0 No general call detected 1 General call address detected</p> <p>Value after reset is low.</p>
4	XRDY	0 1	<p>Transmit data ready IRQ status. Set to '1' by core when transmitter and when new data is requested. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear. Transmit mode only (I2C mode).</p> <p>This read/clear only bit (XRDY) is set to 1 when the I2C peripheral is a master or slave transmitter, the CPU needs to send data through the I2C bus, and the module (transmitter) requires new data to be served. Note that a master transmitter requests new data if the FIFO TX level is below the threshold (TXTRSH) and the required amount of data remained to be transmitted (I2C_BUFSTAT.TXSTAT) is greater than the threshold. A slave transmitter requests new data when the FIFO TX level is below the threshold (if TXTRSH > 1), or anytime there is a read request from external master (for each acknowledge received from the master), if TXTRSH = 1.</p> <p>When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can also poll this bit (refer to the FIFO Management subsection for details about XRDY generation). The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.</p> <p>Note: If the DMA transmit mode is enabled (I2C_BUF.XDMA_EN is set, together with I2C_DMATXENABLE_SET), this bit is forced to 0 and no interrupt will be generated; instead, a DMA TX request to the main DMA controller of the system is generated.</p> <p>0 Transmission ongoing 1 Transmit data ready</p> <p>Value after reset is low.</p>

Table 15-8. I2C_IRQSTATUS_RAW Register (I2C Status Raw) Field Descriptions (continued)

Bit	Field	Value	Description																					
3	RRDY	0 1	<p>Receive mode only (I2C mode).</p> <p>This read/clear only RRDY is set to 1 when the RX FIFO level is above the configured threshold (RXTRSH). When this bit is set to 1 by the core, CPU is able to read new data from the I2C_DATA register. If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU to read the received data in I2C_DATA register can also poll this bit (refer to the FIFO Management subsection for details about RRDY generation).</p> <p>The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect.</p> <p>If the DMA receive mode is enabled (I2C_BUF.RDMA_EN is set, together with I2C_DMARXENABLE_SET), this bit is forced to 0 and no interrupt will be generated; instead a DMA RX request to the main DMA controller of the system is generated.</p> <p>0 Receive FIFO threshold not reached 1 Receive data ready for read (RX FIFO threshold reached)</p> <p>Value after reset is low.</p>																					
2	ARDY	0 1	<p>I2C mode only. This read/clear only bit, when set to 1, indicates that the previously programmed data and command (receive or transmit, master or slave) has been performed and status bit has been updated. The CPU uses this flag to let it know that the I2C registers are ready to be accessed again. The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect.</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th>Mode</th> <th>Others</th> <th>ARDY Set Condition</th> </tr> </thead> <tbody> <tr> <td>I2C Master transmit</td> <td>STP = 1</td> <td>DCOUNT = 0</td> </tr> <tr> <td>I2C Master receive</td> <td>STP = 1</td> <td>DCOUNT = 0 and receiver FIFO empty</td> </tr> <tr> <td>I2C Master transmit</td> <td>STP = 0</td> <td>DCOUNT passed 0</td> </tr> <tr> <td>I2C Master receive</td> <td>STP = 0</td> <td>DCOUNT passed 0 and receiver FIFO empty</td> </tr> <tr> <td>I2C Master transmit</td> <td>-</td> <td>Stop or restart condition received from master</td> </tr> <tr> <td>I2C Slave receive</td> <td>-</td> <td>Stop or restart condition and receiver FIFO empty</td> </tr> </tbody> </table> <p>0 No action 1 Access ready</p> <p>Value after reset is low.</p>	Mode	Others	ARDY Set Condition	I2C Master transmit	STP = 1	DCOUNT = 0	I2C Master receive	STP = 1	DCOUNT = 0 and receiver FIFO empty	I2C Master transmit	STP = 0	DCOUNT passed 0	I2C Master receive	STP = 0	DCOUNT passed 0 and receiver FIFO empty	I2C Master transmit	-	Stop or restart condition received from master	I2C Slave receive	-	Stop or restart condition and receiver FIFO empty

1	NACK	0 1	<p>No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. Write '1' to clear this bit. I2C mode only.</p> <p>The read/clear only No Acknowledge flag bit is set when the hardware detects No Acknowledge has been received. When a NACK event occurs on the bus, this bit is set to 1, the core automatically ends the transfer and clears the MST/STP bits in the I2C_CON register and the I2C becomes a slave. Clearing the FIFOs from remaining data might be required.</p> <p>The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.</p> <p>0 Normal operation 1 Not Acknowledge detected</p> <p>Value after reset is low.</p>																					
0	AL	0 1	<p>Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. I2C mode only.</p> <p>The read/clear only Arbitration Lost flag bit is set to 1 when the device (configured in master mode) detects it has lost an arbitration (in Address Phase). This happens when two or more masters initiate a transfer on the I2C bus almost simultaneously or when the I2C attempts to start a transfer while BB (bus busy) is 1.</p> <p>When this is set to 1 due to arbitration lost, the core automatically clears the MST/STP bits in the I2C_CON register and the I2C becomes a slave receiver.</p> <p>The CPU can only clear this bit by writing a 1 to this register. Writing 0 has no effect.</p> <p>0 Normal operation 1 Arbitration lost detected</p> <p>Value after reset is low.</p>																					

15.3.6 I2C_IRQSTATUS Register (I2C Status)

This register provides core status information for interrupt handling, showing all active and enabled events and masking the others. The fields are read-write. Writing a 1 to a bit will clear it to 0, that is, clear the IRQ. Writing a 0 will have no effect, that is, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

For all the internal fields of the I2C_IRQSTATUS register, the descriptions given in the I2C_IRQSTATUS_RAW subsection are valid.

Table 15-9. I2C_IRQSTATUS Register (I2C Status) Field Descriptions (continued)

Bit	Field	Value	Description
5	GC		General call IRQ enabled status. Set to '1' by core when General call address detected and interrupt signaled to MPUSS. Write '1' to clear.
		0	No general call detected
		1	General call address detected
4	XRDY		Transmit data ready IRQ enabled status. Set to '1' by core when transmitter and when new data is requested. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear.
		0	Transmission ongoing
		1	Transmit data ready
3	RRDY		Receive data ready IRQ enabled status. Set to '1' by core when receiver mode, a new data is able to be read. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear.
		0	No data available
		1	Receive data available
2	ARDY		Register access ready IRQ enabled status. When set to '1' it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPUSS. Write '1' to clear.
		0	Module busy
		1	Access ready
1	NACK		No acknowledgement IRQ enabled status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. Write '1' to clear this bit.
		0	Normal operation
		1	Not Acknowledge detected
0	AL		Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0.
		0	Normal operation
		1	Arbitration lost detected

15.3.7 I2C_IRQENABLE_SET Register (I2C Interrupt Enable Set)

All 1-bit fields enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit will enable the field. Writing a 0 will have no effect, that is, the register value will not be modified.

For all the internal fields of the I2C_IRQENABLE_SET register, the descriptions given in the I2C_IRQSTATUS_RAW subsection are valid.

15.3.9 I2C_WE Register (I2C Wakeup Enable)

Every 1-bit field in the I2C_WE register enables a specific (synchronous) IRQ request source to generate an asynchronous wakeup (on the appropriate swakeup line). When a bit location is set to 1 by the local host, a wakeup is signaled to the local host if the corresponding event is captured by the core of the I2C controller. Value after reset is low (all bits).

NOTE:

- There is no need for an Access Error WakeUp event, since this event occurs only when the module is in Active Mode (for Interface/OCF accesses to FIFO) and is signaled by an interrupt.
- With the exception of Start Condition WakeUp, which is asynchronously detected when the Functional clock is turned-off, all the other WakeUp events require the Functional (System) clock to be enabled.

Figure 15-22. I2C_WE Register (I2C Wakeup Enable)

		1	Receive overrun wakeup enabled
10	XUDF_WE	0	Transmit underflow wakeup disabled
		1	Transmit underflow wakeup enabled

Table 15-12. I2C_WE Register (I2C Wakeup Enable) Field Descriptions (continued)

Bit	Field	Value	Description
9	AAS_WE	0 1	Address as slave IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode, and external master addresses the I2C module as a slave. This allows for the module to inform the CPU that it can check which of the own addresses was used by the external master to access the I2C core. Addressed as slave wakeup disabled Addressed as slave wakeup enabled
8	BF_WE	0 1	Bus free IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode and the I2C bus became free. This allows for the module to inform the CPU that it can initiate its own transfer on the I2C line. Bus Free wakeup disabled Bus Free wakeup enabled
7	Reserved	0	Reserved
6	STC_WE	0 1	Start condition IRQ wakeup set. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode (with the functional clock inactive) and a possible start condition is detected on the I2C line. The STC WakeUp is generated only if the I2C_SYSC.ClockActivity field indicates that the functional clock can be disabled. Note that if the functional clock is not active, the start condition is asynchronously detected (no filtering and synchronization is used). For this reason, it is possible that the signaled start condition to be a glitch. If the functional clock cannot be disabled (I2C_SYSC.ClockActivity = 10 or 11), the programmer should not enable this wakeup, since the module has other synchronously detected WakeUp event that might be used to exit from idle mode, only if the detected transfer is accessing the I2C module. Start condition wakeup disabled Start condition wakeup enabled
5	GC_WE	0 1	General call IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode and a general call is received on I2C line. General call wakeup disabled General call wakeup enabled
4	Reserved	0	Reserved
3	DRDY_WE	0 1	Receive/Transmit data ready IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example module are set in F/S I2C master transmitter mode and FIFO is full). If in the middle of such a transaction, the FIFO buffer needs more data to be transferred, CPU must be informed to write (in case of transmitter mode) or read (if receiver mode) in/from the FIFO. Transmit/receive data ready wakeup disabled Transmit/receive data ready wakeup enabled
2	ARDY_WE	0 1	Register access ready IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example the module is set in F/S I2C master transmitter mode and FIFO is full). If the current transaction is finished, the module needs to inform CPU about transmission completion. Register access ready wakeup disabled Register access ready wakeup enabled
1	NACK_WE	0 1	No acknowledgment IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example the module is set in F/S I2C master transmitter mode and FIFO is full). If in the middle of such of a transaction a Not Acknowledgment event is raised, the module needs to inform CPU about transmission error. Not Acknowledge wakeup disabled Not Acknowledge wakeup enabled

Table 15-12. I2C_WE Register (I2C Wakeup Enable) Field Descriptions (continued)

Bit	Field	Value	Description
0	AL_WE		<p>Arbitration lost IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is configured as a master and it loses the arbitration. This wake up is very useful when the module is configured as a master transmitter, all the necessary data is provided in the FIFO Tx, STT is enabled and the module enters in Idle Mode. If the module loses the arbitration, an Arbitration Lost event is raised and the module needs to inform CPU about transmission error.</p> <p>Note: The AL wakeup must be enabled only for multimaster communication. If the AL_WE is not enabled and the scenario described above occurs, the module will not be able to inform the CPU about the state of the transfer and it will be blocked in an undetermined state.</p>
		0	Arbitration lost wakeup disabled
		1	Arbitration lost wakeup enabled

15.3.10 I2C_DMARXENABLE_SET Register (Receive DMA Enable Set)

The 1-bit field enables a receive DMA request. Writing a 1 to this field will set it to 1. Writing a 0 will have no effect, that is, the register value is not modified. Note that the I2C_BUF.RDMA_EN field is the global (slave) DMA enabler, and that it is disabled by default. The I2C_BUF.RDMA_EN field should also be set to 1 to enable a receive DMA request.

Figure 15-23. I2C_DMARXENABLE_SET Register (Receive DMA Enable Set)

Table 15-20. I2C_BUF Register (Buffer Configuration) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	RDMA_EN	0 1	Receive DMA channel enable. When this bit is set to 1, the receive DMA channel is enabled and the receive data ready status bit (I2C_IRQSTATUS_RAW: RRDY) is forced to 0 by the core. 0 Receive DMA channel disabled 1 Receive DMA channel enabled Value after reset is low.
14	RXFIFO_CLR	0 1	Receive FIFO clear. When set, receive FIFO is cleared (hardware reset for RX FIFO generated). This bit is automatically reset by the hardware. During reads, it always returns 0. 0 Normal mode 1 Rx FIFO is reset Value after reset is low.
13-8	RXTRSH	0-3Fh 0 1 - - 3Fh	Threshold value for FIFO buffer in RX mode. The receive threshold value is used to specify the trigger level for data receive transfers. The value is specified from the Interface/OCP point of view. 0 Receive Threshold value = 1 1 Receive Threshold value = 2 - - 3Fh Receive Threshold value = 64 Value after reset is 00h. For the FIFO management description, see the FIFO Management subsection. Note1: programmed threshold cannot exceed the actual depth of the FIFO. Note2: the threshold must not be changed while a transfer is in progress (after STT was configured or after the module was addressed as a slave).
7	XDMA_EN	0 1	Transmit DMA channel enable. When this bit is set to 1, the transmit DMA channel is enabled and the transmit data ready status (I2C_IRQSTATUS_RAW: XRDY) bit is forced to 0 by the core. 0 Transmit DMA channel disabled 1 Transmit DMA channel enabled Value after reset is low.
6	TXFIFO_CLR	0 1	Transmit FIFO clear. When set, transmit FIFO is cleared (hardware reset for TX FIFO). This bit is automatically reset by the hardware. During reads, it always returns 0. 0 Normal mode 1 Tx FIFO is reset Value after reset is low.

Table 15-20. I2C_BUF Register (Buffer Configuration) Field Descriptions (continued)

Bit	Field	Value	Description
5-0	TXTRSH	0-3Fh 0 1 - - 3Fh	<p>Threshold value for FIFO buffer in TX mode. The Transmit Threshold value is used to specify the trigger level for data transfers. The value is specified from the OCP point of view.</p> <p>Transmit Threshold value = 1</p> <p>Transmit Threshold value = 2</p> <p>Transmit Threshold value = 64</p> <p>Value after reset is 00h</p> <p>Note1: programmed threshold cannot exceed the actual depth of the FIFO.</p> <p>Note2: the threshold must not be changed while a transfer is in progress (after STT was configured or after the module was addressed as a slave).</p>

15.3.18 I2C_CNT Register (Data Counter)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This read/write register is used to control the numbers of bytes in the I2C data payload.

Figure 15-31. I2C_CNT Register (Data Counter)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-21. I2C_CNT Register (Data Counter) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	DCOUNT	0-FFFFh	<p>Data count. I2C Master Mode only (receive or transmit; F/S).</p> <p>This 16-bit countdown counter decrements by 1 for every byte received or sent through the I2C interface. A write initializes DCOUNT to a saved initial value. A read returns the number of bytes that are yet to be received or sent. A read into DCOUNT returns the initial value only before a start condition and after a stop condition.</p> <p>When DCOUNT reaches 0, the core generates a stop condition if a stop condition was specified (I2C_CON.STP = 1) and the ARDY status flag is set to 1 in the I2C_IRQSTATUS_RAW register.</p> <p>Note that DCOUNT must not be reconfigured after I2C_CON.STT was enabled and before ARDY is received.</p> <p>Note1: In case of I2C mode of operation, if I2C_CON.STP = 0, then the I2C asserts SCL = 0 when DCOUNT reaches 0. The CPU can then reprogram DCOUNT to a new value and resume sending or receiving data with a new start condition (restart). This process repeats until the CPU sets to 1 the I2C_CON.STP bit.</p> <p>The ARDY flag is set each time DCOUNT reaches 0 and DCOUNT is reloaded to its initial value.</p> <p style="margin-left: 20px;">0 Data counter = 65536 bytes (2¹⁶)</p> <p style="margin-left: 20px;">1 Data counter = 1 bytes</p> <p style="margin-left: 20px;">- </p> <p style="margin-left: 20px;">- </p> <p style="margin-left: 20px;">FFFFh Data counter = 65535 bytes (2¹⁶ - 1)</p> <p>Values after reset are low (all 16 bits).</p> <p>Note2: Since for DCOUNT = 0, the transfer length is 65536, the module does not allow the possibility to initiate zero data bytes transfers.</p>

15.3.19 I2C_DATA Register (Data Access)

This register is the entry point for the local host to read data from or write data to the FIFO buffer.

Figure 15-32. I2C_DATA Register (Data Access)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-22. I2C_DATA Register (Data Access) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	DATA	0-FFh	Transmit/Receive data FIFO endpoint. When read, this register contains the received I2C data. When written, this register contains the byte value to transmit over the I2C data. In SYSTEST loop back mode (I2C_SYSTEST: TMODE = 11), this register is also the entry/receive point for the data. Values after reset are unknown (all 8-bits). Note: A read access, when the buffer is empty, returns the previous read data value. A write access, when the buffer is full, is ignored. In both events, the FIFO pointers are not updated and an Access Error (AERR) Interrupt is generated.

15.3.20 I2C_CON Register (I2C Configuration)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register (except STP enable). Changing it may result in an unpredictable behavior.

Note: DCOUNT is data count value in I2C_CNT register.																							

15.3.21 I2C_OA Register (I2C Own Address)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the module's base I2C 7-bit or 10-bit address (base own address).

Figure 15-34. I2C_OA Register (I2C Own Address)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-24. I2C_OA Register (I2C Own Address) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	OA	0-3FFh	Own address. This field specifies either: <ul style="list-style-type: none"> A 10-bit address coded on OA [9:0] when XOA (Expand Own Address, I2C_CON[7]) is set to 1. A 7-bit address coded on OA [6:0] when XOA (Expand Own Address, I2C_CON[7]) is cleared to 0. In this case, OA [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

15.3.22 I2C_SA Register (I2C Slave Address)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the addressed I2C module 7-bit or 10-bit address (slave address).

Figure 15-35. I2C_SA Register (I2C Own Address)

	Reserved				SA
	R-0				R/W-3FFh

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-25. I2C_SA Register (I2C Slave Address) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	SA	0-3FFh	Slave address. This field specifies either: <ul style="list-style-type: none"> • A 10-bit address coded on SA [9:0] when XSA (Expand Slave Address, I2C_CON[8]) is set to 1. • A 7-bit address coded on SA [6:0] when XSA (Expand Slave Address, I2C_CON[8]) is cleared to 0. In this case, SA [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

15.3.23 I2C_PSC Register (I2C Clock Prescaler)

CAUTION

During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the internal clocking of the I2C peripheral core.

Figure 15-36. I2C_PSC Register (I2C Own Address)

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	PSC	0-FFh	Fast/Standard mode prescale sampling clock divider value. The core uses this 8-bit value to divide the system clock (SCLK) and generates its own internal sampling clock (ICLK) for Fast and Standard operation modes. The core logic is sampled at the clock rate of the system clock for the module divided by (PSC + 1). 0h Divide by 1 1h Divide by 2 - - FFh Divide by 256 Value after reset is low (all 8 bits).

Figure 15-37. Clock Divider

15.3.24 I2C_SCLL Register (I2C SCL Low Time)

CAUTION

During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to determine the SCL low time value when master.

Figure 15-38. I2C_SCLL Register (I2C SCL Low Time)

31		8 7	0
	Reserved		SCLL
	R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-27. I2C_SCLL Register (I2C SCL Low Time) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	SCLL	0-FFh	Fast/Standard mode SCL low time. I2C master mode only (FS). This 8-bit value is used to generate the SCL low time value (tLOW) when the peripheral is operated in master mode. $t_{LOW} = (SCLL + 7) * I_{CLK}$ time period, Value after reset is low (all 8 bits).

15.3.25 I2C_SCLH Register (I2C SCL High Time)

CAUTION

During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to determine the SCL high time value when master.

Figure 15-39. I2C_SCLH Register (I2C SCL High Time)

31		8 7	0
	Reserved		SCLH
	R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-28. I2C_SCLH Register (I2C SCL High Time) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	SCLH	0-FFh	Fast/Standard mode SCL low time. I2C master mode only (FS). This 8-bit value is used to generate the SCL high time value (tHIGH) when the peripheral is operated in master mode. $t_{HIGH} = (SCLH + 5 + \text{floor}[t_{rise}/I_{CLK} \text{ Period}]) * I_{CLK}$ time period. Value after reset is low (all 8 bits).

15.3.26 I2C_SYSTEST Register (System Test)

CAUTION
Never enable this register for normal I2C operation

This register is used to facilitate system-level tests by overriding some of the standard functional features of the peripheral. It allows testing of SCL counters, controlling the signals that connect to I/O pins, or creating digital loop-back for self-test when the module is configured in system test (SYSTEST) mode. It also provides stop/non-stop functionality in the debug mode.

Figure 15-40. I2C_SYSTEST Register (System Test)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-29. I2C_SYSTEST Register (System Test) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	ST_EN	0	System test enable. This bit must be set to 1 to permit other system test registers bits to be set. Normal mode. All others bits in register are read only.
		1	System test enabled. Permit other system test registers bits to be set.
			Value after reset is low.
14	FREE		Free running mode (on breakpoint). This bit is used to determine the state of the I2C controller when a breakpoint is encountered in the HLL debugger. Note: This bit can be set independently of ST_EN value. FREE = 0: the I2C controller stops immediately after completion of the on-going bit transfer. Stopping the transfer is achieved by forcing the SCL line low. Note that in this case there will be no status register updates. FREE = 1: the I2C interface runs free. When Suspend indication will be asserted, there will be no accesses on the OCP Interface (the CPU is in debug mode) and consequently the FIFOs will reach full/empty state (according to RX or TX modes) and the I2C SDA line will be kept low. Note that the status registers will be updated, but no DMA, IRQ or WakeUp will be generated. The status registers likely to be updated in this mode are: I2C_IRQSTATUS_RAW.XRDY, I2C_IRQSTATUS_RAW.RRDY, I2C_IRQSTATUS_RAW.XUDF, I2C_IRQSTATUS_RAW.ROVR, I2C_IRQSTATUS_RAW.ARDY and I2C_IRQSTATUS_RAW.NACK.
		0	Stop mode (on breakpoint condition). If Master mode, it stops after completion of the on-going bit transfer. In slave mode, it stops during the phase transfer when 1 byte is completely transmitted/received.
		1	Free running mode Value after reset is low.

Table 15-29. I2C_SYSTEST Register (System Test) Field Descriptions (continued)

Bit	Field	Value	Description
13-12	TMODE	0 1h 2h 3h	<p>Test mode select. In normal functional mode (ST_EN = 0), these bits are don't care. They are always read as 00 and a write is ignored.</p> <p>In system test mode (ST_EN = 1), these bits can be set according to the following table to permit various system tests.</p> <p>Functional mode (default)</p> <p>Reserved</p> <p>Test of SCL counters (SCLL, SCLH, PSC). SCL provides a permanent clock with master mode.</p> <p>Loop back mode select + SDA/SCL IO mode select</p> <p>Values after reset are low (2 bits).</p> <p>SCL counter test mode: in this mode, the SCL pin is driven with a permanent clock as if mastered with the parameters set in the I2C_PSC, I2C_SCLL, and I2C_SCLH registers.</p> <p>Loop back mode: in the master transmit mode only, data transmitted out of the I2C_DATA register (write action) is received in the same I2C_DATA register via an internal path through the FIFO buffer. The DMA and interrupt requests are normally generated if enabled.</p> <p>SDA/SCL IO mode: in this mode, the SCL IO and SDA IO are controlled via the I2C_SYSTEST [5:0] register bits.</p>
11	SSB	0 1	<p>Set status bits. Writing 1 into this bit also sets the 6 read/clear-only status bits contained in I2C_IRQSTATUS_RAW register (bits 5:0) to 1. Writing 0 into this bit doesn't clear status bits that are already set; only writing 1 into a set status bit can clear it (see I2C_IRQSTATUS_RAW operation). This bit must be cleared prior attempting to clear a status bit.</p> <p>No action</p> <p>Set all interrupt status bits to 1</p> <p>Value after reset is low.</p>
10-9	Reserved	0	Reserved

Table 15-29. I2C_SYSTEST Register (System Test) Field Descriptions (continued)

Bit	Field	Value	Description
2	SCL_O	Read:0 Read:1	SCL line drive output value. In normal functional mode (ST_EN = 0), this bit is don't care. It always reads 0 and a write is ignored. In system test mode (ST_EN = 1 & TMODE = 11), a 0 forces a low level on the SCL line and a 1 puts the I2C output driver to a high-impedance state. Forces 0 on the SCL data line SCL output driver in high-impedance state Value after reset is low.
1	SDA_I	Read:0 Read:1	SDA line sense input value. In normal functional mode (ST_EN = 0), this read-only bit always reads 0. In system test mode (ST_EN = 1 & TMODE = 11), this read-only bit returns the logical state taken by the SDA line (either 1 or 0). Read 0 from SDA line Read 1 from SDA line Value after reset is low.
0	SDA_O	0 1	SDA line drive output value. In normal functional mode (ST_EN = 0), this bit is don't care. It reads as 0 and a write is ignored. In system test mode (ST_EN = 1 & TMODE = 11), a 0 forces a low level on the SDA line and a 1 puts the I2C output driver to a high-impedance state. Write 0 to SDA line Write 1 to SDA line Value after reset is low.

15.3.27 I2C_BUFSTAT Register (I2C Buffer Status)

This read-only register reflects the status of the internal buffers for the FIFO management (see the FIFO Management subsection).

Figure 15-41. I2C_BUFSTAT Register (I2C Buffer Status)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-30. I2C_BUFSTAT Register (I2C Buffer Status) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-14	FIFODEPTH	0 1h 2h 3h	Internal FIFO buffers depth. This read-only bit indicates the internal FIFO buffer depth. 8-bytes FIFO 16-bytes FIFO 32-bytes FIFO 64-bytes FIFO Value after reset is given by the boundary module generic parameter.
13-8	RXSTAT	0-3Fh	RX buffer status. This read-only field indicates the number of bytes to be transferred from the FIFO at the end of the I2C transfer (when RDR is asserted). It corresponds to the level indication of the RX FIFO (number of written locations). Value after reset is 0.
7-6	Reserved	0	Reserved
5-0	TXSTAT	0-3Fh	TX buffer status. This read-only field indicates the number of data bytes still left to be written in the TX FIFO (it's equal with the initial value of I2C_CNT.DCOUNT minus the number of data bytes already written in the TX FIFO through the OCP Interface). Value after reset is equal with 0.

15.3.28 I2C_OA1 Register (OA1) (Own Address 1)

CAUTION

During an active transfer phase (between STT has been set to 1 and receiving of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the first alternative I2C 7-bit or 10-bit address (own address 1 - OA1).

Figure 15-42. I2C_OA1 Register (OA1) (Own Address 1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-33. I2C_OA3 Register (I2C Own Address 3) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	OA3	0-3FFh	Own address 2. This field specifies either: <ul style="list-style-type: none"> A 10-bit address coded on OA3 [9:0] when XOA3 (Expand Own Address 3 - XOA3, I2C_CON[4]) is set to 1. A 7-bit address coded on OA3 [6:0] when XOA1 (Expand Own Address 3 – XOA3, I2C_CON[4]) is cleared to 0. In this case, OA3 [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

15.3.31 I2C_ACTOA Register (Active Own Address)

This read-only register is used to indicate which one of the module's four own addresses the external master used when addressing the module. The CPU can read this register when the AAS indication was activated. The indication is cleared at the end of the transfer.

Figure 15-45. I2C_ACTOA Register (Active Own Address)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-34. I2C_ACTOA Register (Active Own Address) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	OA3_ACT	0 1	Own address 3 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module. Own address inactive Own address active Value after reset is low.
2	OA2_ACT	0 1	Own address 2 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module. Own address inactive Own address active Value after reset is low.
1	OA1_ACT	0 1	Own address 1 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module. Own address inactive Own address active Value after reset is low.
0	OA0_ACT	0 1	Own address 0 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module. Own address inactive Own address active Value after reset is low.

15.3.32 I2C_SBLOCK Register (I2C Clock Blocking Enable)

This read/write register controls the automatic blocking of I2C clock feature in slave mode. It is used for the Local Host to configure for which of the 4 own addresses, the core must block the I2C clock (keep SCL line low) right after the Address Phase, when it is addressed as a slave.

Figure 15-46. I2C_SBLOCK Register (I2C Clock Blocking Enable)

Table 15-35. I2C_SBLOCK Register (I2C Clock Blocking Enable) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	OA3_EN	0 1	Enable I2C clock blocking for own address 3. When the CPU sets a bit location to 1, if an external master using the corresponding own address addresses the core, the core will block the I2C clock right after the address phase. For releasing the I2C clock the CPU must write '0' in the corresponding field. I2C clock released I2C clock blocked Value after reset is low.
2	OA2_EN	0 1	Enable I2C clock blocking for own address 2. When the CPU sets a bit location to 1, if an external master using the corresponding own address addresses the core, the core will block the I2C clock right after the address phase. For releasing the I2C clock the CPU must write '0' in the corresponding field. I2C clock released I2C clock blocked Value after reset is low.
1	OA1_EN	0 1	Enable I2C clock blocking for own address 1. When the CPU sets a bit location to 1, if an external master using the corresponding own address addresses the core, the core will block the I2C clock right after the address phase. For releasing the I2C clock the CPU must write '0' in the corresponding field. I2C clock released I2C clock blocked Value after reset is low.
0	OA0_EN	0 1	Enable I2C clock blocking for own address 0. When the CPU sets a bit location to 1, if an external master using the corresponding own address addresses the core, the core will block the I2C clock right after the address phase. For releasing the I2C clock the CPU must write '0' in the corresponding field. I2C clock released I2C clock blocked Value after reset is low.

Multichannel Audio Serial Port (McASP)

This chapter is a description of the IP of the multichannel audio serial port (McASP).

Topic	Page
16.1 Introduction	1981
16.2 Architecture	1993
16.3 McASP Registers	2036

16.1 Introduction

16.1.1 Purpose of the Peripheral

The multichannel audio serial port (McASP) functions as a general-purpose audio serial port optimized for the needs of multichannel audio applications. The McASP is useful for time-division multiplexed (TDM) stream, Inter-Integrated Sound (I2S) protocols, and intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony / Philips digital interface (S/PDIF) transmit physical layer component. The McASP consists of transmit and receive sections that may operate synchronized, or completely independently with separate master clocks, bit clocks, and frame syncs, and using different transmit modes with different bit-stream formats. The McASP module also includes serializers that can be individually enabled to either transmit or receive.

Although intercomponent digital audio interface reception (DIR) mode (that is, S/PDIF stream receiving) is NOT natively supported by the McASP module, a specific TDM mode implementation for the McASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

16.1.2 Features

Features of the McASP include:

- Two independent clock generator modules for transmit and receive.
 - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- Independent transmit and receive modules, each includes:
 - Programmable clock and frame sync generator.
 - TDM streams from 2 to 32, and 384 time slots.
 - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
 - Data formatter for bit manipulation.
- Individually assignable serial data pins.
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT) supports (up to 10 transmit pins):
 - S/PDIF, IEC60958-1, AES-3 formats.
 - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
 - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Extensive error checking and recovery.
 - Transmit underruns and receiver overruns due to the system not meeting real-time requirements.
 - Early or late frame sync in TDM mode.
 - Out-of-range high-frequency master clock for both transmit and receive.
 - External error signal coming into the AMUTEIN input.
 - DMA error due to incorrect programming.
- up to 16 serial data pins depending of the McASP instance in use (see your device-specific data manual) - each serializer having associated one transmit (Tx) and one receive (Rx) channel, which allows support of:
 - 16 data channels, each configurable to either transmit or receive at a time
 - A single 32-bit buffer per serializer for transmit and receive operations
 - One transmit interrupt request (AXINT) and one receive interrupt request (ARINT) linked with each of the 16 serializers

NOTE: Because a serializer receive and transmit channels data is shared on the same MCASP data pin, you can choose to have either Tx or Rx function from a serializer, NOT both at the same time.

16.1.3 Protocols Supported

The McASP supports a wide variety of protocols.

- Transmit section supports:
 - Wide variety of I2S and similar bit-stream formats.
 - TDM streams from 2 to 32 time slots.
 - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
 - Wide variety of I2S and similar bit-stream formats.
 - TDM streams from 2 to 32 time slots.
 - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections may each be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length.
- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
 - Automatically aligns data internally in either Q31 or integer formats.
 - Automatically masks non-significant bits (sets to 0, 1, or extends value of another bit).

In DIT mode for McASP, additional features of the transmitter are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Bi-phase encoded 3.3 V output.
- Support for consumer and professional applications.
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.

In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

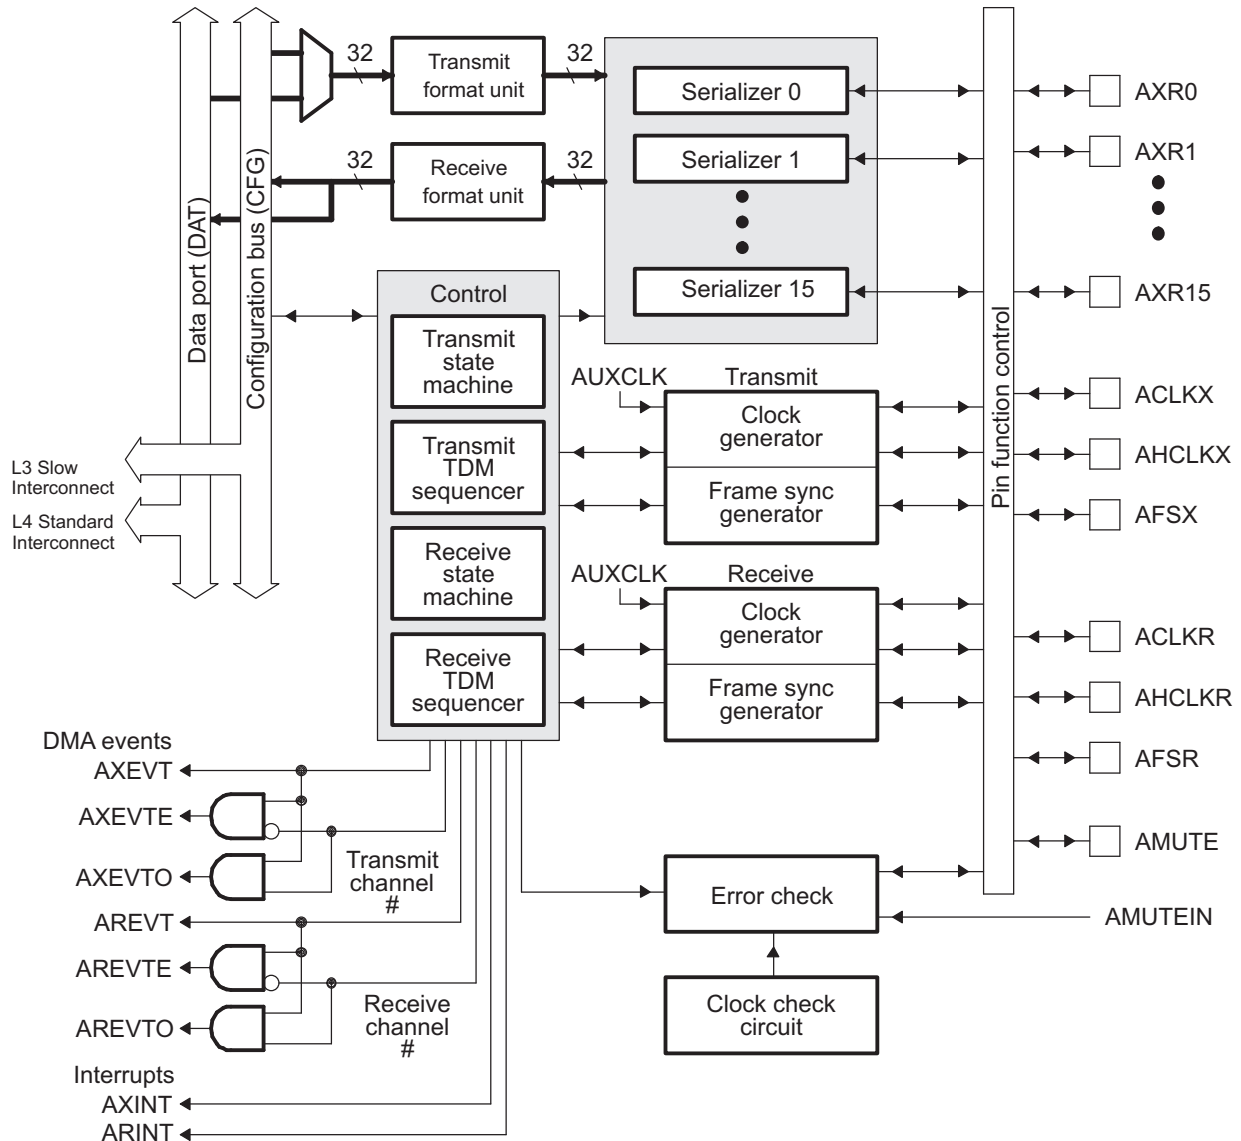

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphasic Mark Encoded Data).

The MCASP does NOT natively support DIR-mode reception (that is, receiving in the S/PDIF format). To allow this, the MCASP can use a DIR-input to I2S-output converter implemented by an external device (that is, external DIR component). To facilitate reception in this case, the TDM mode of MCASP receivers logic is extended to support a non-standard 384-slot TDM stream.

16.1.4 Functional Block Diagram

Figure 16-1 shows the major blocks of the McASP. The McASP has independent receive/transmit clock generators and frame sync generators.

Figure 16-1. McASP Block Diagram

- A McASP has up to 16 serial data pins depending of the McASP instance in use (see your device-specific data manual). When referring to AXRn data pins in this document, n will be up to 15.
- B AMUTEIN is not a dedicated McASP pin, but typically comes from one of the external interrupt pins.

16.1.4.1 System Level Connections

Figure 16-2 through Figure 16-6 show examples of McASP usage in digital audio encoder/decoder systems.

16.1.5 Supported Use Case Statement

16.1.6 Industry Standard Compliance Statement

The McASP supports the following industry standard interfaces.

16.1.6.1 TDM Format

The McASP transmitter and receiver support the multichannel, synchronous time-division-multiplexed (TDM) format via the TDM transfer mode. Within this transfer mode, a wide variety of serial data formats are supported, including formats compatible with devices using the Inter-Integrated Sound (I2S) protocol. This section briefly discusses the TDM format and the I2S protocol.

16.1.6.1.1 TDM Format

The TDM format is typically used when communicating between integrated circuit devices on the same printed circuit board or on another printed circuit board within the same piece of equipment. For example, the TDM format is used to transfer data between the processor and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices.

The TDM format consists of three components in a basic synchronous serial transfer: clock (CLK), data (AXRn), and the frame sync (FS). In a TDM transfer, all data bits (AXRn) are synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (as defined in [Section 16.1.7](#)). The "slots" are also commonly referred to as "time slots" or "channels" in TDM terminology. A frame consists of multiple slots (or channels). Each TDM frame is defined by the frame sync signal (AFSX or AFSR). Data transfer is continuous and periodic, since the TDM format is most commonly used to communicate with data converters that operate at a fixed sample rate.

There are no delays between slots. The last bit of slot N is followed immediately on the next serial clock cycle with the first bit of slot N + 1, and the last bit of the last slot is followed immediately on the next serial clock with the first bit of the first slot. However, the frame sync may be offset from the first bit of the first slot with a 0, 1, or 2-cycle delay.

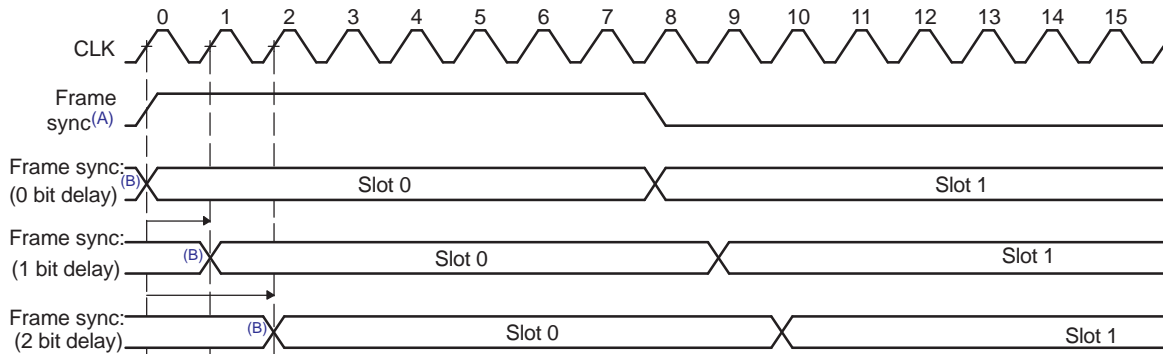

It is required that the transmitter and receiver in the system agree on the number of bits per slot, since the determination of a slot boundary is not made by the frame sync signal (although the frame sync marks the beginning of slot 0 and the beginning of a new frame).

[Figure 16-7](#) shows the TDM format. [Figure 16-8](#) shows the different bit delays from the frame sync.

A FS duration of slot is shown. FS duration of single bit is also supported.

Figure 16-8. TDM Format Bit Delays from Frame Sync

- A FS duration of slot is shown. FS duration of single bit is also supported.
- B Last bit of last slot of previous frame. No gap between this bit and the first bit of slot 0 is allowed.

In a typical audio system, one frame of data is transferred during each data converter sample period f_s . To support multiple channels, the choices are to either include more time slots per frame (thus operating with a higher bit clock rate), or to use additional data pins to transfer the same number of channels (thus operating with a slower bit clock rate).

For example, a particular six channel DAC may be designed to transfer over a single serial data pin AXRn as shown in Figure 16-7. In this case the serial clock must run fast enough to transfer a total of 6 channels within each frame period. Alternatively, a similar six channel DAC may be designed to use three serial data pins AXR[0,1,2], transferring two channels of data on each pin during each sample period. In the latter case, if the sample period remains the same, the serial clock can run three times slower than the former case. The McASP is flexible enough to support either type of DAC.

16.1.6.1.2 Inter-Integrated Sound (I2S) Format

The inter-integrated sound (I2S) format is used extensively in audio interfaces. The TDM transfer mode of the McASP supports the I2S format when configured to 2 slots per frame.

I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format is the same as the slot size. The frame signal is also referred to as "word select" in the I2S format. Figure 16-9 shows the I2S protocol.

The McASP supports transfer of multiple stereo channels over multiple AXRn pins.

Figure 16-9. Inter-Integrated Sound (I2S) Format

- A 1 to 16 data pins may be supported.

16.1.6.2 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphasemark encoded output. The S/PDIF format is supported by the digital audio interface transmit (DIT) transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

16.1.6.2.1 Biphasemark Code (BMC)

In S/PDIF format, the digital signal is coded using the biphasemark code (BMC). The clock, frame, and data are embedded in only one signal—the data pin AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals to the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 16-10 and Table 16-1 show how data is encoded to the BMC format.

As shown in Figure 16-10, the frequency of the clock is twice the unencoded data bit rate. In addition, the clock is always programmed to $128 \times f_s$, where f_s is the sample rate (see Section 16.1.6.2.3 for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

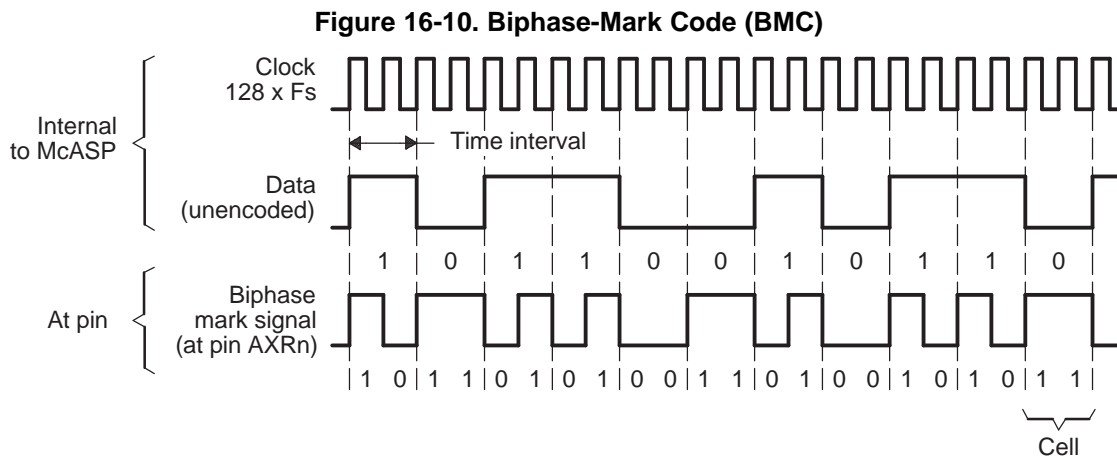

Table 16-1. Biphasemark Encoder

Data (Unencoded)	Previous State at Pin	
	AXRn	BMC-Encoded Cell Output at AXRn
0	0	11
0	1	00
1	0	10
1	1	01

16.1.6.2.2 Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered from 0 to 31. Figure 16-11 shows a subframe.

- **Time intervals 0-3** carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is *not* encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 16-2.
- **Time intervals 4-27** carry the audio sample word in linear 2s-complement representation. The most-significant bit (MSB) is carried by time interval 27. When a 24-bit coding range is used, the least-significant bit (LSB) is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4-7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (either 20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field may carry any other information.
- **Time interval 28** carries the validity bit (V) associated with the main data field in the subframe.
- **Time interval 29** carries the user data channel (U) associated with the main data field in the subframe.
- **Time interval 30** carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- **Time interval 31** carries a parity bit (P) such that time intervals 4-31 carry an even number of 1s and an even number of 0s (even parity). As shown in Table 16-2, the preambles (time intervals 0-3) are also defined with even parity.

Figure 16-11. S/PDIF Subframe Format

Table 16-2. Preamble Codes

Preamble Code ⁽¹⁾	Previous Logical State	Logical States on pin AXRn ⁽²⁾	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

⁽¹⁾ Historically, preamble codes are referred to as B, M, W. For use in professional applications, preambles are referred to as Z, X, Y, respectively.

⁽²⁾ The preamble is not BMC encoded. Each logical state is synchronized to the serial clock. These 8 logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

As shown in Table 16-2, the McASP DIT only generates one polarity of preambles and it assumes the previous logical state to be 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

16.1.6.2.3 Frame Format

An S/PDIF frame is composed of two subframes (Figure 16-12). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s . The S/PDIF format clock rate is therefore $128 \times f_s$ ($128 = 32 \text{ cells/subframe} \times 2 \text{ clocks/cell} \times 2 \text{ subframes/sample}$). For example, for an S/PDIF stream at a 192 kHz sampling frequency, the serial clock is $128 \times 192 \text{ kHz} = 24.58 \text{ MHz}$.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data. The first subframe (**left** or **A** channel in stereophonic operation and **primary** channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (**right** or **B** channel in stereophonic operation and **secondary** channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 16-12. S/PDIF Frame Format

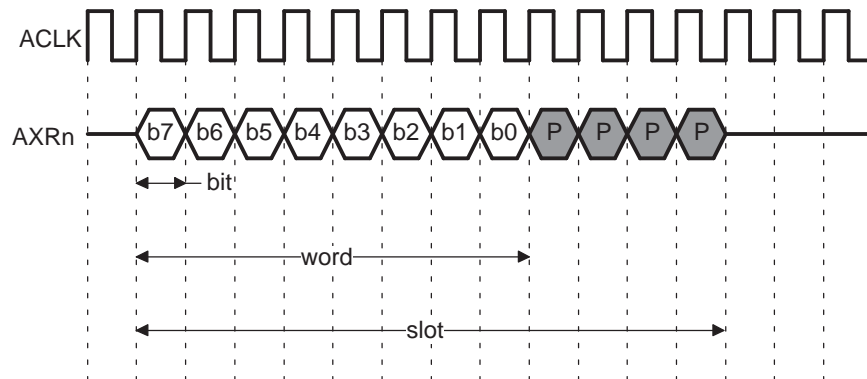

16.1.7 Definition of Terms

The serial bit stream transmitted or received by the McASP is a long sequence of 1s and 0s, either output or input on one of the audio transmit/receive pins (AXRn). However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. Figure 16-13 shows two of the three basic components—the clock (ACLK) and the data (AXRn). Figure 16-13 does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, the transmitter uses ACLKX as the serial clock, and the receiver uses ACLKR as the serial clock. Optionally, the receiver can use ACLKX as the serial clock when the transmitter and receiver of the McASP are configured to operate synchronously.

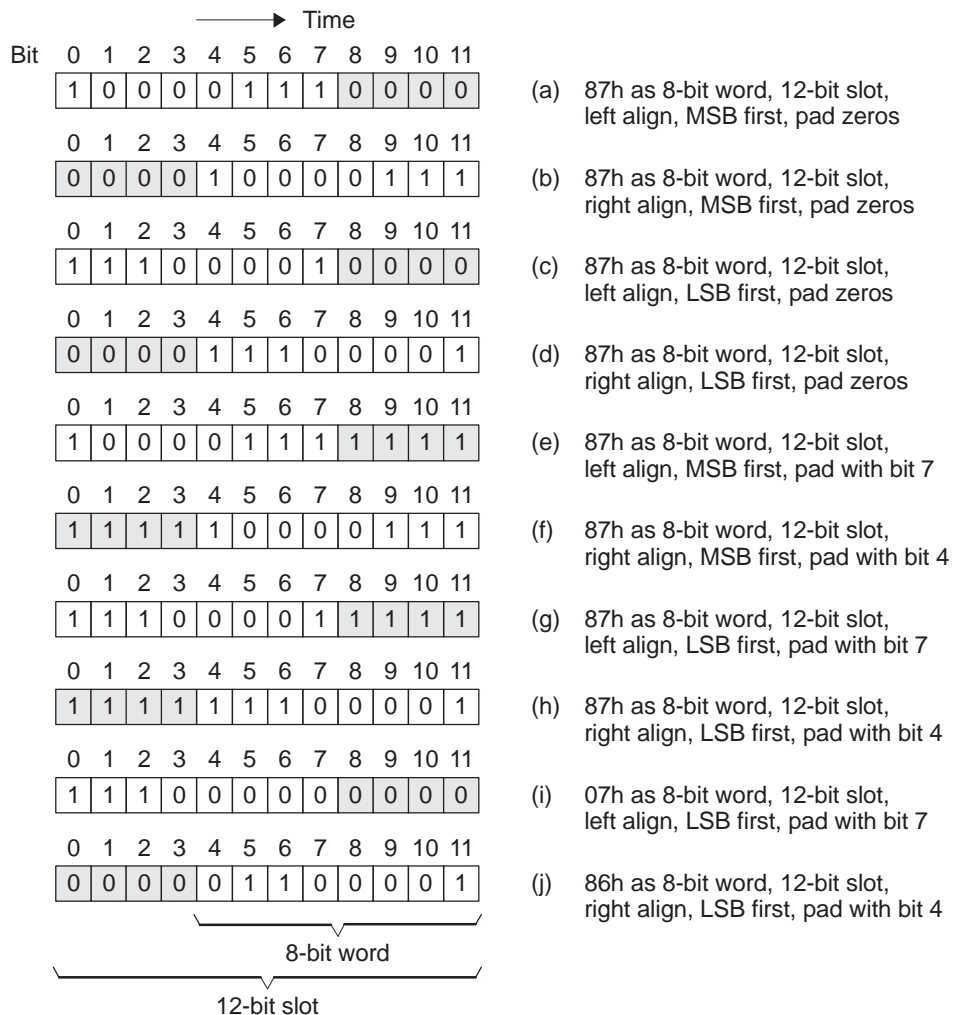

Bit	A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A "1" is represented by a logic high on the AXRn pin for the entire duration of the bit. A "0" is represented by a logic low on the AXRn pin for the entire duration of the bit.
Word	A word is a group of bits that make up the data being transferred between the processor and the external device. Figure 16-13 shows an 8-bit word.
Slot	A slot consists of the bits that make up the word, and may consist of additional bits used to pad the word to a convenient number of bits for the interface between the processor and the external device. In Figure 16-13, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with 4 zeros (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits may be shifted in/out of the McASP on the AXRn pin either MSB or LSB first. When the word size is smaller than the slot size, the word may be aligned to the left (beginning) of the slot or to the right (end) of the slot. The additional bits in the slot not belonging to the word may be padded with 0, 1, or with one of the bits (the MSB or the LSB typically) from the data word. These options are shown in Figure 16-14.

Figure 16-13. Definition of Bit, Word, and Slot

- (1) b7:b0 - bits. Bits b7 to b0 form a word.
- (2) P - pad bits. Bits b7 to b0, together with the four pad bits, form a slot.
- (3) In this example, the data is transmitted MSB first, left aligned.

Figure 16-14. Bit Order and Word Alignment Within a Slot Examples

- | | | | |
|---|-------------------------------|---|--------------------------|
| 1 | Unshaded: bit belongs to word | 1 | Shaded: bit is a pad bit |
|---|-------------------------------|---|--------------------------|

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync (FS) in this document.

Frame	A frame contains one or multiple slots, as determined by the desired protocol. Figure 16-15 shows an example frame of data and the frame definitions. Figure 16-15 does not specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, the transmitter uses AFSX and the receiver uses AFSR. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously.
--------------	--

This section only shows the generic definition of the frame sync. See [Section 16.1.6](#) and [Section 16.2.6.1](#) for details on the frame sync formats required for the different transfer modes and protocols (burst mode, TDM mode and I2S format, DIT mode and S/PDIF format).

Figure 16-15. Definition of Frame and Frame Sync Width

(1) In this example, there are two slots in a frame, and FS duration of slot length is shown.

Other terms used throughout the document:

TDM	Time-division multiplexed. See Section 16.1.6.1 for details on the TDM protocol.
DIR	Digital audio interface receive. The McASP does not natively support receiving in the S/PDIF format. The McASP supports I2S format output by an external DIR device.
DIT	Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on up to all data pins configured as outputs.
I2S	Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
Slot or Time Slot	For TDM format, the term time slot is interchangeable with the term slot defined in this section. For DIT format, a McASP time slot corresponds to a DIT subframe.

16.2 Architecture

16.2.1 Overview

Figure 16-1 shows the major blocks of the McASP. The McASP has independent receive/transmit clock generators and frame sync generators, error-checking logic, and up to 16 serial data pins. Refer to the device-specific data manual for the features available on your device.

All the McASP pins on the device may be individually programmed as general-purpose I/O (GPIO) if they are not used for serial port functions.

The McASP includes the following pins:

- Serializers;
 - Data pins AXRn: Up to 16 pins per McASP.
- Transmit clock generator:
 - AHCLKX: McASP transmit high-frequency master clock.
 - ACLKX: McASP transmit bit clock.
- Transmit Frame Sync Generator;
 - AFSX: McASP transmit frame sync or left/right clock (LRCLK).
- Receive clock generator;
 - AHCLKR: McASP receive high-frequency master clock.
 - ACLKR: McASP receive bit clock.
- Receive Frame Sync Generator;
 - AFSR: McASP receive frame sync or left/right clock (LRCLK).
- Mute in/out;
 - AMUTEIN: McASP mute input (from external device).
 - AMUTE: McASP mute output.

16.2.2 Clock and Frame Sync Generators

The McASP clock generators are able to produce two independent clock zones: transmit and receive clock zones. The serial clock generators may be programmed independently for the transmit section and the receive section, and may be completely asynchronous to each other. The serial clock (clock at the bit rate) may be sourced:

- Internally - by passing through two clock dividers off the internal clock source (AUXCLK).
- Externally - directly from ACLKR/X pin, which are configured as inputs. In this case, the Rx/Tx high-speed clock logic is bypassed for the XCLK/RCLK generation.
- Mixed - an external high-frequency clock is input to the McASP on either the AHCLKX or AHCLKR pins, and divided down to produce the bit rate clock.

In the internal/mixed cases, the bit rate clock is generated internally and should be driven out on the ACLKX (for transmit) or ACLKR (for receive) pins. In the internal case, an internally-generated high-frequency clock may be driven out onto the AHCLKX or AHCLKR pins to serve as a reference clock for other components in the system.

The McASP requires a minimum of a bit clock and a frame sync to operate, and provides the capability to reference these clocks from an external high-frequency master clock. In DIT mode, it is possible to use only internally-generated clocks and frame syncs.

A typical role of the McASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

16.2.2.1 Transmit Clock

The transmit bit clock, ACLKX, (Figure 16-16) may be either externally sourced from the ACLKX pin or internally generated, as selected by the CLKXM bit. If internally generated (CLKXM = 1), the clock is divided down by a programmable bit clock divider (CLKXDIV) from the transmit high-frequency master clock (AHCLKX).

Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock, XCLK, (Figure 16-16). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If CLKXP = 0, the CLKXP mux directly passes ACLKX to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If CLKXP = 1, the CLKXP mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

The transmit high-frequency master clock, AHCLKX, may be either externally sourced from the AHCLKX pin or internally generated, as selected by the HCLKXM bit. If internally generated (HCLKXM = 1), the clock is divided down by a programmable high clock divider (HCLKXDIV) from McASP internal clock source AUXCLK. The transmit high-frequency master clock may be (but is not required to be) output on the AHCLKX pin where it is available to other devices in the system.

The transmit clock configuration is controlled by the following registers:

- ACLKXCTL
- AHCLKXCTL

Figure 16-16. Transmit Clock Generator Block Diagram

(1) Refer to the device-specific data manual for multiplexing options.

16.2.2.2 Receive Clock

The MCASP receive clock generator is built on a very similar circuit to the transmit clock generator (but independent) circuit. The receiver also has the option to operate synchronously from the ACLKX and AFSX signals. This is achieved when the ASYNC bit in the transmit clock control register (ACLKXCTL) is cleared to 0 (see Figure 16-17). The receiver may be configured with different polarity (CLKRP) and frame sync data delay options from those options of the transmitter.

The receive clock configuration is controlled by the following registers:

- ACLKRCTL
- AHCLRCTL

In case the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the CLKRM bit (from ACLKRCTL register) must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (CLKRDIV bit field in ACLKRCTL register) from the source signal. If the receive high-frequency master clock, AHCLKR, is also sourced internally, the HCLKRM bit (AHCLRCTL register) must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (HCLKRDIV bit field in AHCLRCTL register) from the MCASP internal clock source AUXCLK.

The receive high-frequency master clock, AHCLKR, may be (but is not required to be) output on the AHCLKR pin where it is available to other devices in the system. Regardless if AHCLKR is either internally generated or externally sourced, polarity of the high-frequency clock may be programmed via bit HCLKRP to be either rising or falling edge.

Figure 16-17. Receive Clock Generator Block Diagram

(1) Refer to the device-specific date manual for multiplexing options.

16.2.2.3 Frame Sync Generator

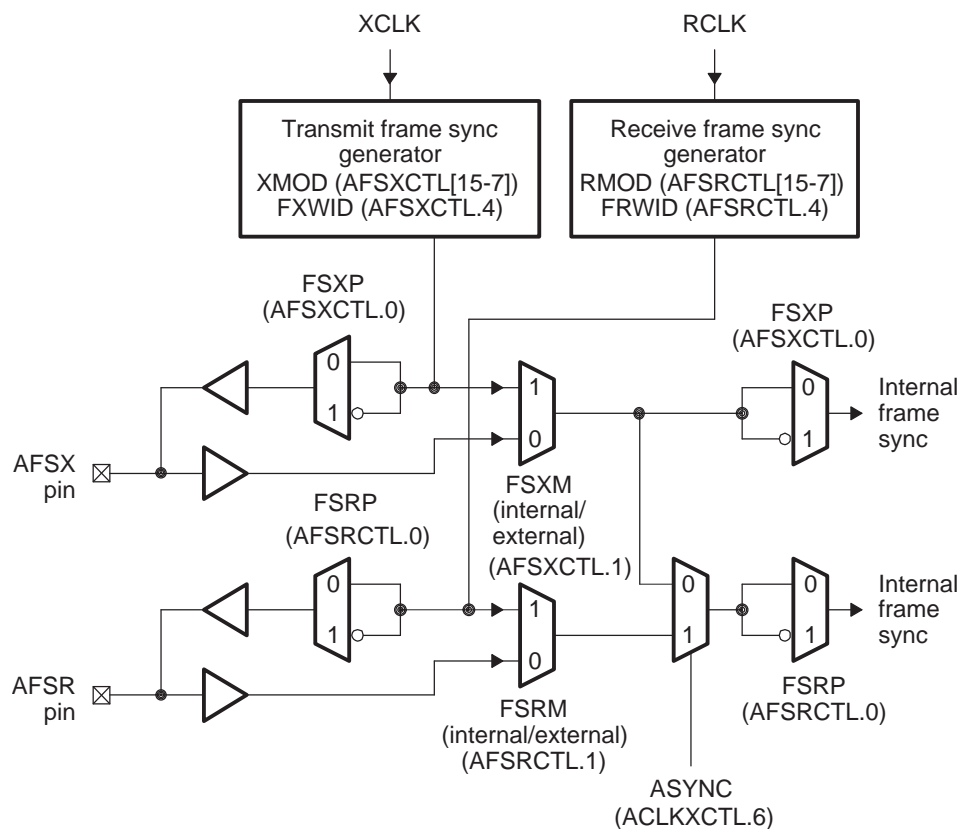

There are two different modes for frame sync: burst and TDM. A block diagram of the frame sync generator is shown in Figure 16-18. The frame sync options are programmed by the receive and transmit frame sync control registers (AFSRCTL and AFSXCTL). The options are:

- Internally-generated or externally-generated via configuring bit AFSXCTL[1] FSXM for transmit or AFSRCTL[1] FSRM for receive logic
- Frame sync polarity: rising edge or falling edge via configuring bit AFSXCTL[0] FSXP for transmit or AFSRCTL[0] FSRP for receive logic
- Frame sync width: single bit or single word via configuring bit AFSXCTL[4] FXWID for transmit or AFSRCTL[4] FRWID for receive logic
- Bit delay: 0, 1, or 2 cycles before the first data bit
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit, ACLKXCTL[6] ASYNC, used to define the receiver internal clock source.

The transmit frame sync pin is AFSX and the receive frame sync pin is AFSR. A typical usage for these pins is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

Regardless if the AFSX/AFSR is internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSRP/FSRP = 1, the frame sync polarity is falling edge.

Figure 16-18. Frame Sync Generator Block Diagram

16.2.2.4 Clocking Examples

Some examples of processes using the McASP clocking and frame flexibility are:

- Receive data from a DVD at 48 kHz, but output up-sampled or decoded audio at 96 kHz or 192 kHz. This could be accomplished by inputting a high-frequency master clock (for example, 512 x receive FS), receiving with an internally-generated bit clock ratio of divide-by-8, and transmitting with an internally-generated bit clock ratio of divide-by-4 or divide-by-2.
- Transmit/receive data based on one sample rate (for example, 44.1 kHz), and transmit/receive data at a different sample rate (for example, 48 kHz).

16.2.3 Memory Map

See the device-specific data manual for information describing the device memory-map.

16.2.4 Signal Descriptions

The signals used on the McASP audio interface are listed in [Table 16-3](#).

Table 16-3. McASP Interface Signals

Pin ⁽¹⁾	I/O/Z	Device Reset (RESET = 0)	Description
Transmitter Control			
AHCLKX	I/O/Z	Input	Transmit high-frequency master clock
AFSX	I/O/Z	Input	Transmit frame sync or left/right clock (LRCLK)
ACLKX	I/O/Z	Input	Transmit bit clock
Receiver Control			
AHCLKR	I/O/Z	Input	Receive high-frequency master clock
AFSR	I/O/Z	Input	Receive frame sync or left/right clock (LRCLK)
ACLKR	I/O/Z	Input	Receive bit clock
Mute			
AMUTE	I/O/Z	Input	Mute output
AMUTEIN	I/O/Z	Input	Mute input
Data			
AXRn	I/O/Z	Input	TX/RX data pins. Up to 16 data pins are supported (n = 0 to 15).

⁽¹⁾ Due to pinout restrictions, not all interface signals are supported on all devices or all McASP instances. Refer to your device-specific data manual for details.

16.2.5 Pin Multiplexing

The McASP signals share pins with other processor functions. For detailed information on the McASP pin multiplexing and configuration, see the pin multiplexing information in the device-specific data manual.

16.2.6 Transfer Modes

16.2.6.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

When operating in burst frame sync mode (Figure 16-19), as specified for transmit (XMOD = 0 in AFSXCTL) and receive (RMOD = 0 in AFSRCTL), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (FRWID = 0 in AFSRCTL, FXWID = 0 in AFSXCTL).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUF[n] (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF[n] (for every serializer set to operate as a receiver) has been read.

Figure 16-19. Burst Frame Sync Mode

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- PFUNC: The clock, frame, data pins must be configured for McASP function.
- PDIR: The clock, frame, data pins must be configured to the direction desired.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable. Leave at default.
- GBLCTL: Follow the initialization sequence in Section 16.2.10.2 to configure this register.
- AMUTE: Not applicable. Leave at default.
- DLBCTL: If loopback mode is desired, configure this register according to Section 16.2.8.5, otherwise leave this register at default.
- DITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- RMASK/XMASK: Mask desired bits according to Section 16.2.7.2 and Section 16.2.8.3.
- RFMT/XFMT: Program all fields according to data format desired. See Section 16.2.8.3.
- AFSRCTL/AFSXCTL: Clear **RMOD/XMOD** bits to 0 to indicate burst mode. Clear **FRWID/FXWID** bits to 0 for single bit frame sync duration. Configure other fields as desired.
- ACLKRCTL/ACLKXCTL: Program all fields according to bit clock desired. See Section 16.2.2.
- AHCLKRCTL/AHCLKXCTL: Program all fields according to high-frequency clock desired. See Section 16.2.2.

- RTDM/XTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- RINTCTL/XINTCTL: Program all fields according to interrupts desired.
- RCLKCHK/XCLKCHK: Not applicable. Leave at default.
- SRCTLn: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- DITCSRA[n], DITCSRB[n], DITUDRA[n], DITUDRB[n]: Not applicable. Leave at default.

16.2.6.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in [Section 16.1.6.1](#).

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock.
- AFSX - transmit frame sync (or commonly called left/right clock).
- One or more serial data pins, AXRn, whose serializers have been configured to transmit.

The transmitter has the option to receive the ACLKX bit clock as an input, or to generate the ACLKX bit clock by dividing down the AHCLKX high-frequency master clock. The transmitter can either generate AHCLKX internally or receive AHCLKX as an input. See [Section 16.2.2.1](#).

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock.
- AFSR - receive frame sync (or commonly called left/right clock).
- One or more serial data pins, AXRn, whose serializers have been configured to receive.

The receiver has the option to receive the ACLKR bit clock as an input or to generate the ACLKR bit clock by dividing down the AHCLKR high-frequency master clock. The receiver can either generate AHCLKR internally or receive AHCLKR as an input. See [Section 16.2.2.2](#) and [Section 16.2.2.3](#).

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are in bold face:

- PFUNC: The clock, frame, data pins must be configured for McASP function.
- PDIR: The clock, frame, data pins must be configured to the direction desired.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable. Leave at default.
- GBLCTL: Follow the initialization sequence in [Section 16.2.10.2](#) to configure this register.
- AMUTE: Program all fields according to mute control desired.
- DLBCTL: If loopback mode is desired, configure this register according to [Section 16.2.8.5](#), otherwise leave this register at default.
- DITCTL: DITEN must be left at default 0 to select TDM mode. Leave the register at default.
- RMASK/XMASK: Mask desired bits according to [Section 16.2.7.2](#) and [Section 16.2.8.3](#).
- RFMT/XFMT: Program all fields according to data format desired. See [Section 16.2.8.3](#).
- AFSRCTL/AFSXCTL: Set **RMOD/XMOD** bits to 2-32 for TDM mode. Configure other fields as desired.
- ACLKRCTL/ACLKXCTL: Program all fields according to bit clock desired. See [Section 16.2.2](#).
- AHCLKRCTL/AHCLKXCTL: Program all fields according to high-frequency clock desired. See [Section 16.2.2](#).
- RTDM/XTDM: Program all fields according to the time slot characteristics desired.
- RINTCTL/XINTCTL: Program all fields according to interrupts desired.
- RCLKCHK/XCLKCHK: Program all fields according to clock checking desired.
- SRCTLn: Program all fields according to serializer operation desired.
- DITCSRA[n], DITCSRB[n], DITUDRA[n], DITUDRB[n]: Not applicable. Leave at default.

16.2.6.2.1 TDM Time Slots

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring XTDM and/or RTDM (this allows multiple processors to communicate on the same TDM serial bus).

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either XTDM or RTDM to determine if the McASP should transmit/receive in that time slot.

If the transmit/receive bit is active, the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated.

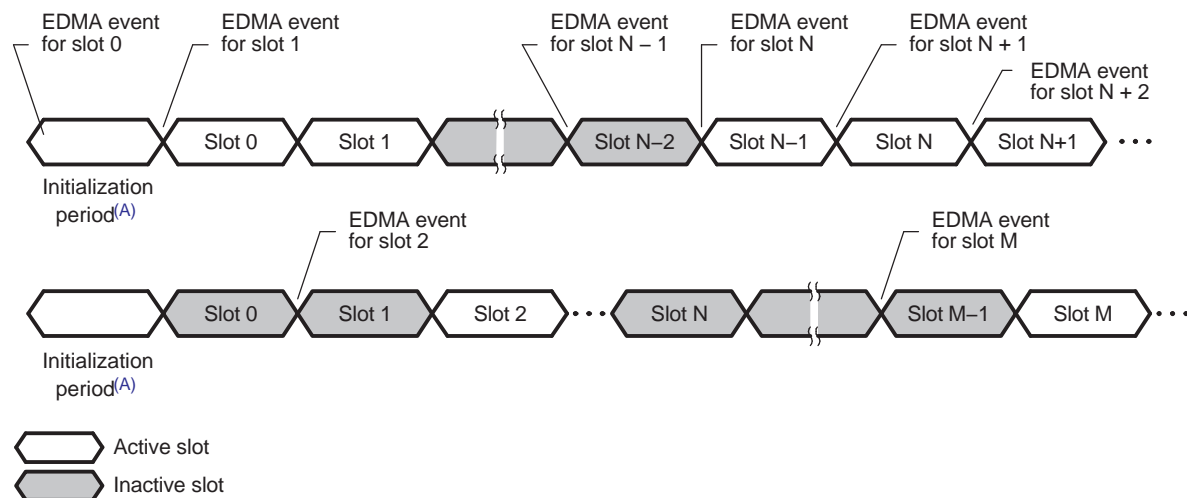

Transmit pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bit DISMOD in SRCTL[n].

Figure 16-20 shows when the transmit DMA event AXEVT is generated. See Section 16.2.8.1.1 for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless if the previous time slot (slot N - 1) is active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUF[n] to XRSR[n] generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA request generation does not need this capability, since the receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

Figure 16-20. Transmit DMA Event (AXEVT) Generation in TDM Time Slots

A See Section 16.2.10.2, step 7a.

16.2.6.2.2 Special 384 Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF, AES-3, IEC-60958 receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The advantage to using the 384 time slot TDM mode is that interrupts may be generated synchronous to the S/PDIF, AES-3, IEC-60958, such as the last slot interrupt.

The receive TDM time slot register (RTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block).

To receive data in the DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock.
- AFSR - receive frame sync (or commonly called left/right clock). In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK.
- One or more serial data pins, AXRn, whose serializers have been configured to receive.

For this special DIR mode, the control registers can be configured just as for TDM mode, except set RMOD in AFSRCTL to 384 to receive 384 time slots.

16.2.6.3 Digital Audio Interface Transmit (DIT) Transfer Mode

In addition to the TDM and burst transfer modes, which are suitable for transmitting audio data between ICs inside the same system, the digital audio interface transmit (DIT) transfer mode of the McASP also supports transmission of audio data in the S/PDIF, AES-3, or IEC-60958 format. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode only applies to serializers configured as transmitters, not receivers. Refer to [Section 16.1.6.2](#) for a description of the S/PDIF format.

16.2.6.3.1 Transmit DIT Encoding

The McASP operation in DIT mode is basically identical to the 2 time slot TDM mode, but the data transmitted is output as a biphase mark encoded bit stream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bit stream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

The transmit TDM time slot register (XTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in the DIT mode, the following pins are typically needed:

- AHCLKX - transmit high-frequency master clock.
- One or more serial data pins, AXRn, whose serializers have been configured to transmit.

AHCLKX is optional (the internal clock source may be used instead), but if used as a reference, the processor provides a clock check circuit that continually monitors the AHCLKX input for stability.

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23-0 after passing through the first three stages of the transmit format unit.

For left-aligned Q31 data, the following transmit format unit settings process the data into right aligned 24-bit audio data ready for transmission:

- XROT = 010 (rotate right by 8 bits).
- XRVRS = 0 (no bit reversal, LSB first).
- XMASK = FFFF FF00h-FFFF 0000h (depending upon whether 24, 23, 22, 21, 20, 19, 18, 17, or 16 valid audio data bits are present).
- XPAD = 00 (pad extra bits with 0).

For right-aligned data, the following transmit format unit settings process the data into right aligned 24-bit audio data ready for transmission:

- XROT = 000 (rotate right by 0 bits).
- XRVRS = 0 (no bit reversal, LSB first).
- XMASK = 00FF FFFFh to 0000 FFFFh (depending upon whether 24, 23, 22, 21, 20, 19, 18, 17, or 16 valid audio data bits are present).
- XPAD = 00 (pad extra bits with 0).

16.2.6.3.2 Transmit DIT Clock and Frame Sync Generation

The DIT transmitter only works in the following configuration:

- In transmit frame control register (AFSXCTL):
 - Internally-generated transmit frame sync, FSXM = 1.
 - Rising-edge frame sync, FSXP = 0.
 - Bit-width frame sync, FXWID = 0.
 - 384-slot TDM, XMOD = 1 1000 0000b.
- In transmit clock control register (ACLKXCTL), ASYNC = 1.
- In transmit bitstream format register (XFMT), XSSZ = 1111 (32-bit slot size).

All combinations of AHCLKX and ACLKX are supported.

This is a summary of the register configurations required for DIT mode. The DIT mode specific bit fields are in bold face:

- PFUNC: The data pins (AXRn) must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function.
- PDIR: The data pins (AXRn) must be configured as outputs. If AHCLKX is used as an input reference, it should be configured as input. If internal clock source AUXCLK is used as the reference clock, it may be output on the AHCLKX pin by configuring AHCLKX as an output.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable for DIT operation. Leave at default.
- GBLCTL: Follow the initialization sequence in [Section 16.2.10.2](#) to configure this register.
- AMUTE: Program all fields according to mute control desired.
- DLBCTL: Not applicable. Loopback is not supported for DIT mode. Leave at default.
- DITCTL: **DITEN** bit must be set to 1 to enable DIT mode. Configure other bits as desired.
- RMASK: Not applicable. Leave at default.
- RFMT: Not applicable. Leave at default.
- AFSRCTL: Not applicable. Leave at default.
- ACLKRCTL: Not applicable. Leave at default.
- AHCLKRCTL: Not applicable. Leave at default.
- RTDM: Not applicable. Leave at default.
- RINTCTL: Not applicable. Leave at default.
- RCLKCHK: Not applicable. Leave at default.
- **XMASK**: Mask desired bits according to the discussion in this section, depending upon left-aligned or right-aligned internal data.

- **XFMT: XDATDLY** = 0. **XRVRS** = 0. **XPAD** = 0. **XPBIT** = default (not applicable). **XSSZ** = Fh (32-bit slot). **XBUSEL** = configured as desired. **XROT** bit is configured according to the discussion in this section, either 0 or 8-bit rotate.
- **AFSXCTL**: Configure the bits according to the discussion in this section.
- **ACLKXCTL: ASYNC** = 1. Program CLKXDIV bits to obtain the bit clock rate desired. Configure CLKXP and CLKXM bits as desired, because CLKX is not actually used in the DIT protocol.
- **AHCLKXCTL**: Program all fields according to high-frequency clock desired.
- **XTDM**: Set to FFFF FFFFh for all active slots for DIT transfers.
- **XINTCTL**: Program all fields according to interrupts desired.
- **XCLKCHK**: Program all fields according to clock checking desired.
- **SRCTLn**: Set **SRMOD** = 1 (transmitter) for the DIT pins. DISMOD field is don't care for DIT mode.
- **DITCSRA[n], DITCSRB[n]**: Program the channel status bits as desired.
- **DITUDRA[n], DITUDRB[n]**: Program the user data bits as desired.

16.2.6.3.3 DIT Channel Status and User Data Register Files

The channel status registers (DITCSRA_n and DITCSRB_n) and user data registers (DITUDRA_n and DITUDRB_n) are not double buffered. Typically the programmer uses one of the synchronizing interrupts, such as last slot, to create an event at a safe time so the register may be updated. In addition, the CPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a requirement that the software avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it will be indeterminate whether the old or new data is used to encode the bitstream.

The DIT subframe format is defined in [Section 16.1.6.2.2](#). The channel status information (C) and User Data (U) are defined in these DIT control registers:

- DITCSRA0 to DITCSRA5: The 192 bits in these six registers contain the channel status information for the LEFT channel within each frame.
- DITCSRB0 to DITCSRB5: The 192 bits in these six registers contain the channel status information for the RIGHT channel within each frame.
- DITUDRA0 to DITUDRA5: The 192 bits in these six registers contain the user data information for the LEFT channel within each frame.
- DITUDRB0 to DITUDRB5: The 192 bits in these six registers contain the user data information for the RIGHT channel within each frame.

The S/PDIF block format is shown in [Figure 16-12](#). There are 192 frames within a block (frame 0 to frame 191). Within each frame there are two subframes (subframe 1 and 2 for left and right channels, respectively). The channel status and user data information sent on each subframe is summarized in [Table 16-4](#).

Table 16-4. Channel Status and User Data for Each DIT Block

16.2.7 General Architecture

16.2.7.1 Serializers

Figure 16-21 shows the block diagram of the serializer and its interface to other units within the McASP. The serializers take care of shifting serial data in and out of the McASP. Each serializer consists of a shift register (XRSR), a data buffer (XRBUF), a control register (SRCTL), and logic to support the data alignment options of the McASP. For each serializer (XRSR_n), there is a dedicated serial data pin (AXR_n) and a dedicated control register (SRCTL_n). The control register allows the serializer to be configured as a transmitter, receiver, or as inactive. When configured as a transmitter the serializer shifts out data to the serial data pin AXR_n. When configured as a receiver, the serializer shifts in data from the AXR_n pin. The serializer is clocked from the transmit/receive section clock (ACLKX/ACLKR) if configured to transmit/receive respectively.

All serializers that are configured to transmit operate in lock-step. Similarly, all serializers that are configured to receive also operate in lock-step. This means that at most there are two zones per McASP, one for transmit and one for receive.

Figure 16-21. Individual Serializer and Connections Within McASP

For receive, data is shifted in through the AXR_n pin to the shift register XRSR. Once the entire slot of data is collected in the XRSR, the data is copied to the data buffer XRBUF. The data is now ready to be read by the processor through the RBUF register, which is an alias of the XRBUF for receive. When the processor reads from the RBUF, the McASP passes the data from RBUF through the receive format unit and returns the formatted data to the processor.

For transmit, the processor services the McASP by writing data into the XBUF register, which is an alias of the XRBUF for transmit. The data automatically passes through the transmit format unit before actually reaching the XRBUF register in the serializer. The data is then copied from XRBUF to XRSR, and shifted out from the AXR_n synchronously to the serial clock.

In DIT mode, in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.).

The serializer configuration is controlled by SRCTL_n. A serializer *n* is configured as inactive via setting bitfield SRCTL_n[1:0] SRMOD to 0. For a transmitting serializer, the SRCTL_n[3:2] DISMOD bitfield defines the AXR_n pin output state during inactive slots (logic high, logic low, or 3-state). A serializer *n* is configured in a transmit function via setting bitfield SRCTL_n[1:0] SRMOD to 1. A serializer *n* is configured in a receive function via setting bitfield SRCTL_n[1:0] SRMOD to 2h.

16.2.7.2 Format Unit

The McASP has two data formatting units, one for transmit and one for receive. These units automatically remap the data bits within the transmitted and received words between a natural format for the processor (such as a Q31 representation) and the required format for the external serial device (such as "I2S format"). During the remapping process, the format unit also can mask off certain bits or perform sign extension.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP will not transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers. However, the McASP can transmit in one format while receiving in a completely different format.

This formatting unit consists of three stages:

- Bit mask and pad (masks off bits, performs sign extension)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

The McASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
 - Left aligned = word shifted first, remaining bits are pad
 - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
 - MSB: most-significant bit of word is shifted out first, last bit is LSB
 - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register, (R/X)FMT:

- XRVR: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

[Figure 16-22](#) shows a block diagram of the receive formatting unit, and [Figure 16-23](#) shows the transmit formatting unit. Note that the order in which data flows through the three stages is different between the transmit and receive formatting units.

As shown in [Figure 16-23](#), the data to the transmit format unit (TFU) can come from the configuration port (CFG) or the data port (DATA). The selection is made through the RFMT[3] RBUSEL bit. According to port type selected, data transfer has different behavior.

Figure 16-22. Receive Format Unit

Figure 16-23. Transmit Format Unit

The bit mask and pad stage includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits.

The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the (R/X)FMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation.

The bit reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order.

Finally, note that the (R/X)DATDLY bits in (R/X)FMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, (R/X)DATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay.

The combination of all the options in (R/X)FMT means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the internal processor representation.

[Section 16.2.8.3](#) provides more detail and specific examples. The examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

16.2.7.3 State Machine

The receive and transmit sections have independent state machines. Each state machine controls the interactions between the various units in the respective section. In addition, the state machine keeps track of error conditions and serial port status.

No serial transfers can occur until the respective state machine is released from reset. See initialization sequence for details ([Section 16.2.10](#)).

The receive state machine is controlled by the RFMT register, and it reports the McASP status and error conditions in the RSTAT register. Similarly, the transmit state machine is controlled by the XFMT register, and it reports the McASP status and error conditions in the XSTAT register.

16.2.7.4 TDM Sequencer

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of (R/X)TDM and determines if the McASP should receive/transmit in that time slot.

If the McASP should participate (transmit/receive bit is active) in the time slot, the McASP functions normally. If the McASP should not participate (transmit/receive bit is inactive) in the time slot, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot. In addition, the serializers programmed as transmitters place their data output pins in a predetermined state (logic low, high, or high impedance) as programmed by each serializer control register (SRCTL). Refer also to [Section 16.2.6.2](#) for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

The receive TDM sequencer is controlled by register RTDM and reports current receive slot to RSLOT. The transmit TDM sequencer is controlled by register XTDM and reports current transmit slot to XSLOT.

16.2.7.5 Clock Check Circuit

A common source of error in audio systems is a serial clock failure due to instabilities in the off-chip DIR circuit. To detect a clock error quickly, a clock-check circuit is included in the McASP for both transmit and receive clocks, since both may be sourced from off chip.

The clock check circuit can detect and recover from transmit and receive clock failures. See [Section 16.2.8.4.6](#) for implementation and programming details.

16.2.7.6 Pin Function Control

All McASP pins except AMUTEIN are bidirectional input/output pins. In addition, these bidirectional pins function either as McASP or general-purpose I/O (GPIO) pins. The following registers control the pin functions:

- Pin function register (PFUNC): selects pin to function as McASP or GPIO.
- Pin direction register (PDIR): selects pin to be input or output.
- Pin data input register (PDIN): shows data input at the pin.
- Pin data output register (PDOUT): data to be output at the pin if the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1). Not applicable when the pin is configured as McASP pin (PFUNC[n] = 0).
- Pin data set register (PDSET): alias of PDOUT. Writing a 1 to PDSET[n] sets the respective PDOUT[n] to 1. Writing a 0 has no effect. Applicable only when the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1).
- Pin data clear register (PDCLR): alias of PDOUT. Writing a 1 to PDCLR[n] clears the respective PDOUT[n] to 0. Writing a 0 has no effect. Applicable only when the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1).

See the register descriptions in [Section 16.3](#) for details on the mapping of each McASP pin to the register bits. [Figure 16-24](#) shows the pin control block diagram.

Figure 16-24. McASP I/O Pin Control Block Diagram

16.2.7.6.1 McASP Pin Control-Transmit and Receive

You must correctly set the McASP GPIO registers PFUNC and PDIR, even when McASP pins are used for their serial port (non-GPIO) function.

Serial port functions include:

- Clock pins (ACLKX, ACLKR, AHCLKX, AHCLKR, AFSX, AFSR) used as clock inputs and outputs.
- Serializer data pins (AXRn) used to transmit or receive.
- AMUTE used as a mute output signal.

When using these pins in their serial port function, you must clear PFUNC[n] to 0 for each pin.

Also, certain outputs require PDIR[n] = 1, such as clock pins used as clock outputs, serializer data pins used to transmit, and AMUTE used as mute output.

Clock inputs and serializers configured to receive must have PDIR[n] = 0.

PFUNC and PDIR do not control the AMUTEIN signal, it is usually tied to a device level interrupt pin (consult device datasheet). If used as a mute input, this pin needs to be configured as an input in the appropriate peripheral.

Finally, there is an important advantage to having separate control of pin direction (by PDIR), and the choice of internal versus external clocking (by CLKRM/CLKXM). Depending on the specific device and usage, you might select an external clock (CLKRM = 0), while enabling the internal clock divider, and the clock pin as an output in the PDIR register (PDIR[ACLKR] = 1). In this case, the bit clock is an output (PDIR[ACLKR] = 1) and, therefore, routed to the ACLKR pin. However, because CLKRM = 0, the bit clock is then routed back to the McASP module as an "external" clock source. This may result in less skew between the clock inside the McASP and the clock in the external device, thus producing more balanced setup and hold times for a particular system. As a result, this may allow a higher serial clock rate interface.

16.2.8 Operation

This section discusses the operation of the McASP.

16.2.8.1 Data Transmission and Reception

The processor services the McASP by writing data to the XBUF register(s) for transmit operations, and by reading data from the RBUF register(s) for receive operations. The McASP sets status flag and notifies the processor whenever data is ready to be serviced. [Section 16.2.8.1.1](#) discusses data ready status in detail.

The XBUF and RBUF registers can be accessed through one of the two peripheral ports of the device:

- The data port (DAT): This port is dedicated for data transfers on the device.
- The configuration bus (CFG): This port is used for both data transfers and peripheral configuration control on the device.

[Section 16.2.8.1.2](#) and [Section 16.2.8.1.3](#) discuss how to perform transfers through the data port and the configuration bus.

Either the CPU or the DMA can be used to service the McASP through any of these two peripheral ports. The CPU and DMA usages are discussed in [Section 16.2.8.1.4](#) and [Section 16.2.12.2](#).

16.2.8.1.1 Data Ready Status and Event/Interrupt Generation

16.2.8.1.1.1 Transmit Data Ready

The transmit data ready flag XDATA bit in the XSTAT register reflects the status of the XBUF register. The XDATA flag is set when data is transferred from the XRBUF[n] buffers to the XRSR[n] shift registers, indicating that the XBUF is empty and ready to accept new data from the processor. The transmit data ready event is individually indicated per serializer in its corresponding control register SRCTLn[4] XRDY status bit. When this bit is set to 1, it notifies the host that this serializer Tx buffer must be serviced (written). When XBUFn is written to by the host, the SRCTLn[4] XRDY is deasserted to 0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the MCASP host (XDATA = 1). The XRDY flags have to be sequentially scanned by user software to determine which serializer TXBUFn register has to be currently written. Once all requested TXBUFn are written, the serializers control XRDY flags are cleared to 0. As a consequence, XDATA flag is deasserted to 0 to indicate to software that write operation is completed for all serializers. The global XDATA flag can be cleared when the XSTAT[5] XDATA bit is written to 1 or once TXBUFn registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, an DMA event AXEVT is automatically generated to notify the DMA of the XBUF empty status. An interrupt AXINT is also generated if XDATA interrupt is enabled in the XINTCTL register (See [Section 16.2.11.1](#) for details).

For DMA requests, the McASP does not require XSTAT to be read between DMA events. This means that even if XSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Since all serializers act in lockstep, only one DMA event is generated to indicate that all active transmit serializers are ready to be written to with new data.

Figure 16-25 shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to 5 McASP system clocks (AXEVT Latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the processor can begin servicing the McASP by writing Word C into the XBUF (Processor Service Time). The processor must write Word C into the XBUF no later than the setup time required by the McASP (Setup Time).

The maximum Processor Service Time (Figure 16-25) can be calculated as:

$$\text{Processor Service Time} = \text{Time Slot} - \text{AXEVT Latency} - \text{Setup Time}$$

Figure 16-25. Processor Service Time Upon Transmit DMA Event (AXEVT)

A Refer to the device-specific data manual for the McASP system clock source. This is not the same as AUXCLK.

Example 16-1. Processor Service Time Calculation for Transmit DMA Event (AXEVT)

The following is an example to show how to calculate Processor Service Time. Assume the following setup:

- Device: C64x+ DSP at 300 MHz.
- McASP transmits in I2S format at 192 kHz frame rate. Assume slot size is 32 bit.

With the above setup, we obtain the following parameters corresponding to [Figure 16-25](#):

- Calculation of McASP system clock cycle:
 - C64x+ DSP uses SYSCLK2 as the McASP system clock. It runs at 150 MHz (half of device frequency).
 - Therefore, McASP system clock cycle = $1/150 \text{ MHz} = 6.7 \text{ ns}$.
- Calculation of ACLKX clock cycle:
 - This example has two 32-bit slots per frame, for a total of 64 bits per frame.
 - ACLKX clock cycle is $(1/192 \text{ kHz})/64 = 81.4 \text{ ns}$.
- Time Slot between AXEVT events:
 - For I2S format, McASP generates two AXEVT events per 192 kHz frame.
 - Therefore, Time Slot between AXEVT events is $(1/192 \text{ kHz})/2 = 2604 \text{ ns}$.
- AXEVT Latency:
 - = 5 McASP system clocks
 - = $6.7 \text{ ns} \times 5 = 33.5 \text{ ns}$
- Setup Time
 - = 3 McASP system clocks + 4 ACLKX cycles
 - = $(6.7 \text{ ns} \times 3) + (81.4 \text{ ns} \times 4)$
 - = 345.7 ns
- Processor Service Time
 - = Time Slot - AXEVT Latency - Setup Time
 - = $2604 \text{ ns} - 33.5 \text{ ns} - 345.7 \text{ ns}$
 - = 2225 ns

16.2.8.1.1.2 Receive Data Ready

Similarly, the receive data ready flag, RDATA, in the RSTAT register reflects the data ready status of XRBUF_n buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSR_n to its corresponding XRBUF_n data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer, RXBUF_n, already contains received data (that is, a buffer is full) and is ready to transfer it to the host (MPU). The receive data ready event is individually indicated per serializer in its corresponding control register SRCTL_n [5] RRDY status bit. When this bit is set to 1, it notifies to host that this serializer Rx buffer must be serviced (read). When RXBUF_n is read from the host, the SRCTL_n [5] RRDY is deasserted to 0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the MCASP host (RDATA = 1). The RRDY flags have to be sequentially scanned by user software to determine which serializer RXBUF_n register has to be currently read. Once all requested RXBUF_n are read, the serializers control RRDY flags are cleared to 0. As a consequence, RDATA flag is deasserted to 0, to indicate to software that read operation is completed for all n serializers. The global RDATA flag can be cleared when the RSTAT[5] RDATA bit is written to 1 or once RXBUF_n registers of all the serializers, that have previously raised their RRDY flags, are read by the host. (See Section 16.2.11.2 for details).

For DMA requests, the McASP does not require RSTAT to be read between DMA events. This means that even if RSTAT already has the RDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Since all serializers act in lockstep, only one DMA event is generated to indicate that all active receive serializers are ready to receive new data.

Figure 16-26 shows the timing details of when AREVT is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to 5 McASP system clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the processor can begin servicing the McASP by reading Word A from the RBUF (Processor Service Time). The processor must read Word A from the XBUF no later than the setup time required by the McASP (Setup Time).

The maximum Processor Service Time (Figure 16-26) can be calculated as:

$$\text{Processor Service Time} = \text{Time Slot} - \text{AREVT Latency} - \text{Setup Time}$$

The Processor Service Time calculation for receive is similar to the calculation for transmit. See Example 16-1 for Processor Service Time calculation using transmit as an example.

Figure 16-26. Processor Service Time Upon Receive DMA Event (AREVT)

A The device uses SYSCLK2 as the McASP system clock source.

16.2.8.1.2 Transfers Through the Data Port (DAT)

NOTE: The data port (DAT) addresses are located in L3 and L4 tables in the device data sheet for the appropriate data peripheral registers. To perform internal transfers through the data port, clear XBUSEL/RBUSEL bit to 0 in the respective XFMT/RFMT registers. Failure to do so will result in software malfunction.

Typically, you will access the McASP XRBUF registers through the data port. To access through the data port, simply have the CPU or DMA access the XRBUF through its data port location. Refer to the device-specific data manual for the exact memory address. Through the data port, the DMA/CPU can service all the serializers through a single address. The McASP automatically cycles through the appropriate serializers.

For transmit operations through the data port, the DMA/CPU should write to the same XBUF data port address to service all of the active transmit serializers. In addition, the DMA/CPU should write to the XBUF for all active transmit serializers in incremental (although not necessarily consecutive) order. For example, if serializers 0, 4, and 5, are set up as active transmitters, the DMA/CPU should write to the XBUF data port address four times with data for serializers 0, 4, and 5, upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

Similarly, for receive operations through the data port, the DMA/CPU should read from the same RBUF data port address to service all of the active receive serializers. In addition, reads from the active receive serializers through the data port return data in incremental (although not necessarily consecutive) order. For example, if serializers 1, 2, and 3, are set up as active receivers, the DMA/CPU should read from the RBUF data port address four times to obtain data for serializers 1, 2, and 3, in this exact order, upon each receive data ready event.

When transmitting, the DMA/CPU must write data to each serializer configured as "active" (active slot in XTDM register) and "transmit" (Tx enabled in SCRCTLn register) within each time slot. Failure to do so results in a buffer underrun condition ([Section 16.2.8.4.2](#)). Similarly, when receiving, data must be read from each serializer configured as "active" (active slot in RTDM register) and "receive" (Rx enabled in SCRCTLn register) within each time slot. Failure to do results in a buffer overrun condition ([Section 16.2.8.4.3](#)).

To perform internal transfers through the data port, clear XBUSEL/RBUSEL bit to 0 in the respective XFMT/RFMT registers.

16.2.8.1.3 Transfers Through the Configuration Bus (CFG)

NOTE: To perform internal transfers through the configuration bus, set XBUSEL/RBUSEL bit to 1 in the respective XFMT/RFMT registers. Failure to do so will result in software malfunction.

In this method, the DMA/CPU accesses the XRBUF registers through the configuration bus address. The exact XRBUF register address for any particular serializer is determined by adding the offset for that particular serializer to the base address for the particular McASP (found in the device-specific data manual). XRBUF for the serializers configured as transmitters is given the name XBUF n . For example, the XRBUF associated with transmit serializer 2 is named XBUF2. Similarly, XRBUF for the serializers configured as receivers is given the name RBUF n .

Accessing the XRBUF registers through the data port is different because the CPU/DMA only needs to access one single address. When accessing through the configuration bus, the CPU/DMA must provide the exact XBUF n or RBUF n address for each access.

When transmitting, DMA/CPU must write data to each serializer configured as "active" and "transmit" within each time slot. Failure to do so results in a buffer underrun condition ([Section 16.2.8.4.2](#)). Similarly when receiving, data must be read from each serializer configured as "active" and "receive" within each time slot. Failure to do results in a buffer overrun condition ([Section 16.2.8.4.3](#)).

To perform internal transfers through the configuration bus, set XBUSEL/RBUSEL bit to 1 in the respective XFMT/RFMT registers.

16.2.8.1.4 Using the CPU for McASP Servicing

The CPU can be used to service the McASP through interrupt (upon AXINT/ARINT interrupts) or through polling the XDATA bit in the XSTAT register and the RDATA bit in the RSTAT register. As discussed in [Section 16.2.8.1.2](#) and [Section 16.2.8.1.3](#), the CPU can access XRBUF serializer buffer through either the data port or through the configuration bus.

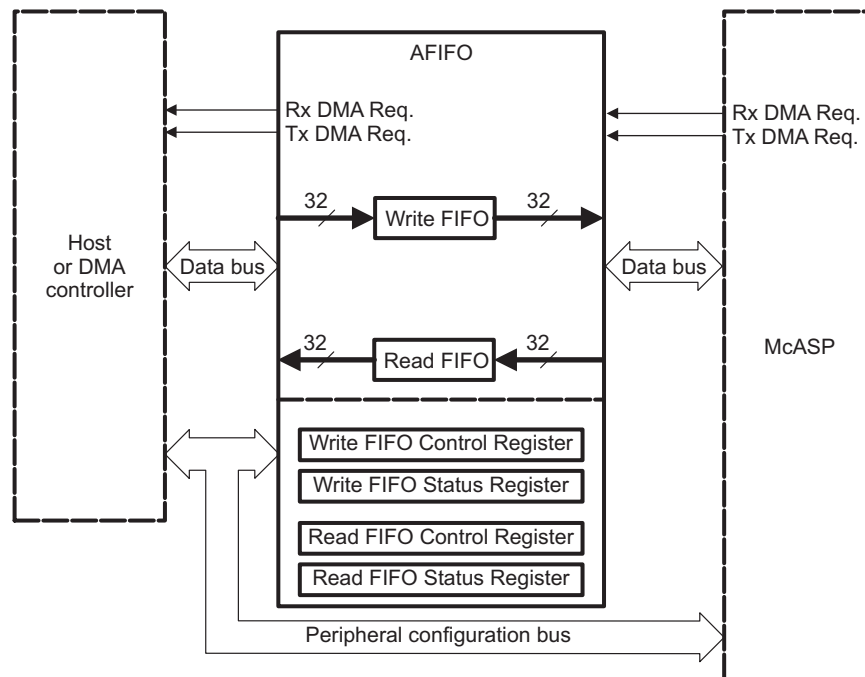

To use the CPU to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective XINTCTL/RINTCTL registers, to generate interrupts AXINT/ARINT to the CPU upon data ready.

16.2.8.2 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See [Figure 16-27](#) for a high-level block diagram of the AFIFO.

The AFIFO may be enabled/disabled and configured via the WFIFOCTL and RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP (see [Section 16.2.10.2](#) for details).

Figure 16-27. McASP Audio FIFO (AFIFO) Block Diagram

16.2.8.2.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP.

When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller.

If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes *WNUMDMA* 32-bit words to the McASP if and when there are at least *WNUMDMA* words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes *WNUMDMA* words to the McASP. (See description for WFIFOCTL.WNUMDMA in [Section 16.3.43](#).)

If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded.

Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

16.2.8.2.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced.

If the Write FIFO has space to accept *WNUMEVT* 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once *WNUMEVT* words have been written to the FIFO, it checks again to see if there is space for *WNUMEVT* 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled.

Note that if transmit DMA event pacing is desired, *WFIFOCTL.WNUMEVT* should be set to a non-zero integer multiple of the value in *WFIFOCTL.WNUMDMA*. If transmit DMA event pacing is not desired, then the value in *WFIFOCTL.WNUMEVT* should be set equal to the value in *WFIFOCTL.WNUMDMA*.

16.2.8.2.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP.

When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller.

If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads *RNUMDMA* 32-bit words from the McASP, if and when the RFIFO has space for *RNUMDMA* words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads *RNUMDMA* words from the McASP. (See description for *RFIFOCTL.RNUMDMA* in [Section 16.3.45](#).)

If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than *RNUMEVT* words, those words will be read correctly, emptying the FIFO.

16.2.8.2.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced.

If the Read FIFO contains at least *RNUMEVT* 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once *RNUMEVT* 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another *RNUMEVT* words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty.

Note that if receive DMA event pacing is desired, *RFIFOCTL.RNUMEVT* should be set to a non-zero integer multiple of the value in *RFIFOCTL.RNUMDMA*. If receive DMA event pacing is not desired, then the value in *RFIFOCTL.RNUMEVT* should be set equal to the value in *RFIFOCTL.RNUMDMA*.

16.2.8.2.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

16.2.8.3 Formatter

16.2.8.3.1 Transmit Bit Stream Data Alignment

The McASP transmitter supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits.
- Word size \leq Slot size.
- Alignment when more bits/slot than bits/words, then:
 - Left aligned = word shifted first, remaining bits are pad.
 - Right aligned = pad bits are shifted first, word occupies the last bits in slot.
- Order of bits shifted out:
 - MSB: most-significant bit of word is shifted out first, last bit is LSB.
 - LSB: least-significant bit of word is shifted out last, last bit is MSB.

Hardware support for these serial formats comes from the programmable options in the transmit bitstream format register (XFMT):

- XRVRS: bit reverse (1) or no bit reverse (0).
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits.
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits.

XSSZ should always be programmed to match the slot size of the serial stream. The word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

Table 16-5 and Figure 16-28 show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

This discussion assumes that all slot size (SLOT in Table 16-5) and word size (WORD in Table 16-5) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit (see Figure 16-23), and the data is aligned in the same representation as it is written to the transmitter by the processor (typically Q31 or integer).

Table 16-5. Transmit Bitstream Data Alignment

Figure 16-28	Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	XFMT Bit	
				XROT ⁽¹⁾	XRVRS
(a) ⁽²⁾	MSB first	Left aligned	Q31 fraction	0	1
(b)	MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
(c)	LSB first	Left aligned	Q31 fraction	32 - WORD	0
(d)	LSB first	Right aligned	Q31 fraction	32 - SLOT	0
(e) ⁽²⁾	MSB first	Left aligned	Integer	WORD	1
(f)	MSB first	Right aligned	Integer	SLOT	1
(g)	LSB first	Left aligned	Integer	0	0
(h)	LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

⁽¹⁾ WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

⁽²⁾ To transmit in I2S format, use MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

Figure 16-28. Data Flow Through Transmit Format Unit, Illustrated

16.2.8.3.2 Receive Bit Stream Data Alignment

The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits.
- Word size ≤ Slot size.
- Alignment when more bits/slot than bits/words, then:
 - Left aligned = word shifted first, remaining bits are pad.
 - Right aligned = pad bits are shifted first, word occupies the last bits in slot.
- Order of bits shifted out:
 - MSB: most-significant bit of word is shifted out first, last bit is LSB.
 - LSB: least-significant bit of word is shifted out last, last bit is MSB.

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register (RFMT):

- RRVRS: bit reverse (1) or no bit reverse (0).
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits.
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits.

RSSZ should always be programmed to match the slot size of the serial stream. The word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 16-6 and Figure 16-29 show the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

This discussion assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 16-22), and the data is aligned in the same representation as it is read from the receiver by the processor (typically Q31 or integer).

Table 16-6. Receive Bitstream Data Alignment

Figure 16-29	Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	RFMT Bit	
				RROT ⁽¹⁾	RRVRS
(a) ⁽²⁾	MSB first	Left aligned	Q31 fraction	SLOT	1
(b)	MSB first	Right aligned	Q31 fraction	WORD	1
(c)	LSB first	Left aligned	Q31 fraction	$(32 - (\text{SLOT} - \text{WORD})) \% 32$	0
(d)	LSB first	Right aligned	Q31 fraction	0	0
(e) ⁽²⁾	MSB first	Left aligned	Integer	SLOT - WORD	1
(f)	MSB first	Right aligned	Integer	0	1
(g)	LSB first	Left aligned	Integer	32 - SLOT	0
(h)	LSB first	Right aligned	Integer	32 - WORD	0

⁽¹⁾ WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

⁽²⁾ To transmit in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

Figure 16-29. Data Flow Through Receive Format Unit, Illustrated

16.2.8.4 Error Handling and Management

To support the design of a robust audio system, the McASP includes error-checking capability for the serial protocol, data underrun, and data overrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX/AHCLKR clock cycles. The timer value can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

Upon the detection of any one or more errors (software selectable), or the assertion of the AMUTEIN input pin, the AMUTE output pin may be asserted to a high or low level to immediately mute the audio output. In addition, an interrupt may be generated if desired, based on any one or more of the error sources.

16.2.8.4.1 Unexpected Frame Sync Error

An unexpected frame sync occurs when:

- In burst mode, when the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- In TDM mode, a further constraint is that the frame sync must occur exactly during the correct bit clock (not a cycle earlier or later) and only before slot 0. An unexpected frame sync occurs if this condition is not met.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. Early: An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
 - Error interrupt flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
 - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. Late: A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
 - Error interrupt flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
 - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in both burst mode and TDM mode; however, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

16.2.8.4.2 Buffer Underrun Error - Transmitter

A buffer underrun can only occur for serializers programmed to be transmitters. A buffer underrun occurs when the serializer is instructed by the transmit state machine to transfer data from XRBUF[n] to XRSR[n], but XRBUF[n] has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the processor explicitly writes a 1 to the XUNDRN bit to clear the XUNDRN bit.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at $128 \times f_s$). By shifting out a pair of zeros, a clock may be recovered on the receiver. To recover, reset the McASP and start again with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

16.2.8.4.3 Buffer Overrun Error - Receiver

A buffer overrun can only occur for serializers programmed to be receivers. A buffer overrun occurs when the serializer is instructed to transfer data from XRSR[n] to XRBUF[n], but XRBUF[n] has not yet been read by either the DMA or the processor. When this occurs, the receiver state machine sets the ROVRN flag. However, the individual serializer writes over the data in the XRBUF[n] register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the processor catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the processor explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

16.2.8.4.4 DMA Error - Transmitter

A transmit DMA error, as indicated by the XDMAERR flag in the XSTAT register, occurs when the DMA (or CPU) writes more words to the DAT port of the McASP than it should. For each DMA event, the DMA should write exactly as many words as there are serializers enabled as transmitters.

XDMAERR indicates that the DMA (or CPU) wrote too many words to the McASP for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in XSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or CPU. You should reinitialize both the McASP transmitter and the DMA to resynchronize them.

16.2.8.4.5 DMA Error - Receiver

A receive DMA error, as indicated by the RDMAERR flag in the RSTAT register, occurs when the DMA (or CPU) reads more words from the DAT port of the McASP than it should. For each DMA event, the DMA should read exactly as many words as there are serializers enabled as receivers.

RDMAERR indicates that the DMA (or CPU) read too many words from the McASP for a given receive DMA event. Reading too few words results in a receiver overrun error setting ROVRN in RSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or CPU. You should reinitialize both the McASP receiver and the DMA to resynchronize them.

16.2.8.4.6 Clock Failure Detection

16.2.8.4.6.1 Clock-Failure Check Startup

It is expected, initially, that the clock-failure circuits will generate an error until at least one measurement has been taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not immediately be enabled, but be enabled only after a specific startup procedure. The startup procedure is:

1. For the transmit clock failure check:
 - (a) Configure transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (XCLKCHK).
 - (b) Clear transmit clock failure flag (XCKFAIL) in the transmit status register (XSTAT).
 - (c) Wait until first measurement is taken (> 32 AHCLKX clock periods).
 - (d) Verify no clock failure is detected.
 - (e) Repeat steps b–d until clock is running and is no longer issuing clock failure errors.
 - (f) After the transmit clock is measured and falls within the acceptable range, the following may be enabled:
 - (i) transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (XINTCTL).
 - (ii) mute option (XCKFAIL) in the mute control register (AMUTE).
2. For the receive clock failure check:
 - (a) Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (RCLKCHK).
 - (b) Clear receive clock failure flag (RCKFAIL) in the receive status register (RSTAT).
 - (c) Wait until first measurement is taken (> 32 AHCLKR clock periods).
 - (d) Verify no clock failure is detected.
 - (e) Repeat steps b–d until clock is running and is no longer issuing clock failure errors.
 - (f) After the receive clock is measured and falls within the acceptable range, the following may be enabled:
 - (i) receive clock failure interrupt enable bit (RCKFAIL) in the receiver interrupt control register (RINTCTL).
 - (ii) mute option (RCKFAIL) in the mute control register (AMUTE).

16.2.8.4.6.2 Transmit Clock Failure Check and Recovery

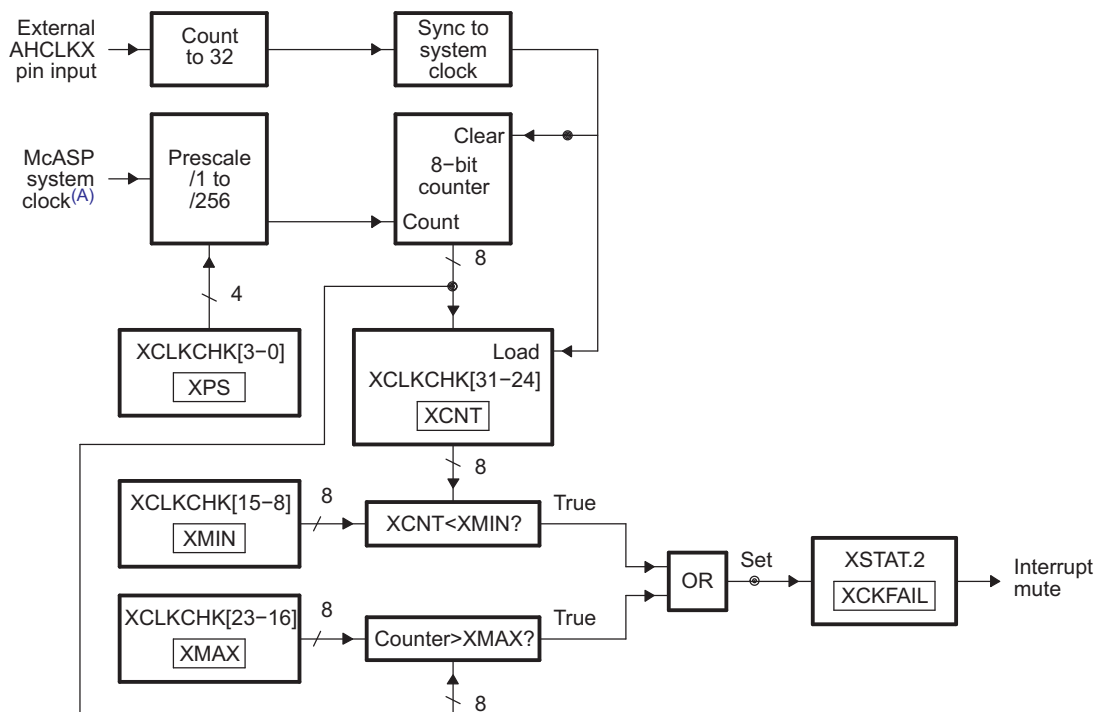

The transmit clock failure check circuit (Figure 16-30) works off both the internal McASP system clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (XCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in XSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than XMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (XMAX). This is in case the external clock completely stops, so that the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. Note that the XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected, or that the audio source has changed and a new sample rate is being used.

In order for the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKX is internally generated or externally sourced.

Figure 16-30. Transmit Clock Failure Detection Circuit Block Diagram

A Refer to the device data manual for the McASP system clock source. This is not the same as AUXCLK.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in XSTAT is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in XINTCTL is set.

16.2.8.4.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (Figure 16-31) works off both the internal McASP system clock and the external high-frequency serial clock (AHCLKR). It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an interrupt (RCKFAIL in RSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKR is internally generated or externally sourced.

Figure 16-31. Receive Clock Failure Detection Circuit Block Diagram

A Refer to device data manual for the McASP system clock source. This is not the same as AUXCLK.

16.2.8.5 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows testing of the McASP code in TDM mode with a single processor device. In loopback mode, output of the transmit serializers is connected internally to the input of the receive serializers. Therefore, you can check the receive data against the transmit data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 180h) or burst mode (XMOD = 0).

Figure 16-32 shows the basic logical connection of the serializers in loopback mode. Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register (DLBCTL) as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, you should configure odd serializers to be transmitters and even serializers to be receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, you should configure even serializers to be transmitters and odd serializers to be receivers.

Data can be externally visible at the I/O pin of the transmit serializer if the pin is configured as a McASP output pin by setting the corresponding PFUNC bit to 0 and PDIR bit to 1.

In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bit of the DLBCTL register to 01b and the ASYNC bit of the ACLKXCTL register to 0.

Figure 16-32. Serializers in Loopback Mode

16.2.8.5.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format:

- The DLBEN bit in DLBCTL must be set to 1 to enable loopback mode.
- The MODE bits in DLBCTL must be set to 01b for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The ORD bit in DLBCTL must be programmed appropriately to select odd or even serializers to be transmitters or receivers. The corresponding serializers must be configured accordingly.
- The ASYNC bit in ACLKXCTL must be cleared to 0 to ensure synchronous transmit and receive operations.
- RMOD field in AFSRCTL and XMOD field in AFSXCTL must be set to 2h to 20h to indicate TDM mode. Loopback mode does not apply to DIT or burst mode.

16.2.9 Reset Considerations

The McASP has two reset sources: software reset and hardware reset.

16.2.9.1 Software Reset Considerations

The transmitter and receiver portions of the McASP may be put in reset through the global control register (GBLCTL). Note that a valid serial clock must be supplied to the desired portion of the McASP (transmit and/or receive) in order to assert the software reset bits in GBLCTL. see [Section 16.2.10.2](#) for details on how to ensure reset has occurred.

The entire McASP module may also be reset through the Power and Sleep Controller (PSC). Note that from the McASP perspective, this reset appears as a hardware reset to the entire module.

16.2.9.2 Hardware Reset Considerations

When the McASP is reset due to device reset, the entire serial port (including the transmitter and receiver state machines, and other registers) is reset.

16.2.10 Setup and Initialization

This section discusses steps necessary to use the McASP module.

16.2.10.1 Considerations When Using a McASP

The following is a list of things to be considered for systems using a McASP:

16.2.10.1.1 Clocks

For each receive and transmit section:

- External or internal generated bit clock and high frequency clock?
- If internally generated, what is the bit clock speed and the high frequency clock speed?
- Clock polarity?
- External or internal generated frame sync?
- If internally generated, what is frame sync speed?
- Frame sync polarity?
- Frame sync width?
- Transmit and receive sync or asynchronous?

16.2.10.1.2 Data Pins

For each pin of each McASP:

- McASP or GPIO?
- Input or output?

16.2.10.1.3 Data Format

For each transmit and receive data:

- Internal numeric representation (integer, Q31 fraction)?
- I2S or DIT (transmit only)?
- Time slot delay (0, 1, or 2 bit)?
- Alignment (left or right)?
- Order (MSB first, LSB first)?
- Pad (if yes, pad with what value)?
- Slot size?
- Rotate?
- Mask?

16.2.10.1.4 Data Transfers

- Internal: DMA or CPU?
- External: TDM or burst?
- Bus: configuration bus (CFG) or data port (DAT)?

16.2.10.2 Transmit/Receive Section Initialization

You must follow the following steps to properly configure the McASP. If external clocks are used, they should be present prior to the following initialization steps.

1. Reset McASP to default values by setting GBLCTL = 0. Poll the bits to ensure that the active reset value (0) is successfully latched into the GBLCTL register.
2. Configure all McASP registers except GBLCTL in the following order:
 - (a) Receive registers: RMASK, RFMT, AFSRCTL, ACLKRCTL, AHCLKRCTL, RTDM, RINTCTL, RCLKCHK. If external clocks AHCLKR and/or ACLKR are used, they must be running already for proper synchronization of the GBLCTL register.
 - (b) Transmit registers: XMASK, XFMT, AFSXCTL, ACLKXCTL, AHCLKXCTL, XTDM, XINTCTL, XCLKCHK. If external clocks AHCLKX and/or ACLKX are used, they must be running already for proper synchronization of the GBLCTL register.
 - (c) Serializer registers: SRCTL[n].
 - (d) Global registers: Registers PFUNC, PDIR, DITCTL, DLBCTL, AMUTE. Note that PDIR should only be programmed after the clocks and frames are set up in the steps above. This is because the moment a clock pin is configured as an output in PDIR, the clock pin starts toggling at the rate defined in the corresponding clock control register. Therefore you must ensure that the clock control register is configured appropriately before you set the pin to be an output. A similar argument applies to the frame sync pins. Also note that the reset state for the transmit high-frequency clock divide register (HCLKXDIV) is divide-by-1, and the divide-by-1 clocks are not gated by the transmit high-frequency clock divider reset enable (XHCLKRST).
 - (e) DIT registers: For DIT mode operation, set up registers DITCSRA[n], DITCSR[n], DITUDRA[n], and DITUDRB[n].
3. Start the respective high-frequency serial clocks AHCLKX and/or AHCLKR. This step is necessary even if external high-frequency serial clocks are used:
 - (a) Take the respective internal high-frequency serial clock divider(s) out of reset by setting the RHCLKRST bit for the receiver and/or the XHCLKRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be held at 0.
 - (b) Software must read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.

4. Start the respective serial clocks ACLKX and/or ACLKR. This step can be skipped if external serial clocks are used and they are running:
 - (a) Take the respective internal serial clock divider(s) out of reset by setting the RCLKRST bit for the receiver and/or the XCLKRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
 - (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
5. Setup data acquisition as required:
 - (a) If DMA is used to service the McASP, set up data acquisition as desired and start the DMA in this step, before the McASP is taken out of reset.
 - (b) If CPU interrupt is used to service the McASP, enable the transmit and/ or receive interrupt as required.
 - (c) If CPU polling is used to service the McASP, no action is required in this step.
6. Activate serializers.
 - (a) Before starting, clear the respective transmitter and receiver status registers by writing XSTAT = FFFFh and RSTAT = FFFFh.
 - (b) Take the respective serializers out of reset by setting the RSRCLR bit for the receiver and/or the XSRCLR bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
 - (c) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
7. Verify that all transmit buffers are serviced. Skip this step if the transmitter is not used. Also, skip this step if time slot 0 is selected as inactive (special cases, see [Figure 16-20](#), second waveform). As soon as the transmit serializer is taken out of reset, XDATA in the XSTAT register is set, indicating that XBUF is empty and ready to be serviced. The XDATA status causes an DMA event AXEVT to be generated, and can cause an interrupt AXINT to be generated if it is enabled in the XINTCTL register.
 - (a) If DMA is used to service the McASP, the DMA automatically services the McASP upon receiving AXEVT. Before proceeding in this step, you should verify that the XDATA bit in the XSTAT is cleared to 0, indicating that all transmit buffers are already serviced by the DMA.
 - (b) If CPU interrupt is used to service the McASP, interrupt service routine is entered upon the AXINT interrupt. The interrupt service routine should service the XBUF registers. Before proceeding in this step, you should verify that the XDATA bit in XSTAT is cleared to 0, indicating that all transmit buffers are already serviced by the CPU.
 - (c) If CPU polling is used to service the McASP, the XBUF registers should be written to in this step.
8. Release state machines from reset.
 - (a) Take the respective state machine(s) out of reset by setting the RSMRST bit for the receiver and/or the XSMRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
 - (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
9. Release frame sync generators from reset. Note that it is necessary to release the internal frame sync generators from reset, even if an external frame sync is being used, because the frame sync error detection logic is built into the frame sync generator.
 - (a) Take the respective frame sync generator(s) out of reset by setting the RFRST bit for the receiver, and/or the XFRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
 - (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.

10. Upon the first frame sync signal, McASP transfers begin. The McASP synchronizes to an edge on the frame sync pin, not the level on the frame sync pin. This makes it easy to release the state machine and frame sync generators from reset.
 - (a) For example, if you configure the McASP for a rising edge transmit frame sync, then you do not need to wait for a low level on the frame sync pin before releasing the McASP transmitter state machine and frame sync generators from reset.

16.2.10.3 Separate Transmit and Receive Initialization

In many cases, it is desirable to separately initialize the McASP transmitter and receiver. For example, you may delay the initialization of the transmitter until the type of data coming in on the receiver is recognized. Or a change in the incoming data stream on the receiver may necessitate a reinitialization of the transmitter.

In this case, you may still follow the sequence outlined in [Section 16.2.10.2](#), but use it for each section (transmit, receive) individually. The GBLCTL register is aliased to RGBLCTL and XGBLCTL to facilitate separate initialization of transmit and receive sections.

16.2.10.4 Importance of Reading Back GBLCTL

In [Section 16.2.10.2](#), steps 3b, 4b, 6c, 8b, and 9b state that GBLCTL should be read back until the bits that were written are successfully latched. This is important, because the transmitter and receiver state machines run off of the respective bit clocks, which are typically about tens to hundreds of times slower than the processor's internal bus clock. Therefore, it takes many cycles between when the processor writes to GBLCTL (or RGBLCTL and XGBLCTL), and when the McASP actually recognizes the write operation. If you skip this step, then the McASP may never see the reset bits in the global control registers get asserted and de-asserted; resulting in an uninitialized McASP.

Therefore, the logic in McASP has been implemented such that once the processor writes GBLCTL, RGBLCTL, or XGBLCTL, the resulting write is not visible by reading back GBLCTL until the McASP has recognized the change. This typically requires two bit clocks plus two processor bus clocks to occur.

Also, if the bit clocks can be completely stopped, any software that polls GBLCTL should be implemented with a time-out. If GBLCTL does not have a time-out, and the bit clock stops, the changes written to GBLCTL will not be reflected until the bit clock restarts.

Finally, please note that while RGBLCTL and XGBLCTL allow separate changing of the receive and transmit halves of GBLCTL, they also immediately reflect the updated value (useful for debug purposes). Only GBLCTL can be used for the read back step.

16.2.10.5 Synchronous Transmit and Receive Operation (ASYNC = 0)

When ASYNC = 0 in ACLKXCTL, the transmit and receive sections operate synchronously from the transmit section clock and transmit frame sync signals ([Figure 16-16](#)). The receive section may have a different (but compatible in terms of slot size) data format.

When ASYNC = 0, the receive frame sync generator is internally disabled. If the AFSX pin is configured as an output, it serves as the frame sync signal for both transmit and receive. The AFSR pin should not be used because the transmit frame sync generator output, which is used by both the transmitter and the receiver when ASYNC = 0, is not propagated to the AFSR pin ([Figure 16-18](#)).

When ASYNC = 0, the transmit and receive sections must share some common settings, since they both use the same clock and frame sync signals:

- DITEN = 0 in DITCTL (TDM mode is enabled).
- The total number of bits per frame must be the same (that is, RSSZ × RMOD must equal to XSSZ × XMOD).
- Both transmit and receive should either be specified as burst or TDM mode, but not mixed.
- The settings in ACLKRCTL are irrelevant.
- FSXM must match FSRM.
- FXWID must match FRWID.

For all other settings, the transmit and receive sections may be programmed independently.

16.2.10.6 Asynchronous Transmit and Receive Operation (ASYNC = 1)

When ASYNC = 1 in ACLKXCTL, the transmit and receive sections operate completely independently and have separate clock and frame sync signals (Figure 16-16, Figure 16-17, and Figure 16-18). The events generated by each section come asynchronously.

16.2.11 Interrupts

16.2.11.1 Transmit Data Ready Interrupt

The transmit data ready interrupt (XDATA) is generated if XDATA is 1 in the XSTAT register and XDATA is also enabled in XINTCTL. Section 16.2.8.1.1 provides details on when XDATA is set in the XSTAT register.

A transmit start of frame interrupt (XSTAFRM) is triggered by the recognition of transmit frame sync. A transmit last slot interrupt (XLAST) is a qualified version of the data ready interrupt (XDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended was next-to-last TDM slot, current slot is last slot).

16.2.11.2 Receive Data Ready Interrupt

The receive data ready interrupt (RDATA) is generated if RDATA is 1 in the RSTAT register and RDATA is also enabled in RINTCTL. Section 16.2.8.1.2 provides details on when RDATA is set in the RSTAT register.

A receiver start of frame interrupt (RSTAFRM) is triggered by the recognition of a receiver frame sync. A receiver last slot interrupt (RLAST) is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

16.2.11.3 Error Interrupts

Upon detection, the following error conditions generate interrupt flags:

- In the receive status register (RSTAT):
 - Receiver overrun (ROVRN).
 - Unexpected receive frame sync (RSYNCERR).
 - Receive clock failure (RCKFAIL).
 - Receive DMA error (RDMAERR).
- In the transmit status register (XSTAT):
 - Transmit underrun (XUNDRN).
 - Unexpected transmit frame sync (XSYNCERR).
 - Transmit clock failure (XCKFAIL).
 - Transmit DMA error (XDMAERR).

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (RINTCTL) and transmit interrupt control register (XINTCTL). If the enable bit is set in RINTCTL or XINTCTL, an interrupt is requested when the interrupt flag is set in RSTAT or XSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

16.2.11.4 Audio Mute (AMUTE) Function

The McASP includes an automatic audio mute function (Figure 16-33) that asserts in hardware the AMUTE pin to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register (AMUTE). The AMUTE pin is asserted when one of the interrupt flags is set or an external device issues an error signal on the AMUTEIN input. Typically, the AMUTEIN input is shared with a device interrupt pin (for example EXT_INT4).

The AMUTEIN input allows the on-chip logic to consider a mute input from other devices in the system, so that all errors may be considered. The AMUTEIN input has a programmable polarity to allow it to adapt to different devices, as selected by the INPOL bit in AMUTE, and it must be enabled explicitly.

In addition to the external AMUTEIN input, the AMUTE pin output may be asserted when one of the error interrupt flags is set and its mute function is enabled in AMUTE.

When one or more of the errors is detected and enabled, the AMUTE pin is driven to an active state that is selected by MUTEN in AMUTE. The active polarity of the AMUTE pin is programmable by MUTEN (and the inactive polarity is the opposite of the active polarity). The AMUTE pin remains driven active until software clears all the error interrupt flags that are enabled to mute, and until the AMUTEIN is inactive.

Figure 16-33. Audio Mute (AMUTE) Block Diagram

16.2.11.5 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in RSTAT or XSTAT is set and the interrupt is enabled in RINTCTL or XINTCTL.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit/receive interrupt ports, but that request has not yet been serviced.
- **Serviced:** The CPU writes to RSTAT or XSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the transmitter with the interrupt flag set in XSTAT and the interrupt enabled in XINTCTL generates a request on the McASP transmit interrupt port AXINT.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit interrupt port.

The transmit interrupt is serviced with the CPU writing to XSTAT. If any interrupt requests are active after the write, a new request is generated on the McASP transmit interrupt port.

The receiver operates in a similar way, but using RSTAT, RINTCTL, and the McASP receive interrupt port ARINT.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

16.2.12 EDMA Event Support

16.2.12.1 EDMA Events

There are six EDMA events.

16.2.12.2 Using the DMA for McASP Servicing

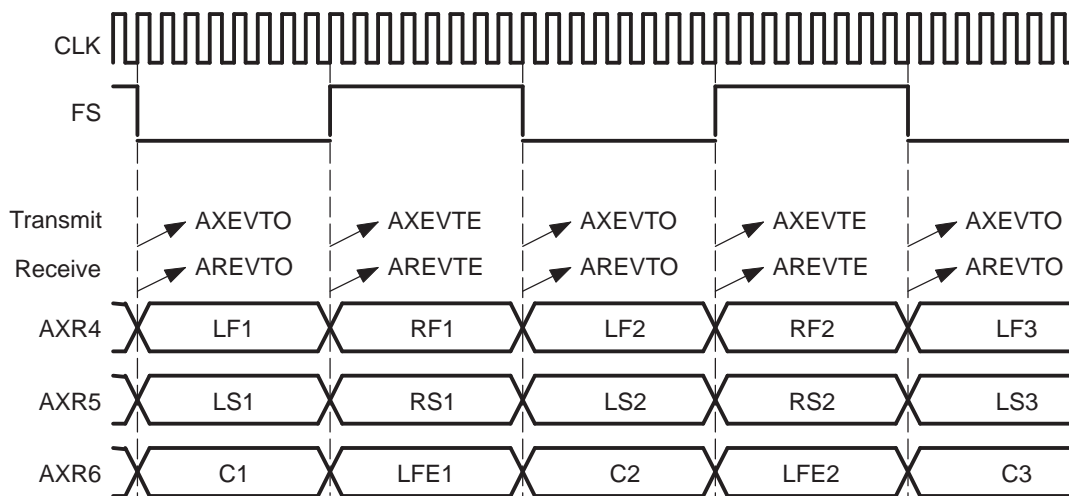

The most typical scenario is to use the DMA to service the McASP through the data port, although the DMA can also service the McASP through the configuration bus. Two possibilities exist for using the DMA events to service the McASP:

1. Use **AXEVT/AREVT**: Triggered upon each XDATA/RDATA transition from 0 to 1.
2. Use **AXEVTO/AREVTO** and **AXEVTE/AREVTE**: Alternating AXEVT/AREVT events for odd/even slots. Upon AXEVT/AREVT, AXEVTO/AREVTO is triggered if the event is for an odd channel, and AXEVTE/AREVTE is triggered if the event is for an even channel.

NOTE: Check the device-specific data manual to see if AXEVTO/AREVTO and AXEVTE/AREVTE are supported. These are optional.

[Figure 16-34](#) and [Figure 16-35](#) show an example audio system with six audio channels (LF, RF, LS, RS, C, and LFE) transmitted from three AXRn pins on the McASP. [Figure 16-34](#) and [Figure 16-35](#) show when events AXEVT, AXEVTO, and AXEVTE are triggered. [Figure 16-34](#) and [Figure 16-35](#) also apply for the receive audio channels and show when events AREVT, AREVTO, and AREVTE are triggered.

You can either use the DMA to service the McASP upon events AXEVT and AREVT ([Figure 16-34](#)) or upon events AXEVTO, AREVTO, AXEVTE, and AREVTE ([Figure 16-35](#)).

Figure 16-34. DMA Events in an Audio Example—Two Events (Scenario 1)

Figure 16-35. DMA Events in an Audio Example—Four Events (Scenario 2)

In scenario 1 (Figure 16-34), a DMA event AXEVT/AREVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (Time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Similarly, AREVT is triggered for each of the receive audio channel time slot. Scenario 1 allows for the use of a single DMA to transmit all audio channels, and a single DMA to receive all audio channels.

In scenario 2 (Figure 16-35), two alternating DMA events are triggered for each time slot. In the example, AXEVT0 (even) is triggered for the time slot for the even audio channels (LF, LS, C) and AXEVT1 (odd) is triggered for the time slot for the odd audio channels (RF, RS, LFE). AXEVT0 and AXEVT1 alternate in time. The same is true in the receive direction with the use of AREVTO and AREVTE. This scenario allows for the use of two DMA channels (odd and even) to transmit all audio channels, and two DMA channels to receive all audio channels.

Here are some guidelines on using the different DMA events:

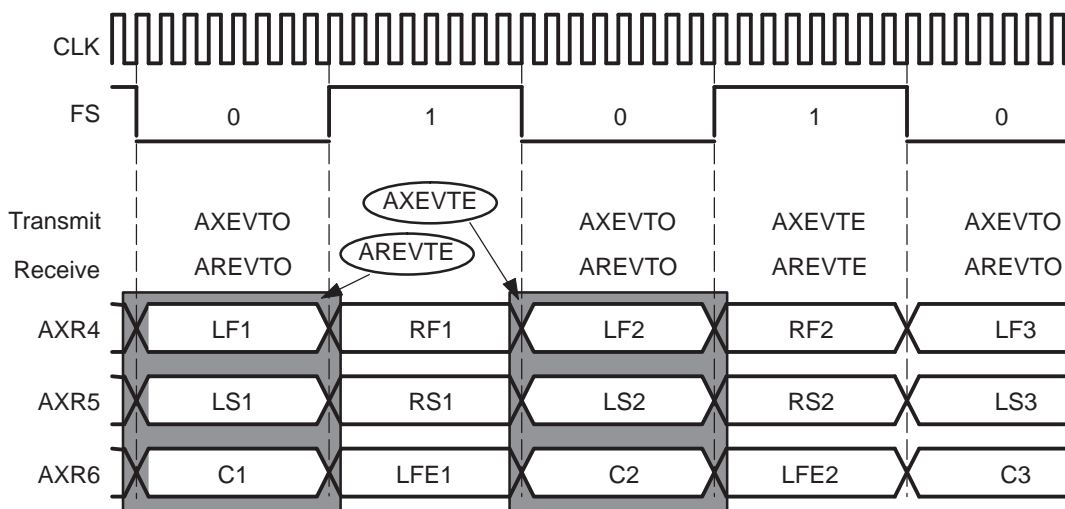

- Either use AXEVT, or the combination of AXEVTO and AXEVTE, to service the McASP. Never use all three at the same time. Similarly for receive, either use AREVT, or the combination of AREVTO and AREVTE.
- The McASP generates transmit DMA events independently from receive DMA events; therefore, separate schemes can be used for transmit and receive DMA. For example, scenario 1 could be used for the transmit data (AXEVT) and scenario 2 could be used for the receive data (AREVTO, AREVTE), and conversely.

Note the difference between DMA event generation and the CPU interrupt generation. DMA events are generated automatically upon data ready; whereas CPU interrupt generation needs to be enabled in the XINTCTL/RINTCTL register.

In Figure 16-35, scenario 2, each transmit DMA request is for data in the next time slot, while each receive DMA request is for data in the previous time slot. For example, Figure 16-36 shows a circled AXEVTE event for an even time slot transmit DMA request. The transmitter always requests a DMA transfer for data it will need to transmit during the next time slot. So, in this example, the circled event AXEVTE is a request for data for samples LF2, LS2, and C2.

On the other hand, the circled AREVTE event is an even time slot receive DMA request. The receiver always requests a DMA transfer for data it received during the previous time slot. In this example, the circled event AREVTE is a request for samples LF1, LS1, and C1.

Figure 16-36. DMA Events in an Audio Example

16.2.13 Power Management

The McASP can be placed in reduced power modes to conserve power during periods of low activity.

16.2.14 Emulation Considerations

NOTE: The receive buffer registers (RBUF n) and transmit buffer registers (XBUF n) should not be accessed by the emulator when the McASP is running. Such an access will cause the RDY/XRDY bit in the serializer control register n (SRCTL n) to be updated.

The McASP does not support the emulation suspend. If the McASP is placed into a suspended state, software needs to ensure that the registers/internal logic is reset to its default values by performing a module power cycle before restarting the initialization sequence.

16.3 McASP Registers

Table 16-7 lists the control registers for the McASP. The control registers are accessed through the configuration bus of the device. The receive buffer registers (RBUF n) and transmit buffer registers (XBUF n) can also be accessed through the data port of the device, as listed in Table 16-8.

Control registers for the McASP Audio FIFO (AFIFO) are summarized in Table 16-9. Note that the AFIFO Write FIFO (WFIFO) and Read FIFO (RFIFO) have independent control and status registers. The AFIFO control registers are accessed through the peripheral configuration port.

Table 16-7. McASP Registers Accessed Through Configuration Bus

Offset	Acronym	Register Description	Section
0h	REV	Revision identification register	Section 16.3.1
10h	PFUNC	Pin function register	Section 16.3.2

Table 16-8. McASP Registers Accessed Through Data Port

Hex Address	Register Name	Register Description
Read Accesses	RBUF ⁽¹⁾	Receive buffer data peripheral register address. Cycles through receive serializers, skipping over transmit serializers and inactive serializers. Starts at the lowest serializer at the beginning of each time slot. DAT BUS only if XBUSEL = 0. See the device specific data manual for address location.
Write Accesses	XBUF ⁽¹⁾	Transmit buffer data peripheral register address. Cycles through transmit serializers, skipping over receive and inactive serializers. Starts at the lowest serializer at the beginning of each time slot. DAT BUS only if RBUSEL = 0. See the device specific data manual for address location.

⁽¹⁾ RBUF and XBUF are at the same address location. Reads access RBUF and writes access XBUF.

Table 16-9. McASP AFIFO Registers Accessed Through Peripheral Configuration Port

Offset	Acronym	Register Description	Section
1000h	WFIFOCTL	Write FIFO control register	Section 16.3.43
1004h	WFIFOSTS	Write FIFO status register	Section 16.3.44

100Ch	RFIFOSTS	Read FIFO status register	Section 16.3.46

16.3.1 Revision Identification Register (REV)

The revision identification register (REV) contains identification data for the peripheral. The REV is shown in [Figure 16-37](#) and described in [Table 16-10](#).

Figure 16-37. Revision Identification Register (REV)

LEGEND: R = Read only; -n = value after reset

Table 16-10. Revision Identification Register (REV) Field Descriptions

Bit	Field	Value	Description
31-0	REV	4430 7302h	Identifies revision of peripheral.

16.3.2 Pin Function Register (PFUNC)

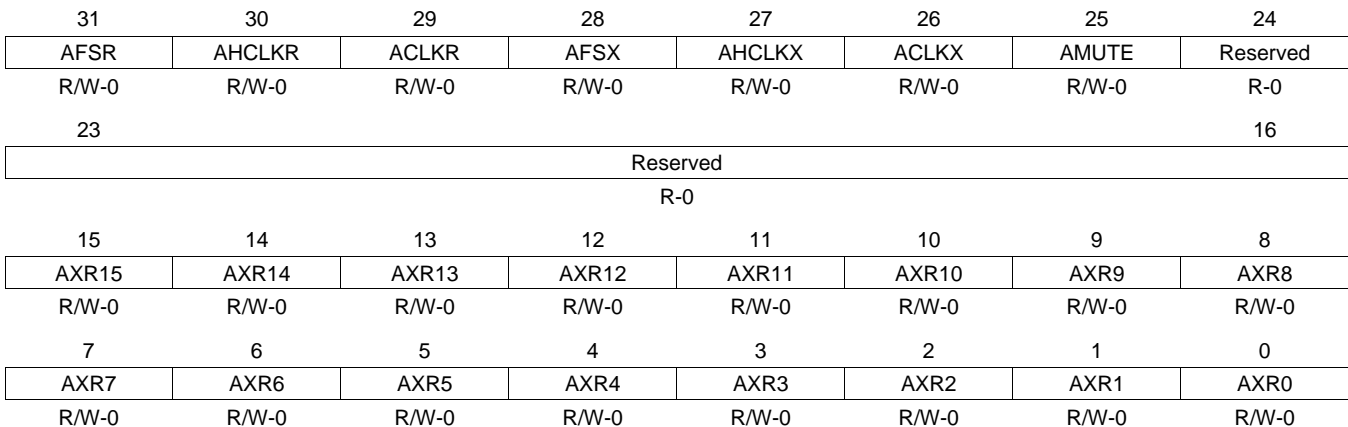

The pin function register (PFUNC) specifies the function of AXRn, ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either a McASP pin or a general-purpose input/output (GPIO) pin. The PFUNC is shown in [Figure 16-38](#) and described in [Table 16-11](#).

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 16-38. Pin Function Register (PFUNC)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-11. Pin Function Register (PFUNC) Field Descriptions

Bit	Field	Value	Description
31	AFSR	0	Determines if AFSR pin functions as McASP or GPIO. Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
30	AHCLKR	0	Determines if AHCLKR pin functions as McASP or GPIO. Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
29	ACLKR	0	Determines if ACLKR pin functions as McASP or GPIO. Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
28	AFSX	0	Determines if AFSX pin functions as McASP or GPIO. Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
27	AHCLKX	0	Determines if AHCLKX pin functions as McASP or GPIO. Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
26	ACLKX	0	Determines if ACLKX pin functions as McASP or GPIO. Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
25	AMUTE	0	Determines if AMUTE pin functions as McASP or GPIO. Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]	0	Determines if AXRn pin functions as McASP or GPIO. Pin functions as McASP pin.
		1	Pin functions as GPIO pin.

16.3.3 Pin Direction Register (PDIR)

The pin direction register (PDIR) specifies the direction of AXR_n, ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either an input or an output pin. The PDIR is shown in [Figure 16-39](#) and described in [Table 16-12](#). Refer to the device-specific data manual for the number of pins available on your device.

Regardless of the pin function register (PFUNC) setting, each PDIR bit must be set to 1 for the specified pin to be enabled as an output and each PDIR bit must be cleared to 0 for the specified pin to be an input.

For example, if the McASP is configured to use an internally-generated bit clock and the clock is to be driven out to the system, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be set to 1 (an output).

When AXR_n is configured to transmit, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be set to 1 (an output). Similarly, when AXR_n is configured to receive, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be cleared to 0 (an input).

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 16-39. Pin Direction Register (PDIR)

31	30	29	28	27	26	25	24
AFSR	AHCLKR	ACLKR	AFSX	AHCLKX	ACLKX	AMUTE	Reserved
R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R-0

AXR7	AXR6	AXR5	AXR4	AXR3	AXR2	AXR1	AXR0
R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-12. Pin Direction Register (PDIR) Field Descriptions

Bit	Field	Value	Description
31	AFSR	0	Determines if AFSR pin functions as an input or output. Pin functions as input.
		1	Pin functions as output.
30	AHCLKR	0	Determines if AHCLKR pin functions as an input or output. Pin functions as input.
		1	Pin functions as output.
29	ACLKR	0	Determines if ACLKR pin functions as an input or output. Pin functions as input.
		1	Pin functions as output.
28	AFSX	0	Determines if AFSX pin functions as an input or output. Pin functions as input.
		1	Pin functions as output.
27	AHCLKX	0	Determines if AHCLKX pin functions as an input or output. Pin functions as input.
		1	Pin functions as output.
26	ACLKX	0	Determines if ACLKX pin functions as an input or output. Pin functions as input.
		1	Pin functions as output.
25	AMUTE	0	Determines if AMUTE pin functions as an input or output. Pin functions as input.
		1	Pin functions as output.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]	0	Determines if AXRn pin functions as an input or output. Pin functions as input.
		1	Pin functions as output.

16.3.4 Pin Data Output Register (PDOUT)

The pin data output register (PDOUT) holds a value for data out at all times, and may be read back at all times. The value held by PDOUT is not affected by writing to PDIR and PFUNC. However, the data value in PDOUT is driven out onto the McASP pin only if the corresponding bit in PFUNC is set to 1 (GPIO function) and the corresponding bit in PDIR is set to 1 (output).

When reading data, it returns the corresponding PDOUT[n] bit value and does not return the input from I/O pin. When writing data, it writes to the corresponding PDOUT[n] bit.

The PDOUT is shown in [Figure 16-40](#) and described in [Table 16-13](#).

PDOUT has these aliases or alternate addresses:

- PDSET - when written to at this address, writing a 1 to a bit in PDSET sets the corresponding bit in PDOUT to 1; writing a 0 has no effect and keeps the bits in PDOUT unchanged.
- PDCLR - when written to at this address, writing a 1 to a bit in PDCLR clears the corresponding bit in PDOUT to 0; writing a 0 has no effect and keeps the bits in PDOUT unchanged.

There is only one set of data out bits, PDOUT[31-0]. The other registers, PDSET and PDCLR, are just different addresses for the same control bits, with different behaviors during writes.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 16-40. Pin Data Output Register (PDOUT)

31	30	29	28	27	26	25	24

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-13. Pin Data Output Register (PDOUT) Field Descriptions

Bit	Field	Value	Description
31	AFSR	0 1	Determines drive on AFSR output pin when the corresponding PFUNC[31] and PDIR[31] bits are set to 1. Pin drives low. Pin drives high.
30	AHCLKR	0 1	Determines drive on AHCLKR output pin when the corresponding PFUNC[30] and PDIR[30] bits are set to 1. Pin drives low. Pin drives high.
29	ACLKR	0 1	Determines drive on ACLKR output pin when the corresponding PFUNC[29] and PDIR[29] bits are set to 1. Pin drives low. Pin drives high.
28	AFSX	0 1	Determines drive on AFSX output pin when the corresponding PFUNC[28] and PDIR[28] bits are set to 1. Pin drives low. Pin drives high.
27	AHCLKX	0 1	Determines drive on AHCLKX output pin when the corresponding PFUNC[27] and PDIR[27] bits are set to 1. Pin drives low. Pin drives high.
26	ACLKX	0 1	Determines drive on ACLKX output pin when the corresponding PFUNC[26] and PDIR[26] bits are set to 1. Pin drives low. Pin drives high.
25	AMUTE	0 1	Determines drive on AMUTE output pin when the corresponding PFUNC[25] and PDIR[25] bits are set to 1. Pin drives low. Pin drives high.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]	0 1	Determines drive on AXR[n] output pin when the corresponding PFUNC[n] and PDIR[n] bits are set to 1. Pin drives low. Pin drives high.

16.3.5 Pin Data Input Register (PDIN)

The pin data input register (PDIN) holds the I/O pin state of each of the McASP pins. PDIN allows the actual value of the pin to be read, regardless of the state of PFUNC and PDIR. The value after reset for registers 1 through 15 and 24 through 31 depends on how the pins are being driven. The PDIN is shown in [Figure 16-41](#) and described in [Table 16-14](#).

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 16-41. Pin Data Input Register (PDIN)

31	30	29	28	27	26	25	24

Table 16-14. Pin Data Input Register (PDIN) Field Descriptions

Bit	Field	Value	Description
31	AFSR	0	Logic level on AFSR pin. Pin is logic low.
		1	Pin is logic high.
30	AHCLKR	0	Logic level on AHCLKR pin. Pin is logic low.
		1	Pin is logic high.
29	ACLKR	0	Logic level on ACLKR pin. Pin is logic low.
		1	Pin is logic high.
28	AFSX	0	Logic level on AFSX pin. Pin is logic low.
		1	Pin is logic high.
27	AHCLKX	0	Logic level on AHCLKX pin. Pin is logic low.
		1	Pin is logic high.
26	ACLKX	0	Logic level on ACLKX pin. Pin is logic low.
		1	Pin is logic high.
25	AMUTE	0	Logic level on AMUTE pin. Pin is logic low.
		1	Pin is logic high.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]	0	Logic level on AXR[n] pin. Pin is logic low.
		1	Pin is logic high.

16.3.6 Pin Data Set Register (PDSET)

The pin data set register (PDSET) is an alias of the pin data output register (PDOOUT) for writes only. Writing a 1 to the PDSET bit sets the corresponding bit in PDOOUT and, if PFUNC = 1 (GPIO function) and PDIR = 1 (output), drives a logic high on the pin. PDSET is useful for a multitasking system because it allows you to set to a logic high only the desired pin(s) within a system without affecting other I/O pins controlled by the same McASP. The PDSET is shown in [Figure 16-42](#) and described in [Table 16-15](#).

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 16-42. Pin Data Set Register (PDSET)

31	30	29	28	27	26	25	24

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-15. Pin Data Set Register (PDSET) Field Descriptions

Bit	Field	Value	Description
31	AFSR	0	Allows the corresponding AFSR bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port. No effect.
		1	PDOUT[31] bit is set to 1.
30	AHCLKR	0	Allows the corresponding AHCLKR bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port. No effect.
		1	PDOUT[30] bit is set to 1.
29	ACLKR	0	Allows the corresponding ACLKR bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port. No effect.
		1	PDOUT[29] bit is set to 1.
28	AFSX	0	Allows the corresponding AFSX bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port. No effect.
		1	PDOUT[28] bit is set to 1.
27	AHCLKX	0	Allows the corresponding AHCLKX bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port. No effect.
		1	PDOUT[27] bit is set to 1.
26	ACLKX	0	Allows the corresponding ACLKX bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port. No effect.
		1	PDOUT[26] bit is set to 1.
25	AMUTE	0	Allows the corresponding AMUTE bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port. No effect.
		1	PDOUT[25] bit is set to 1.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]	0	Allows the corresponding AXR[n] bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port. No effect.
		1	PDOUT[n] bit is set to 1.

16.3.7 Pin Data Clear Register (PDCLR)

The pin data clear register (PDCLR) is an alias of the pin data output register (PDOOUT) for writes only. Writing a 1 to the PDCLR bit clears the corresponding bit in PDOOUT and, if PFUNC = 1 (GPIO function) and PDIR = 1 (output), drives a logic low on the pin. PDCLR is useful for a multitasking system because it allows you to clear to a logic low only the desired pin(s) within a system without affecting other I/O pins controlled by the same McASP. The PDCLR is shown in [Figure 16-43](#) and described in [Table 16-16](#).

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 16-43. Pin Data Clear Register (PDCLR)

Table 16-16. Pin Data Clear Register (PDCLR) Field Descriptions

Bit	Field	Value	Description
31	AFSR		Allows the corresponding AFSR bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[31] bit is cleared to 0.
30	AHCLKR		Allows the corresponding AHCLKR bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[30] bit is cleared to 0.
29	ACLKR		Allows the corresponding ACLKR bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[29] bit is cleared to 0.
28	AFSX		Allows the corresponding AFSX bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[28] bit is cleared to 0.
27	AHCLKX		Allows the corresponding AHCLKX bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[27] bit is cleared to 0.
26	ACLKX		Allows the corresponding ACLKX bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[26] bit is cleared to 0.
25	AMUTE		Allows the corresponding AMUTE bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[25] bit is cleared to 0.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]		Allows the corresponding AXR[n] bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[n] bit is cleared to 0.

16.3.8 Global Control Register (GBLCTL)

The global control register (GBLCTL) provides initialization of the transmit and receive sections. The GBLCTL is shown in [Figure 16-44](#) and described in [Table 16-17](#).

The bit fields in GBLCTL are synchronized and latched by the corresponding clocks (ACLKX for bits 12-8 and ACLKR for bits 4-0). Before GBLCTL is programmed, you must ensure that serial clocks are running. If the corresponding external serial clocks, ACLKX and ACLKR, are not yet running, you should select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL, and ACLKRCTL before GBLCTL is programmed. Also, after programming any bits in GBLCTL you should not proceed until you have read back from GBLCTL and verified that the bits are latched in GBLCTL.

Figure 16-44. Global Control Register (GBLCTL)

Table 16-17. Global Control Register (GBLCTL) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XFRST	0 1	Transmit frame sync generator reset enable bit. 0 Transmit frame sync generator is reset. 1 Transmit frame sync generator is active. When released from reset, the transmit frame sync generator begins counting serial clocks and generating frame sync as programmed.
11	XSMRST	0 1	Transmit state machine reset enable bit. 0 Transmit state machine is held in reset. AXRn pin state: If PFUNC[n] = 0 and PDIR[n] = 1; then the serializer drives the AXRn pin to the state specified for inactive time slot (as determined by DISMOD bits in SRCTL). 1 Transmit state machine is released from reset. When released from reset, the transmit state machine immediately transfers data from XRBUF[n] to XRSR[n]. The transmit state machine sets the underrun flag (XUNDRN) in XSTAT, if XRBUF[n] have not been preloaded with data before reset is released. The transmit state machine also immediately begins detecting frame sync and is ready to transmit. Transmit TDM time slot begins at slot 0 after reset is released.
10	XSRCLR	0 1	Transmit serializer clear enable bit. By clearing then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun will occur. 0 Transmit serializers are cleared. 1 Transmit serializers are active. When the transmit serializers are first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in XSTAT is set to indicate XBUF is ready to be written.
9	XHCLKRST	0 1	Transmit high-frequency clock divider reset enable bit. 0 Transmit high-frequency clock divider is held in reset and passes through its input as divide-by-1. 1 Transmit high-frequency clock divider is running.
8	XCLKRST	0 1	Transmit clock divider reset enable bit. 0 Transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 1 Transmit clock divider is running.

Table 16-17. Global Control Register (GBLCTL) Field Descriptions (continued)

Bit	Field	Value	Description
7-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	RFRST	0 1	Receive frame sync generator reset enable bit. 0 Receive frame sync generator is reset. 1 Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.
3	RSMRST	0 1	Receive state machine reset enable bit. 0 Receive state machine is held in reset. 1 Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.
2	RSRCLR	0 1	Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed. 0 Receive serializers are cleared. 1 Receive serializers are active.
1	RHCLKRST	0 1	Receive high-frequency clock divider reset enable bit. 0 Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1. 1 Receive high-frequency clock divider is running.
0	RCLKRST	0 1	Receive clock divider reset enable bit. 0 Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 1 Receive clock divider is running.

16.3.9 Audio Mute Control Register (AMUTE)

The audio mute control register (AMUTE) controls the McASP audio mute (AMUTE) output pin. The value after reset for register 4 depends on how the pins are being driven. The AMUTE is shown in [Figure 16-45](#) and described in [Table 16-18](#).

Figure 16-45. Audio Mute Control Register (AMUTE)

31	Reserved						16

R/W-0	R/W-0	R/W-0	R-0	R/W-0	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-18. Audio Mute Control Register (AMUTE) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XDMAERR	0	Drive is disabled. Detection of transmit DMA error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of transmit DMA error, AMUTE is active and is driven according to MUTEN bit.
11	RDMAERR	0	Drive is disabled. Detection of receive DMA error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of receive DMA error, AMUTE is active and is driven according to MUTEN bit.
10	XCKFAIL	0	Drive is disabled. Detection of transmit clock failure is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of transmit clock failure, AMUTE is active and is driven according to MUTEN bit.
9	RCKFAIL	0	Drive is disabled. Detection of receive clock failure is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of receive clock failure, AMUTE is active and is driven according to MUTEN bit.
8	XSYNCERR	0	Drive is disabled. Detection of unexpected transmit frame sync error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of unexpected transmit frame sync error, AMUTE is active and is driven according to MUTEN bit.
7	RSYNCERR	0	Drive is disabled. Detection of unexpected receive frame sync error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of unexpected receive frame sync error, AMUTE is active and is driven according to MUTEN bit.
6	XUNDRN	0	Drive is disabled. Detection of transmit underrun error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of transmit underrun error, AMUTE is active and is driven according to MUTEN bit.

Table 16-18. Audio Mute Control Register (AMUTE) Field Descriptions (continued)

Bit	Field	Value	Description
5	ROVRN		If receiver overrun error (ROVRN), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of receiver overrun error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of receiver overrun error, AMUTE is active and is driven according to MUTEN bit.
4	INSTAT		Status of mute in pin, determines drive on AXRn pin when PFUNC[n] and PDIR[n] bits are set to 1.
		0	AMUTEIN pin is inactive.
		1	AMUTEIN pin is active. Audio mute in error is detected.
3	INEN		Drive AMUTE active when AMUTEIN error is active (INSTAT = 1).
		0	Drive is disabled. AMUTEIN is ignored by AMUTE.
		1	Drive is enabled (active). INSTAT = 1 drives AMUTE active.
2	INPOL		Audio mute in (AMUTEIN) polarity select bit.
		0	Polarity is active high. A high on AMUTEIN sets INSTAT to 1.
		1	Polarity is active low. A low on AMUTEIN sets INSTAT to 1.
1-0	MUTEN	0-3h	AMUTE pin enable bit (unless overridden by GPIO registers).
		0	AMUTE pin is disabled, pin goes to tri-state condition.
		1h	AMUTE pin is driven high if error is detected.
		2h	AMUTE pin is driven low if error is detected.
		3h	Reserved

16.3.10 Digital Loopback Control Register (DLBCTL)

The digital loopback control register (DLBCTL) controls the internal loopback settings of the McASP in TDM mode. The DLBCTL is shown in [Figure 16-46](#) and described in [Table 16-19](#). Note that loopback is NOT supported if McASP is configured in DIT mode.

Figure 16-46. Digital Loopback Control Register (DLBCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-19. Digital Loopback Control Register (DLBCTL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3-2	MODE	0-3h 0 1h 2h-3h	<p>Loopback generator mode bits. Applies only when loopback mode is enabled (DLBEN = 1).</p> <p>0 Default and reserved on loopback mode (DLBEN = 1). When in non-loopback mode (DLBEN = 0), MODE should be left at default (00). When in loopback mode (DLBEN = 1), MODE = 00 is reserved and is not applicable.</p> <p>1h MODE must be set to 01 when McASP operates in loopback mode (DLBEN = 1). This is necessary to allow transmit clock and frame sync generators to be used by both transmit and receive sections.</p> <p>2h-3h Reserved.</p>
1	ORD	0 1	<p>Loopback order bit when loopback mode is enabled (DLBEN = 1).</p> <p>0 Odd serializers N + 1 transmit to even serializers N that receive. The corresponding serializers must be programmed properly.</p> <p>1 Even serializers N transmit to odd serializers N + 1 that receive. The corresponding serializers must be programmed properly.</p>
0	DLBEN	0 1	<p>Loopback mode enable bit.</p> <p>0 Loopback mode is disabled (normal McASP operation)</p> <p>1 Loopback mode is enabled (TDM mode only).</p>

16.3.11 Digital Mode Control Register (DITCTL)

The DIT mode control register (DITCTL) controls DIT operations of the McASP. The DITCTL is shown in [Figure 16-47](#) and described in [Table 16-20](#).

Figure 16-47. Digital Mode Control Register (DITCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-20. Digital Mode Control Register (DITCTL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3	VB	0 1	Valid bit for odd time slots (DIT right subframe). V bit is 0 during odd DIT subframes. V bit is 1 during odd DIT subframes.
2	VA	0 1	Valid bit for even time slots (DIT left subframe). V bit is 0 during even DIT subframes. V bit is 1 during even DIT subframes.
1	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
0	DITEN	0 1	DIT mode enable bit. DITEN should only be changed while the XSMRST bit in GBLCTL is in reset (and for startup, XSRCLR also in reset). However, it is not necessary to reset the XCLKRST or XHCLKRST bits in GBLCTL to change DITEN. 0 DIT mode is disabled. Transmitter operates in TDM or burst mode. 1 DIT mode is enabled. Transmitter operates in DIT encoded mode.

16.3.12 Receiver Global Control Register (RGLCTL)

Alias of the global control register (GBLCTL). Writing to the receiver global control register (RGLCTL) affects only the receive bits of GBLCTL (bits 4-0). Reads from RGLCTL return the value of GBLCTL. RGLCTL allows the receiver to be reset independently from the transmitter. The RGLCTL is shown in Figure 16-48 and described in Table 16-21. See Section 16.3.8 for a detailed description of GBLCTL.

Figure 16-48. Receiver Global Control Register (RGLCTL)

31	Reserved						16

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-21. Receiver Global Control Register (RGLCTL) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XFRST	x	Transmit frame sync generator reset enable bit. A read of this bit returns the XFRST bit value of GBLCTL. Writes have no effect.
11	XSMRST	x	Transmit state machine reset enable bit. A read of this bit returns the XSMRST bit value of GBLCTL. Writes have no effect.
10	XSRCLR	x	Transmit serializer clear enable bit. A read of this bit returns the XSRCLR bit value of GBLCTL. Writes have no effect.
9	XHCLKRST	x	Transmit high-frequency clock divider reset enable bit. A read of this bit returns the XHCLKRST bit value of GBLCTL. Writes have no effect.
8	XCLKRST	x	Transmit clock divider reset enable bit. A read of this bit returns the XCLKRST bit value of GBLCTL. Writes have no effect.
7-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	RFRST	0 1	Receive frame sync generator reset enable bit. A write to this bit affects the RFRST bit of GBLCTL. 0 Receive frame sync generator is reset. 1 Receive frame sync generator is active.
3	RSMRST	0 1	Receive state machine reset enable bit. A write to this bit affects the RSMRST bit of GBLCTL. 0 Receive state machine is held in reset. 1 Receive state machine is released from reset.
2	RSRCLR	0 1	Receive serializer clear enable bit. A write to this bit affects the RSRCLR bit of GBLCTL. 0 Receive serializers are cleared. 1 Receive serializers are active.
1	RHCLKRST	0 1	Receive high-frequency clock divider reset enable bit. A write to this bit affects the RHCLKRST bit of GBLCTL. 0 Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1. 1 Receive high-frequency clock divider is running.
0	RCLKRST	0 1	Receive clock divider reset enable bit. A write to this bit affects the RCLKRST bit of GBLCTL. 0 Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 1 Receive clock divider is running.

16.3.13 Receive Format Unit Bit Mask Register (RMASK)

The receive format unit bit mask register (RMASK) determines which bits of the received data are masked off and padded with a known value before being read by the CPU or DMA. The RMASK is shown in Figure 16-49 and described in Table 16-22.

Figure 16-49. Receive Format Unit Bit Mask Register (RMASK)

LEGEND: R/W = Read/Write; -n = value after reset

Table 16-22. Receive Format Unit Bit Mask Register (RMASK) Field Descriptions

Bit	Field	Value	Description
31-0	RMASK[31-0]	0	Receive data mask <i>n</i> enable bit.
		0	Corresponding bit of receive data (after passing through reverse and rotate units) is masked out and then padded with the selected bit pad value (RPAD and RPBIT bits in RFMT).
		1	Corresponding bit of receive data (after passing through reverse and rotate units) is returned to CPU or DMA.

16.3.14 Receive Bit Stream Format Register (RFMT)

The receive bit stream format register (RFMT) configures the receive data format. The RFMT is shown in Figure 16-50 and described in Table 16-23.

Figure 16-50. Receive Bit Stream Format Register (RFMT)

31										18		17	16

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-23. Receive Bit Stream Format Register (RFMT) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
17-16	RDATDLY	0-3h	Receive frame sync delay of AXRn.
		0	0-bit delay. The first receive data bit, AXRn, occurs in same ACLKR cycle as the receive frame sync (AFSR).
		1h	1-bit delay. The first receive data bit, AXRn, occurs one ACLKR cycle after the receive frame sync (AFSR).
		2h	2-bit delay. The first receive data bit, AXRn, occurs two ACLKR cycles after the receive frame sync (AFSR).
		3h	Reserved.
15	RRVRS		Receive serial bitstream order.
		0	Bitstream is LSB first. No bit reversal is performed in receive format bit reverse unit.
		1	Bitstream is MSB first. Bit reversal is performed in receive format bit reverse unit.
14-13	RPAD	0-3h	Pad value for extra bits in slot not belonging to the word. This field only applies to bits when RMASK[n] = 0.
		0	Pad extra bits with 0.
		1h	Pad extra bits with 1.
		2h	Pad extra bits with one of the bits from the word as specified by RPBIT bits.
		3h	Reserved.
12-8	RPBIT	0-1Fh	RPBIT value determines which bit (as read by the CPU or DMA from RBUF[n]) is used to pad the extra bits. This field only applies when RPAD = 2h.
		0	Pad with bit 0 value.
		1h-1Fh	Pad with bit 1 to bit 31 value.

Table 16-23. Receive Bit Stream Format Register (RFMT) Field Descriptions (continued)

Bit	Field	Value	Description
7-4	RSSZ	0-Fh 0-2h 3h 4h 5h 6h 7h 8h 9h Ah Bh Ch Dh Eh Fh	Receive slot size. Reserved Slot size is 8 bits. Reserved Slot size is 12 bits. Reserved Slot size is 16 bits. Reserved Slot size is 20 bits. Reserved Slot size is 24 bits Reserved Slot size is 28 bits. Reserved Slot size is 32 bits.
3	RBUSEL	0 1	Selects whether reads from serializer buffer XRBUF[n] originate from the configuration bus (CFG) or the data (DAT) port. Reads from XRBUF[n] originate on data port. Reads from XRBUF[n] on configuration bus are ignored. Reads from XRBUF[n] originate on configuration bus. Reads from XRBUF[n] on data port are ignored.
2-0	RROT	0-7h 0 1h 2h 3h 4h 5h 6h 7h	Right-rotation value for receive rotate right format unit. Rotate right by 0 (no rotation). Rotate right by 4 bit positions. Rotate right by 8 bit positions. Rotate right by 12 bit positions. Rotate right by 16 bit positions. Rotate right by 20 bit positions. Rotate right by 24 bit positions. Rotate right by 28 bit positions.

16.3.15 Receive Frame Sync Control Register (AFSRCTL)

The receive frame sync control register (AFSRCTL) configures the receive frame sync (AFSR). The AFSRCTL is shown in [Figure 16-51](#) and described in [Table 16-24](#).

Figure 16-51. Receive Frame Sync Control Register (AFSRCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-24. Receive Frame Sync Control Register (AFSRCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-7	RMOD	0-1FFh 0 1h 2h-20h 21h-17Fh 180h 181h-1FFh	Receive frame sync mode select bits. Burst mode. Reserved. 2-slot TDM (I2S mode) to 32-slot TDM. Reserved. 384-slot TDM (external DIR IC inputting 384-slot DIR frames to McASP over I2S interface). Reserved.
6-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	FRWID	0 1	Receive frame sync width select bit indicates the width of the receive frame sync (AFSR) during its active period. Single bit. Single word. Single word is not supported if RMOD is set to burst mode.
3-2	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
1	FSRM	0 1	Receive frame sync generation select bit. Externally-generated receive frame sync. Internally-generated receive frame sync.
0	FSRP	0 1	Receive frame sync polarity select bit. A rising edge on receive frame sync (AFSR) indicates the beginning of a frame. A falling edge on receive frame sync (AFSR) indicates the beginning of a frame.

16.3.16 Receive Clock Control Register (ACLKRCTL)

The receive clock control register (ACLKRCTL) configures the receive bit clock (ACLKR) and the receive clock generator. The ACLKRCTL is shown in [Figure 16-52](#) and described in [Table 16-25](#).

Figure 16-52. Receive Clock Control Register (ACLKRCTL)

31	Reserved	16
	R-0	
15	8 7 6 5 4	0
	Reserved	CLKRP Rsvd CLKRM CLKRDIV
	R-0	R/W-0 R-0 R/W-1 R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-25. Receive Clock Control Register (ACLKRCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	CLKRP	0 1	Receive bitstream clock polarity select bit. 0 Falling edge. Receiver samples data on the falling edge of the serial clock, so the external transmitter driving this receiver must shift data out on the rising edge of the serial clock. 1 Rising edge. Receiver samples data on the rising edge of the serial clock, so the external transmitter driving this receiver must shift data out on the falling edge of the serial clock.
6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	CLKRM	0 1	Receive bit clock source bit. Note that this bit does not have any effect, if ACLKXCTL.ASYNC = 0. 0 External receive clock source from ACLKR pin. 1 Internal receive clock source from output of programmable bit clock divider.
4-0	CLKRDIV	0-1Fh 0 1h 2h-1Fh	Receive bit clock divide ratio bits determine the divide-down ratio from AHCLKR to ACLKR. Note that this bit does not have any effect, if ACLKXCTL.ASYNC = 0. 0 Divide-by-1. 1h Divide-by-2. 2h-1Fh Divide-by-3 to divide-by-32.

16.3.17 Receive High-Frequency Clock Control Register (AHCLKRCTL)

The receive high-frequency clock control register (AHCLKRCTL) configures the receive high-frequency master clock (AHCLKR) and the receive clock generator. The AHCLKRCTL is shown in [Figure 16-53](#) and described in [Table 16-26](#).

Figure 16-53. Receive High-Frequency Clock Control Register (AHCLKRCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-26. Receive High-Frequency Clock Control Register (AHCLKRCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15	HCLKRM	0	Receive high-frequency clock source bit. External receive high-frequency clock source from AHCLKR pin.
		1	Internal receive high-frequency clock source from output of programmable high clock divider.
14	HCLKRP	0	Receive bitstream high-frequency clock polarity select bit. AHCLKR is not inverted before programmable bit clock divider. In the special case where the receive bit clock (ACLKR) is internally generated and the programmable bit clock divider is set to divide-by-1 (CLKRDIV = 0 in ACLKRCTL), AHCLKR is directly passed through to the ACLKR pin.
		1	AHCLKR is inverted before programmable bit clock divider. In the special case where the receive bit clock (ACLKR) is internally generated and the programmable bit clock divider is set to divide-by-1 (CLKRDIV = 0 in ACLKRCTL), AHCLKR is directly passed through to the ACLKR pin.
13-12	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
11-0	HCLKRDIV	0-FFFh	Receive high-frequency clock divide ratio bits determine the divide-down ratio from AUXCLK to AHCLKR.
		0	Divide-by-1.
		1h	Divide-by-2.
		2h-FFFh	Divide-by-3 to divide-by-4096.

16.3.18 Receive TDM Time Slot Register (RTDM)

The receive TDM time slot register (RTDM) specifies which TDM time slot the receiver is active. The RTDM is shown in [Figure 16-54](#) and described in [Table 16-27](#).

Figure 16-54. Receive TDM Time Slot Register (RTDM)

LEGEND: R/W = Read/Write; -n = value after reset

Table 16-27. Receive TDM Time Slot Register (RTDM) Field Descriptions

Bit	Field	Value	Description
31-0	RTDMS[31-0]	0	Receiver mode during TDM time slot <i>n</i> . Receive TDM time slot <i>n</i> is inactive. The receive serializer does not shift in data during this slot.
		1	Receive TDM time slot <i>n</i> is active. The receive serializer shifts in data during this slot.

16.3.19 Receiver Interrupt Control Register (RINTCTL)

The receiver interrupt control register (RINTCTL) controls generation of the McASP receive interrupt (RINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates RINT. The RINTCTL is shown in Figure 16-55 and described in Table 16-28. See Section 16.3.20 for a description of the interrupt conditions.

Figure 16-55. Receiver Interrupt Control Register (RINTCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-28. Receiver Interrupt Control Register (RINTCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	RSTAFRM	0	Receive start of frame interrupt enable bit. Interrupt is disabled. A receive start of frame interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive start of frame interrupt generates a McASP receive interrupt (RINT).
6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	RDATA	0	Receive data ready interrupt enable bit. Interrupt is disabled. A receive data ready interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive data ready interrupt generates a McASP receive interrupt (RINT).
4	RLAST	0	Receive last slot interrupt enable bit. Interrupt is disabled. A receive last slot interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive last slot interrupt generates a McASP receive interrupt (RINT).
3	RDMAERR	0	Receive DMA error interrupt enable bit. Interrupt is disabled. A receive DMA error interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive DMA error interrupt generates a McASP receive interrupt (RINT).
2	RCKFAIL	0	Receive clock failure interrupt enable bit. Interrupt is disabled. A receive clock failure interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive clock failure interrupt generates a McASP receive interrupt (RINT).
1	RSYNCERR	0	Unexpected receive frame sync interrupt enable bit. Interrupt is disabled. An unexpected receive frame sync interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. An unexpected receive frame sync interrupt generates a McASP receive interrupt (RINT).
0	ROVRN	0	Receiver overrun interrupt enable bit. Interrupt is disabled. A receiver overrun interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receiver overrun interrupt generates a McASP receive interrupt (RINT).

16.3.20 Receiver Status Register (RSTAT)

The receiver status register (RSTAT) provides the receiver status and receive TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated. The RSTAT is shown in [Figure 16-56](#) and described in [Table 16-29](#).

Figure 16-56. Receiver Status Register (RSTAT)

31							9	8
Reserved							RERR	
R-0							R/W-0	
7	6	5	4	3	2	1	0	
RDMAERR	RSTAFRM	RDATA	RLAST	RTDMSLOT	RCKFAIL	RSYNCERR	ROVRN	
R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R-0	R/W1C-0	R/W1C-0	R/W1C-0	

LEGEND: R/W = Read/Write; R = Read only; W1C = Writing a 1 clears this bit; writing a 0 has no effect.; -n = value after reset

Table 16-29. Receiver Status Register (RSTAT) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
8	RERR	0 1	RERR bit always returns a logic-OR of:ROVRN RSYNCERR RCKFAIL RDMAERR Allows a single bit to be checked to determine if a receiver error interrupt has occurred. 0 No errors have occurred. 1 An error has occurred.
7	RDMAERR	0 1	Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the data port in a given time slot than were programmed as receivers. Causes a receive interrupt (RINT), if this bit is set and RDMAERR in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0 Receive DMA error did not occur. 1 Receive DMA error did occur.
6	RSTAFRM	0 1	Receive start of frame flag. Causes a receive interrupt (RINT), if this bit is set and RSTAFRM in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0 No new receive frame sync (AFSR) is detected. 1 A new receive frame sync (AFSR) is detected.
5	RDATA	0 1	Receive data ready flag. Causes a receive interrupt (RINT), if this bit is set and RDATA in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0 No new data in RBUF. 1 Data is transferred from XRSR to RBUF and ready to be serviced by the CPU or DMA. When RDATA is set, it always causes a DMA event (AREVT).
4	RLAST	0 1	Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. Causes a receive interrupt (RINT), if this bit is set and RLAST in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0 Current slot is not the last slot in a frame. 1 Current slot is the last slot in a frame. RDATA is also set.
3	RTDMSLOT	0 1	Returns the LSB of RSLOT. Allows a single read of RSTAT to determine whether the current TDM time slot is even or odd. 0 Current TDM time slot is odd. 1 Current TDM time slot is even.
2	RCKFAIL	0 1	Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error (see <i>Clock Failure Detection</i>). Causes a receive interrupt (RINT), if this bit is set and RCKFAIL in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0 Receive clock failure did not occur. 1 Receive clock failure did occur.

Table 16-29. Receiver Status Register (RSTAT) Field Descriptions (continued)

Bit	Field	Value	Description
1	RSYNCERR	0 1	Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. Causes a receive interrupt (RINT), if this bit is set and RSYNCERR in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. Unexpected receive frame sync did not occur. Unexpected receive frame sync did occur.
0	ROVRN	0 1	Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU or DMA. Causes a receive interrupt (RINT), if this bit is set and ROVRN in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. Receiver overrun did not occur. Receiver overrun did occur.

16.3.21 Current Receive TDM Time Slot Registers (RSL0T)

The current receive TDM time slot register (RSL0T) indicates the current time slot for the receive data frame. The RSL0T is shown in [Figure 16-57](#) and described in [Table 16-30](#).

Figure 16-57. Current Receive TDM Time Slot Registers (RSL0T)

LEGEND: R = Read only; -n = value after reset

Table 16-30. Current Receive TDM Time Slot Registers (RSL0T) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
8-0	RSL0TCNT	0-17Fh	Current receive time slot count. Legal values: 0 to 383 (17Fh). TDM function is not supported for > 32 time slots. However, TDM time slot counter may count to 383 when used to receive a DIR block (transferred over TDM format). In I2S mode, this should only be read by the DSP since frame sync initializes it to zero.

16.3.22 Receive Clock Check Control Register (RCLKCHK)

The receive clock check control register (RCLKCHK) configures the receive clock failure detection circuit. The RCLKCHK is shown in [Figure 16-58](#) and described in [Table 16-31](#).

Figure 16-58. Receive Clock Check Control Register (RCLKCHK)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-31. Receive Clock Check Control Register (RCLKCHK) Field Descriptions

Bit	Field	Value	Description																				
31-24	RCNT	0-FFh	Receive clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 receive high-frequency master clock (AHCLKR) signals, and stores the count in RCNT until the next measurement is taken.																				
23-16	RMAX	0-FFh	Receive clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If the current counter value is greater than RMAX after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.																				
15-8	RMIN	0-FFh	Receive clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If RCNT is less than RMIN after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.																				
7-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.																				
3-0	RPS	0-Fh	Receive clock check prescaler value. <table style="width: 100%; border: none;"> <tr><td style="width: 10%; border: none;">0</td><td style="border: none;">McASP system clock divided by 1.</td></tr> <tr><td style="border: none;">1h</td><td style="border: none;">McASP system clock divided by 2.</td></tr> <tr><td style="border: none;">2h</td><td style="border: none;">McASP system clock divided by 4.</td></tr> <tr><td style="border: none;">3h</td><td style="border: none;">McASP system clock divided by 8.</td></tr> <tr><td style="border: none;">4h</td><td style="border: none;">McASP system clock divided by 16.</td></tr> <tr><td style="border: none;">5h</td><td style="border: none;">McASP system clock divided by 32.</td></tr> <tr><td style="border: none;">6h</td><td style="border: none;">McASP system clock divided by 64.</td></tr> <tr><td style="border: none;">7h</td><td style="border: none;">McASP system clock divided by 128.</td></tr> <tr><td style="border: none;">8h</td><td style="border: none;">McASP system clock divided by 256.</td></tr> <tr><td style="border: none;">9h-Fh</td><td style="border: none;">Reserved.</td></tr> </table>	0	McASP system clock divided by 1.	1h	McASP system clock divided by 2.	2h	McASP system clock divided by 4.	3h	McASP system clock divided by 8.	4h	McASP system clock divided by 16.	5h	McASP system clock divided by 32.	6h	McASP system clock divided by 64.	7h	McASP system clock divided by 128.	8h	McASP system clock divided by 256.	9h-Fh	Reserved.
0	McASP system clock divided by 1.																						
1h	McASP system clock divided by 2.																						
2h	McASP system clock divided by 4.																						
3h	McASP system clock divided by 8.																						
4h	McASP system clock divided by 16.																						
5h	McASP system clock divided by 32.																						
6h	McASP system clock divided by 64.																						
7h	McASP system clock divided by 128.																						
8h	McASP system clock divided by 256.																						
9h-Fh	Reserved.																						

16.3.23 Receiver DMA Event Control Register (REVTCTL)

The receiver DMA event control register (REVTCTL) contains a disable bit for the receiver DMA event. The REVTCTL is shown in [Figure 16-59](#) and described in [Table 16-32](#).

NOTE: Device-specific registers

Accessing REVTCTL not implemented on a specific device may cause improper device operation.

Figure 16-59. Receiver DMA Event Control Register (REVTCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-32. Receiver DMA Event Control Register (REVTCTL) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
0	RDATDMA	0	Receive data DMA request enable bit. If writing to this bit, always write the default value of 0.
		1	Reserved

16.3.24 Transmitter Global Control Register (XGBLCTL)

Alias of the global control register (GBLCTL). Writing to the transmitter global control register (XGBLCTL) affects only the transmit bits of GBLCTL (bits 12-8). Reads from XGBLCTL return the value of GBLCTL. XGBLCTL allows the transmitter to be reset independently from the receiver. The XGBLCTL is shown in Figure 16-60 and described in Table 16-33. See Section 16.3.8 for a detailed description of GBLCTL.

Figure 16-60. Transmitter Global Control Register (XGBLCTL)

Table 16-33. Transmitter Global Control Register (XGBLCTL) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0-FFh	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XFRST	0 1	Transmit frame sync generator reset enable bit. A write to this bit affects the XFRST bit of GBLCTL. 0 Transmit frame sync generator is reset. 1 Transmit frame sync generator is active.
11	XSMRST	0 1	Transmit state machine reset enable bit. A write to this bit affects the XSMRST bit of GBLCTL. 0 Transmit state machine is held in reset. 1 Transmit state machine is released from reset.
10	XSRCLR	0 1	Transmit serializer clear enable bit. A write to this bit affects the XSRCLR bit of GBLCTL. 0 Transmit serializers are cleared. 1 Transmit serializers are active.
9	XHCLKRST	0 1	Transmit high-frequency clock divider reset enable bit. A write to this bit affects the XHCLKRST bit of GBLCTL. 0 Transmit high-frequency clock divider is held in reset and passes through its input as divide-by-1. 1 Transmit high-frequency clock divider is running.
8	XCLKRST	0 1	Transmit clock divider reset enable bit. A write to this bit affects the XCLKRST bit of GBLCTL. 0 Transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 1 Transmit clock divider is running.
7-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	RFRST	x	Receive frame sync generator reset enable bit. A read of this bit returns the RFRST bit value of GBLCTL. Writes have no effect.
3	RSMRST	x	Receive state machine reset enable bit. A read of this bit returns the RSMRST bit value of GBLCTL. Writes have no effect.
2	RSRCLR	x	Receive serializer clear enable bit. A read of this bit returns the RSRCLR bit value of GBLCTL. Writes have no effect.
1	RHCLKRST	x	Receive high-frequency clock divider reset enable bit. A read of this bit returns the RHCLKRST bit value of GBLCTL. Writes have no effect.
0	RCLKRST	x	Receive clock divider reset enable bit. A read of this bit returns the RCLKRST bit value of GBLCTL. Writes have no effect.

16.3.25 Transmit Format Unit Bit Mask Register (XMASK)

The transmit format unit bit mask register (XMASK) determines which bits of the transmitted data are masked off and padded with a known value before being shifted out the McASP. The XMASK is shown in [Figure 16-61](#) and described in [Table 16-34](#).

Figure 16-61. Transmit Format Unit Bit Mask Register (XMASK)

LEGEND: R/W = Read/Write; -n = value after reset

Table 16-34. Transmit Format Unit Bit Mask Register (XMASK) Field Descriptions

Bit	Field	Value	Description
31-0	XMASK[31-0]	0	Corresponding bit of transmit data (before passing through reverse and rotate units) is masked out and then padded with the selected bit pad value (XPAD and XPBIT bits in XFMT), which is transmitted out the McASP in place of the original bit.
		1	Corresponding bit of transmit data (before passing through reverse and rotate units) is transmitted out the McASP.

16.3.26 Transmit Bit Stream Format Register (XFMT)

The transmit bit stream format register (XFMT) configures the transmit data format. The XFMT is shown in Figure 16-62 and described in Table 16-35.

Figure 16-62. Transmit Bit Stream Format Register (XFMT)

31											18		17	16

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-35. Transmit Bit Stream Format Register (XFMT) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
17-16	XDATDLY	0-3h	Transmit frame sync delay of AXRn.
		0	0-bit delay. The first transmit data bit, AXRn, occurs in same ACLKX cycle as the transmit frame sync (AFSX).
		1h	1-bit delay. The first transmit data bit, AXRn, occurs one ACLKX cycle after the transmit frame sync (AFSX).
		2h	2-bit delay. The first transmit data bit, AXRn, occurs two ACLKX cycles after the transmit frame sync (AFSX).
		3h	Reserved.
15	XRVRS		Transmit serial bitstream order.
		0	Bitstream is LSB first. No bit reversal is performed in transmit format bit reverse unit.
		1	Bitstream is MSB first. Bit reversal is performed in transmit format bit reverse unit.
14-13	XPAD	0-3h	Pad value for extra bits in slot not belonging to word defined by XMASK. This field only applies to bits when XMASK[n] = 0.
		0	Pad extra bits with 0.
		1h	Pad extra bits with 1.
		2h	Pad extra bits with one of the bits from the word as specified by XPBIT bits.
		3h	Reserved.
12-8	XPBIT	0-1Fh	XPBIT value determines which bit (as written by the CPU or DMA to XBUF[n]) is used to pad the extra bits before shifting. This field only applies when XPAD = 2h.
		0	Pad with bit 0 value.
		1-1Fh	Pad with bit 1 to bit 31 value.

Table 16-35. Transmit Bit Stream Format Register (XFMT) Field Descriptions (continued)

Bit	Field	Value	Description
7-4	XSSZ	0-Fh 0-2h 3h 4h 5h 6h 7h 8h 9h Ah Bh Ch Dh Eh Fh	Transmit slot size. Reserved. Slot size is 8 bits. Reserved. Slot size is 12 bits. Reserved. Slot size is 16 bits. Reserved. Slot size is 20 bits. Reserved. Slot size is 24 bits. Reserved. Slot size is 28 bits. Reserved. Slot size is 32 bits.
3	XBUSEL	0 1	Selects whether writes to serializer buffer XRBUF[n] originate from the configuration bus (CFG) or the data (DAT) port. Writes to XRBUF[n] originate from the data port. Writes to XRBUF[n] from the configuration bus are ignored with no effect to the McASP. Writes to XRBUF[n] originate from the configuration bus. Writes to XRBUF[n] from the data port are ignored with no effect to the McASP.
2-0	XROT	0-7h 0 1h 2h 3h 4h 5h 6h 7h	Right-rotation value for transmit rotate right format unit. Rotate right by 0 (no rotation). Rotate right by 4 bit positions. Rotate right by 8 bit positions. Rotate right by 12 bit positions. Rotate right by 16 bit positions. Rotate right by 20 bit positions. Rotate right by 24 bit positions. Rotate right by 28 bit positions.

16.3.27 Transmit Frame Sync Control Register (AFSXCTL)

The transmit frame sync control register (AFSXCTL) configures the transmit frame sync (AFSX). The AFSXCTL is shown in [Figure 16-63](#) and described in [Table 16-36](#).

Figure 16-63. Transmit Frame Sync Control Register (AFSXCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-36. Transmit Frame Sync Control Register (AFSXCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-7	XMOD	0-1FFh	Transmit frame sync mode select bits.
		0	Burst mode.
		1h	Reserved.
		2h-20h	2-slot TDM (I2S mode) to 32-slot TDM.
		21h-17Fh	Reserved.
		180h	384-slot DIT mode.
		181h-1FFh	Reserved.
6-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	FXWID		Transmit frame sync width select bit indicates the width of the transmit frame sync (AFSX) during its active period.
		0	Single bit.
		1	Single word. Single word is not supported if XMOD is set to burst mode.
3-2	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
1	FSXM		Transmit frame sync generation select bit.
		0	Externally-generated transmit frame sync.
		1	Internally-generated transmit frame sync.
0	FSXP		Transmit frame sync polarity select bit.
		0	A rising edge on transmit frame sync (AFSX) indicates the beginning of a frame.
		1	A falling edge on transmit frame sync (AFSX) indicates the beginning of a frame.

16.3.28 Transmit Clock Control Register (ACLKXCTL)

The transmit clock control register (ACLKXCTL) configures the transmit bit clock (ACLKX) and the transmit clock generator. The ACLKXCTL is shown in [Figure 16-64](#) and described in [Table 16-37](#).

Figure 16-64. Transmit Clock Control Register (ACLKXCTL)

31	Reserved										16
R-0											
15	Reserved				8	7	6	5	4	0	
R-0				CLKXP	ASYNC	CLKXM	CLKXDIV				
R-0				R/W-0	R/W-1	R/W-1	R/W-0				

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-37. Transmit Clock Control Register (ACLKXCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	CLKXP	0	Rising edge. External receiver samples data on the falling edge of the serial clock, so the transmitter must shift data out on the rising edge of the serial clock.
		1	Falling edge. External receiver samples data on the rising edge of the serial clock, so the transmitter must shift data out on the falling edge of the serial clock.
6	ASYNC	0	Synchronous. Transmit clock and frame sync provides the source for both the transmit and receive sections. Note that in this mode, the receive bit clock is an inverted version of the transmit bit clock.
		1	Asynchronous. Separate clock and frame sync used by transmit and receive sections.
5	CLKXM	0	External transmit clock source from ACLKX pin.
		1	Internal transmit clock source from output of programmable bit clock divider.
4-0	CLKXDIV	0-1Fh	Transmit bit clock divide ratio bits determine the divide-down ratio from AHCLKX to ACLKX.
		0	Divide-by-1.
		1h	Divide-by-2.
		2h-1Fh	Divide-by-3 to divide-by-32.

16.3.29 Transmit High-Frequency Clock Control Register (AHCLKXCTL)

The transmit high-frequency clock control register (AHCLKXCTL) configures the transmit high-frequency master clock (AHCLKX) and the transmit clock generator. The AHCLKXCTL is shown in [Figure 16-65](#) and described in [Table 16-38](#).

Figure 16-65. Transmit High-Frequency Clock Control Register (AHCLKXCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-38. Transmit High-Frequency Clock Control Register (AHCLKXCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15	HCLKXM	0	External transmit high-frequency clock source from AHCLKX pin.
		1	Internal transmit high-frequency clock source from output of programmable high clock divider.
14	HCLKXP	0	AHCLKX is not inverted before programmable bit clock divider. In the special case where the transmit bit clock (ACLKX) is internally generated and the programmable bit clock divider is set to divide-by-1 (CLKXDIV = 0 in ACLXCTL), AHCLKX is directly passed through to the ACLKX pin.
		1	AHCLKX is inverted before programmable bit clock divider. In the special case where the transmit bit clock (ACLKX) is internally generated and the programmable bit clock divider is set to divide-by-1 (CLKXDIV = 0 in ACLXCTL), AHCLKX is directly passed through to the ACLKX pin.
13-12	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
11-0	HCLKXDIV	0-FFFh	Transmit high-frequency clock divide ratio bits determine the divide-down ratio from AUXCLK to AHCLKX.
		0	Divide-by-1.
		1h	Divide-by-2.
		2h-FFFh	Divide-by-3 to divide-by-4096.

16.3.30 Transmit TDM Time Slot Register (XTDM)

The transmit TDM time slot register (XTDM) specifies in which TDM time slot the transmitter is active. TDM time slot counter range is extended to 384 slots (to support SPDIF blocks of 384 subframes). XTDM operates modulo 32, that is, XTDM specifies the TDM activity for time slots 0, 32, 64, 96, 128, etc. The XTDM is shown in [Figure 16-66](#) and described in [Table 16-39](#).

Figure 16-66. Transmit TDM Time Slot Register (XTDM)

LEGEND: R/W = Read/Write; -n = value after reset

Table 16-39. Transmit TDM Time Slot Register (XTDM) Field Descriptions

Bit	Field	Value	Description
31-0	XTDMS[31-0]	0	Transmitter mode during TDM time slot <i>n</i> . Transmit TDM time slot <i>n</i> is inactive. The transmit serializer does not shift out data during this slot.
		1	Transmit TDM time slot <i>n</i> is active. The transmit serializer shifts out data during this slot according to the serializer control register (SRCTL).

16.3.31 Transmitter Interrupt Control Register (XINTCTL)

The transmitter interrupt control register (XINTCTL) controls generation of the McASP transmit interrupt (XINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates XINT. The XINTCTL is shown in Figure 16-67 and described in Table 16-40. See Section 16.3.32 for a description of the interrupt conditions.

Figure 16-67. Transmitter Interrupt Control Register (XINTCTL)

	Reserved						
	R-0

R/W-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-40. Transmitter Interrupt Control Register (XINTCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	XSTAFRM	0	Interrupt is disabled. A transmit start of frame interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit start of frame interrupt generates a McASP transmit interrupt (XINT).
6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	XDATA	0	Interrupt is disabled. A transmit data ready interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit data ready interrupt generates a McASP transmit interrupt (XINT).
4	XLAST	0	Interrupt is disabled. A transmit last slot interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit last slot interrupt generates a McASP transmit interrupt (XINT).
3	XDMAERR	0	Interrupt is disabled. A transmit DMA error interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit DMA error interrupt generates a McASP transmit interrupt (XINT).
2	XCKFAIL	0	Interrupt is disabled. A transmit clock failure interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit clock failure interrupt generates a McASP transmit interrupt (XINT).
1	XSYNCERR	0	Interrupt is disabled. An unexpected transmit frame sync interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. An unexpected transmit frame sync interrupt generates a McASP transmit interrupt (XINT).
0	XUNDRN	0	Interrupt is disabled. A transmitter underrun interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmitter underrun interrupt generates a McASP transmit interrupt (XINT).

16.3.32 Transmitter Status Register (XSTAT)

The transmitter status register (XSTAT) provides the transmitter status and transmit TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated. The XSTAT is shown in [Figure 16-68](#) and described in [Table 16-41](#).

Figure 16-68. Transmitter Status Register (XSTAT)

31							9	8
Reserved							XERR	
R-0							R/W-0	
7	6	5	4	3	2	1	0	
XDMAERR	XSTAFRM	XDATA	XLAST	XTDMSLOT	XCKFAIL	XSYNCERR	XUNDRN	
R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R-0	R/W1C-0	R/W1C-0	R/W1C-0	

LEGEND: R/W = Read/Write; R = Read only; W1C = Writing a 1 clears this bit; writing a 0 has no effect; -n = value after reset

Table 16-41. Transmitter Status Register (XSTAT) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
8	XERR	0 1	XERR bit always returns a logic-OR of: XUNDRN XSYNCERR XCKFAIL XDMAERR Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0 No errors have occurred. 1 An error has occurred.
7	XDMAERR	0 1	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more serializers through the data port in a given time slot than were programmed as transmitters. Causes a transmit interrupt (XINT), if this bit is set and XDMAERR in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0 Transmit DMA error did not occur. 1 Transmit DMA error did occur.
6	XSTAFRM	0 1	Transmit start of frame flag. Causes a transmit interrupt (XINT), if this bit is set and XSTAFRM in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0 No new transmit frame sync (AFSX) is detected. 1 A new transmit frame sync (AFSX) is detected.
5	XDATA	0 1	Transmit data ready flag. Causes a transmit interrupt (XINT), if this bit is set and XDATA in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0 XBUF is written and is full. 1 Data is copied from XBUF to XRSR. XBUF is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).
4	XLAST	0 1	Transmit last slot flag. XLAST is set along with XDATA, if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT), if this bit is set and XLAST in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0 Current slot is not the last slot in a frame. 1 Current slot is the last slot in a frame. XDATA is also set.
3	XTDMSLOT	0 1	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd. 0 Current TDM time slot is odd. 1 Current TDM time slot is even.
2	XCKFAIL	0 1	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error (see <i>Clock Failure Detection</i>). Causes a transmit interrupt (XINT), if this bit is set and XCKFAIL in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0 Transmit clock failure did not occur. 1 Transmit clock failure did occur.

Table 16-41. Transmitter Status Register (XSTAT) Field Descriptions (continued)

Bit	Field	Value	Description
1	XSYNCERR	0 1	Unexpected transmit frame sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT), if this bit is set and XSYNCERR in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. Unexpected transmit frame sync did not occur. Unexpected transmit frame sync did occur.
0	XUNDRN	0 1	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF to XRSR, but XBUF has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT), if this bit is set and XUNDRN in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. Transmitter underrun did not occur. Transmitter underrun did occur. For details on McASP action upon underrun conditions, see <i>Buffer Underrun Error - Transmitter</i> .

16.3.33 Current Transmit TDM Time Slot Register (XSLOT)

The current transmit TDM time slot register (XSLOT) indicates the current time slot for the transmit data frame. The XSLOT is shown in [Figure 16-69](#) and described in [Table 16-42](#).

Figure 16-69. Current Transmit TDM Time Slot Register (XSLOT)

LEGEND: R = Read only; -n = value after reset

Table 16-42. Current Transmit TDM Time Slot Register (XSLOT) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
9-0	XSLOTCNT	0-17Fh	Current transmit time slot count. Legal values: 0 to 383 (17Fh). During reset, this counter value is 383 so the next count value, which is used to encode the first DIT group of data, will be 0 and encodes the B preamble. TDM function is not supported for >32 time slots. However, TDM time slot counter may count to 383 when used to transmit a DIT block.

16.3.34 Transmit Clock Check Control Register (XCLKCHK)

The transmit clock check control register (XCLKCHK) configures the transmit clock failure detection circuit. The XCLKCHK is shown in [Figure 16-70](#) and described in [Table 16-43](#).

Figure 16-70. Transmit Clock Check Control Register (XCLKCHK)

31	24	23	16
XCNT			XMAX
R-0			R/W-0
15	8	7	0
XMIN	Reserved		XPS
R/W-0	R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-43. Transmit Clock Check Control Register (XCLKCHK) Field Descriptions

Bit	Field	Value	Description
31-24	XCNT	0	Transmit clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 transmit high-frequency master clock (AHCLKX) signals, and stores the count in XCNT until the next measurement is taken.
23-16	XMAX	0-FFh	Transmit clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If the current counter value is greater than XMAX after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.
15-8	XMIN	0-FFh	Transmit clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If XCNT is less than XMIN after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.
7-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3-0	XPS	0-Fh	Transmit clock check prescaler value.
		0	McASP system clock divided by 1.
		1h	McASP system clock divided by 2.
		2h	McASP system clock divided by 4.
		3h	McASP system clock divided by 8.
		4h	McASP system clock divided by 16.
		5h	McASP system clock divided by 32.
		6h	McASP system clock divided by 64.
		7h	McASP system clock divided by 128.
		8h	McASP system clock divided by 256.
		9h-Fh	Reserved.

16.3.35 Transmitter DMA Event Control Register (XEVTCTL)

The transmitter DMA event control register (XEVTCTL) contains a disable bit for the transmit DMA event. The XEVTCTL is shown in [Figure 16-71](#) and described in [Table 16-44](#).

NOTE: Device-specific registers

Accessing REVTCTL not implemented on a specific device may cause improper device operation.

Figure 16-71. Transmitter DMA Event Control Register (XEVTCTL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-44. Transmitter DMA Event Control Register (XEVTCTL) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
0	XDATDMA	0	Transmit data DMA request enable bit. If writing to this bit, always write the default value of 0.
		0	Transmit data DMA request is enabled.
		1	Reserved

16.3.36 Serializer Control Registers (SRCTL_n)

Each serializer on the McASP has a serializer control register (SRCTL). There are up to 16 serializers per McASP. The SRCTL is shown in [Figure 16-72](#) and described in [Table 16-45](#).

NOTE: Device-specific registers

Accessing SRCTL_n not implemented on a specific device may cause improper device operation.

Figure 16-72. Serializer Control Registers (SRCTL_n)

31	Reserved								16		
R-0											
15	Reserved				6	5	4	3	2	1	0
R-0					RRDY	XRDY	DISMOD	SRMOD			
R-0					R-0	R-0	R/W-0	R/W-0			

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-45. Serializer Control Registers (SRCTL_n) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	RRDY	0 1	Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSR to RBUF. 0 Receive buffer (RBUF) is empty. 1 Receive buffer (RBUF) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.
4	XRDY	0 1	Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0). 0 Transmit buffer (XBUF) contains data. 1 Transmit buffer (XBUF) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.
3-2	DISMOD	0-3h 0 1h 2h 3h	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (PFUNC = 0). 0 Drive on pin is 3-state. 1h Reserved. 2h Drive on pin is logic low. 3h Drive on pin is logic high.
1-0	SRMOD	0-3h 0 1h 2h 3h	Serializer mode bit. 0 Serializer is inactive. 1h Serializer is transmitter. 2h Serializer is receiver. 3h Reserved.

16.3.37 DIT Left Channel Status Registers (DITCSRA0-DITCSRA5)

The DIT left channel status registers (DITCSRA) provide the status of each left channel (even TDM time slot). Each of the six 32-bit registers (Figure 16-73) can store 192 bits of channel status data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register file in time, if a different set of data need to be sent.

Figure 16-73. DIT Left Channel Status Registers (DITCSRA0-DITCSRA5)

LEGEND: R/W = Read/Write; -n = value after reset

16.3.38 DIT Right Channel Status Registers (DITCSRB0-DITCSRB5)

The DIT right channel status registers (DITCSRB) provide the status of each right channel (odd TDM time slot). Each of the six 32-bit registers (Figure 16-74) can store 192 bits of channel status data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register file in time, if a different set of data need to be sent.

Figure 16-74. DIT Right Channel Status Registers (DITCSRB0-DITCSRB5)

LEGEND: R/W = Read/Write; -n = value after reset

16.3.39 DIT Left Channel User Data Registers (DITUDRA0-DITUDRA5)

The DIT left channel user data registers (DITUDRA) provides the user data of each left channel (even TDM time slot). Each of the six 32-bit registers (Figure 16-75) can store 192 bits of user data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register in time, if a different set of data need to be sent.

Figure 16-75. DIT Left Channel User Data Registers (DITUDRA0-DITUDRA5)

LEGEND: R/W = Read/Write; -n = value after reset

16.3.40 DIT Right Channel User Data Registers (DITUDRB0-DITUDRB5)

The DIT right channel user data registers (DITUDRB) provides the user data of each right channel (odd TDM time slot). Each of the six 32-bit registers (Figure 16-76) can store 192 bits of user data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register in time, if a different set of data need to be sent.

Figure 16-76. DIT Right Channel User Data Registers (DITUDRB0-DITUDRB5)

LEGEND: R/W = Read/Write; -n = value after reset

16.3.41 Transmit Buffer Registers (XBUF_n)

The transmit buffers for the serializers (XBUF) hold data from the transmit format unit. For transmit operations, the XBUF (Figure 16-77) is an alias of the XRBUF in the serializer.

NOTE: Device-specific registers

Accessing XBUF registers not implemented on a specific device may cause improper device operation.

Figure 16-77. Transmit Buffer Registers (XBUF_n)

LEGEND: R/W = Read/Write; -n = value after reset

16.3.42 Receive Buffer Registers (RBUF_n)

The receive buffers for the serializers (RBUF) hold data from the serializer before the data goes to the receive format unit. For receive operations, the RBUF (Figure 16-78) is an alias of the XRBUF in the serializer.

NOTE: Device-specific registers

Accessing RBUF registers not implemented on a specific device may cause improper device operation.

Figure 16-78. Receive Buffer Registers (RBUF_n)

LEGEND: R/W = Read/Write; -n = value after reset

16.3.43 Write FIFO Control Register (WFIFOCTL)

Note that this register is only available if the Write FIFO is configured. The Write FIFO control register (WFIFOCTL) is shown in [Figure 16-79](#) and described in [Table 16-46](#).

NOTE: The WNUMEVT and WNUMDMA values must be set prior to enabling the Write FIFO.
If the Write FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.

Figure 16-79. Write FIFO Control Register (WFIFOCTL)

31	Reserved		17	16
	R-0			WENA
				R/W-0
15	8	7		
	WNUMEVT		WNUMDMA	
	R/W-10h		R/W-4h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-46. Write FIFO Control Register (WFIFOCTL) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	WENA	0	Write FIFO is disabled. The WLVL bit in the Write FIFO status register (WFIFOSTS) is reset to 0 and pointers are initialized, that is, the Write FIFO is "flushed."
		1	Write FIFO is enabled. If Write FIFO is to be enabled, it must be enabled prior to taking McASP out of reset.
15-8	WNUMEVT	0-FFh	Write word count per DMA event (32-bit). When the Write FIFO has space for at least WNUMEVT words of data, then an AXEVT (transmit DMA event) is generated to the host/DMA controller. This value should be set to a non-zero integer multiple of the number of serializers enabled as transmitters. This value must be set prior to enabling the Write FIFO.
		0	0 words
		1h	1 word
		2h	2 words
		3h-40h	3 to 64 words
		41h-FFh	Reserved
7-0	WNUMDMA	0-FFh	Write word count per transfer (32-bit words). Upon a transmit DMA event from the McASP, WNUMDMA words are transferred from the Write FIFO to the McASP. This value must equal the number of McASP serializers used as transmitters. This value must be set prior to enabling the Write FIFO.
		0	0 words
		1h	1 word
		2h	2 words
		3h-10h	3-16 words
		11h-FFh	Reserved

16.3.44 Write FIFO Status Register (WFIFOSTS)

Note that this register is only available if the Write FIFO is configured. The Write FIFO status register (WFIFOSTS) is shown in [Figure 16-80](#) and described in [Table 16-47](#).

Figure 16-80. Write FIFO Status Register (WFIFOSTS)

LEGEND: R = Read only; -n = value after reset

Table 16-47. Write FIFO Status Register (WFIFOSTS) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	WLVL	0-FFh	Write level (read-only). Number of 32-bit words currently in the Write FIFO.
		0	0 words currently in Write FIFO.
		1h	1 word currently in Write FIFO.
		2h	2 words currently in Write FIFO.
		3h-40h	3 to 64 words currently in Write FIFO.
		41h-FFh	Reserved

16.3.45 Read FIFO Control Register (RFIFOCTL)

Note that this register is only available if the Read FIFO is configured. The Read FIFO control register (RFIFOCTL) is shown in [Figure 16-81](#) and described in [Table 16-48](#).

NOTE: The RNUMEVT and RNUMDMA values must be set prior to enabling the Read FIFO.

If the Read FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.

Figure 16-81. Read FIFO Control Register (RFIFOCTL)

31	Reserved		17	16

				R/W-0
15	8	7		0
	RNUMEVT		RNUMDMA	
	R/W-10h		R/W-4h	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-48. Read FIFO Control Register (RFIFOCTL) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	RENA	0	Read FIFO is disabled. The RLVL bit in the Read FIFO status register (RFIFOSTS) is reset to 0 and pointers are initialized, that is, the Read FIFO is "flushed."
		1	Read FIFO is enabled. If Read FIFO is to be enabled, it must be enabled prior to taking McASP out of reset.
15-8	RNUMEVT	0-FFh	Read word count per DMA event (32-bit). When the Read FIFO contains at least RNUMEVT words of data, then an AREVT (receive DMA event) is generated to the host/DMA controller. This value should be set to a non-zero integer multiple of the number of serializers enabled as receivers. This value must be set prior to enabling the Read FIFO.
		0	0 words
		1h	1 word
		2h	2 words
		3h-40h	3 to 64 words
		41h-FFh	Reserved
7-0	RNUMDMA	0-FFh	Read word count per transfer (32-bit words). Upon a receive DMA event from the McASP, the Read FIFO reads RNUMDMA words from the McASP. This value must equal the number of McASP serializers used as receivers. This value must be set prior to enabling the Read FIFO.
		0	0 words
		1	1 word
		2	2 words
		3h-10h	3-16 words
		11h-FFh	Reserved

16.3.46 Read FIFO Status Register (RFIFOSTS)

Note that this register is only available if the Read FIFO is configured. The Read FIFO status register (RFIFOSTS) is shown in [Figure 16-82](#) and described in [Table 16-49](#).

Figure 16-82. Read FIFO Status Register (RFIFOSTS)

		0	0 words currently in Read FIFO.
		1h	1 word currently in Read FIFO.
		2h	2 words currently in Read FIFO.
		3h-40h	3 to 64 words currently in Read FIFO.
		41h-FFh	Reserved

Multichannel Buffered Serial Port (McBSP)

This chapter describes the multichannel buffered serial port (McBSP).

Topic	Page
17.1 Introduction	2091
17.2 Architecture	2093
17.3 McBSP Registers	2143

17.1 Introduction

17.1.1 Overview

The multichannel buffered serial port (McBSP) provides a full duplex direct serial interface between the host chip and other devices in a system such as application chips, codecs. It can accommodate to a wide range of peripherals and protocols thanks to its high level of versatility.

17.1.2 Features

The main features of the McBSP modules are:

- OCP-IP2.0 compliant interface (32-bit data bus)
- 512-byte internal buffer for transmit operation (fixed size)
- 512-byte internal buffer for receive operation (fixed size)
- Auto-gating clocks for power saving
- Power Management interface
- Full-duplex communication
- Buffered transmission and reception that allows a continuous data stream
- Independent clocking and framing for reception and for transmission
- Capability to generate interrupts or DMA requests on internal events
- 128 channels for transmission and for reception
- Multi-channel selection modes that allow to enable or block transfers in each one of the channels
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices (I2S compliant devices)
- Support for external generation of clock signals and frame-synchronization (frame-synchronization) signals
- A programmable sample rate generator for internal generation and control of clock signals and frame-synchronization signals
- Programmable polarity for frame-synchronization pulses and for clock signals
- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Bit reordering (send/receive LSB)
- Status bits for flagging exception/error conditions
- Full/Half cycle mode on both transmit and receive side

The McBSP supports dual phase frames in order to provide I2S fully compliant capabilities. The limitation on dual phase frame is that the number of words per phase must be set to 1 for both first and second phase.

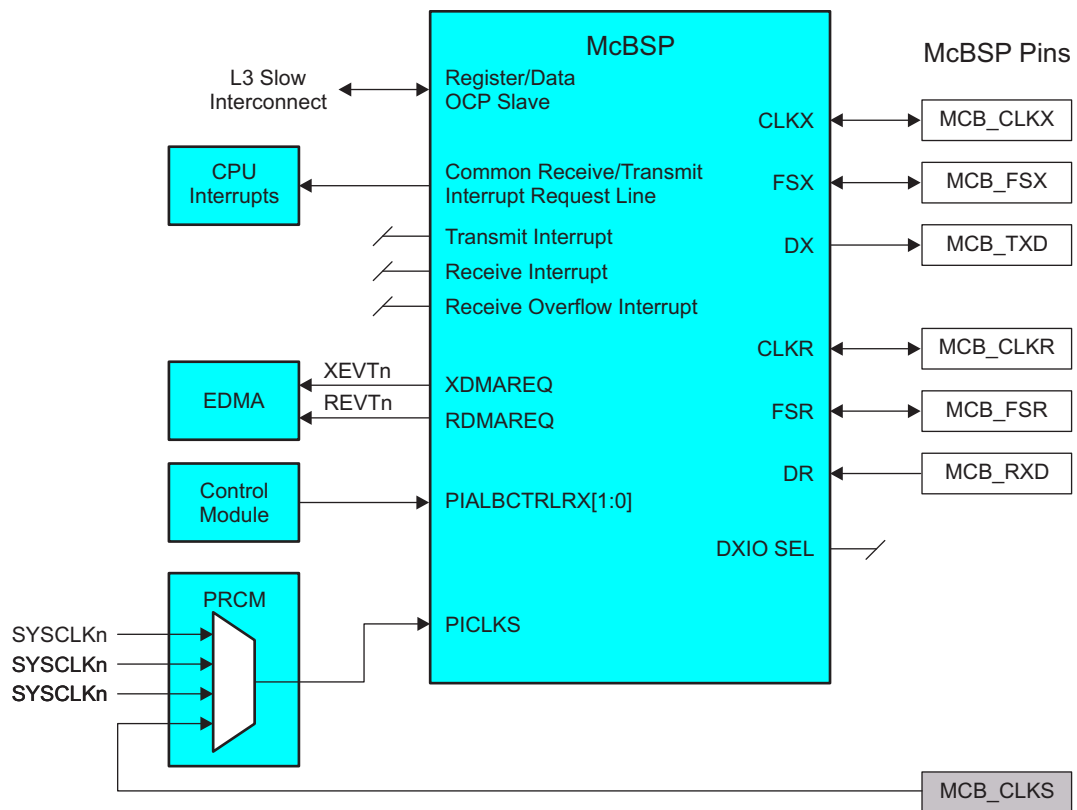

Four operating modes are defined for the module:

- **Active mode:** the module is running synchronously on the interface clock, interrupts and DMA requests can be generated according to the configuration and the external signals.
- **Smart Idle mode:** the module is in a waiting state, interface/functional clocks can be stopped, no interrupt can be generated, a wake-up signal can be generated according the configuration and external signals.
- **Force Idle mode:** the module has no activity, interface clock can be stopped, no interrupts and DMA requests can be generated, and the wake-up feature is inhibited. The software must disable the McBSP module (receive/transmit parts) prior to enter Force Idle mode.
- **No Idle mode:** the module is active but cannot respond to host interface requests.

The Smart/Force Idle modes are configured within the module and activated on request by the host processor through system interface sideband signals.

17.1.3 Block Diagram

Figure 17-1. McBSP Block Diagram

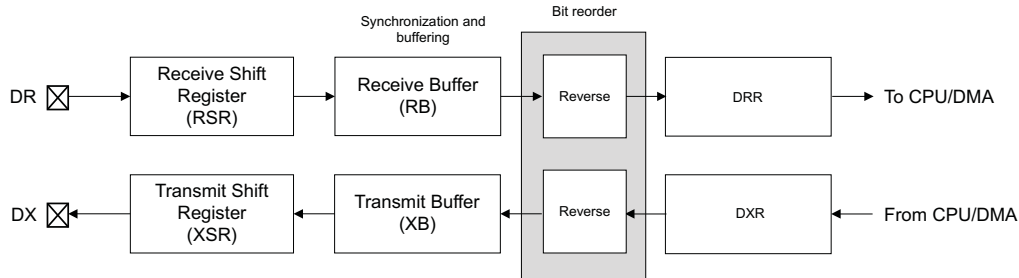

Note: The number of SYSCLKn varies per device implementation. See Control Module Chapter for details.

17.2 Architecture

17.2.1 McBSP Data Transfer Process

Figure 17-2 shows the McBSP data transfer paths. McBSP receive operations and transmit operations are buffered (up to 512-byte buffers organized on 32-bit words are used). Input/output registers are 32-bit long words.

Figure 17-2. McBSP Data Transfer Paths

17.2.1.1 Data Transfer Process for 8/12/16/20/24/32-bit Long Words

Receive data arrives on the McBSP.DR pin and is shifted into receive shift register. When a full word is received, the content of the shift register is copied into receive buffer under condition receive buffer is not full. When the receive buffer threshold is reached, the McBSP asserts DMA or interrupt request and the receive buffer content is then transferred to the host (the CPU or the DMA controller reads the data receive register DRR_REG).

Transmit data is written by the CPU or the DMA controller to data transmit register DXR_REG using the byte enable input (when a byte is not enabled the byte value in the memory will contain the previous written value). If there is no previous data in transmit shift register, the value from the transmit buffer is copied to transmit shift register; otherwise, the content is copied to transmit shift register when the last bit of the previous data is shifted out on the McBSP.DX pin.

Note that the byte enable is used for transmit data register DXR_REG only and the value is ignored when the CPU accesses are targeting other registers. When writing to DXR_REG, the bytes are independently enabled by the byte enable pattern (for example, byte enable is "0001" then only the less significant byte will be written).

17.2.1.2 Bit Reordering (option to transfer LSB first)

Generally, the McBSP transmits or receives all data with the most significant bit (MSB) first. However, certain data protocols require the least significant bit (LSB) to be transferred first.

If you set XREVERSE = 01b in XCR2_REG[4:3], the bit ordering of the data words is reversed (LSB first) before being sent to the serial port.

If you set RREVERSE = 01b in RCR2_REG[4:3], the bit ordering of the data words is reversed during reception.

This feature is available for all the data formats from 8 up to 32-bit data length.

17.2.1.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

17.2.1.3.1 Clocking

Data is shifted one bit at a time from the McBSP.DR pin to the receive shift registers or from the transmit shift registers to the McBSP.DX pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR) controls bit transfers from the McBSP.DR pin to the receive shift registers. The transmit clock signal (CLKX) controls bit transfers from the transmit shift registers to the McBSP.DX pin. CLKR or CLKX can be derived from a pin at the boundary of the McBSP (McBSP.CLKR and McBSP.CLKX respectively) or derived from inside the McBSP. The polarities of CLKR and CLKX are programmable.

Figure 17-3 gives an example in which the clock signal controls the timing of each bit transfer on the pin.

The McBSP is constrained to operate at an internal functional frequency up to 55 MHz while CPU interface (OCP compliant interface) can operate at a frequency up to 110 MHz. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to 110 MHz) and divide down value (CLKGDV). Please see the device datasheet for maximum McBSP CLKX cycle time supported on your device.

17.2.1.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (McBSP.DR or McBSP.DX) are transferred in a group called a serial word. You can define how many bits are in a word.

Bits coming in on the McBSP.DR pin are held in RSR until RSR holds a full serial word. Only then is the word passed to the receive buffer RB (and ultimately to the DRR_REG register).

During transmission, XSR accept new data from transmit buffer XB after a full serial word has been passed from XSR to the McBSP.DX pin.

In the example in Figure 17-3, an 8-bit word size was defined (see bits 7 through 0 of word B being transferred).

17.2.1.3.3 Frames and Frame Synchronization

One or more words are transferred in a group called a frame. You can define how many words are in a frame. All of the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP receives/transmits the next frame, and so on. Pulses on the receive frame-synchronization (FSR) signal initiate frame transfers on McBSP.DR. Pulses on the transmit frame-synchronization (FSX) signal initiate frame transfers on McBSP.DX. FSR or FSX can be derived from a pin at the boundary of the McBSP (McBSP.FSR and McBSP.FSX respectively) or derived from inside the McBSP. In the example in Figure 17-3, a one-word frame is transferred when a frame-synchronization pulse occurs. In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occurs.

17.2.1.3.4 Detecting Frame–Synchronization Pulses, Even in Reset State

The McBSP can generate receive and transmit interrupts to the CPU to indicate specific events in the McBSP. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame–synchronization pulses. Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating RINT when the receiver is in reset). In this case, FSRM/FSXM and FSRP/FSXP still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the CPU clock and then sent to the CPU in the form of RINT and XINT at the point at which they feed the receiver and transmitter of the serial port. Consequently, a new frame–synchronization pulse can be detected, and after this occurs the CPU can take the serial port out of reset safely.

17.2.1.3.5 Ignoring Frame–Synchronization Pulses

The McBSP ignores transmit and/or receive frame–synchronization pulses while the frame transfer has been already started by a previous frame–synchronization pulse (unexpected frame–synchronization pulses). The McBSP does not support features like re-transmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame–synchronization pulses until the desired frame length or number of words is reached. For more details on unexpected frame–synchronization pulses, see [Section 17.2.3.2](#) and [Section 17.2.3.5](#).

17.2.1.3.6 Frame Frequency

The frame frequency is determined by the period between frame–synchronization pulses and is defined as shown in the following equation:

$$\text{Frame frequency} = \text{Clock frequency} / (\text{Number of clock cycles between frame – synchronization pulses})$$

The frame frequency can be increased by decreasing the time between frame–synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

17.2.1.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

$$\text{Maximum frame frequency} = \text{Clock frequency} / \text{Number of bits per frame}$$

[Figure 17-4](#) shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

Figure 17-4. McBSP Operating at Maximum Packet Frequency

If there is a 1-bit data delay as shown in this figure, the frame–synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

For XDATDLY = 0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX).

17.2.1.4 Frame Phases (dual phase frame I2S support)

The McBSP allows you to configure each frame to contain one or two phases. The support for dual phase frames is required in order to provide I2S fully compliant capabilities. The limitation on dual phase frame support is that the number of words per phase must be set to 1 for both first and second phase.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user might define a frame as consisting of one phase containing one word of 16 bits, followed by a second phase consisting of one word of 32 bits. This configuration allows the user to compose frames for custom applications such as I2S protocol.

17.2.1.4.1 Number of Phases, Words, and Bits per Frame

Table 17-1 shows which bit fields in the receive control registers (RCR1_REG and RCR2_REG) and in the transmit control registers (XCR1_REG and XCR2_REG) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to the table:

- RPHASE = RCR2_REG[15]
- XPHASE = XCR2_REG[15]
- RFRLN1 = RCR1_REG[14:8] (cleared to 0 if using dual-phase)
- RFRLN2 = RCR2_REG[14:8] (cleared to 0 if using dual-phase)
- XFRLN1 = XCR1_REG[14:8] (cleared to 0 if using dual-phase)
- XFRLN2 = XCR2_REG[14:8] (cleared to 0 if using dual-phase)
- RWDLEN1 = RCR1_REG[7:5]
- RWDLEN2 = RCR2_REG[7:5]
- XWDLEN1 = XCR1_REG[7:5]
- XWDLEN2 = XCR2_REG[7:5]

Table 17-1. Phases, Words and Bits Per Frame Control Bits

Operation	Number of Phases
Reception	1 (RPHASE = 0)
Reception	2 (RPHASE = 1)
Transmission	1 (XPHASE = 0)
Transmission	2 (XPHASE = 1)

17.2.1.4.2 Single-phase Frame Example

Figure 17-5 shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the McBSP.DX and McBSP.DR pins are available one clock cycle after FS(R/X) goes active. The figure makes the following assumptions:

- RPHASE (RCR2_REG[15]) and XPHASE (XCR2_REG[15]) = 0: Single-phase frame
- RFRLN1 (RCR1_REG[14:8]) and XFRLEN1 (XCR1_REG[14:8]) = 0: 1 word per frame
- RWDLEN1 (RCR1_REG[7:5]) and XWDLEN1 (XCR1_REG[7:5]) = 0: 8-bit word length
- RFRLN2 (RCR2_REG[14:8]) and XWDLEN2 (XCR2_REG[14:8]) are ignored
- CLKRP (PCR_REG[0]) and CLKXP (PCR_REG[1]) = 0: Receive data clocked on falling edge; transmit data clocked on rising edge
- FSRP (PCR_REG[2]) and FSXP (PCR_REG[3]) = 0: Active-high frame-synchronization signals
- RDATDLY (RCR2_REG[1:0]) and XDARDLY (XCR2_REG[1:0]) = 01b: 1-bit data delay

Figure 17-5. Single-Phase Frame for a McBSP Data Transfer

17.2.1.4.3 Dual-Phase Frame Example

Figure 17-6 shows an example of a frame where the first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bit stream in the frame is contiguous. There are no gaps between words/phases.

Figure 17-6. Dual-Phase Frame for a McBSP Data Transfer

17.2.1.5 McBSP Reception

This section explains the fundamental process of reception in the McBSP.

Figure 17-7 and Figure 17-8 show how reception occurs in the McBSP. Figure 17-7 shows the physical path for the data. Figure 17-8 is a timing diagram showing signal activity for one possible reception scenario. A description of the process follows the figures.

Figure 17-7. McBSP Reception Physical Data Path

Figure 17-8. McBSP Reception Signal Activity

RRDY: Status of receiver ready bit (high is 1)

The following process describes how data travels from the McBSP.DR pin to the CPU or to the DMA controller:

1. The McBSP waits for a receive frame-synchronization pulse on internal FSR.
2. When the pulse arrives, the McBSP inserts the appropriate data delay that is selected with the RDATDLY bits of RCR2_REG[1:0] register. In the preceding timing diagram a 1-bit data delay is selected.
3. The McBSP accepts data bits on the McBSP.DR pin and shifts them into the receive shift register.
4. When a full word is received, the McBSP copies the contents of the receive shift register to the receive buffer, provided that RB is not full.
5. When the programmed receive threshold is reached the McBSP asserts the receiver ready bit (RRDY) in SPCR1_REG. This indicates that receive data is ready to be read by the CPU or the DMA controller by accessing DRR_REG register. The data copied from RB to DRR_REG is justified and bit filled according to the RJUST bits.
6. The CPU or the DMA controller reads the data from the data receive register. When the receive buffer is empty, RRDY bit is cleared.

When activity is not properly timed, errors can occur. See the following topics for more details:

- Overrun in the Receiver
- Underflow in the receiver
- Unexpected Receive Frame–Synchronization Pulse

17.2.1.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP. Figure 17-9 and Figure 17-10 show how transmission occurs in the McBSP.

Figure 17-9 shows the physical path for the data. Figure 17-10 is a timing diagram showing signal activity for one possible transmission scenario. A description of the process follows the figures.

Figure 17-9. McBSP Transmission Physical Data Path

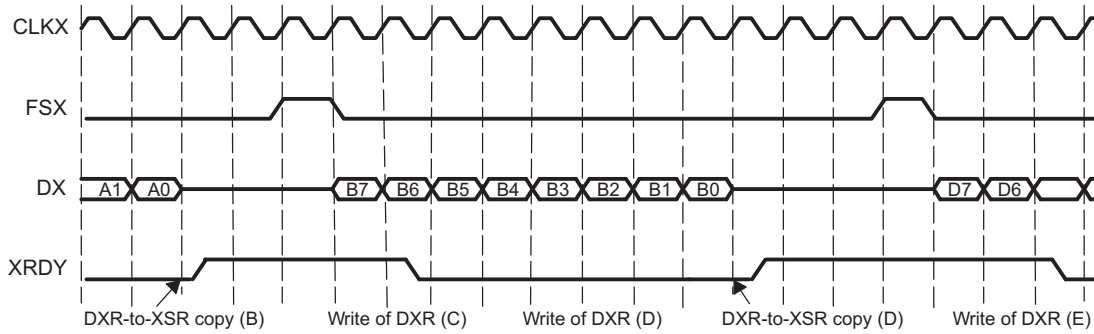

Figure 17-10. McBSP Transmission Signal Activity

The following process shows how.....

1. The CPU or the DMA controller writes data to the data transmit register. When the transmit buffer is reached the transmitter ready bit (XRDY) is cleared in SPCR2_REG[1] register to indicate that the transmitter is not ready for new data.
2. When new data arrives in DXR_REG register, the McBSP copies the content of the data transmit register to the transmit buffer. In addition, the Transmit Ready bit (XRDY) is set as long as the buffer contains at least the transmit threshold number of free locations. This indicates that the transmitter is ready to accept new data from the CPU or the DMA controller.
3. The McBSP waits for a transmit frame–synchronization pulse on internal FSX.
4. When the pulse arrives, the McBSP inserts the appropriate data delay that is selected with the XCR2_REG[1:0] register XDADLY bits. In the preceding timing diagram, a 1-bit data delay is selected.
5. The McBSP shifts data bits from the transmit shift register to the McBSP.DX pin.

When activity is not properly timed, errors can occur. See the following topics for more details:

- Underflow in the transmitter
- Overflow in the transmitter
- Unexpected transmit frame-synchronization pulse

17.2.1.7 Enable/Disable the Transmit and Receive Processes

The McBSP has the option to stop-resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable XDISABLE/RDISABLE bit in XCCR_REG/RCCR_REG register is set, the McBSP will stop the transmit/receive operation at the next frame boundary (frame corruption avoided).

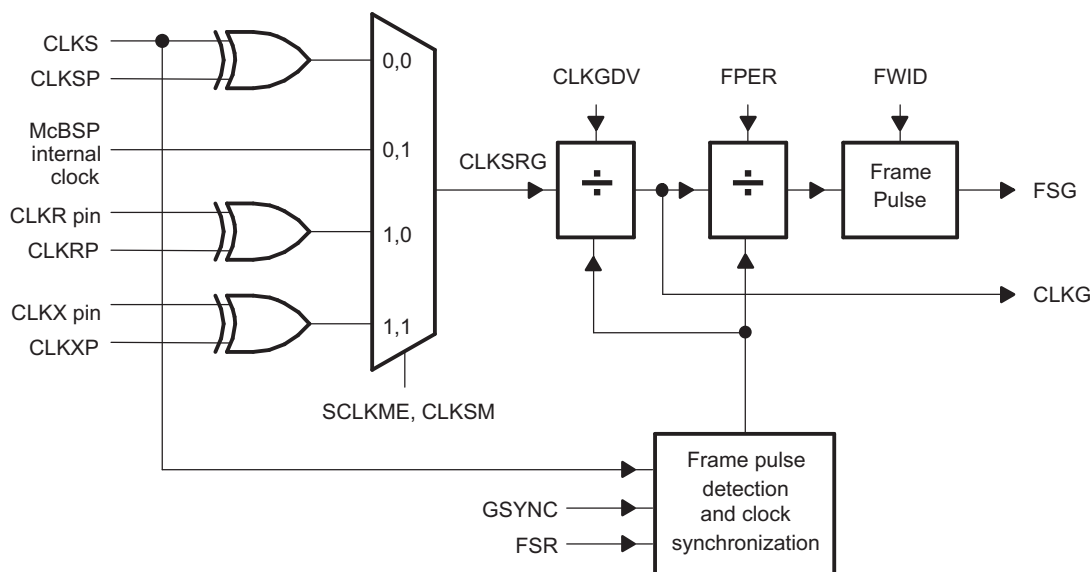

As soon as the XDISABLE/RDISABLE bit is cleared, the transmit/receive process will resume at the next frame boundary.

Note that it is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (XBUFFERSTAT/RBUFFERSTAT indicating the occupied/available buffer locations), since this register is a CPU (OCP) clock synchronous register and does not reflect the exact number of occupied/free locations available on the functional clock domain.

17.2.2 McBSP Sample Rate Generator

The McBSP contains a sample rate generator that can be used to generate an internal data clock (CLKG) and an internal frame-synchronization signal (FSG). CLKG can be used for bit shifting on the data receive (McBSP.DR) pin and/or the data transmit (McBSP.DX) pin. FSG can be used to initiate frame transfers on McBSP.DR and/or McBSP.DX. Figure 17-11 is a conceptual block diagram of the sample rate generator.

Figure 17-11. Sample Rate Generator Block Diagram

The source clock for the sample rate generator (labeled CLKSRG in the diagram) can be supplied by either the FCLK functional clock (OCP interface clock), or by an external pin (McBSP.CLKS, McBSP.CLKX, or McBSP.CLKR). The source is selected with the SCLKME bit of the PCR_REG[7] register and the CLKSM bit of the SRGR2_REG[13] register.

If a pin is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (CLKSP bit of SRGR2_REG[14] register, CLKXP bit of PCR_REG register, or CLKRP bit of PCR_REG[0] register).

The sample rate generator has a three-stage clock divider that gives CLKG and FSG programmability.

The three stages provide:

- Clock divide-down. The source clock is divided according to the SRGR1_REG[7:0] register CLKGDV bits to produce CLKG .
- Frame period divide-down. CLKG is divided according to the SRGR2_REG[11:0] register FPER bit field to control the period from the start of a frame-pulse to the start of the next pulse.
- Frame-synchronization pulse-width countdown. CLKG cycles are counted according to the SRGR1_REG[15:8] register FWID bits to control the width of each frame-synchronization pulse.

Note: The McBSP cannot operate at an internal functional frequency faster than 55 MHz. Choose an input clock frequency and a CLKGDV value such that CLKG is less than or equal to 55 MHz. Please see the device datasheet for maximum McBSP CLKX cycle time supported on your device.

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the McBSP.FSR pin. This feature is enabled or disabled with the SRGR2_REG[15] register GSYNC bit.

CLKG is used as source in order to generate the output clocks CLKX/CLKR when the CLKXM/CLKRM indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting given by the CLKXP/CLKRP as follows: when falling edge, the CLKX/CLKR is CLKG inverted.

17.2.2.1 Clock Generation in the Sample Rate Generator

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the sample rate generator to drive clocking is controlled by the clock mode bits (CLKRM and CLKXM) in the pin control register (PCR_REG[8] and PCR_REG[9] respectively) and polarity mode bits (CLKRP and CLKXP).

When a clock mode bit is set to 1 (CLKRM = 1 for reception, CLKXM = 1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal sample rate generator output clock (CLKG) according with the polarity setting.

The effects of CLKRM = 1 and CLKXM = 1 on the McBSP are partially affected by the use of the digital loop back mode, the analog loop back mode and by the synchronous receive/transmit setting, respectively, as described in [Table 17-2](#). The analog loop back mode is selected with the SPCR1_REG[15] register ALB bit. The digital loop back mode is selected with the DLB bit of the XCCR_REG register. The synchronous mode is controlled by the ALBRXCTRL input pin.

When using the sample rate generator as a clock source, make sure the sample rate generator is enabled (GRST = 1).

Table 17-2. Effects of DLB and ALB Bits on Clock Modes

Mode Bit Settings		Effect
CLKRM = 1	DLB = 0 & ALB = 0 (Digital & analog loop back mode disabled)	CLKR is an output pin driven by the sample rate generator output clock (CLKG).
	DLB = 0 & ALB = 1 (Analog loop back mode enabled)	CLKR is an output pin driven by the sample rate generator output clock (CLKG). The receive functional part internal clock is driven by CLKX input pin CLKXI. The source of CLKX depends on the CLKXM bit. The receive frame synchronization is driven by FSX input pin (FSXI). The receive data is driven by the DX loop back pin (DXI).
	DLB = 1 & ALB = 0 (Digital loop back mode enabled)	CLKR is not driven. The sample rate generator and the frame synchronization generator need to be enabled. The internal transmit and receive clocks are driven by SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the receive input data. Note that in digital loop back mode no serial link activity will be seen by the remote device because CLKREN, CLKXEN, FSREN, FSRXEN, DXEN are not active.
	DLB = 1 & ALB = 1 (reserved mode)	Undefined functionality.

Table 17-2. Effects of DLB and ALB Bits on Clock Modes (continued)

Mode Bit Settings		Effect
CLKXM = 1	DLB = 0 & ALB = 0 (Digital & analog loop back mode disabled)	CLKX is an output pin driven by the sample rate generator output clock (CLKG).
	DLB = 0 & ALB = 1 (Analog loop back mode enabled)	CLKX is an output pin driven by the sample rate generator output clock (CLKG).
	DLB = 1 & ALB = 0 (Digital loop back mode enabled)	CLKX is not driven. The sample rate generator and the frame synchronization generator need to be enabled. The internal transmit and receive clocks are driven by SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the receive input data. Note that in digital loop back mode no serial link activity will be seen by the remote device because CLKREN, CLKXEN, FSREN, FSRXEN, DXEN are not active.
	DLB = 1 & ALB = 1 (reserved mode)	Undefined functionality.
	ALBRXCTRL[0] = 1 (synchronous mode DLB = 0 & ALB = 0)	CLKX is an output pin driven by the sample rate generator output clock (CLKG). CLKR is connected to the CLKX.

17.2.2.2 Frame Synchronization Generation in the Sample Rate Generator

The sample rate generator can produce a frame–synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure PCR_REG[10] register FSRM bit = 1. (When FSRM = 0, receive frame synchronization is supplied via the McBSP.FSR pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- FSXM = 1 in PCR_REG[11] register: This indicates that transmit frame synchronization is supplied by the McBSP itself rather than from the McBSP.FSX pin
- FSGM = 1 in SRGR2_REG[12] register: This indicates that when FSXM = 1, transmit frame synchronization is supplied by the sample rate generator. (When FSGM = 0 and FSXM = 1, the transmit frame-synchronization signal (FSX) is generated when transmit buffer is not empty. When FSGM = 0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition).

In either case, the sample rate generator must be enabled (SPCR2_REG[6] register GRST bit = 1) and the frame–synchronization logic in the sample rate generator must be enabled (SPCR2_REG[7] register FRST bit = 0).

17.2.2.2.1 Choosing the Width of the Frame-Synchronization Pulse

Each pulse on FSG has a programmable width. You program the SRGR1_REG[15:8] register FWID bits, and the resulting pulse width is (FWID + 1) CLKG cycles, where CLKG is the output clock of the sample rate generator.

17.2.2.2.2 Controlling the Period Between the Starting Edges of the Frame-Synchronization Pulses

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the sample rate generator:

- If the sample rate generator is using an external input clock and SRGR2_REG[15] register GSYNC bit = 1, FSG pulses in response to an inactive–to–active transition on the McBSP.FSR pin. Thus, an external device controls the frame–synchronization period.
- Otherwise, you program the FPER bits of SRGR2_REG[11:0] register, and the resulting frame–synchronization period is (FPER + 1) CLKG cycles, where CLKG is the output clock of the sample rate generator.

17.2.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the sample rate generator, the GSYNC bit of SRGR2_REG[15] register and the McBSP.FSR pin can be used to configure the timing of FSG pulses.

GSYNC = 1 ensures that the McBSP and an external device are dividing down the input clock with the same phase relationship. If GSYNC = 1, an inactive-to-active transition on the McBSP.FSR pin triggers a resynchronization of CLKG and generation of FSG.

17.2.2.3 Synchronizing Sample Rate Generator Outputs to an External Clock

The sample rate generator can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) based on an input clock signal that is either the FCLK functional clock signal or a signal at the McBSP.CLKS, McBSP.CLKR, or McBSP.CLKX pin. When an external clock is selected to drive the sample rate generator, the GSYNC bit of SRGR2_REG[15] register and the McBSP.FSR pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock.

Make GSYNC = 1 when you want the McBSP and an external device to divide down the input clock with the same phase relationship. If GSYNC = 1:

- An inactive-to-active transition on the McBSP.FSR pin triggers a resynchronization of CLKG and a pulsing of FSG.
- CLKG always begins with a high state after synchronization.
- FSR is always detected at the same edge of the input clock signal that generates CLKG, no matter how long the FSR pulse is.
- The SRGR2_REG[11:0] register FPER bits are ignored because the frame-synchronization period on FSG is determined by the arrival of the next frame-synchronization pulse on the McBSP.FSR pin.

If GSYNC = 0, CLKG runs freely and is not resynchronized, and the frame-synchronization period on FSG is determined by FPER.

17.2.2.3.1 Operating the Transmitter Synchronously with the Receiver

When GSYNC = 1, the transmitter can operate synchronously with the receiver, provided that:

- FSX is programmed to be driven by FSG (FSGM = 1 in SRGR2_REG[12] register and FSXM = 1 in PCR_REG[11] register). If the input FSR has appropriate timing so that it can be sampled by the falling edge of CLKG, it can be used, instead, by setting FSXM = 0 and connecting FSR to FSX externally.
- The sample rate generator clock drives the transmit and receive clocking (PCR_REG[8] CLKRM bit and PCR_REG[9] CLKXM bit are set to 1). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

17.2.2.3.2 Synchronization Examples

Figure 17-12 and Figure 17-13 show the clock and frame-synchronization operation with various polarities of CLKS (the chosen input clock) and FSR. These figures assume FWID = 0 in SRGR1_REG[15:8] register, for an FSG pulse that is one CLKG cycle wide. The FPER bits of SRGR2_REG[11:0] register are not programmed; the period from the start of a frame-synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the McBSP.FSR pin. Each of the figures shows what happens to CLKG when it is initially synchronized and GSYNC = 1, and when it is not initially synchronized and GSYNC = 1. Figure 17-13 has a slower CLKG frequency (it has a larger divide-down value in the CLKGDV bits of SRGR1_REG[7:0] register).

Figure 17-12. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 1)

Figure 17-13. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 3h)

17.2.3 McBSP Exception/Error Conditions

There are several serial port events that can constitute a system error. Any of these error conditions may be sources of an interrupt:

- Receiver Overrun

(ROVFLSTAT bit is set to 1 in IRQSTATUS register, and legacy mode RFULL bit is set to 1 in SPCR1_REG register)

This occurs when receive buffer is full and RSR(s) are full with another new word shifted in from McBSP.DR. Therefore, ROVFLSTAT (RFULL) indicates an error condition wherein any new data that can arrive at this time on McBSP.DR replaces the contents of the RSR, and the previous word is lost. The RSR continues to be overwritten as long as new data arrives on McBSP.DR and DRR_REG register is not read.

- Unexpected Receive Frame-Synchronization Pulse

(RSYNCERR bit is set to 1 in IRQSTATUS register, and legacy mode RSYNCERR bit is set to 1 in SPCR1_REG register)

This occurs during reception when an unexpected frame-synchronization pulse arrives. An unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been received. Such a pulse is ignored by the receiver, but sets the RSYNCERR bit in SPCR1_REG.

- Receiver Underflow

(RUNDFLSTAT bit is set to 1 in IRQSTATUS register)

This occurs when DMA controller or CPU reads data from an empty receive buffer.

- Transmitter Underflow

(XUNDFLSTAT bit is set to 1 in IRQSTATUS register, and legacy mode XEMPTY bit is cleared to 0 in SPCR2_REG register)

If a new frame-synchronization signal arrives when transmit buffer is empty, the previous data in the XSR is sent again. This procedure continues for every new frame-synchronization pulse that arrives until DXR_REG register is loaded with new data (and the XB buffer will be no longer empty).

- Unexpected Transmit Frame-Synchronization Pulse

(XSYNCERR bit is set to 1 in IRQSTATUS register, and legacy mode XSYNCERR bit is set to 1 in SPCR2_REG register)

This occurs during transmission when an unexpected frame-synchronization pulse arrives. An unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been transferred. Such a pulse is ignored by the transmitter, but sets the XSYNCERR bit in SPCR2_REG.

- Transmitter Overflow

(XOVFLSTAT bit is set to 1 in IRQSTATUS register)

This occurs when DMA controller or CPU write data to a full transmit buffer.

17.2.3.1 Overrun in the Receiver

(ROVFLSTAT bit set to 1 in IRQSTATUS register, and legacy mode RFULL bit set to 1 in SPCR1_REG register)

Indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

- DRR_REG is not read even if the RRDY bit in IRQSTATUS register is set (legacy mode: RRDY bit in SPCR1_REG register) and DMA or interrupt request has been asserted.
- RB is full
- RSR is full

As previously described, data arriving on McBSP.DR is continuously shifted into. Once a complete word is shifted into the RSR, an RSR-to-RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode RFULL bit and allows subsequent transfers to be read properly:

- The CPU or DMA controller reads DRR_REG.
- The receiver is reset individually (SPCR1_REG[0] register RRST bit = 0) or as part of an Global reset.

Another frame-synchronization pulse is required to restart the receiver.

According to the IRQENABLE register setting, this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

Figure 17-14 shows the receive overrun condition.

Figure 17-14. Overrun in the McBSP Receiver

17.2.3.2 Unexpected Receive Frame-Synchronization Pulse

17.2.3.2.1 Possible Responses to Receive Frame-Synchronization Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse, and the receiver sets the receive frame-synchronization error bit RSYNCERR in IRQSTATUS (and the legacy RSYNCERR bit SPCR1_REG[3]) register.

According to the IRQENABLE register settings this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

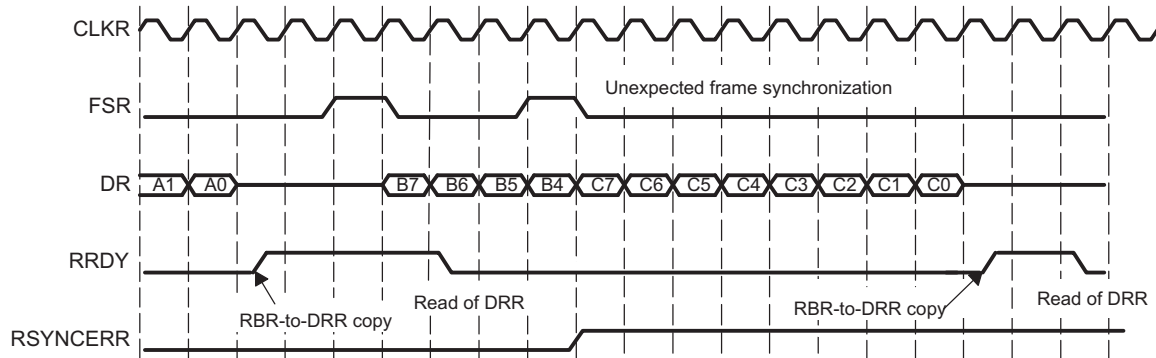

Using the legacy mode, RSYNCERR bit in SPCR1_REG can be cleared only by a receiver reset or by a write of 0 to this bit. If you want the McBSP to notify the CPU of receive frame-synchronization errors, you can set the legacy mode receive interrupt with the SPCR1_REG[5:4] register RINTM bits. When RINTM = 11b, the McBSP sends a receive interrupt (legacy mode RINT) request to the CPU each time that RSYNCERR is set.

17.2.3.2.2 Example of an Unexpected Receive Frame-Synchronization Pulse

Figure 17-15 shows an unexpected receive frame-synchronization pulse during normal operation of the serial port, with time intervals between data packets.

Note that the unexpected receive frame-synchronization pulse does not influence the data receive process, being ignored by the data receive state machine.

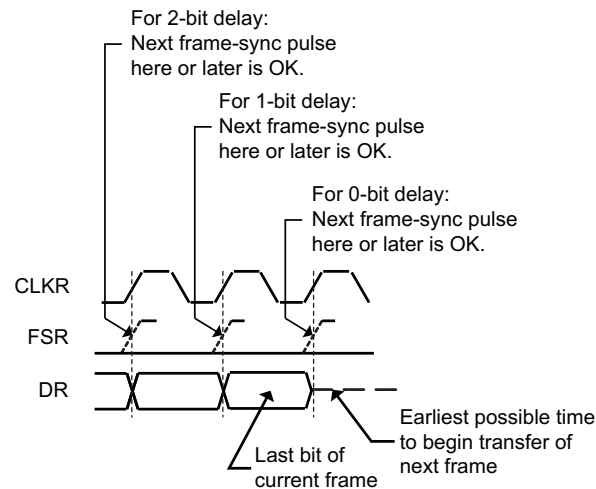

Figure 17-15. Unexpected Frame-Synchronization Pulse During a McBSP Reception

17.2.3.2.3 Preventing Unexpected Receive Frame-Synchronization Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKR cycles, depending on the value of the RCR2_REG[1:0] RDATDLY bits. For each possible data delay, Figure 17-16 shows when a new frame-synchronization pulse on FSR can safely occur relative to the last bit of the current frame.

Figure 17-16. Proper Positioning of Receive Frame-Synchronization Pulses

17.2.3.3 Underflow in the Receiver

The McBSP indicates a receiver underflow condition by setting the RUNDLSTAT bit in IRQSTATUS register. This error occurs when DMA controller or CPU reads data from an empty receive buffer (this may happen only if the CPU or DMA controller does not respect the DMA length, does not wait for DMA request or does not check the buffer status before reading data. According to the IRQENABLE register settings this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

17.2.3.4 Underflow in the Transmitter

The McBSP indicates a transmitter empty (or underflow) condition by setting the XUNDFLSTAT bit in IRQSTATUS register. Also the legacy mode XEMPTY bit in SPCR2_REG[2] register is cleared. Either of the following events activates XEMPTY (XEMPTY = 0):

- DXR_REG has not been loaded and transmit buffer is empty, and all bits of the data word in the XSR have been shifted out on the McBSP.DX pin.
- The transmitter is reset (by forcing XRST = 0 in SPCR2_REG[0] register, or by an Global reset) and is then restarted.

XEMPTY is deactivated (XEMPTY = 1) when a new word in DXR_REG is transferred to XB. If FSXM = 1 in PCR_REG[11] and FSGM = 0 in SRGR2_REG[12], the transmit frame-synchronization signal (FSX) is generated when transmit buffer is not empty. When FSGM = 0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame-synchronization pulse before sending out the next frame on McBSP.DX.

When the transmitter is taken out of reset (XRST = 1), it is in a transmitter ready state (SPCR2_REG[1] register XRDY bit = 1) and transmitter empty (XEMPTY = 0) state. If DXR_REG is loaded by the CPU or the DMA controller before internal FSX goes active high, a valid XB-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-synchronization pulse is generated or detected. Alternatively, if a transmit frame-synchronization pulse is detected before DXR_REG is loaded, zeros are output on McBSP.DX.

The XUNDFLSTAT in IRQSTATUS register indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during transmit process. According to the IRQENABLE register settings this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

17.2.3.5 Unexpected Transmit Frame-Synchronization Pulse

17.2.3.5.1 Possible Responses to Transmit Frame-Synchronization Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse, and the transmitter sets the transmit frame-synchronization error bit XSYNCERR in IRQSTATUS (and the legacy XSYNCERR bit in SPCR2_REG[3]) register.

According to the IRQENABLE register settings this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

Using the legacy mode, XSYNCERR bit in SPCR2_REG can be cleared only by a transmitter reset or by a write of 0 to this bit. If you want the McBSP to notify the CPU of frame-synchronization errors, you can set a special transmit interrupt mode with the SPCR2_REG[5:4] register XINTM bits. When XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU each time that XSYNCERR is set.

17.2.3.5.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Figure 17-17 shows an unexpected transmit frame-synchronization pulse during normal operation of the serial port with intervals between the data packets.

Note that the unexpected transmit frame-synchronization pulse does not influence the data transmit process, being ignored by the data transmit state machine.

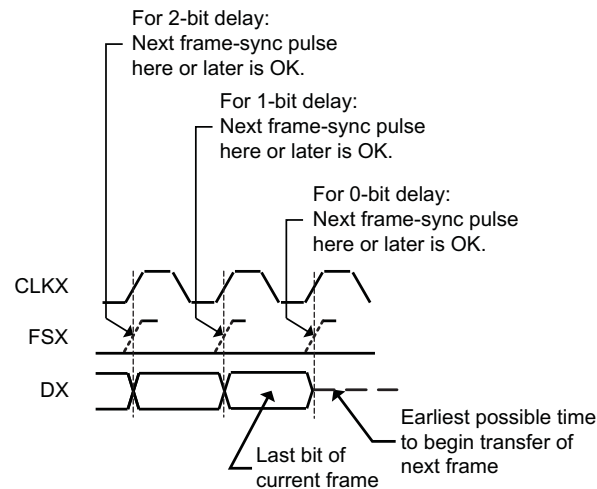

Figure 17-17. Unexpected Frame-Synchronization Pulse During a McBSP Transmission

17.2.3.5.3 Preventing Unexpected Transmit Frame-Synchronization Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the XCR2_REG[1:0] register XDATDLY bits. For each possible data delay, Figure 17-18 shows when a new frame-synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

Figure 17-18. Proper Positioning of Transmit Frame-Synchronization Pulses

17.2.3.6 Overflow in the Transmitter

The McBSP indicates a transmitter overflow condition by setting the XOVLSTAT bit in IRQSTATUS[11] register. This error occurs when DMA controller or CPU write data to a full transmit buffer (this may happen only if the CPU or DMA controller does not respect the DMA length, does not wait for DMA request or does not check the buffer status before writing data). According to the IRQENABLE register settings this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

17.2.4 McBSP DMA Configuration

The McBSP receive and transmit data DMA requests are active after the receive RRRST and transmit XRST are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting zero the RDMAEN, XDMAEN bits in RCCR_REG respectively XCCR_REG. When disabling the DMA the DMA request line is deasserted even if a DMA transfer is pending and the DMA state machine is not reset.

The DMA threshold and length configuration is done through THRSH1_REG and THRSH2_REG registers as follows:

- (THRSH1_REG + 1) value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the RB occupied locations level is above or equal to the THRSH1_REG value plus one, the DMA request will be asserted. After transferring the configured (THRSH1_REG + 1) number of words, the receive DMA request (McBSP.REVNT) will be deasserted and reasserted as soon as the conditions are met again.
- (THRSH2_REG + 1) value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the XB free locations level is above or equal to the THRSH2_REG value plus one the DMA request will be asserted. After transferring the configured (THRSH2_REG + 1) number of words, the transmit DMA request (McBSP.XEVNT) will be deasserted and reasserted as soon as the conditions are met again.

Note that the CPU may decide not to use the DMA to transfer the data. In this case the DMA must be disabled (or the DMA request can be ignored by CPU) and the common interrupt line can be used. The RRDY bit for receive and XRDY bit for transmit will indicate when the threshold values are reached. Also, by reading the receive buffer status RBUFFSTAT_REG register and transmit buffer status XBUFFSTAT_REG register the CPU may decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the CPU needs to read this data. Since no interrupt or DMA request is asserted the only option in this case is to read the receive buffer status register value and to transfer the remaining data without using the DMA or interrupt indication.

17.2.5 Multichannel Selection Modes

17.2.5.1 Channels, Blocks, and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. The McBSP supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into 8 blocks that each contains 16 contiguous channels:

Table 17-3. Channels, Block, Partitions

Block 0: Channels 0–15	Block 4: Channels 64–79
Block 1: Channels 16–31	Block 5: Channels 80–95
Block 2: Channels 32–47	Block 6: Channels 96–111
Block 3: Channels 48–63	Block 7: Channels 112–127

The blocks are assigned to partitions according to the selected partition mode. In the 2–partition mode, you assign one even–numbered block (0, 2, 4, or 6) to partition A and one odd–numbered block (1, 3, 5, or 7) to partition B. In the 8–partition mode, blocks 0 through 7 are automatically assigned to partitions, A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

17.2.5.2 Multichannel Selection

When a McBSP uses a time–division multiplexed (TDM) data stream while communicating with other McBSPs or serial devices, the McBSP may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP has one receive multichannel selection mode and three transmit multichannel selection modes.

17.2.5.3 Configuring a Frame for Multichannel Selection

Before you enable a multichannel selection mode, make sure you properly configure the data frame:

- Select a single–phase frame (RCR2_REG[15] register RPHASE bit and XCR2_REG[15] register XPHASE bit = 0). Each frame represents a TDM data stream.
- Set a frame length (in RCR1_REG[14:8] register RFRLN1 bit field and in XCR1_REG[14:8] register XFRLN1 bit field) that includes the highest–numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLN1 = 39). If XFRLN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

17.2.5.4 Using Eight Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions. If you choose the 8-partition mode (RMCME = 1 for reception, XMCME = 1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8-partition mode, the (R/X)PABLK and (R/X)PBBLK bits are ignored and the 16-channel blocks are assigned to the partitions as shown in the following tables. These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Figure 17-19 shows an example of the McBSP using the 8-partition mode. In response to a frame-synchronization pulse, the McBSP begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

Table 17-4. Eight Partitions – Receive Channel Assignment and Control

Receive Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: channels 0 through 15	RCERA_REG
B	Block 1: channels 16 through 31	RCERB_REG
C	Block 2: channels 32 through 47	RCERC_REG
D	Block 3: channels 48 through 63	RCERD_REG
E	Block 4: channels 64 through 79	RCERE_REG
F	Block 5: channels 80 through 95	RCERF_REG
G	Block 6: channels 96 through 111	RCERG_REG
H	Block 7: channels 112 through 127	RCERH_REG

Table 17-5. Eight Partitions – Transmit Channel Assignment and Control

Transmit Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: channels 0 through 15	XCERA_REG
B	Block 1: channels 16 through 31	XCERB_REG
C	Block 2: channels 32 through 47	XCERC_REG
D	Block 3: channels 48 through 63	XCERD_REG
E	Block 4: channels 64 through 79	XCERE_REG
F	Block 5: channels 80 through 95	XCERF_REG
G	Block 6: channels 96 through 111	XCERG_REG
H	Block 7: channels 112 through 127	XCERH_REG

Figure 17-19. McBSP Data Transfer in the 8-Partition Mode

17.2.5.5 Receive Multichannel Selection Mode

The MCR1_REG[0] register RMCM bit determines whether all channels or only selected channels are enabled for reception. When RMCM = 0, all 128 receive channels are enabled and cannot be disabled. When RMCM = 1, the receive multichannel selection mode is enabled. In this mode:

- Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate receive channel enable registers (RCER[A,H]_REG). The way channels are assigned to the RCER[A,H]_REG registers depends on the number of receive channel partitions (two or eight), as defined by the MCR1_REG[9] register RMCME bit.
- If a receive channel is disabled, any bits received in that channel are not transferred to the receive buffer (RB), and as a result, does not set the receiver ready bit (RRDY). Therefore, no DMA synchronization event (REVT) is generated and, if the receiver interrupt mode depends on RRDY (RINTM = 00b), no interrupt is generated.

As an example of how the McBSP behaves in the receive multichannel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP:

- Accepts bits shifted in from the McBSP.DR pin in channel 0
- Ignores bits received in channels 1–14
- Accepts bits shifted in from the McBSP.DR pin in channel 15
- Ignores bits received in channels 16–38
- Accepts bits shifted in from the McBSP.DR pin in channel 39

17.2.5.6 Using Two Partitions (legacy only)

For multichannel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions. If you choose the 2-partition mode (RMCME = 0 for reception, XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

17.2.5.6.1 Assigning Blocks to Partitions A and B

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point in time. Similarly, any two of the eight transmit-channel blocks (up to 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the RPABLK bits. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register A (RCERA_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the RPBBLK bits. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (RCERB_REG).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the XPABLK bits. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register A (XCERA_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the XPBBLK bits. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (XCERB_REG).

Figure 17-20 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame-synchronization pulse, the McBSP begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 17-20. Alternating Between Partitions A and B Channels

2-partition mode. Example with fixed block assignments

17.2.5.7 Transmit Multichannel Selection Modes

The MCR2_REG[1:0] register XMCM bits determine whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP has three transmit multichannel selection modes (XMCM = 01b, XMCM = 10b, and XMCM = 11b), which are described in Table 17-6.

As an example of how the McBSP behaves in a transmit multichannel selection mode, suppose that XMCM = 01b (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP:

- Shifts data to the McBSP.DX pin in channel 0
- Places the McBSP.DX pin in the high impedance state in channels 1–14
- Shifts data to the McBSP.DX pin in channel 15
- Places the McBSP.DX pin in the high impedance state in channels 16–38
- Shifts data to the McBSP.DX pin in channel 39

Table 17-6. Selecting a Transmit Multichannel Selection Mode with the XMCM Bit Field

XMCM	Transmit Multichannel Selection Mode
00b	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
01b	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (XCER[A,H]_REG). If enabled, a channel in this mode is also unmasked. The MCR2_REG[9] register XMCME bit determines whether 32 channels or 128 channels are selectable in the XCER[A,H]_REG registers.
10b	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (XCER[A,H]_REG). The MCR2_REG[9] register XMCME bit determines whether 32 channels or 128 channels are selectable in the XCER[A,H]_REG registers.
11b	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (RCER[A,H]_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (XCER[A,H]_REG). The MCR2_REG[9] register XMCME bit determines whether 32 channels or 128 channels are selectable in RCER[A,H]_REG registers and XCER[A,H]_REG registers.

17.2.5.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

Table 17-7. McBSP Channel Control Options

Enabled channel	A channel that can begin transmission by passing data from the data transmit register (DXR_REG) to the transmit shift register (XSR) through XB.
Masked channel	A channel that cannot complete transmission. The McBSP.DX pin is held in the high impedance state; data cannot be shifted out on the McBSP.DX pin. In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.
Disabled channel	A channel that is not enabled. A disabled channel is also masked. Because no DXR-to-XB copy occurs, the SPCR2_REG[1] register XRDY bit is not set. Therefore, no DMA synchronization event (XEVT) is generated, and if the transmit interrupt mode depends on XRDY (XINTM = 00b in SPCR2_REG[5:4]), no interrupt is generated. The SPCR2_REG[2] register XEMPTY bit is not affected.
Unmasked channel	A channel that is not masked. Data in the XSR(s) is shifted out on the McBSP.DX pin.

17.2.5.7.2 Activity on McBSP Pins for Different Values of XMCM Bit

Figure 17-21 shows the activity on the McBSP pins for the various XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE = 0: Single-phase frame (required for multichannel selection modes)
- XFRLLEN1 = 0000011b: 4 words per frame
- XWDLEN1 = 000b: 8 bits per word
- XMCM = 0: 2-partition mode (only partitions A and B used)

In the case where XMCM = 11b, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLLEN1, and XWDLEN1, respectively. In Figure 17-21, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

Figure 17-21. Activity on McBSP Pins for the Possible Values of XMCM Bit

(a) XMCM = 00b: All channels enabled and unmasked.

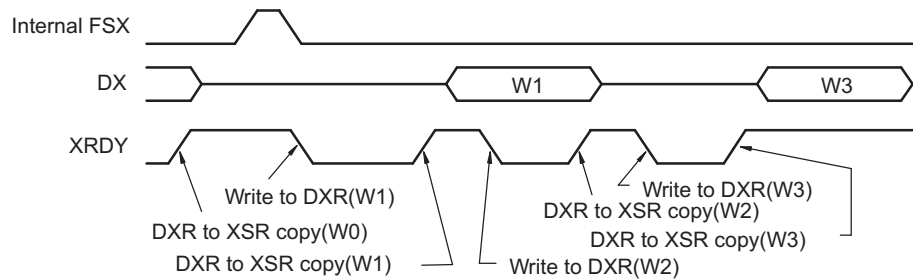

Words W0, W1, W2, W3 are written to the transmit buffer and W0, W1, W2, W3 from the transmit buffer are transferred by McBSP.DX

(b) XMCM = 01b, XPABLK = 00b, XCERA = 1010b: Only channels 1 and 3 enabled and unmasked

Words W1, W3 are written to the transmit buffer and W1, W3 from the transmit buffer are transferred by McBSP.DX

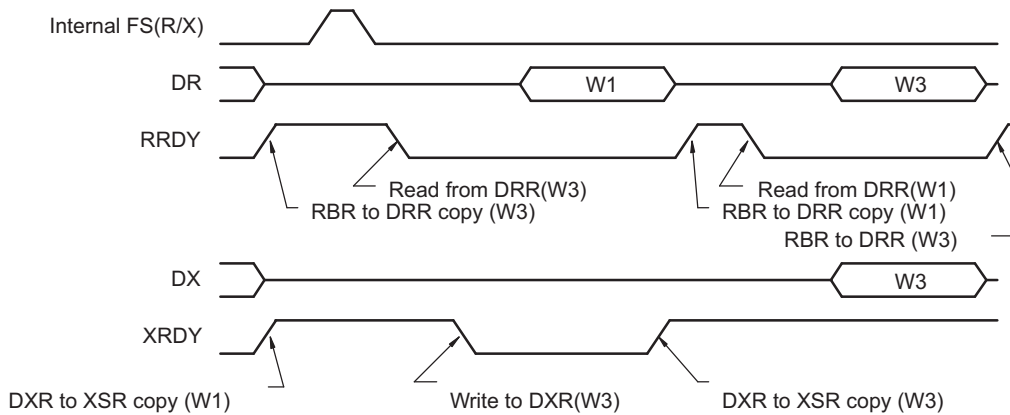

(c) XMCM = 10b, XPABLK = 00b, XCERA = 1010b: All channels enabled, only 1 and 3 unmasked

Words W0, W1, W2, W3 are written to the transmit buffer but only W1 and W3 from the transmit buffer are transferred by McBSP.DX

(d) XMCM = 11b, RPABLK = 00b, XPABLK = X, RCERA = 1010b, XCERA = 1000b

Receive channels: 1 and 3 enabled; Transmit channels: 1 and 3 enabled, but only 3 unmasked

Words W1, W3 are written to the transmit buffer but only W3 from the transmit buffer is transferred by McBSP.DX

17.2.6 McBSP Full/Half Cycle Modes

The following figures are for data delay set to 1.

17.2.6.1 Transmit Full Cycle Mode

When configured in full cycle mode (XCCR[11] register, XFULL_CYCLE bit field), the FSX is sampled on the configured CLKX edge and the data is driven on the same configured edge:

Figure 17-22. Transmit Full Cycle Mode

Data driven on positive CLKX edge, FSX sampled on positive CLKX edge.

17.2.6.2 Transmit Half Cycle Mode

When configured in half cycle mode (XCCR[11] register, XFULL_CYCLE bit field), the FSX is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge:

Figure 17-23. Transmit Half Cycle Mode

Data driven on positive CLKX edge, FSX sampled on negative CLKX edge.

17.2.6.3 Receive Full Cycle Mode

When configured in full cycle mode (RCCR[11] register, RFULL_CYCLE bit field), the FSR is sampled on the configured CLKR edge and the data is sampled on the same configured edge:

Figure 17-24. Receive Full Cycle Mode

Data sampled on negative CLKR edge, FSR sampled on negative CLKR edge.

17.2.6.4 Receive Half Cycle Mode

When configured in half cycle mode (RCCR[11] register, RFULL_CYCLE bit field), the FSR is sampled on the opposite configured CLKR edge and the data is sampled on the next configured edge:

Figure 17-25. Receive Half Cycle Mode

Data sampled on negative CLKR edge, FSR sampled on positive CLKR edge.

17.2.7 Power Management

17.2.7.1 Forceldle Behavior

When configured in Forceldle the module should respond immediately (according to the OCP guideline description) to a McBSP.MIDLREQ, regardless of the internal state of the module. Entering in this mode, the module will freeze all the internal activity when the clocks are switched off by the power management external module. If the functional part, transmit or receive, is running within this period of time, the internal state of the module will not be idle (FSM states, processes, etc.), and when the module exits from the Forceldle state unexpected behavior may happen in both receiver and transmitter. In order to avoid this both receive and transmit parts need to be disabled by software prior to MIdleReq assertion.

17.2.7.2 SmartIdle Behavior

When configured in SmartIdle, the sources for wake-up generation are a subset of the interrupt sources. The wakeup sources are enabled by setting the corresponding bit in WAKEUPEN register.

For receive WAKEUP there are 4 possible configuration scenarios:

- **RRDYEN** - The McBSP asserts the McBSP.WAKEUP request when the RB reaches the high threshold (THRSH1_REG + 1) register value. If the corresponding bit is set in IRQENABLE register, McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exiting from idle mode (interrupt will be asserted once the RRDY bit changes from 0 to 1, indicating that receive data is ready to be read).
- **REOFEN** - The McBSP asserts the McBSP.WAKEUP request at the end of the frame. If the corresponding bit is set in IRQENABLE register McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exit from idle mode.
- **RSYNCERREN** - The McBSP asserts the McBSP.WAKEUP request when an unexpected receive frame-synchronization pulse is detected. If the corresponding bit is set in IRQENABLE register, McBSP sends an interrupt (McBSP.COMMONIRQ) request o the CPU when exiting from idle mode (interrupt will be asserted once the RSYNCERR bit changes from 0 to 1, indicating that a receive error occurred).

For transmit WAKEUP there are four possible configuration scenarios:

- **XRDYEN** - The McBSP asserts the McBSP.WAKEUP request when the XB reaches the high threshold (THRSH2_REG + 1) register value. If the corresponding bit is set in IRQENABLE register, McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exiting from idle mode (interrupt will be asserted once the XRDY bit changes from 0 to 1, indicating that transmit buffer data is ready to accept new data).
- **XEOFEN** - The McBSP asserts the McBSP.WAKEUP request at the end of the frame. If the corresponding bit is set in IRQENABLE register, the McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exiting from idle mode.
- **XFSXEN** - The McBSP sends a McBSP.WAKEUP request when a transmit frame-synchronization pulse is detected while the module is in idle mode. If the corresponding bit is set in IRQENABLE register, the McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exiting from idle mode.
- **XSYNCERREN** - The McBSP asserts the McBSP.WAKEUP request when an unexpected transmit frame-synchronization pulse is detected. If the corresponding bit is set in IRQENABLE register, the McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exiting from idle mode (interrupt will be asserted once the XSYNCERR bit changes from 0 to 1, indicating that a transmit error occurred).

17.2.7.2.1 Analysis of the Receiver Smart Idle Behavior

The analysis of the power mode behavior is depicted in [Table 17-8](#).

Table 17-8. Analysis of the Receiver Smart Idle Behavior

CLKRM	CLKXM	Behavior
0	0	McBSP is configured as a slave, (functional clocks are provided from outside). The module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity.
0	1	<p>McBSP is configured as a transmit master (the source clock can be CLKS, CLKR or OCP).</p> <p>When OCP clock is used as source clock and CLOCKACTIVITY is indicating that the OCP clock will be switched off, or CLKS clock is used as source clock and CLOCKACTIVITY is indicating that the functional clock is switched off, the McBSP will not acknowledge the SmartIdle request unless:</p> <ul style="list-style-type: none"> the transmit part is disabled (XDISABLE) or under software reset (XRST) and the receive part is not using the transmit loop-back clock (ALBCTRLRX[0] pin is asserted). both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) <p>The SmartIdle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames where completed in case of transmit and/or receive disable.</p> <p>When OCP or CLKS is used as source clock and the CLOCKACTIVITY indicates that the corresponding clock will not be switched off, the module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).</p> <p>When CLKR is used as source (functional clock is provided from outside) then the module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.</p>
1	0	<p>McBSP is configured as a receive master (the source clock can be CLKS, CLKX or OCP).</p> <p>When OCP clock is used as source clock and CLOCKACTIVITY is indicating that the OCP clock will be switched off, or CLKS clock is used as source clock and CLOCKACTIVITY is indicating that the functional clock is switched off, the McBSP will not acknowledge the SmartIdle request unless:</p> <ul style="list-style-type: none"> the receive part is disabled (RDISABLE) or under software reset (RRST). <p>The acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames where completed in case of transmit and/or receive disable.</p> <p>When OCP or CLKS is used as source clock and the CLOCKACTIVITY indicates that the corresponding clock will not be switched off, the module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).</p> <p>When CLKX is used as source (functional clock is provided from outside) then the module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.</p>

Table 17-8. Analysis of the Receiver Smart Idle Behavior (continued)

CLKRM	CLKXM	Behavior
1	1	<p>McBSP is configured as transmit and receive master (the source clock can be CLKS or OCP).</p> <p>When OCP clock is used as source clock and CLOCKACTIVITY is indicating that the OCP clock will be switched off, or CLKS clock is used as source clock and CLOCKACTIVITY is indicating that the functional clock is switched off, the McBSP will not acknowledge the SmartIdle request unless:</p> <ul style="list-style-type: none"> both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) <p>The SmartIdle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames where completed in case of transmit and/or receive disable. Note that no wakeup event will be available in this mode since the entire McBSP and remote device activity will be frozen.</p> <p>When OCP or CLKS is used as source clock and the CLOCKACTIVITY indicates that the corresponding clock will not be switched off, the module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).</p>

Notes:

- The RFSREN/XFSXEN mode is suitable for wake-up generation when both clocks (functional and OCP) are switched off and McBSP.FSR/McBSP.FSX is configured as input. The frame synchronization-pulse is asynchronously detected during idle.
- The RSYNCERREN/XSYNCERREN mode can be used to wake-up the McBSP only by a remote module implementing such a feature, to use this type of error in order to trigger a wake-up. This mode requires functional clock to be active.
- When McBSP.FSR/McBSP.FSX is configured as an output, the McBSP.FSR/ McBSP.FSX wake-up generation makes no sense (the module cannot be in SmartIdle mode).
- Detection of RSYNCERR/XSYNCERR during idle mode can be used only when McBSP.FSR/ McBSP.FSX is configured as an input and the remote system knows to assert such an error in order to trigger the wake-up of the McBSP.
- The module does not implement IRQ assertion when configured as GPIO; also a wake-up capability in this mode is not available.

17.2.8 Programming Model

17.2.8.1 McBSP Initialization Procedure

The serial port initialization procedure is as follows:

- Clear SPCR1_REG[0] register RRST bit, SPCR2_REG[7] register FRST bit, and SPCR2_REG[0] register XRST bit to 0. If coming out of a global reset, this step is not required.
- While the serial port is in the reset state, program only the McBSP configuration registers (not the data registers) as required.
- Wait for two clock cycles. This ensures proper internal synchronization
- Set SPCR1_REG[0] register RRST bit and SPCR2_REG[0] register XRST bit to 1 to enable the serial port. Make sure that as you set these reset bits, you do not modify any of the other bits in SPCR1_REG and SPCR2_REG registers. Otherwise, you would change the configuration set in step 2.
- Set up data acquisition as required (such as writing to DXR_REG register).
- Set SPCR2_REG[7] register FRST bit to 1 if internally generated frame synchronization is required.
- Wait for two clock cycles for the receiver and transmitter to become active.

Alternatively, on write (step 1 or 5), the transmitter and receiver can be placed in or taken out of reset by modifying the desired bit.

The previous procedure for reset/initialization can be applied in general when the receiver or transmitter has to be reset during its normal operation, and also when the sample rate generator is not used for either operation.

Notes:

- The necessary duration of the active-low period of XRST or RRST is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (SPCR1_REG, PCR_REG, RCR1_REG, RCR2_REG, XCR1_REG, XCR2_REG, SRGR1_REG and SRGR2_REG) should only be modified when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (DXR_REG) should be loaded by the CPU or the DMA controller only when the transmitter is enabled (XRST = 1). An exception to this rule is when these registers are used for loop back internal data.
- The bits of the channel control registers (MCR1_REG, MCR2_REG, RCER{A-H}_REG and XCER{A-H}_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode
- The sample rate generator is reset by clearing SPCR2_REG[6] register GRST bit to 0.

17.2.8.2 Reset and Initialization Procedure for the Sample Rate Generator

To reset and initialize the sample rate generator:

1. Place the McBSP/sample rate generator in reset. During a Global reset, the sample rate generator, the receiver, and the transmitter reset bits (GRST, RRST, and XRST) are automatically forced to 0. Otherwise, during normal operation, the sample rate generator can be reset by making GRST = 0 in SPCR2_REG[6] register, provided that CLKG and/or FSG is not used by any portion of the McBSP. Depending on your system you may also want to reset the receiver (RRST = 0 in SPCR1_REG[0]) and reset the transmitter (SPCR2_REG[0] register XRST bit = 0).
2. Program the registers that affect the sample rate generator. Program the sample rate generator registers (SPCR1_REG and SPCR2_REG) as required for your application. If necessary, other control registers can be loaded with desired values provided the respective portion of the McBSP (the receiver or transmitter) is in reset. After the sample rate generator registers are programmed, wait 2 CLKSRG cycles. This ensures proper synchronization internally.
3. Enable the sample rate generator (take it out of reset). In SPCR2_REG[6], set GRST bit to 1 to enable the sample rate generator. After the sample rate generator is enabled, wait two CLKG cycles for the sample rate generator logic to stabilize. On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to $(\text{input clock frequency}) / (\text{CLKGDV} + 1)$ where the input clock is selected with the SCLKME bit of PCR_REG[7] register and the SRGR2_REG[13] register CLKSM bit in one of the following configurations:

Table 17-9. Input Clock Selection for Sample Rate Generator

SCLKME bit	CLKSM bit	Input Clock for Sample Rate Generator
0	0	Signal on McBSP.CLKS pin
0	1	McBSP_FCLK clock
1	0	Signal on McBSP.CLKR pin
1	1	Signal on McBSP.CLKX pin

4. If necessary, enable the receiver and/or the transmitter. If necessary, remove the receiver and/or transmitter from reset by setting RRST and/or XRST = 1.
5. Necessary, enable the frame-synchronization logic of the sample rate generator. After the required data acquisition setup is done (DXR_REG is loaded with data), set GRST = 1 in SPCR2_REG[6] if an internally generated frame-synchronization pulse is required. FSG is generated with an active-high edge after the programmed number of CLKG clocks (FPER + 1) has elapsed.

17.2.8.3 Data Transfer DMA Request Configuration

To configure the McBSP receive/transmit data DMA requests, perform the following procedure:

1. Write the receive THRSH1_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the RB occupied locations level is above or equal to the THRSH1_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH1_REG + 1 number of words, the receive DMA request (McBSP.REVNT) will be deasserted and reasserted as soon as the conditions are met again.
Note that in case of a number of transfers that exceed the number of the programmed DMA length the McBSP will respond to the command, and will perform the transfer regardless of the receive buffer empty condition. When the receive buffer is empty a data transfer access will trigger a receive underflow interrupt, if enabled by RUNDL_EN bit in IRQENSTAT_REG register.
2. Write the transmit THRSH2_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the XB free locations level is above or equal to the THRSH2_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH2_REG + 1 number of words, the transmit DMA request (McBSP.XEVNT) will be deasserted and reasserted as soon as the conditions are met again.
Note that in case of a number of transfers that exceed the number of the programmed DMA length the McBSP will respond to the command, and will perform the transfer regardless of the transmit buffer full condition. When the transmit buffer is full a data transfer access will trigger a transmit overflow interrupt, if enabled by XOVFL_EN bit in IRQENSTAT_REG register

17.2.8.4 Interrupt Configuration

The McBSP offers two interrupt schemes:

- OCP compliant interrupt request scheme using a common receive/transmit interrupt request line.
- The legacy interrupt compliant scheme using 3 interrupt lines: one for receive, one for transmit and the receive overflow interrupt line.

The OCP compliant interrupt line can be configured by using the IRQENABLE register. When the IRQSTATUS bit is set and the corresponding IRQENABLE bit is set to 1, the interrupt line is asserted. Writing one to a bit in IRQSTATUS register will clear the bit.

There are several conditions, which may be configured to generate an interrupt as follows:

- Transmit Buffer Overflow (XOVFLSTAT bit is set to 1 when transmit buffer overflow; the data which is written while overflow condition is discarded).
- Transmit Buffer Underflow (XUNDFLSTAT bit is set to 1 when the transmit data buffer is empty new data is required to be transmitted).
- Transmit Buffer Threshold Reached (XRDY bit is set to 1 when the transmit buffer free locations are equal or above the (THRSH2_REG + 1) value).
- Transmit End of Frame (XEOF is set to 1 when a complete frame was transmitted).
- Transmit Frame Synchronization (XFSX bit is set to 1 when a new transmit frame synchronization is asserted).
- Transmit Frame Synchronization Error (XSYNCERR is set to 1 when a transmit frame synchronization error is detected).
- Receive Buffer Overflow (ROVFLSTAT bit is set to 1 when receive buffer overflow; the data which is written while overflow condition is discarded).
- Receive Buffer Underflow (RUNDLSTAT bit is set to 1 when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined).
- Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the (THRSH1_REG + 1) value).
- Receive End of Frame (REOF is set to 1 when a complete frame was received).
- Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted).
- Receive Frame Synchronization Error (RSYNCERR is set to 1 when a receive frame synchronization error is detected).

17.2.8.5 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP/receiver in reset.
2. Program the McBSP registers for the desired receiver operation.
3. Take the receiver out of reset.

17.2.8.5.1 Programming the McBSP Registers for the Desired Receiver Configuration

The following is a list of important tasks to be performed when you are configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields. Note that SRG is Sample Rate Generator.

Global Behavior

1. Set the receiver pins to operate as McBSP pins.
2. Enable/disable the digital loop back mode.
3. Enable/disable the analog loop back mode.
4. Enable/disable the synchronous transmit-receive mode.
5. Enable/disable the receive multichannel selection mode.

Data behavior:

1. Choose 1 or 2 phases for the receive frame.
2. Set the receive word length(s).
3. Set the receive frame length (one word per phase if dual-phase selected).
4. Enable/disable the receive frame–synchronization ignore function.
5. Set the receive data delay.
6. Set the receive sign–extension and justification mode.
7. Set the receive interrupt mode.

Frame–synchronization behavior:

1. Set the receive frame–synchronization mode.
2. Set the receive frame–synchronization polarity.
3. Set the sample rate generator (SRG) frame–synchronization period and pulse width.

Clock behavior:

1. Set the receive clock mode.
2. Set the receive clock polarity.
3. Set the SRG clock divide–down value.
4. Set the SRG clock synchronization mode.
5. Set the SRG clock mode (choose an input clock).
6. Set the SRG input clock polarity.

17.2.8.5.2 Resetting and Enabling the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take it out of reset).

The serial port can be reset in the following two ways:

- A global reset places the receiver, transmitter, and sample rate generator in reset. When the device reset is removed, GRST, FRST, RRST and XRST bits = 0, keeping the entire serial port in the reset state.
- The serial port transmitter and receiver can be reset directly using the RRST and XRST bits in the SPCR1_REG register. The sample rate generator can be reset directly using the GRST bit in SPCR2_REG[6] register.

17.2.8.5.3 Set the Receiver Pins to Operate as McBSP Pins

The RIOEN bit (PCR_REG[12]) determines whether the receiver pins are McBSP pins or general-purpose I/O pins.

Refer to [Section 17.2.8.7](#) for further information.

17.2.8.5.4 Enable/Disable the Synchronous Transmit-Receive Mode

The ALBCTRLRX input pin is used to configure the synchronous transmit-receive mode. The ALBCTRLRX[0/1] input pin selection is determined by programming the Control Module AUD_CTRL Register.

The ALBCTRLRX [0] controls the multiplexer which connects the functional receive input clock (CLKR is connected to the CLKX input pin CLKXI when ALBCTRLRX[0] = 1).

The ALBCTRLRX[1] controls the multiplexer which connects the receive frame synchronization (FSR is connected to the FSX input pin FSXI when ALBCTRLRX[1] = 1).

17.2.8.5.5 Enable/Disable the Analog Loop Back Mode

The ALB bit (SPCR1_REG[15]) determines whether the analog loop-back mode is on or off.

In the analog loop-back mode, the receive signals are connected internally through multiplexers to the corresponding transmit loop back signals (DR is connected to transmit loop back data on DXI pin, FSR is connected to FRX input pin FSXI, and CLKR is connected to the CLKX input pin CLKXI). This mode allows testing of serial port; the McBSP receives the data it transmits. This loop back mode is done through pads testing also the IO buffers.

17.2.8.5.6 Enable/Disable the Digital Loop Back Mode

The DLB bit (XCCR_REG) determines whether the digital loop-back mode is on or off. In the digital loop-back mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals (DR is connected to transmit data on DX output pin DXO, FSR is connected to FRX output pin FSXO, and CLKR is connected to the CLKX output pin CLKXO). This mode allows testing of serial port; the McBSP receives the data it transmits. This loop back mode is not done through pads, all output signals being disabled (CLKREN, CLKXEN, FSREN, FSRXEN, DXEN are not active).

Note that in digital loop back mode the sample rate generator and the frame synchronization generator need to be enabled in order to generate the CLKX and FSX signals.

17.2.8.5.7 Enable/Disable the Receive Multichannel Selection Mode

The RMCM bit (MCR1_REG[0]) determines whether the receive multichannel selection mode is on or off.

17.2.8.5.8 Choose 1 or 2 Phases for the Receive Frame

The RPHASE bit (RCR2_REG[15]) determines whether the receive data frame has one or two phases. When dual-phase is selected the number of words per phase must be set to 1.

17.2.8.5.9 Set the Receive Word Length(s)

The RWDLEN1 (RCR1_REG[7:5]) and RWDLEN2 (RCR2_REG[7:5]) bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

Each frame can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be cleared to 0 (one word per phase).

17.2.8.5.10 Set the Receive Frame Length

The RFLEN1 (RCR1_REG[14:8]) and RFLEN2 (RCR2_REG[14:8]) bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

The receive frame length is the number of serial words in the receive frame. Each frame can have one or two phases, depending on value that you load into the RPHASE bit.

If a single-phase frame is selected (RPHASE = 0), the frame length is equal to the length of phase 1. If a dual-phase frame is selected (RPHASE = 1), the frame length is the length is two (one word for phase 1 plus the one word for phase 2).

The 7-bit RFLEN1 field allow up to 128 words per phase when single-phase frame. See Table 17-10 for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the RFLEN fields with [w minus 1], where w represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into RFLEN1.

Table 17-10. How to Calculate the Length of the Receive Frame

RPHASE	RFLEN1	RFLEN2	Frame Length
0	0 <= RFLEN1 <= 127	Don't care	(RFLEN1 + 1) words
1	RFLEN1 = 0	RFLEN2 = 0	2 words

17.2.8.5.11 Set the Receive Reverse Mode

The RREVERSE bit field (RCR2_REG[4:3]) determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

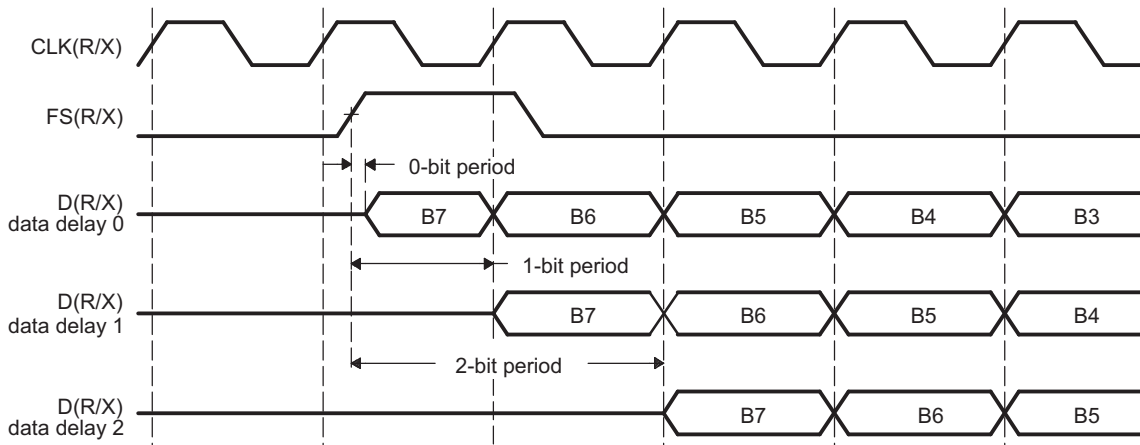

17.2.8.5.12 Set the Receive Data Delay

The RDATDLY bit field (RCR2_REG[1:0]) determines the length of the data delay for the receive frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

RDATDLY specifies the data delay for reception. The range of programmable data delay is 0 to 2 bit-clocks (RDATDLY = 00b-10b), as shown in Figure 17-26. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Figure 17-26. Range of Programmable Data Delay

0-bit data delay:

Normally, a frame–synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0–bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active–high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on McBSP.DX. The transmitter then asynchronously detects the frame–synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the McBSP.DX pin.

2-bit delay:

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1–bit delay and data appears after a 2–bit delay), the serial port essentially discards the framing bit from the data stream, as shown in [Figure 17-27](#). In this figure, the data transferred is an 8–bit value with bits labeled B7, B6, B5, and so on.

Figure 17-27. 2-Bit Data Delay Used to Skip a Framing Bit

17.2.8.5.13 Set the Receive Sign-Extension and Justification Mode

The RJUST bit field (SPCR1_REG[14:13]) determines whether data received by the McBSP is sign–extended or not and how it is justified.

RJUST bit field selects whether data in RB is right– or left–justified (with respect to the MSB) in DRR_REG register and whether unused bits in DRR_REG are filled with zeroes or with sign bits.

The following tables show the effects of various RJUST values. [Table 17-11](#) shows the effect on an example 12–bit receive–data value ABCCh, [Table 17-12](#) shows the effect on an example 20–bit receive–data value ABCDEh.

Table 17-11. Example: Use of RJUST Bit Field with 12-Bit Data Value ABCCh

RJUST	Justification	Extension	Value in DRR_REG
00b	Right	Zero fill MSBs	0000 0ABCCh
01b	Right	Sign extend data into MSBs	FFFF FABCh
10b	Left	Zero fill LSBs	ABC0 0000h
11b	Reserved	Reserved	Reserved

Table 17-12. Example: Use of RJUST Bit Field with 20-Bit Data Value ABCDE

RJUST	Justification	Extension	Value in DRR_REG
00b	Right	Zero fill MSBs	000A BCDEh
01b	Right	Sign extend data into MSBs	FFFA BCDEh
10b	Left	Zero fill LSBs	ABCD E000h
11b	Reserved	Reserved	Reserved

17.2.8.5.14 Set the Receive Interrupt Mode (legacy only)

The RINTM bit field (SPCR1_REG[5:4]) determines which event generates a receive interrupt request to the CPU. The receive interrupt (RINT) informs the CPU of changes to the serial port status. Four options exist for configuring this interrupt.

- RINTM = 00: RINT generated when the RRDY bit (SPCR1_REG[1]) changes from 0 to 1. Interrupt on every serial word by tracking the RRDY bit in the SPCR1_REG register. Regardless of the value of RINTM, RRDY can be read to detect the RRDY = 1 condition.
- RINTM = 01: RINT generated by an end-of-frame condition in the receive multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- RINTM = 10: RINT generated by a new receive frame-synchronization pulse. Interrupt on detection of receive frame-synchronization pulses. This generates an interrupt even when the receiver is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the CPU clock and sending it to the CPU via RINT.
- RINTM = 11: RINT generated when RSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see [Section 17.2.3.2](#).

The McBSP provides also a common interrupt line McBSP.COMMONIRQ, which can be used by setting the IRQENABLE register. All the above settings have equivalent enable bits in the IRQENABLE register in order to enable the common interrupt line (RRDYEN is equivalent with RINTM = 00, REOFEN is equivalent with RINTM = 01 (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode), RFSREN is equivalent with RINTM = 10 and RSYNCERREN is equivalent with RINTM = 11 setting). This interrupt line has its own status register.

17.2.8.5.15 Set the Receive Frame-Synchronization Mode

FSRM bit (PCR_REG[10]), GSYNC bit (SRGR2_REG[15]), ALB bit (SPCR1_REG[15]) and DLB bit field (XCCR_REG) are used to determine the source for receive frame synchronization and the function of the McBSP.FSR pin.

[Table 17-13](#) shows how you can select various sources to provide the receive frame-synchronization signal and the effect on the McBSP.FSR pin. The polarity of the signal on the McBSP.FSR pin is determined by the FSRP bit.

In digital loop-back mode (DLB = 1), the transmit frame-synchronization signal is used as the receive frame-synchronization signal.

Also in the analog loop back mode, the internal receive clock signal (CLKR), the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

In the digital loop-back mode (DLB = 1) or analog loop-back mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal.

Table 17-13. FSRM and GSYNC Effects on Frame-Synchronization Signal and McBSP.FSR Pin

FSRM	GSYNC	Source of Receive Frame Synchronization	McBSP.FSR Pin Status
0	0 or 1	An external frame synchronization signal enters the McBSP through the McBSP.FSR pin. The signal is then inverted as determined by FSRP before being used as internal FSR.	Input
1	0	Internal FSR is driven by the sample rate generator frame-synchronization signal (FSG).	Output. FSG is inverted as determined by FSRP before being driven out on the McBSP.FSR pin.
1	1	Internal FSR is driven by the sample rate generator frame-synchronization signal (FSG).	Input. The external frame-synchronization input on the McBSP.FSR pin is used to synchronize CLKG and generate FSG pulses.

17.2.8.5.16 Set the Receive Frame-Synchronization Polarity

The FSRP bit (PCR_REG[2]) determines whether frame-synchronization pulses are active high or active low on the McBSP.FSR pin.

Receive frame-synchronization pulses can be generated internally by the sample rate generator or driven by an external source. The source of frame synchronization is selected by programming the PCR_REG[10] register FSRM mode bit. FSR is also affected by the SRGR2_REG[15] register GSYNC bit. For information about the effects of FSRM and GSYNC, see the Frame Synchronization Generation in the Sample Rate Generator section. Similarly, receive clocks can be selected to be inputs or outputs by programming the PCR_REG[8] register CLKRM mode bit (see the Clock Generation in the Sample Rate Generator section).

When FSR and FSX are inputs (FSXM = FSRM = 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the McBSP.DR pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the McBSP.DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP bits in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1, and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the McBSP.CLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the McBSP.CLKR pin.

Note that CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge. [Figure 17-28](#) shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 17-28. Data Externally Clocked on a Rising Edge and Sampled on a Falling Edge

17.2.8.5.17 Set the SRG Frame-Synchronization Period and Pulse Width

FPER bit field (SRGR2_REG[11:0]) is used to set the SRG frame-synchronization period and FWID bit field (SRGR1_REG[15:8]) is used to set the SRG pulse width. The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. If the sample rate generator is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC = 1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID + 1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 17-29 shows a frame-synchronization period of 16 CLKG periods (FPER = 15 or 0000 1111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID = 1).

When the sample rate generator comes out of reset, FSG is in its inactive state. Then, when GRST = 1 and FSGM = 1, a frame-synchronization pulse is generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER + 1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

17.2.8.5.18 Set the Receive Clock Mode

CLKRM bit (PCR_REG[8]), ALB bit (SPCR1_REG[15]) and DLB bit field (XCCR_REG) are used to set the receive clock mode.

Table 17-14 shows how you can select various sources to provide the receive clock signal and affect the McBSP.CLKR pin. The CLKRP bit determines the polarity of the signal on the McBSP.CLKR pin.

In the digital loop-back mode (DLB = 1) or analog loop-back mode (ALB = 1), the transmit clock signal is used as the receive clock signal.

Table 17-14. CLKRM Effect on Receive Clock Signal and McBSP.CLKR Pin

CLKRM	Source of Receive Clock	McBSP.CLKR Pin Status
0	The McBSP.CLKR pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP before being used.	Input
1	The sample rate generator clock (CLKG) drives internal CLKRM.	Output. CLKG, inverted as determined by CLKRP, is driven out on the McBSP.CLKR pin.

17.2.8.5.19 Set the Receive Clock Polarity

CLKRP bit (PCR_REG[0]) is used to set the receive clock polarity.

Receive frame–synchronization pulses can be generated internally by the sample rate generator or driven by an external source. The source of frame synchronization is selected by programming the PCR_REG[10] register FSRM mode bit. FSR is also affected by the GSYNC bit in SRGR2_REG[15]. Similarly, receive clocks can be selected to be inputs or outputs by programming the PCR_REG[8] register CLKRM mode bit.

When FSR and FSX are inputs (FSXM = FSRM = 0, external frame–synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the McBSP.DR pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the McBSP.DX pin is output on the rising edge of internal CLKX. FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame–synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP = FSXP = 1, the external active–low frame–synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active–high frame–synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling–edge triggered input clock on CLKX is inverted to a rising–edge triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising–edge triggered) clock, internal CLKX, is inverted before being sent out on the McBSP.CLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising–edge triggered input clock on CLKR is inverted to a falling–edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling–edge triggered clock is inverted to a rising–edge triggered clock before being sent out on the McBSP.CLKR pin.

Note that CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

17.2.8.5.20 Set the SRG Clock Divide-Down Value

CLKGDV bit field (SRGR1_REG[7:0]) is used to set the sample rate generator clock divide-down value.

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to $1/(\text{CLKGDV} + 1)$ of sample rate generator input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. The CLKG duty cycle is 50%.

17.2.8.5.21 Set the SRG Clock Synchronization Mode

GSYNC bit (SRGR2_REG[15]) is used to set the SRG clock synchronization mode.

17.2.8.5.22 Set the SRG Clock Mode (choose an input clock)

SCLKME bit (PCR_REG[7]) and CLKSM bit (SRGR2_REG[13]) are used to set the SRG clock mode.

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock.

17.2.8.5.23 Set the SRG Input Clock Polarity

CLKSP bit (SRGR2_REG[14]), CLKXP bit (PCR_REG[1]) and CLKRP bit (PCR_REG[0]) are used to set the SRG input clock polarity.

The sample rate generator can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the sample rate generator must be driven by an input clock signal derived from the McBSP_FCLK clock or from an external clock on the McBSP.CLKS, McBSP.CLKX, or McBSP.CLKR pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKSP for the McBSP.CLKS pin, CLKXP for the McBSP.CLKX pin, CLKRP for the McBSP.CLKR pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

17.2.8.6 Transmitter Configuration

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP transmitter in reset
2. Program the McBSP registers for the desired transmitter
3. Take the transmitter out of reset

These three steps are detailed in the following subsections.

17.2.8.6.1 Programming the McBSP Registers for the Desired Transmitter Operation

The following is a list of important tasks to be performed when you are configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

Global behavior:

1. Set the transmitter pins to operate as McBSP pins.
2. Enable/disable the digital loop back mode.
3. Enable/disable the analog loop back mode.
4. Enable/disable the synchronous transmit-receive mode.
5. Enable/disable transmit multichannel selection.

Data behavior:

1. Choose 1 or 2 phases for the transmit frame.
2. Set the transmit word length(s).
3. Set the transmit frame length (one word per phase if dual-phase selected).
4. Enable/disable the transmit frame–synchronization ignore function.
5. Set the transmit data delay.
6. Set the transmit DXENA mode.
7. Set the transmit interrupt mode.

Frame-synchronization behavior:

1. Set the transmit frame–synchronization mode.
2. Set the transmit frame–synchronization polarity.
3. Set the SRG frame–synchronization period and pulse width.

Clock behavior:

1. Set the transmit clock mode.
2. Set the transmit clock polarity.
3. Set the SRG clock divide–down value.
4. Set the SRG clock synchronization mode.
5. Set the SRG clock mode (choose an input clock).
6. Set the SRG input clock polarity.

17.2.8.6.2 Resetting and Enabling the Transmitter

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take it out of reset). The serial port can be reset in the following two ways:

1. A global reset places the receiver, transmitter, and sample rate generator in reset. When the device reset is removed, GRST, FRST, RRST and XRST bits = 0, keeping the entire serial port in the reset state.
2. The serial port transmitter and receiver can be reset directly using the RRST and XRST bits in the SPCR1_REG register. The sample rate generator can be reset directly using the GRST bit in SPCR2_REG register.

17.2.8.6.3 Set the Transmitter Pins to Operate as McBSP Pins

The XIOEN bit (PCR_REG[13]) determines whether the transmitter pins are McBSP pins or general–purpose I/O pins.

Refer to [Section 17.2.8.7](#) for further information.

17.2.8.6.4 Enable/Disable the Digital Loop Back Mode

The DLB bit (XCCR_REG) determines whether the digital loop-back mode is on or off. In the digital loop-back mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals (DR is connected to transmit data on DX output pin DXO, FSR is connected to FRX output pin FSXO, and CLKR is connected to the CLKX output pin CLKXO). This mode allows testing of serial port; the McBSP receives the data it transmits. This loop back mode is not done through pads, all output signals being disabled (CLKREN, CLKXEN, FSREN, FSRXEN, DXEN are not active).

Note that in digital loop back mode the sample rate generator and the frame synchronization generator need to be enabled in order to generate the CLKX and FSX signals.

17.2.8.6.5 Enable/Disable the Transmit Multichannel Selection

The XMCM bit field (MCR2_REG[1:0]) determines whether the transmit multichannel selection mode is on or off.

17.2.8.6.6 Choose 1 or 2 Phases for the Transmit Frame

The XPHASE bit (XCR2_REG[15]) determines whether the transmit data frame has one or two phases.

17.2.8.6.7 Set the Transmit Word Length(s)

The XWDLEN1 (XCR1_REG[7:5]) and XWDLEN2 (XCR2_REG[7:5]) bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the transmit data frame.

Each frame can have one or two phases, depending on the value that you load into the XPHASE bit. If a single-phase frame is selected, XWDLEN1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, XWDLEN1 determines the length of the serial words in phase 1 of the frame and XWDLEN2 determines the word length in phase 2 of the frame.

17.2.8.6.8 Set the Transmit Frame Length

The XFRLN1 (XCR1_REG[14:8]) and XFRLN2 (XCR2_REG[14:8]) bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the transmit data frame.

The transmit frame length is the number of serial words in the transmit frame. Each frame can have one or two phases, depending on value that you load into the XPHASE bit. If a single-phase frame is selected (XPHASE = 0), the frame length is equal to the length of phase 1. If a dual-phase frame is selected (XPHASE = 1), the frame length is 2, the length of phase 1 (one word) plus the length of phase 2 (one word).

The 7-bit XFRLN fields allow up to 128 words per phase. See [Table 17-15](#) for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the XFRLN fields with [w minus 1], where w represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into XFRLN1.

Table 17-15. How to Calculate the Length of the Transmit Frame

XPHASE	XFRLN1	XFRLN2	Frame Length
0	0 <= XFRLN1 <= 127	Don't care	(XFRLN1 + 1) words
1	XFRLN1 = 0	XFRLN2 = 0	2 words

17.2.8.6.9 Set the Transmit Reverse Mode

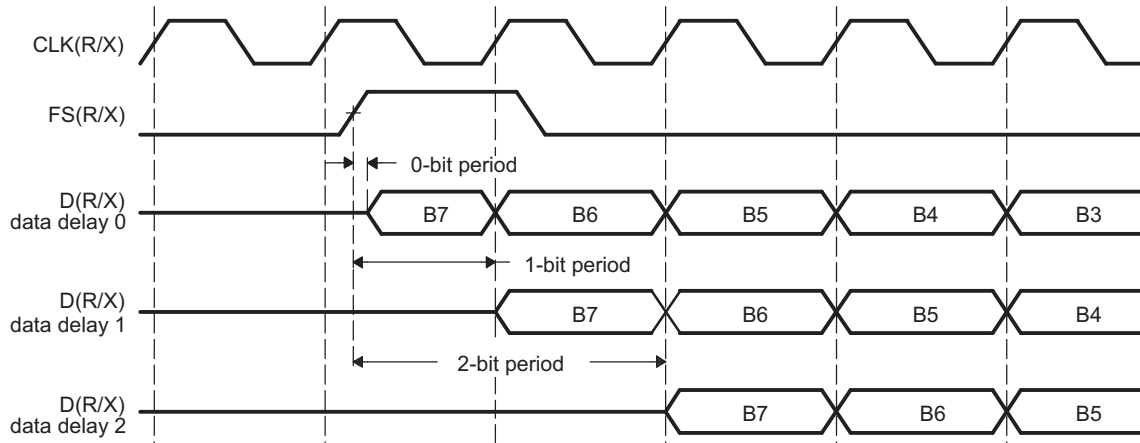

The XREVERSE bit field (XCR2_REG[4:3]) determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

17.2.8.6.10 Set the Transmit Data Delay

The XDATDLY bit field (XCR2_REG[1:0]) determines the length of the data delay for the transmit frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

XDATDLY specifies the data delay for reception. The range of programmable data delay is 0 to 2 bit-clocks (XDATDLY = 00b–10b), as shown in [Figure 17-30](#). In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Figure 17-30. Range of Programmable Data Delay

0-bit data delay:

Normally, a frame–synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0–bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active–high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on McBSP.DX. The transmitter then asynchronously detects the frame–synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the McBSP.DX pin.

Figure 17-31. 2-Bit Data Delay Used to Skip a Framing Bit

17.2.8.6.11 Set the Transmit DXENA Mode

DXENA bit (SPRC1_REG[7]) is used to set the transmit DXENA (DX delay enable) mode.

The DXENA bit controls the delay enabler on the McBSP.DX pin. Set DXENA to enable an extra delay for turn–on time. This bit does not control the data itself, so only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay: 7 ns, 14 ns (default), 20 ns or 28 ns can be set using the DXENDLY bit field in XCCR_REG register. If you tie together the McBSP.DX pins of multiple McBSPs, make sure DXENA = 1 to avoid having more than one McBSP transmitting on the data line at one time.

17.2.8.6.12 Set the Transmit Interrupt Mode (legacy only)

The XINTM bit field (SPCRX_REG[5:4]) determines which event generates a transmit interrupt request to the CPU.

The transmit interrupt (XINT) informs the CPU of changes to the serial port status. Four options exist for configuring this interrupt.

- XINTM = 00: XINT generated when the XRDY bit (SPCR2_REG[1]) changes from 0 to 1. Interrupt on every serial word by tracking the XRDY bit in the SPCR2_REG register. Regardless of the value of XINTM, XRDY can be read to detect the XRDY = 1 condition.
- XINTM = 01: XINT generated by an end-of-frame condition in the transmit multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- XINTM = 10: XINT generated by a new transmit frame-synchronization pulse. Interrupt on detection of transmit frame-synchronization pulses. This generates an interrupt even when the transmitter is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the CPU clock and sending it to the CPU via XINT.
- XINTM = 11: XINT generated when XSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of XINTM, XSYNCERR can be read to detect this condition.

The McBSP provides also a common interrupt line McBSP.COMMONIRQ, which can be used by setting the IRQENABLE register. All the above settings have equivalent enable bits in the IRQENABLE register in order to enable the common interrupt line (XDYEN is equivalent with XINTM = 00, XEOFEN is equivalent with XINTM = 01 (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode), XFSXEN is equivalent with XINTM = 10 and XSYNCERREN is equivalent with XINTM = 11 setting). This interrupt line has its own status register.

17.2.8.6.13 Set the Transmit Frame-Synchronization Mode

FSXM bit (PCR_REG[11]) and FSGM bit (SRGR2_REG[12]) are used to set the transmit frame-synchronization mode.

Table 17-16 shows how FSXM and FSGM select the source of transmit frame-synchronization pulses. The three choices are:

1. External frame-synchronization input
2. Sample rate generator frame-synchronization signal (FSG)
3. Sample rate generator frame-synchronization signal (FSG) gated by the transmit buffer XB empty condition.

Table 17-16 also shows the effect of each bit setting on the McBSP.FSX pin. The FSXP bit determines the polarity of the signal on the McBSP.FSX pin.

Table 17-16. How FSXM and FSGM Select the Source of Transmit Frame-Synchronization Pulses

FSXM	FSGM	Source of Transmit Frame Synchronization	McBSP.FSX Pin Status
0	0 or 1	An external frame-synchronization signal enters the McBSP through the McBSP.FSX pin. The signal is then inverted by FSXP before being used as internal FSX.	Input
1	1	Internal FSX is driven by the sample rate generator frame-synchronization signal (FSG).	Output. FSG is inverted by FSXP before being driven out on McBSP.FSX pin.
1	0	A XB empty condition causes the McBSP not to generate a transmit frame-synchronization pulse. The frame synchronization is generated taking into account the FWID and FPER as long as the transmit buffer is not empty. When the buffer is empty the generated frame synchronization signal is gated.	Output. The generated frame-synchronization pulse is inverted as determined by FSXP before being driven out on McBSP.FSX pin.

If the sample rate generator creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the McBSP.FSR pin.

In the digital loop-back mode (DLB = 1) or analog loop-back mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal.

17.2.8.6.14 Set the Transmit Frame-Synchronization Polarity

The FSXP bit (PCR_REG[3]) determines whether frame-synchronization pulses are active high or active low on the McBSP.FSX pin.

Transmit frame-synchronization pulses can be generated internally by the sample rate generator or driven by an external source. The source of frame synchronization is selected by programming the PCR_REG[11] register FSXM mode bit. FSX is also affected by the FSGM bit (SRGR2_REG[12]). Similarly, transmit clocks can be selected to be inputs or outputs by programming the PCR_REG[9] register CLKXM mode bit.

When FSR and FSX are inputs (FSXM = FSRM = 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the McBSP.DR pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the McBSP.DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected and the polarity bit FS(R/X)P = 1, the internal active-high frame-synchronization signals are inverted before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1, and internal clocking selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the McBSP.CLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the McBSP.CLKR pin.

Note that CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

17.2.8.6.15 Set the SRG Frame-Synchronization Period and Pulse Width

FPER bit field (SRGR2_REG[11:0]) is used to set the SRG frame-synchronization period and FWID bit field (SRGR1_REG[15:8]) is used to set the SRG pulse width. The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. If the sample rate generator is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC = 1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID + 1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 17-32 shows a frame-synchronization period of 16 CLKG periods (FPER = 15 or 0000 1111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID = 1).

When the sample rate generator comes out of reset, FSG is in its inactive state. Then, when GRST = 1 and FSGM = 1, a frame-synchronization pulse is generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER + 1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

17.2.8.6.16 Set the Transmit Clock Mode

CLKXM bit (PCR_REG[9]) is used to set the transmit clock mode

Table 17-17 shows how the CLKXM bit selects the transmit clock and the corresponding status of the McBSP.CLKX pin. The CLKXP bit determines the polarity of the signal on the McBSP.CLKX pin.

If the sample rate generator creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the McBSP.FSR pin.

In the digital loop-back mode (DLB = 1) or analog loop-back mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal.

Table 17-17. CLKXM Bit Effect on Transmit Clock and McBSP.CLKX Pin

CLKXM	Source of Transmit Clock	McBSP.CLKX Pin Status
0	Internal CLKX is driven by an external clock on the McBSP.CLKX pin. CLKX is inverted as determined by CLKXP before being used.	Input
1	Internal CLKX is driven by the sample rate generator clock, CLKG.	Output. CLKG, inverted as determined by CLKXP, is driven out on McBSP.CLKX.

17.2.8.6.17 Set the Transmit Clock Polarity

CLKXP bit (PCR_REG[1]) is used to set the transmit clock polarity.

Transmit frame–synchronization pulses can be either generated internally by the sample rate generator or driven by an external source. The source of frame synchronization is selected by programming the PCR_REG[11] register FSXM mode bit. FSX is also affected by the FSGM bit (SRGR2_REG[12]). Similarly, transmit clocks can be selected to be inputs or outputs by programming the PCR_REG[9] register CLKXM mode bit.

When FSR and FSX are inputs (FSXM = FSRM = 0, external frame–synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the McBSP.DR pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the McBSP.DX pin is output on the rising edge of internal CLKX. FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame–synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active–low frame–synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active–high frame–synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling–edge triggered input clock on CLKX is inverted to a rising–edge triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising–edge triggered) clock, internal CLKX, is inverted before being sent out on the McBSP.CLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising–edge triggered input clock on CLKR is inverted to a falling–edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling–edge triggered clock is inverted to a rising–edge triggered clock before being sent out on the McBSP.CLKR pin. Note that CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

17.2.8.6.18 Set the SRG Clock Divide-Down Value

CLKGDV bit field (SRGR1_REG[7:0]) is used to set the sample rate generator clock divide-down value.

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to $1/(\text{CLKGDV} + 1)$ of sample rate generator input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. The CLKG duty cycle is 50%.

17.2.8.6.19 Set the SRG Clock Synchronization Mode

GSYNC bit (SRGR2_REG[15]) is used to set the SRG clock synchronization mode.

17.2.8.6.20 Set the SRG Clock Mode (choose an input clock)

SCLKME bit (PCR_REG[7]) and CLKSM bit (SRGR2_REG[13]) are used to set the SRG clock mode.

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock.

17.2.8.6.21 Set the SRG Input Clock Polarity

CLKSP bit (SRGR2_REG[14]), CLKXP bit (PCR_REG[1]) and CLKRP bit (PCR_REG[0]) are used to set the SRG input clock polarity.

The sample rate generator can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the sample rate generator must be driven by an input clock signal derived from the McBSP_FCLK clock or from an external clock on the McBSP.CLKS, McBSP.CLKX, or McBSP.CLKR pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKSP for the McBSP.CLKS pin, CLKXP for the McBSP.CLKX pin, CLKRP for the McBSP.CLKR pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

17.2.8.7 General-Purpose I/O on the McBSP Pins (legacy only)

Table 17-18 summarizes how to use the McBSP pins as general-purpose I/O pins. All of the bits mentioned in the table except XRST and RRST bits are in the pin control register (PCR_REG). XRST and RRST are in the serial port control registers (SPCR2_REG[0] and SPCR1_REG[0], respectively).

To use receiver pins McBSP.CLKR, McBSP.FSR, and McBSP.DR as general-purpose I/O pins rather than as serial port pins, you must set two conditions:

1. The receiver of the serial port is in reset (SPCR1_REG[0] RRST bit = 0).
2. General-purpose I/O is enabled for the serial port receiver (RIOEN = 1 in PCR_REG[12]).

The McBSP.CLKR and McBSP.FSR pins can be individually configured as either input or output pins with the CLKRM and FSRM bits, respectively. The McBSP.DR pin can only be an input pin. The following table shows, which bits in PCR_REG are used to read from/write to these pins.

For the transmitter pins McBSP.CLKX, McBSP.FSX, and McBSP.DX, you must meet two conditions:

1. The transmitter of the serial port is in reset (XRST = 0 in SPCR2_REG[0]).
2. General-purpose I/O is enabled for the serial port transmitter (XIOEN = 1 in PCR_REG[12]).

The McBSP.CLKX and McBSP.FSX pins can be individually configured as input or output pins with the CLKXM and FSXM bits, respectively. The McBSP.DX pin can only be an output pin.

For the McBSP.CLKS pin, all of the reset and I/O enable conditions must be met:

1. Both the receiver and transmitter of the serial port are in reset (RRST = 0 and XRST = 0).
2. General-purpose I/O is enabled for both the receiver and the transmitter (RIOEN = 1 and XIOEN = 1).

The McBSP.CLKS pin can only be an input pin. To read the status of the signal on the McBSP.CLKS pin, read the CLKS_STAT bit in PCR_REG.

Table 17-18. Using McBSP Pins for General-Purpose I/O

Pin	General-Purpose Use Enabled by This Bit Combination	Selected as Input When ...	Input Value Read From This Bit
McBSP.CLKX	XRST = 0 XIOEN = 1	CLKXM = 0	CLKXP
McBSP.FSX	XRST = 0 XIOEN = 1	FSXM = 0	FSXP
McBSP.DX	XRST = 0 XIOEN = 1	Never	Does not apply
McBSP.CLKR	RRST = 0 RIOEN = 1	CLKRM = 0	CLKRP
McBSP.FSR	RRST = 0 RIOEN = 1	FSRM = 0	FSRP
McBSP.DR	RRST = 0 RIOEN = 1	Always	DR_STAT
McBSP.CLKS	RRST = XRST = 0 RIOEN = XIOEN = 1	Always	CLKS_STAT

17.3 McBSP Registers

Table 17-19 lists the registers for the McBSP.

17.3.1 Revision Number Register (REVNB)

The Revision Number (REVNB) register is shown in [Figure 17-33](#) and described in [Table 17-20](#).

This read-only register contains the hard-coded revision number of the module. A write to this register has no effect.

Figure 17-33. Revision Number Register (REVNB)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-20. Revision Number Register (REVNB) Field Descriptions

Bits	Field Name	Value	Description
31-30	SCHEME	1h	Used to distinguish between old Scheme and current. Spare bit to encode future schemes.
29-28	Reserved	0	Reads return 0x1.
27-16	FUNC	8h	Function: Indicates a software compatible module family.
15-11	RTL	0h	RTL version.
10-8	MAJOR	0h	Major Revision.
7-6	CUSTOM	0h	Custom ID.
5-0	MINOR	37h	Minor Revision.

17.3.2 System Configuration Register (SYSCONFIG_REG)

The System Configuration (SYSCONFIG_REG) register is shown in [Figure 17-34](#) and described in [Table 17-21](#).

Figure 17-34. System Configuration Register (SYSCONFIG_REG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-22. End of Interrupt Register (EOI) Field Descriptions

Bits	Field Name	Value	Description
31-1	Reserved	0	Reserved.
0	LINE_NUMBER		Software End Of Interrupt (EOI) control. Write number of interrupt output. Write a value of 0 to force the output interrupt to re-assert if any enabled interrupts are pending.

17.3.4 Interrupt Status Raw Register (IRQSTATUS_RAW)

This register provides core status information for interrupt handling, showing all active events (enabled and not enabled ones). The fields are read-write. Writing a 1 to a bit will set it to 1, for example, trigger the IRQ when also enabled (mostly for debug). Writing a 0 will have no effect, for example, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

Interrupts can either be serviced using the highlander standard IRQSTATUS, IRQSTATUS_RAW, IRQENABLE_SET, and IRQENABLE_CLR set of registers, or the legacy IRQSTATUS_REG and IRQENABLE_REG registers, but not both in the same system.

The Interrupt Status Raw (IRQSTATUS_RAW) register is shown in [Figure 17-36](#) and described in [Table 17-23](#).

Figure 17-36. Interrupt Status Raw Register (IRQSTATUS_RAW)

Bits	Field Name	Value	Description
3	RRDY		Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Receive buffer occupied locations are below the THRSH1_REG value). Writing a 0 will have no effect.
		1	Receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit will set it to 1.
2	REOF		Receive End Of Frame (REOF is set to 1 when a complete frame was received). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Complete frame was NOT received. Writing a 0 will have no effect.
		1	Complete frame was received; Writing 1 to this bit will set it to 1.
1	RFSR		Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	New receive frame synchronization is NOT asserted. Writing a 0 will have no effect.
		1	New receive frame synchronization is asserted; Writing 1 to this bit will set it to 1.
0	RSYNCERR		Receive Frame Synchronization Error (RSYNCERR is set to 1 when a receive frame synchronization error is detected). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Receive frame synchronization error is NOT detected. Writing a 0 will have no effect.
		1	Receive frame synchronization error is detected. Writing 1 to this bit will set it to 1.

17.3.5 Interrupt Status Register (IRQSTATUS)

This register provides core status information for interrupt handling, showing all active and enabled events and masking the others. The fields are read-write. Writing a 1 to a bit will clear it to 0, for example, clear the IRQ. Writing a 0 will have no effect, for example, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

Interrupts can either be serviced using the highlander standard IRQSTATUS, IRQSTATUS_RAW, IRQENABLE_SET, and IRQENABLE_CLR set of registers, or the legacy IRQSTATUS_REG and IRQENABLE_REG registers, but not both in the same system.

The Interrupt Status (IRQSTATUS) register is shown in [Figure 17-37](#) and described in [Table 17-24](#).

Table 17-24. Interrupt Status Register (IRQSTATUS) Field Descriptions

Bits	Field Name	Value	Description
31-15	Reserved	0	Reserved.
14	XEMPTYEOF	0 1	Transmit Buffer Empty at end of frame (XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty). XEMPTYEOF is NOT set to when a complete frame was transmitted and the transmit buffer is empty. XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty. Writing 1 to this bit clears the bit.
13	Reserved	0	Reserved.
12	XOVFLSTAT	0 1	Transmit Buffer Overflow (XOVFLSTAT bit is set to 1 when transmit buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit. Transmit buffer NOT overflow. Transmit buffer overflow; Writing 1 to this bit clears the bit.
11	XUNDFLSTAT	0 1	Transmit Buffer Underflow (XUNDFLSTAT bit is set to 1 when the transmit data buffer is empty new data is required to be transmitted). Writing 1 to this bit clears the bit. The transmit data buffer is NOT empty new data is required to be transmitted. The transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit clears the bit.
10	XRDY	0 1	Transmit Buffer Threshold Reached (XRDY bit is set to 1 when the transmit buffer free locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit. Transmit buffer occupied locations are below the THRSH2_REG value). Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.
9	XEOF	0 1	Transmit End Of Frame (XEOF is set to 1 when a complete frame was transmitted). Writing 1 to this bit clears the bit. Complete frame was NOT transmitted. Complete frame was transmitted; Writing 1 to this bit clears the bit.

Table 17-24. Interrupt Status Register (IRQSTATUS) Field Descriptions (continued)

Bits	Field Name	Value	Description
8	XFSX	0 1	Transmit Frame Synchronization (XFSX bit is set to 1 when a new transmit frame synchronization is asserted). Writing 1 to this bit clears the bit. New transmit frame synchronization is NOT asserted. New transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.
7	XSYNCERR	0 1	Transmit Frame Synchronization Error (XSYNCERR is set to 1 when a transmit frame synchronization error is detected). Writing 1 to this bit clears the bit. Transmit frame synchronization error is NOT detected. Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.
6	Reserved	0	Reserved.
5	ROVFLSTAT	0 1	Receive Buffer Overflow (ROVFLSTAT bit is set to 1 when receive buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit. Receive buffer NOT overflow. Receive buffer overflow; Writing 1 to this bit clears the bit.
4	RUNDFLSTAT	0 1	Receive Buffer Underflow (RUNDFLSTAT bit is set to 1 when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Writing 1 to this bit clears the bit. Read operation is performed to the receive data register while receive buffer is NOT empty. Read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit.
3	RRDY	0 1	Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit. Receive buffer occupied locations are below the THRSH1_REG value). Receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
2	REOF	0 1	Receive End Of Frame (REOF is set to 1 when a complete frame was received). Writing 1 to this bit clears the bit. Complete frame was NOT received. Complete frame was received; Writing 1 to this bit clears the bit.
1	RFSR	0 1	Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted). Writing 1 to this bit clears the bit. New receive frame synchronization is NOT asserted. New receive frame synchronization is asserted; Writing 1 to this bit clears the bit.
0	RSYNCERR	0 1	Receive Frame Synchronization Error (RSYNCERR is set to 1 when a receive frame synchronization error is detected). Writing 1 to this bit clears the bit. Receive frame synchronization error is NOT detected. Receive frame synchronization error is detected. Writing 1 to this bit clears the bit.

17.3.6 Interrupt Enable Set Register (IRQENABLE_SET)

All 1-bit fields enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit will enable the field. Writing a 0 will have no effect, for example, the register value will not be modified.

Interrupts can either be serviced using the highlander standard IRQSTATUS, IRQSTATUS_RAW, IRQENABLE_SET, and IRQENABLE_CLR set of registers, or the legacy IRQSTATUS_REG and IRQENABLE_REG registers, but not both in the same system.

The Interrupt Enable Set (IRQENABLE_SET) register is shown in [Figure 17-38](#) and described in [Table 17-25](#).

Figure 17-38. Interrupt Enable Set Register (IRQENABLE_SET)

	Reserved

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-25. Interrupt Enable Set Register (IRQENABLE_SET) Field Descriptions

Bits	Field Name	Value	Description
31-15	Reserved	0	Reserved.
14	XEMPTYEOF	0	Transmit Buffer Empty at end of frame (XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty).
		1	XEMPTYEOF is NOT set to when a complete frame was transmitted and the transmit buffer is empty.
		1	XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty. Writing 1 to this bit clears the bit.
13	Reserved	0	Reserved.
12	XOVFLSTAT	0	Transmit Buffer Overflow (XOVFLSTAT bit is set to 1 when transmit buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit.
		1	Transmit buffer NOT overflow.
		1	Transmit buffer overflow; Writing 1 to this bit clears the bit.
11	XUNDFLSTAT	0	Transmit Buffer Underflow (XUNDFLSTAT bit is set to 1 when the transmit data buffer is empty new data is required to be transmitted). Writing 1 to this bit clears the bit.
		1	The transmit data buffer is NOT empty new data is required to be transmitted.
		1	The transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit clears the bit.
10	XRDY	0	Transmit Buffer Threshold Reached (XRDY bit is set to 1 when the transmit buffer free locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.
		1	Transmit buffer occupied locations are below the THRSH2_REG value).
		1	Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.
9	XEOF	0	Transmit End Of Frame (XEOF is set to 1 when a complete frame was transmitted). Writing 1 to this bit clears the bit.
		1	Complete frame was NOT transmitted.
		1	Complete frame was transmitted; Writing 1 to this bit clears the bit.
8	XFSX	0	Transmit Frame Synchronization (XFSX bit is set to 1 when a new transmit frame synchronization is asserted). Writing 1 to this bit clears the bit.
		1	New transmit frame synchronization is NOT asserted.
		1	New transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.

Table 17-25. Interrupt Enable Set Register (IRQENABLE_SET) Field Descriptions (continued)

Bits	Field Name	Value	Description
7	XSYNCERR		Transmit Frame Synchronization Error (XSYNCERR is set to 1 when a transmit frame synchronization error is detected). Writing 1 to this bit clears the bit.
		0	Transmit frame synchronization error is NOT detected.
		1	Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.
6	Reserved	0	Reserved.
5	ROVFLSTAT		Receive Buffer Overflow (ROVFLSTAT bit is set to 1 when receive buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit.
		0	Receive buffer NOT overflow.
		1	Receive buffer overflow; Writing 1 to this bit clears the bit.
4	RUNDFLSTAT		Receive Buffer Underflow (RUNDFLSTAT bit is set to 1 when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Writing 1 to this bit clears the bit.
		0	Read operation is performed to the receive data register while receive buffer is NOT empty.
		1	Read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit.
3	RRDY		Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
		0	Receive buffer occupied locations are below the THRSH1_REG value).
		1	Receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
2	REOF		Receive End Of Frame (REOF is set to 1 when a complete frame was received). Writing 1 to this bit clears the bit.
		0	Complete frame was NOT received.
		1	Complete frame was received; Writing 1 to this bit clears the bit.
1	RFSR		Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted). Writing 1 to this bit clears the bit.
		0	New receive frame synchronization is NOT asserted.
		1	New receive frame synchronization is asserted; Writing 1 to this bit clears the bit.
0	RSYNCERR		Receive Frame Synchronization Error (RSYNCERR is set to 1 when a receive frame synchronization error is detected). Writing 1 to this bit clears the bit.
		0	Receive frame synchronization error is NOT detected.
		1	Receive frame synchronization error is detected. Writing 1 to this bit clears the bit.

17.3.7 Interrupt Enable Clear Register (IRQENABLE_CLR)

All 1-bit fields clear a specific interrupt event. Writing a 1 to a bit will disable the interrupt field. Writing a 0 will have no effect, for example, the register value will not be modified.

Interrupts can either be serviced using the highlander standard IRQSTATUS, IRQSTATUS_RAW, IRQENABLE_SET, and IRQENABLE_CLR set of registers, or the legacy IRQSTATUS_REG and IRQENABLE_REG registers, but not both in the same system.

The Interrupt Enable Clear (IRQENABLE_CLR) register is shown in [Figure 17-39](#) and described in [Table 17-26](#).

XEMPTYEOF is NOT set to when a complete frame was transmitted and the transmit buffer is empty. XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty. Writing 1 to this bit clears the bit.
13	Reserved	0	Reserved.
12	XOVFLSTAT	0 1	Transmit Buffer Overflow (XOVFLSTAT bit is set to 1 when transmit buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit. Transmit buffer NOT overflow. Transmit buffer overflow; Writing 1 to this bit clears the bit.
11	XUNDFLSTAT	0 1	Transmit Buffer Underflow (XUNDFLSTAT bit is set to 1 when the transmit data buffer is empty new data is required to be transmitted). Writing 1 to this bit clears the bit. The transmit data buffer is NOT empty new data is required to be transmitted. The transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit clears the bit.
10	XRDY	0 1	Transmit Buffer Threshold Reached (XRDY bit is set to 1 when the transmit buffer free locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit. Transmit buffer occupied locations are below the THRSH2_REG value). Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.
9	XEOF	0 1	Transmit End Of Frame (XEOF is set to 1 when a complete frame was transmitted). Writing 1 to this bit clears the bit. Complete frame was NOT transmitted. Complete frame was transmitted; Writing 1 to this bit clears the bit.

Table 17-26. Interrupt Enable Clear Register (IRQENABLE_CLR) Field Descriptions (continued)

Bits	Field Name	Value	Description
8	XFSX		Transmit Frame Synchronization (XFSX bit is set to 1 when a new transmit frame synchronization is asserted). Writing 1 to this bit clears the bit.
		0	New transmit frame synchronization is NOT asserted.
		1	New transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.
7	XSYNCERR		Transmit Frame Synchronization Error (XSYNCERR is set to 1 when a transmit frame synchronization error is detected). Writing 1 to this bit clears the bit.
		0	Transmit frame synchronization error is NOT detected.
		1	Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.
6	Reserved	0	Reserved.
5	ROVFLSTAT		Receive Buffer Overflow (ROVFLSTAT bit is set to 1 when receive buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit.
		0	Receive buffer NOT overflow.
		1	Receive buffer overflow; Writing 1 to this bit clears the bit.
4	RUNDFLSTAT		Receive Buffer Underflow (RUNDFLSTAT bit is set to 1 when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Writing 1 to this bit clears the bit.
		0	Read operation is performed to the receive data register while receive buffer is NOT empty.
		1	Read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit.
3	RRDY		Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
		0	Receive buffer occupied locations are below the THRSH1_REG value).
		1	Receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
2	REOF		Receive End Of Frame (REOF is set to 1 when a complete frame was received). Writing 1 to this bit clears the bit.
		0	Complete frame was NOT received.
		1	Complete frame was received; Writing 1 to this bit clears the bit.
1	RFSR		Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted). Writing 1 to this bit clears the bit.
		0	New receive frame synchronization is NOT asserted.
		1	New receive frame synchronization is asserted; Writing 1 to this bit clears the bit.
0	RSYNCERR		Receive Frame Synchronization Error (RSYNCERR is set to 1 when a receive frame synchronization error is detected). Writing 1 to this bit clears the bit.
		0	Receive frame synchronization error is NOT detected.
		1	Receive frame synchronization error is detected. Writing 1 to this bit clears the bit.

17.3.8 DMA Rx Enable Set Register (DMARXENABLE_SET)

The 1-bit field enables a Receive DMA request. Writing a 1 to this field will set it to 1. Writing a 0 will have no effect, for example, the register value is not modified. Note that the RCCR_REG.RDMAEN field is the global (slave) DMA enabler, and that it is disabled by default. The field RCCR_REG.RDMAEN should also be set to 1 to enable a Receive DMA Request.

The DMA Rx Enable Set (DMARXENABLE_SET) register is shown in [Figure 17-40](#) and described in [Table 17-27](#).

Figure 17-40. DMA Rx Enable Set Register (DMARXENABLE_SET)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-27. DMA Rx Enable Set Register (DMARXENABLE_SET) Field Descriptions

Bits	Field Name	Value	Description
31-1	Reserved	0	Reserved.
0	DMARX_ENABLE_SET		Receive DMA channel enable set.

17.3.9 DMA Tx Enable Set Register (DMATXENABLE_SET)

The 1-bit field enables a Transmit DMA request. Writing a 1 to this field will set it to 1. Writing a 0 will have no effect, for example, the register value is not modified. Note that the XCCR_REG.XDMAEN field is the global (slave) DMA enabler, and that it is disabled by default. The field XCCR_REG.XDMAEN should also be set to 1 to enable a Transmit DMA Request.

The DMA Tx Enable Set (DMATXENABLE_SET) register is shown in [Figure 17-41](#) and described in [Table 17-28](#).

Figure 17-41. DMA Tx Enable Set Register (DMATXENABLE_SET)

Bits	Field Name	Value	Description
31-1	Reserved	0	Reserved.
0	DMATX_ENABLE_SET		Transmit DMA channel enable set.

17.3.10 DMA Rx Enable Clear Register (DMARXENABLE_CLR)

The 1-bit field disables a Receive DMA request. Writing a 1 to a bit will clear it to 0. Another result of setting to '1' the DMARX_ENABLE_CLEAR field, is the reset of the DMA RX request and wakeup lines. Writing a 0 will have no effect, for example, the register value is not modified.

The DMA Rx Enable Clear (DMARXENABLE_CLR) register is shown in [Figure 17-42](#) and described in [Table 17-29](#).

Figure 17-42. DMA Rx Enable Clear Register (DMARXENABLE_CLR)

17.3.14 McBSP Data Receive Register (DRR_REG)

The McBSP_DRR_REG register is shown in [Figure 17-46](#) and described in [Table 17-33](#).

Figure 17-46. McBSP_DRR_REG

LEGEND: R = Read only; -n = value after reset

Table 17-33. McBSP_DRR_REG Field Descriptions

Bits	Field Name	Value	Description
31-0	DRR	0	Data receive register.

17.3.15 McBSP Data Transmit Register (DXR_REG)

The McBSP_DXREG register is shown in [Figure 17-47](#) and described in [Table 17-34](#).

Figure 17-47. McBSP_DXREG

LEGEND: W = Write only; -n = value after reset

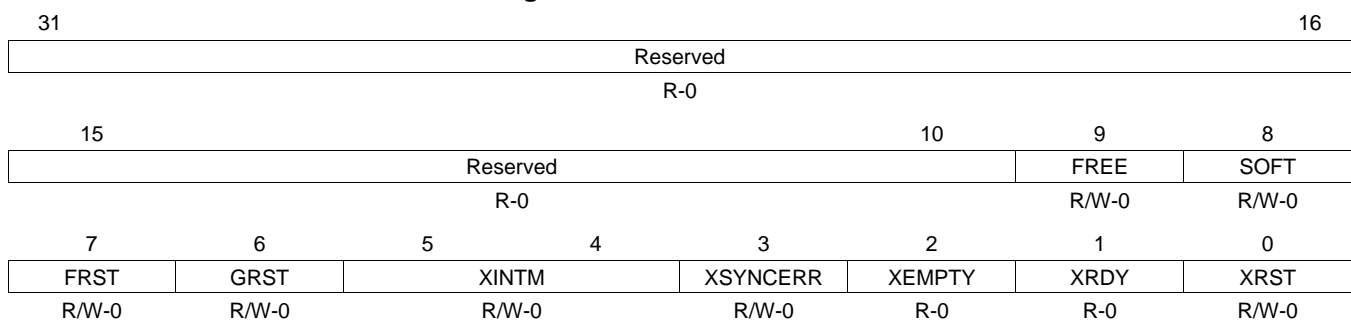

Table 17-34. McBSP_DXREG Field Descriptions

Bits	Field Name	Value	Description
31-0	DXR	0	Data transmit register.

17.3.16 McBSP Serial Port Control Register 2 (SPCR2_REG)

The McBSP_SPCR2_REG register is shown in [Figure 17-48](#) and described in [Table 17-35](#).

Figure 17-48. McBSP_SPCR2_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

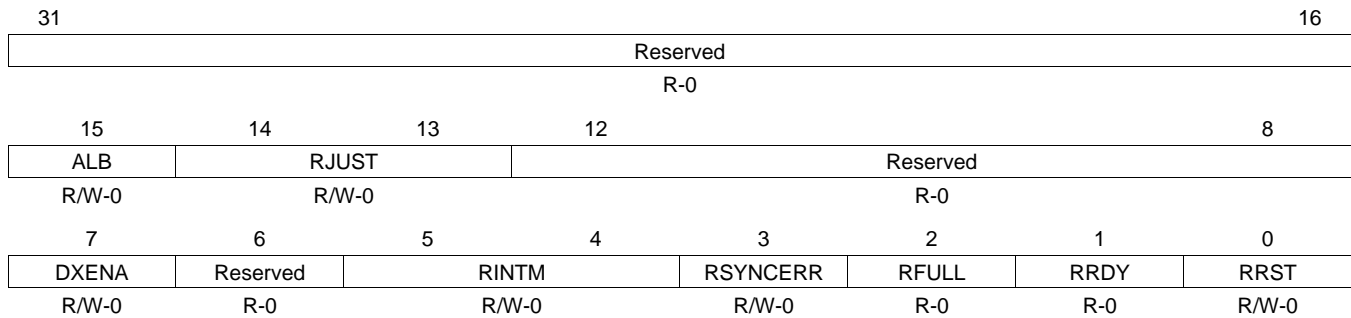

Table 17-35. McBSP_SPCR2_REG Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	FREE	0	Free Running Mode (When this bit is set, the module ignores the Msuspend input)
		0	Free running mode is disabled
		1	Free running mode is enabled
8	SOFT	0	Soft bit. SOFT Mode is disabled: the McBSP module stops its activity immediately following MSuspend assertion.
		1	SOFT Mode is enabled: the McBSP module freezes its state after completion of the current operation when MSuspend is asserted.
7	FRST	0	Frame-Synchronization Generator Reset. Frame-Synchronization logic is reset. Frame-Synchronization signal FSG is not generated by the sample-rate generator.
		1	Frame-Synchronization signal FSG is generated after (FPER+1) number of CLKG clocks; all frame counters are loaded with their programmed values.
6	GRST	0	Sample-Rate Generator Reset. SRG is reset.
		1	SRG is pulled out of reset. CLKG is driven as per programmed value in SRG registers (SRGR[1,2])
5-4	XINTM	0	Transmit Interrupt Mode (legacy). Transmit interrupt is driven by XRDY.
		1h	Transmit interrupt generated by end-of-frame.
		2h	Transmit interrupt generated by a new frame synchronization.
		3h	Transmit interrupt generated by XSYNCERR.
3	XSYNCERR	0	Transmit Synchronization Error. (Writing 0 to this bit clear the legacy transmit interrupt if asserted due to XSYNCERROR condition). No synchronization error.
		1	Synchronization error detected by McBSP.
2	XEMPTY	0	Transmit Shift Register XSR Empty. XSR is empty.
		1	XSR is not empty.
1	XRDY	0	Transmitter ready. Transmitter is not ready.
		1	Transmitter is ready for new data in DXR.
0	XRST	0	Transmitter reset. This resets and enables the transmitter. The serial port transmitter is disabled and in reset state.
		1	The serial port transmitter is enabled.

17.3.17 McBSP Serial Port Control Register 1 (SPCR1_REG)

The McBSP_SPCR1_REG register is shown in [Figure 17-49](#) and described in [Table 17-36](#).

Figure 17-49. McBSP_SPCR1_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-36. McBSP_SPCR1_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15	ALB	0	Analog loopback mode disabled.
		1	Analog loopback mode enabled.
			Analog loopback Mode.
14-13	RJUST	0	Receive Sign-Extension and Justification Mode. Right-justify and zero-fill MSBs in DRR.
		1h	Right-justify and sign-extend MSBs in DRR.
		2h	Left-justify and zero-fill LSBs in DRR.
		3h	Reserved.
12-8	Reserved	0	Reserved
7	DXENA	0	DX Enabler. DX enabler is off.
		1	DX enabler is on.
6	Reserved	0	Reserved
5-4	RINTM	0	Receive Interrupt Mode (legacy). Receive Interrupt driven by RRDY (end of word) and end of frame in A-bis mode.
		1h	Receive Interrupt generated by end-of-block or end-of-frame in multichannel operation.
		2h	Receive Interrupt generated by a new frame synchronization.
		3h	Receive Interrupt generated by RSYNCERR.
3	RSYNCERR	0	Receive Synchronization Error. (Writing 0 to this bit clear the legacy receive interrupt if asserted due to RSYNCERROR condition). No synchronization error.
		1	Synchronization error detected by McBSP.
2	RFULL	0	Receive Shift Register (RSR [1,2]) Full. RB is not in overrun condition.
		1	DRR is not read, RB is full and RSR is also full with new word.
1	RRDY	0	Receiver Ready. Receiver is not ready.
		1	Receiver is ready with data to be read from DRR.
0	RRST	0	Receiver reset. This resets and enables the receiver. The serial port receiver is disabled and in reset state.
		1	The serial port receiver is enabled.

17.3.18 McBSP Receive Control Register 2 (RCR2_REG)

The McBSP_RCR2_REG register is shown in [Figure 17-50](#) and described in [Table 17-37](#).

Figure 17-50. McBSP_RCR2_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-37. McBSP_RCR2_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	RPHASE	0 1	Receive Phases. 0 Single-phase frame. 1 Dual-phase frame.
14-8	RFRLN2		Receive Frame Length 2 Single-phase frame selected: RFRLN2 = don't care. Dual-phase frame selected: RFRLN2 = 000 0000 - 1 word per second phase (other values are reserved).
7-5	RWDLEN2	0 1h 2h 3h 4h 5h 6h-7h	Receive Word Length 2. 0 8 bits 1h 12 bits 2h 16 bits 3h 20 bits 4h 24 bits 5h 32 bits 6h-7h Reserved (do not use)
4-3	RREVERSE	0 1h 2h-3h	Receive reverse mode. 0 Data transfer starts with MSB first. 1h Data transfer starts with LSB first. 2h-3h Reserved (do not use)
2	Reserved	0	Reserved
1-0	RDATDLY	0 1h 2h 3h	Receive Data Delay 0 0-bit data delay 1h 1-bit data delay 2h 2-bit data delay 3h Reserved

17.3.19 McBSP Receive Control Register 1 (RCR1_REG)

The McBSP_RCR1_REG register is shown in [Figure 17-51](#) and described in [Table 17-38](#).

Figure 17-51. McBSP_RCR1_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-38. McBSP_RCR1_REG Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved
14-8	RFRLN1		Receive Frame Length 1. Single-phase frame selected: RFRLN1 = 000 0000 - 1 word per frame RFRLN1 = 000 0001 - 2 words per frame. RFRLN1 = 111 1111 - 128 words per frame. Dual-phase frame selected: RFRLN1 = 000 0000 - 1 word per phase (other values are reserved).
7-5	RWDLEN1	0 1h 2h 3h 4h 5h 6h-7h	Receive Word Length 1 8 bits 12 bits 16 bits 20 bits 24 bits 32 bits Reserved (do not use).
4-0	Reserved	0	Reserved

17.3.20 McBSP Transmit Control Register 2 (XCR2_REG)

The McBSP_XCR2_REG register is shown in [Figure 17-52](#) and described in [Table 17-39](#).

Figure 17-52. McBSP_XCR2_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-39. McBSP_XCR2_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	XPHASE	0 1	Transmit Phases. 0 Single-phase frame. 1 Dual-phase frame.
14-8	XFRLEN2		Transmit Frame Length 2. Single-phase frame selected: XFRLEN2 = don't care. Dual-phase frame selected: XFRLEN2 = 000 0000 - 1 word per second phase (other values are reserved).
7-5	XWDLEN2	0 1h 2h 3h 4h 5h 6h-7h	Transmit Word Length 2 0 8 bits 1h 12 bits 2h 16 bits 3h 20 bits 4h 24 bits 5h 32 bits 6h-7h Reserved (do not use)
4-3	XREVERSE	0 1h 2h-3h	Transmit reverse mode. 0 Data transfer starts with MSB first. 1h Data transfer starts with LSB first. 2h-3h Reserved (do not use).
2	Reserved	0	Reserved
1-0	XDATDLY	0 1h 2h 3h	Transmit Data Delay 0 0-bit data delay 1h 1-bit data delay 2h 2-bit data delay 3h Reserved

17.3.21 McBSP Transmit Control Register 1 (XCR1_REG)

The McBSP_XCR1_REG register is shown in [Figure 17-53](#) and described in [Table 17-40](#).

Figure 17-53. McBSP_XCR1_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

31-15	Reserved	0	Reserved
14-8	XFRLLEN1		Transmit Frame Length 1 Single-phase frame selected: XFRLLEN1 = 000 0000 - 1 word per frame. XFRLLEN1 = 000 0001 - 2 words per frame. XFRLLEN1 = 111 1111 - 128 words per frame. Dual-phase frame selected: XFRLLEN1 = 000 0000 - 1 word per phase (other values are reserved).
7-5	XWDLEN1	0 1h 2h 3h 4h 5h 6h-7h	Transmit Word Length 1 8 bits 12 bits 16 bits 20 bits 24 bits 32 bits Reserved (do not use)
4-0	Reserved	0	Reserved

17.3.22 McBSP Sample Rate Generator Register 2 (SRGR2_REG)

The McBSP_SRGR2_REG register is shown in [Figure 17-54](#) and described in [Table 17-41](#).

Figure 17-54. McBSP_SRGR2_REG

Reserved						
R-0						
31	15	14	13	12	11	0
GSYNC		CLKSP	CLKSM	FSGM	FPER	
R/W-0		R/W-0	R/W-1	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-41. McBSP_SRGR2_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	GSYNC	0 1	Sample Rate Generator (SRG) Synchronization Only used when the external clock (CLKS) drives the SRG clock (CLKSM=0). The SRG clock (CLKG) is free running. The SRG clock (CLKG) is running, but CLKG is resynchronized and frame-synchronization signal (FSG) is generated only after detecting the receive frame-synchronization signal (FSR). Also, frame period, FPER, is a don't care because the period is dictated by the external frame-synchronization pulse.
14	CLKSP	0 1	CLKS Polarity Clock Edge Select Only used when the external clock CLKS drives the SRG clock (CLKSM=0). Rising edge of CLKG and FSG. Falling edge of CLKG and FSG.
13	CLKSM	0 1	McBSP SRG Clock Mode SCLKME = 0: SRG clock derived from the CLKS pin. SCLKME = 1: SRG clock derived from the the CLKRI pin. SCLKME = 0: SRG clock derived from the OCP clock. SCLKME = 1: SRG clock derived from the CLKXI pin.
12	FSGM	0 1	Sample Rate Generator Transmit Frame-Synchronization Mode. Used when FSXM=1 in the PCR. Transmit frame-synchronization signal (FSX) is generated when transmit buffer is not empty. When FSGM = 0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition). Transmit frame-synchronization signal driven by the SRG frame-synchronization signal, FSG.
11-0	FPER	0-FFFh	Frame Period. This value + 1 determines when the next frame-synchronization signal becomes active. Range: 1 to 4096 CLKG periods.

17.3.23 McBSP Sample Rate Generator Register 1 (SRGR1_REG)

The McBSP_SRGR1_REG register is shown in [Figure 17-55](#) and described in [Table 17-42](#).

Figure 17-55. McBSP_SRGR1_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-42. McBSP_SRGR1_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-8	FWID	0-FFh	Frame Width. This value + 1 determines the width of the frame-synchronization pulse, FSG, during its active period. Range: 1 to 256 CLKG periods.
7-0	CLKGDV	1-FFh	Sample Rate Generator Clock Divider. This value is used as the divide-down number to generate the required SRG clock frequency. Default value is 1.

17.3.24 McBSP Multichannel Register 2 (MCR2_REG)

The McBSP_MCR2_REG register is shown in Figure 17-56 and described in Table 17-43.

Figure 17-56. McBSP_MCR2_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-43. McBSP_MCR2_REG Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	XMCME	0	<p>XMCME Transmit multichannel partition mode bit 0.</p> <p>XMCME is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is non-zero).</p> <p>XMCME determines whether only 32 channels or all 128 channels are to be individually selectable.</p> <p>2-partition mode (legacy only):</p> <p>Only partitions A and B are used. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bits.</p> <p>If XMCM = 01b or 10b, assign 16 channels to partition A with the XPABLK bits. Assign 16 channels to partition B with the XPBBLK bits.</p> <p>If XMCM = 11b (for symmetric transmission and reception), assign 16 channels to receive partition A with the RPABLK bits. Assign 16 channels to receive partition B with the RPBBLK bits</p> <p>You control the channels with the appropriate transmit channel enable registers:</p> <p>XCERA: Channels in partition A.</p> <p>XCERB: Channels in partition B.</p>
		1	<p>8-partition mode:</p> <p>All partitions (A through H) are used. 8-7	XPBBLK	0	Transmit Partition B Block (legacy only)
		1h	Block 1. Channel 16 to channel 31
		2h	Block 3. Channel 48 to channel 63
		3h	Block 5. Channel 80 to channel 95
		3h	Block 7. Channel 112 to channel 127
6-5	XPABLK	0	Transmit Partition A Block (legacy only)
		1h	Block 0. Channel 0 to channel 15
		2h	Block 2. Channel 32 to channel 47
		3h	Block 4. Channel 64 to channel 79
		3h	Block 6. Channel 96 to channel 111

Table 17-43. McBSP_MCR2_REG Field Descriptions (continued)

Bit	Field	Value	Description
4-2	Reserved	0	Reserved
1-0	XMCM	0 1h 2h 3h	Transmit Multichannel Selection Enable All channels enabled without masking (DX is always driven during transmission of data). All channels disabled and therefore masked by default. Required channels are selected by enabling XP(A/B)BLK and XCER(A/B) appropriately. Also, these selected channels are not masked and therefore DX is always driven. All channels enabled, but masked. Selected channels enabled via XP(A/B)BLK and XCER(A/B) are unmasked. All channels disabled and therefore masked by default. Required channels are selected by enabling RP(A/B)BLK and RCER(A/B) appropriately. Selected channels can be unmasked by RP(A/B)BLK and XCER(A/B). This mode is used for symmetric transmit and receive operation.

17.3.25 McBSP Multichannel Register 1 (MCR1_REG)

The McBSP_MCR1_REG register is shown in Figure 17-57 and described in Table 17-44.

Figure 17-57. McBSP_MCR1_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-44. McBSP_MCR1_REG Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	RMCME	0	<p>RMCME Receive multichannel partition mode bit 0. Receive multichannel partition mode determines whether only 32 channels or all 128 channels are to be individually selectable. RMCME is only applicable if channels can be individually enabled or disabled for reception (RMCM = 1).</p> <p>2-partition mode (legacy only).</p> <p>Only partitions A and B are used. You can control up to 32 channels in the receive multichannel selection mode (RMCM = 1).</p> <p>Assign 16 channels to partition A with the RPABLK bits. LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-49. McBSP_PCR_REG Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved.
14	IDLE_EN	0 1	Idle enable (legacy only). This bit allows stopping all the clocks in the McBSP module. (legacy) 0 The McBSP is running 1 The clocks in the McBSP are shut off when both IDLE_EN = 1 and this power domain is in idle mode (Force idle or Smart idle)
13	XIOEN	0 1	Transmit General Purpose I/O Mode only when XRST = 0 in SPCR[1,2]. (legacy only) 0 DX, FSX and CLKX are configured as serial port pins and do not function as general-purpose I/Os. 1 DX pin is a general purpose output. FSX and CLKX are general purpose I/Os. These serial port pins do not perform serial port operation.
12	RIOEN	0 1	Receive General Purpose I/O Mode when RRST = 0 in SPCR[1,2]. (legacy) 0 DR, FSR, CLKR and CLKS are configured as serial port pins and do not function as general-purpose I/Os. 1 DR and CLKS pins are general purpose inputs; FSR and CLKR are general purpose I/Os. These serial port pins do not perform serial port operation. The CLKS pin is affected by a combination of RRST and RIOEN signals of the receiver.
11	FSXM	0 1	Transmit Frame-Synchronization Mode. 0 Frame-synchronization signal derived from an external source. 1 Frame synchronization is determined by the SRG frame-synchronization mode bit FSGM in SRGR2.
10	FSRM	0 1	Receive Frame-Synchronization Mode. 0 Frame-Synchronization pulses generated by an external device. FSR is an input pin. 1 Frame synchronization generated internally by SRG. FSR is an output pin except when GSYNC=1 in SRGR.
9	CLKXM	0 1	Transmitter Clock Mode. When digital loop-back mode set (McBSPi.McBSP_XCCR_REG[5] DLB = 1), CLKXM bit is ignored. The internal transmit clock (not the mcbspi_clkx pin) is driven by the internal SRG and mcbspi_clkx pin is in high-impedance. 0 Transmitter clock is driven by an external clock with CLKX as an input pin. 1 CLKX is an output pin and is driven by the internal SRG.

Table 17-49. McBSP_PCR_REG Field Descriptions (continued)

Bit	Field	Value	Description
8	CLKRM	0	Receiver Clock Mode. Case 1: Analog loop back mode not set (ALB = 0) in SPCR1: Receive clock (CLKR) is an input driven by an external clock. Case 2: Analog loop back mode set (ALB = 1) in SPCR1: Receive clock (not the CLKR pin) is driven by transmit clock (CLKX), which is based on the CLKXM bit in the PCR. CLKR pin is in high-impedance.
		1	Case 1: Analog loop back mode not set (ALB = 0) in SPCR1: CLKR is an output pin and is driven by the internal sample rate generator. Case 2: Analog loop back mode set (ALB = 1) in SPCR1: CLKR is an output pin and is driven by the transmit clock. The transmit clock is derived based on the CLKRM bit in the PCR.
7	SCLKME	0	SCLKME Sample rate generator input clock mode bit 0. The sample rate generator can produce a clock signal, CLKG. The frequency of CLKG is: $CLKG \text{ frequency} = (\text{Input clock frequency}) / (\text{CLKGDV} + 1)$ SCLKME is used in conjunction with the CLKSM bit to select the input clock: CLKSM = 0: Signal on CLKS pin. CLKSM = 1: McBSP_OCP clock.
		1	CLKSM = 0: Signal on CLKR pin. CLKSM = 1: Signal on CLKX pin.
6	CLKS_STAT	0	CLKS pin status. Reflects value on CLKS pin when selected as a general purpose input. (legacy) The signal on the CLKS pin is low.
		1	The signal on the CLKS pin is high.
5	DX_STAT	0	DX pin status. Reflects value driven on to DX pin when selected as a general purpose output. (legacy) Drive the signal on the DX pin low.
		1	Drive the signal on the DX pin high.
4	DR_STAT	0	DR pin status. Reflects value on DR pin when selected as a general purpose input. (legacy) The signal on DR pin is low.
		1	The signal on DR pin is high.
3	FSXP	0	Transmit Frame-Synchronization Polarity. Frame-synchronization pulse FSX is active high.
		1	Frame-synchronization pulse FSX is active low.
2	FSRP	0	Receive Frame-Synchronization Polarity. Frame-synchronization pulse FSR is active high.
		1	Frame-synchronization pulse FSR is active low.
1	CLKXP	0	Transmit Clock Polarity. Transmit data driven on rising edge of CLKX.
		1	Transmit data driven on falling edge of CLKX.
0	CLKRP	0	Receive Clock Polarity. Receive data sampled on falling edge of CLKR.
		1	Receive data sampled on rising edge of CLKR.

17.3.31 McBSP Receive Channel Enable Register Partition C (RCERC_REG)

The McBSP_RCERC_REG register is shown in [Figure 17-63](#) and described in [Table 17-50](#).

Figure 17-63. McBSP_RCERC_REG

15-0	XCERH		Transmit Channel Enable. XCERH n = 0. Disables transmission of n-th channel in block in partition H. XCERH n = 1. Enables transmission of n-th channel in block in partition H.

17.3.43 McBSP Transmit Buffer Threshold Register (DMA or IRQ Trigger) (THRSH2_REG)

The McBSP_THRSH2_REG register is shown in [Figure 17-75](#) and described in [Table 17-62](#).

Figure 17-75. McBSP_THRSH2_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-62. McBSP_THRSH2_REG Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reserved
11-0	XTHRESHOLD		Transmit buffer threshold value. The DMA request (if enabled) of interrupt assertion (if enabled) will be triggered if the number of free locations inside transmit buffer are above or equal to the XTHRESHOLD value + 1. Also, this value (XTHRESHOLD value + 1) indicates the number of words transferred during a transmit data DMA request, if transmit DMA is enabled.

17.3.44 McBSP Receive Buffer Threshold Register (DMA or IRQ trigger) (THRSH1_REG)

The McBSP_THRSH1_REG register is shown in [Figure 17-76](#) and described in [Table 17-63](#).

Figure 17-76. McBSP_THRSH1_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-64. McBSP_IRQSTATUS_REG Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved
14	XEMPTYEOF	0 1	Transmit Buffer Empty at end of frame (XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty). Transmit buffer NOT Empty at end of frame. Transmit buffer Empty at end of frame; Writing 1 to this bit clears the bit.
13	Reserved	0	Reserved.
12	XOVFLSTAT	0 1	Transmit Buffer Overflow (XOVFLSTAT bit is set to 1 when transmit buffer overflow; the data which is written while overflow condition is discarded). Transmit buffer NOT overflow. Transmit buffer overflow; Writing 1 to this bit clears the bit.
11	XUNDFLSTAT	0 1	Transmit Buffer Underflow (XUNDFLSTAT bit is set to 1 when the transmit data buffer is empty new data is required to be transmitted). The transmit data buffer is NOT empty new data is required to be transmitted. The transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit clears the bit.
10	XRDY	0 1	Transmit Buffer Threshold Reached (XRDY bit is set to 1 when the transmit buffer free locations are equal or above the THRSH2_REG value). Transmit buffer occupied locations are below the THRSH2_REG value). Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.
9	XEOF	0 1	Transmit End Of Frame (XEOF is set to 1 when a complete frame was transmitted). Complete frame was NOT transmitted. Complete frame was transmitted; Writing 1 to this bit clears the bit.
8	XFSX	0 1	Transmit Frame Synchronization (XFSX bit is set to 1 when a new transmit frame synchronization is asserted). New transmit frame synchronization is NOT asserted. New transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.
7	XSYNCERR	0 1	Transmit Frame Synchronization Error (XSYNCERR is set to 1 when a transmit frame synchronization error is detected). Transmit frame synchronization error is NOT detected. Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.
6	Reserved	0	Reserved.

Table 17-64. McBSP_IRQSTATUS_REG Field Descriptions (continued)

Bit	Field	Value	Description
5	ROVFLSTAT	0 1	Receive Buffer Overflow (ROVFLSTAT bit is set to 1 when receive buffer overflow; the data which is written while overflow condition is discarded). Receive buffer NOT overflow. Receive buffer overflow; Writing 1 to this bit clears the bit.
4	RUNDFLSTAT	0 1	Receive Buffer Underflow (RUNDFLSTAT bit is set to 1 when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Read operation is performed to the receive data register while receive buffer is NOT empty. Read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit.
3	RRDY	0 1	Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the THRSH1_REG value). Receive buffer occupied locations are below the THRSH1_REG value). Receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
2	REOF	0 1	Receive End Of Frame (REOF is set to 1 when a complete frame was received). Writing 1 to this bit clears the bit. Complete frame was NOT received. Complete frame was received; Writing 1 to this bit clears the bit.
1	RFSR	0 1	Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted). New receive frame synchronization is NOT asserted. New receive frame synchronization is asserted; Writing 1 to this bit clears the bit.
0	RSYNCERR	0 1	Receive Frame Synchronization Error (RSYNCERR is set RW 0x0 to 1 when a receive frame synchronization error is detected). Receive frame synchronization error is NOT detected. Receive frame synchronization error is detected. Writing 1 to this bit clears the bit.

17.3.46 McBSP Interrupt Enable Register (OCP compliant IRQ line) (IRQENABLE)

The McBSP_IRQENABLE_REG register is shown in Figure 17-78 and described in Table 17-65.

		0	Receive Frame Synchronization Error WK enable bit.

17.3.48 McBSP Transmit Configuration Control Register (XCCR_REG)

The McBSP_XCCR_REG register is shown in [Figure 17-80](#) and described in [Table 17-67](#).

Figure 17-80. McBSP_XCCR_REG

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-67. McBSP_XCCR_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15	EXTCLKGATE	0 1	External clock gating enable (CLKX and FSX master only). When this bit is set and the transmit clock and FSX are set as output, the CLKX is enabled when FSX is active plus 3 clock cycles after (clock is provided for FWID + 4 clock cycles, assuming that the FSX width, active, is FWID + 1 clock cycles); outside this window the external transmit clock is gated. The receive uses the same gated transmit clock and transmit frame synchronization signals regardless of the CLKRM/FSRM settings. When using this mode the frame synchronization signal must be active during reception of the entire frame (FWID must be programmed accordingly) to ensure the proper receive process, which requires at least 3 cycles after the frame complete to transfer the data into the receive buffer. 0 External clock gating disabled. 1 External clock gating enable.
14	PPCONNECT	0 1	Pair to pair connection. When set the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. 0 non Pair-to-pair connection. The DX pin will go to high-impedance state when there is no frame to transmit. 1 Pair-to-pair connection. When set, the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. This means the DX pin will be driven outside valid frame window. In that case, data sent by McBSP module during inactive channel are not guaranteed.
13-12	DXENDLY	0 1h 2h 3h	When McBSPi.McBSP_SPCR1_REG[7] DXENA bit is set to 1, this field selects the added delay as follow: 0 8 ns 1h 14 ns (default) 2h 20 ns 3h 28 ns
11	XFULL_CYCLE	0 1	Transmit full cycle mode select: 0 McBSP module operates in transmit half-cycle mode (transmit frame synchronization is sampled by the opposite edge of the clock used to drive transmit data). 1 McBSP module operates in transmit full-cycle mode (transmit frame synchronization is sampled by the same edge of the clock used to drive transmit data).
10-6	Reserved	0	Reserved.
5	DLB	0 1	Digital Loopback. When this bit is set the transmit FSX, CLKX and DX are connected to FSR, CLKR, DR. The outputs of the McBSP (CLKR/CLKX, FSR/FSX, DX are not enabled) 0 No DLB. 1 DLB.
4	Reserved	0	Reserved

Table 17-67. McBSP_XCCR_REG Field Descriptions (continued)

Bit	Field	Value	Description
3	XDMAEN		Transmit DMA Enable bit. When cleared to 0 this bit will gate the external transmit DMA request, without resetting the DMA state machine. It is recommended to change this bit value only during transmit reset.
		0	Will gate the external transmit DMA request.
		1	Will NOT gate the external transmit DMA request.
2-1	Reserved	0	Reserved
0	XDISABLE		Transmit Disable bit. When this bit is set the transmit process will stop at the next frame boundary.
		0	The transmit process will NOT stop at the next frame boundary.
		1	The transmit process will stop at the next frame boundary.

17.3.49 McBSP Receive Configuration Control Register (RCCR_REG)

The McBSP_RCCR_REG register is shown in [Figure 17-81](#) and described in [Table 17-68](#).

Figure 17-81. McBSP_RCCR_REG

Table 17-68. McBSP_RCCR_REG Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reserved
11	RFULL_CYCLE	0 1	Receive full cycle mode select: 0 McBSP module operates in receive half-cycle mode (receive frame synchronization is sampled by the opposite edge of the clock used to sample receive data). 1 McBSP module operates in receive full-cycle mode (receive frame synchronization is sampled by the same edge of the clock used to sample receive data).
10-4	Reserved	0	Reserved
3	RDMAEN	0 1	Receive DMA Enable bit. When cleared to 0 this bit will gate the external transmit DMA request, without resetting the DMA state machine. It is recommended to change this bit value only during receive reset. 0 When cleared to 0 this bit will gate the external transmit DMA request. 1 When set to 1 this bit will NOT gate the external transmit DMA request.
2-1	Reserved	0	Reserved
0	RDISABLE	0 1	Receive Disable bit. When this bit is set the receive process will stop at the next frame boundary. 0 The receive process will NOT stop at the next frame boundary. 1 When this bit is set the receive process will stop at the next frame boundary.

17.3.50 McBSP Transmit Buffer Status Registers (XBUFSTAT_REG)

The McBSP_XBUFSTAT_REG registers are shown in [Figure 17-82](#) and described in [Table 17-69](#).

Figure 17-82. McBSP_XBUFSTAT_REG

LEGEND: R = Read only; -n = value after reset

Table 17-69. McBSP_XBUFSTAT_REG Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	XBUFSTAT	80h	Transmit buffer status (indicates the number of free locations inside transmit buffer). The XBUFSTAT value reflects the buffer status on the OCP clock domain and it can be smaller than the real number of the free locations which are seen by the transmit state machine.

17.3.51 McBSP Receive Buffer Status Registers (RBUFSTAT_REG)

The McBSP_RBUFSTAT_REG registers are shown in [Figure 17-83](#) and described in [Table 17-70](#).

Figure 17-83. McBSP_RBUFSTAT_REG

LEGEND: R = Read only; -n = value after reset

Table 17-70. McBSP_RBUFSTAT_REG Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved.
7-0	RBUFSTAT	0	Receive Buffer Status (indicates the number of occupied locations inside receive buffer). The RBUFSTAT value reflects the buffer status on the OCP clock domain and it can be smaller than the real number of the occupied locations which are seen by the receive state machine.

17.3.52 McBSP_STATUS_REG

The McBSP_STATUS_REG register is shown in [Figure 17-84](#) and described in [Table 17-71](#).

Figure 17-84. McBSP_STATUS_REG

LEGEND: R = Read only; -n = value after reset

Table 17-71. McBSP_STATUS_REG Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	CLKMUXSTATUS		Indicates that the McBSP AUDIOBUFFER clock muxing is done after exiting SmartIdle mode. When this bit is set one the response to a different register access is delayed until the muxing process is done. In order to avoid such a situation pooling can be performed to status register in order to evaluate when McBSP is ready. Note that this information is relevant only for the McBSP having AUDIOBUFFER.

Multimedia Card (MMC)/Secure Digital (SD)/ Secure Digital I/O (SDIO) Card Interface

This chapter describes the multimedia card/secure digital/secure digital I/O (MMC/SD/SDIO) card interface.

Topic	Page
18.1 Introduction	2197
18.2 Architecture	2199
18.3 Low-Level Programming Models	2232
18.4 MMC/SD/SDIO Registers	2237

18.1 Introduction

18.1.1 Overview

This device contains a multimedia card high-speed/secure data/secure digital I/O (MMC/SD/SDIO) host controller that provides an interface between a local host (LH), and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

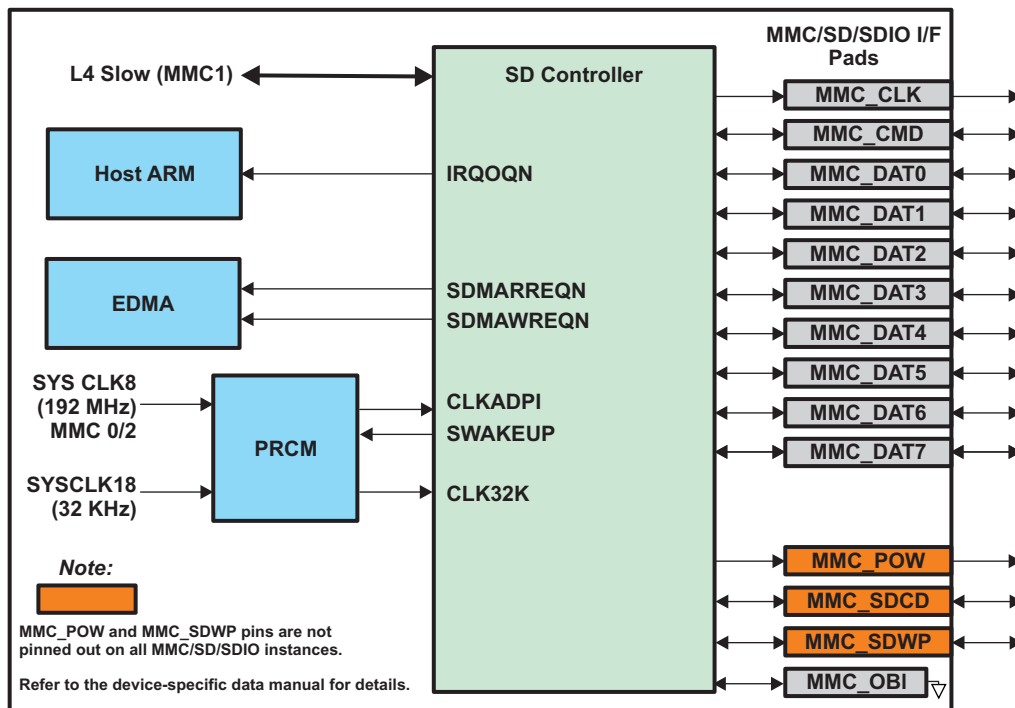

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRC), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and either poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

There are typically three MMC/SD/SDIO host controllers inside the device. [Figure 18-1](#) gives an overview of one MMC/SD/SDIO controller instance. As shown in [Figure 18-1](#), not all pins are available on each instance of the MMC/SD/SDIO peripheral. Specifically, the MMC_SDCD, MMC_SDWP, and MMC_POW may not be pinned out on all instances. In most devices MMC/SD/SDIO1 provides the most full featured connectivity.

Figure 18-1. MMC/SD/SDIO Overview

18.1.2 Features

The main features of the MMC/SD/SDIO host controller are:

- Built-in 1024-byte buffer for read or write
- Full compliance with MMC command/response sets as defined in the *Multimedia Card System Specification*, v4.3.
- Full compliance with SD command/response sets as defined in the *SD Physical Layer Specification*, v2.00.
- Full compliance with SDIO command/response sets and interrupt/read-wait mode as defined in the *SDIO Card Specification, Part E1*, v2.00
- Full compliance with SD Host Controller Standard Specification sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v2.00
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*
- Flexible architecture allowing support for new command structure
- Support:
 - 1-bit or 4-bit transfer mode specifications for SD and SDIO cards
 - 1-bit, 4-bit, or 8-bit transfer mode specifications for MMC cards
 - 1.8v or 3.3v cards (Support varies per MMC/SD/SDIO instance.)
 - Built-in 1024-byte buffer for read or write
 - 32-bit-wide access bus to maximize bus throughput
 - Single interrupt line for multiple interrupt source events
 - Two slave DMA channels (1 for TX, 1 for RX)
 - Designed for low power
 - Programmable clock generation
 - SDIO Read Wait and Suspend/Resume functions
 - Stop at block gap
 - SDA 2.0 Part A2 programming model

NOTE: The device supports both 1.8v and 3.3v cards; however, one or more MMC/SD/SDIO instances may only support 3.3V operation. In addition, on some devices, multiple MMC/SD/SDIO instances may be required to both operate at the same voltage (for example, MMC/SD/SDIO0 and MMC/SD/SDIO1 may be required to both operate at 1.8V, or both at 3.3V). On other devices, the supply voltage can be independent (for example, MMC/SD/SDIO0 may be at 1.8V while MMC/SD/SDIO1 may be at 3.3V).

Refer to the device-specific data manual power group for details.

- Supported Data Rates
 - 192 MHz functional clock source input
 - Up to 384 Mbit/sec (48MByte/sec) in MMC mode 8-bit data transfer
 - Up to 192 Mbit/sec (24MByte/sec) in High-Speed SD mode 4-bit data transfer
 - Up to 24 Mbit/sec (3MByte/sec) in Default SD mode 1-bit data transfer

18.2 Architecture

One MMC/SD/SDIO host controller can support one MMC memory card, one SD card, or one SDIO card. Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

There are up to 3 MMC/SD/SDIO instances named: HSMMC0, HSMMC1, and HSMMC2.

18.2.1 MMC/SD/SDIO Functional Modes

18.2.1.1 MMC/SD/SDIO Connected to an MMC, an SD Card, or an SDIO Card

Figure 18-2 shows the MMC/SD/SDIO host controller connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 18-2. MMC/SD Connectivity to an MMC/SD Card

The following MMC/SD/SDIO controller pins are used

- **MMC_CMD** This pin is used for two-way communication between the connected card and the MMC/SD/SDIO controller. The MMC/SD/SDIO controller transmits commands to the card and the memory card drives responses to the commands on this pin.
- **MMC_DAT7-0** Depending on which type of card you are using, you may need to connect 1, 4, or 8 data lines. The number of DAT pins (the data bus width) is set by the Data Transfer Width (DTW) bit in the MMC control register (MMCHS_HCTL). For more information, see the registers section of this document.
- **MMC_CLK** This pin provides the clock to the memory card from the MMC/SD controller.

Note: The MMC_CLK pin functions as an output but must be configured as an I/O to internally loopback the clock to time the inputs.

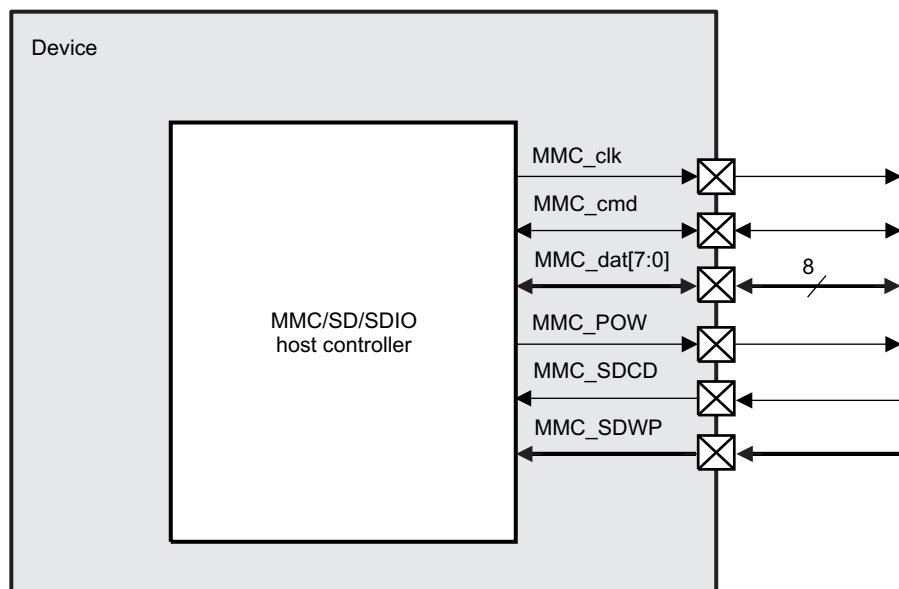

Table 18-1 provides a summary of these pins.

Table 18-1. MMC/SD/SDIO Controller Pins and Descriptions

Pin	Type	1-Bit Mode	4-Bit Mode	8-Bit Mode	Reset Value
MMC_CLK ⁽¹⁾	O	Clock Line	Clock Line	Clock Line	High impedance
MMC_CMD	I/O	Command Line	Command Line	Command Line	High impedance
MMC_DAT0	I/O	Data Line 0	Data Line 0	Data Line 0	0
MMC_DAT1	I/O	(not used)	Data Line 1	Data Line 1	0
MMC_DAT2	I/O	(not used)	Data Line 2	Data Line 2	0
MMC_DAT3	I/O	(not used)	Data Line 3	Data Line 3	0
MMC_DAT4	I/O	(not used)	(not used)	Data Line 4	0
MMC_DAT5	I/O	(not used)	(not used)	Data Line 5	0
MMC_DAT6	I/O	(not used)	(not used)	Data Line 6	0
MMC_DAT7	I/O	(not used)	(not used)	Data Line 7	0

⁽¹⁾ The MMC_CLK pin functions as an output but must be configured as an I/O to internally loopback the clock to time the inputs.

Figure 18-3 shows the MMC/SD/SDIO host controller connected to an MMC, SD, or SDIO card and its related external connections. These are described below.

Figure 18-3. MMC/SD Connectivity to an MMC/SD Card

The following MMC/SD/SDIO controller pins are not provided on all MMC/SD/SDIO instances. Refer to device-specific data manual for details.

- **MMC_POW** Used for MMC/SD card's cards on/off power supply control. When high, denotes power-on condition.
- **MMC_SDCD** This input pin serves as the MMC/SD/SDIO carrier detect. This signal is received from a mechanical switch on the slot.
- **MMC_SDWP** This input pin is used for the SD/SDIO card's write protect. This signal is received from a mechanical protect switch on the slot (system dependant). Applicable only for SD and SDIO cards that have a mechanical sliding tablet on the side of the card.

18.2.1.2 Protocol and Data Format

The bus protocol between the MMC/SD/SDIO host controller and the card is message-based. Each message is represented by one of the following parts:

Command: A command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the `mmc_cmd` line.

Response: A response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the `mmc_cmd` line.

Data: Data are transferred from the MMC/SD/SDIO host controller to the card or from a card to the MMC/SD/SDIO host controller using the DATA lines.

Busy: The `mmc_dat0` signal is maintained low by the card as far as it is programming the data received.

CRC status: CRC result is sent by the card through the `mmc_dat0` line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on `mmc_dat0`. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on `mmc_dat0` and starts the data programming procedure.

18.2.1.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented). See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, and the *SDIO Card Specification, Part E1* for details about commands and programming sequences supported by the MMC, SD, and SDIO cards.

CAUTION
Stream commands are supported only by MMC cards.

Figure 18-4 and Figure 18-5 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmchs_cmd line.

Figure 18-4. Sequential Read Operation (MMC Cards Only)

Figure 18-5. Sequential Write Operation (MMC Cards Only)

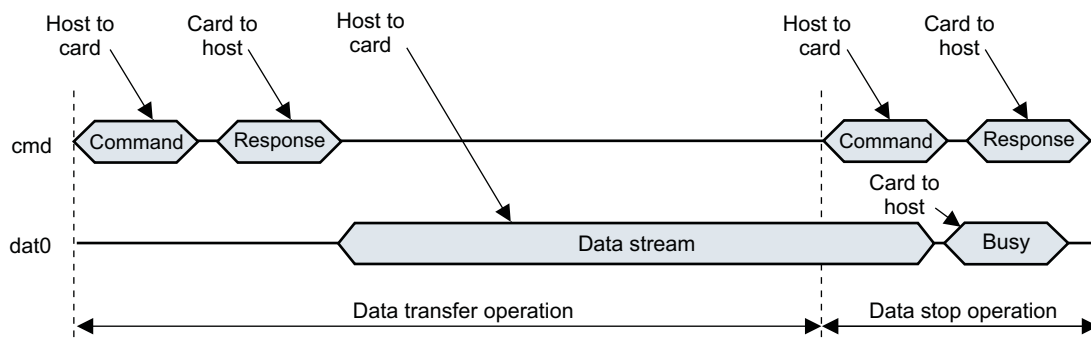

Figure 18-6 and Figure 18-7 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmchs_cmd line. These operations are available for all kinds of cards.

Figure 18-6. Multiple Block Read Operation (MMC Cards Only)

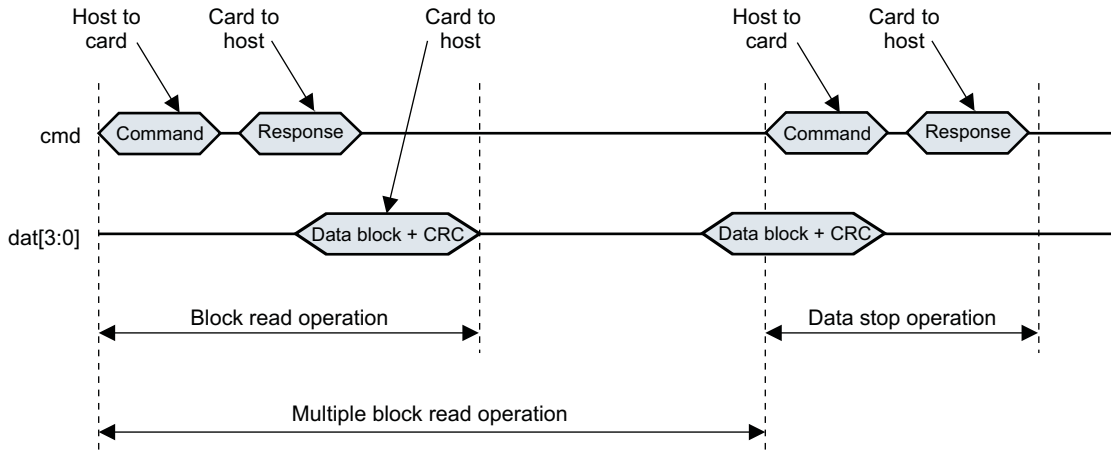

Figure 18-7. Multiple Block Write Operation (MMC Cards Only)

NOTE:

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. It is the software's responsibility to do a software reset after a data timeout to ensure that mmc_clk is stopped. The software reset is done by setting the SRD bit in the MMCHS_SYCTL register to 1.
3. For multiblock transfer, and especially for MMC cards, you can abort a transfer without using a stop command. Use a CMD23 before a data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (provided the MMC card supports this feature).

18.2.1.2.2 Data Format

Coding Scheme for Command Token

Command packets always start with 0 and end with 1. The second bit is a transmitter bit1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 18-8](#)).

Figure 18-8. Command Token Format

Coding Scheme for Response Token

Response packets always start with 0 and end with a 1. The second bit is a transmitter bit0 for a card response. The content is different for each type of response (R1, R2, R3, R4, R5, and R6) and the content is protected by 7-bit CRC checksum. Depending on the type of commands sent to the card, the MMCHS_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 18-2](#)). For more details about response types, see the *Multimedia Card System Specification*, the *SD Memory Card Specification*, or the *SDIO Card Specification*.

Table 18-2. Response Type Summary

Response Type MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCHS_CMD[20] CICE	CRC Check Enable MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5 (R7 for SD cards)
11	1	1	R1b, R5b

[Figure 18-9](#) and [Figure 18-10](#) depict the 48-bit and 136-bit response packets.

Figure 18-9. 48-Bit Response Packet (R1, R3, R4, R5, R6)

Figure 18-10. 136-Bit Response Packet (R2)

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see [Figure 18-11](#), [Figure 18-12](#), [Figure 18-13](#), and [Figure 18-14](#)).

Figure 18-11. Data Packet for Sequential Transfer (1-Bit)

Figure 18-14. Data Packet for Block Transfer (8-Bit)

18.2.2 Resets

18.2.2.1 Hardware Reset

The module is reinitialized by the hardware.

The MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

This hardware reset signal has a global reset action on the module. All configuration registers and all state machines are reset in all clock domains.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

18.2.2.2 Software Reset

The module is reinitialized by software through the MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware reset signal except for:

- Debounce logic
- MMCHS_PSTATE and MMCHS_CAPA registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The MMCHS_SYSCTL[24] SRA bit has the same action as the SOFTRESET bit on the design.

The MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCHS_SYSCTL[26] SRD bit
- MMCHS_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The MMCHS_SYSCTL[26] SRD bit resets all finite state-machines and status management that handle data transfers on both the interface and functional side.
- The MMCHS_SYSCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

NOTE: If **any** of the clock inputs are not present for the MMC/SD/SDIO peripheral, the software reset will not complete.

18.2.3 Clocks

The module receives 3 clocks: OCP CLK (named Interface clock), CLKADPI (named functional clock), and CLK32K. Concerning the activity of these external clocks, two cases can be considered:

- Module is being used: These 2 clocks must be activated in the same time when you want to make an OCP access on register due to the synchronization that is performed on some configuration registers (MMCHS_CMD) but also during the data transfer phase in order to synchronize data and status bits between the functional and the OCP part.
- Module is not being used: The 2 clocks can be turned off because the module is the master, which provides clock to the different type of card, and any transfer can be only initiated by the MMC module.

The CLK32K clock is used for debouncing.

18.2.4 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the PRCM module handshake protocol. When the MMC/SD/SDIO power domain is off, the only way to wake up the power domain and different MMC/SD/SDIO clocks is to monitor the mmc_dat1 input pin state via a different GPIO line for each MMC/SD/SDIO interface.

18.2.4.1 Normal Mode

The autogating of interface clock (OCP clock) and functional clock (ADPI clock) occurs when the following conditions are met:

- The MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L3 (or L4) interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the MMC/SD/SDIO interface starts.

Then the MMC/SD/SDIO host controller enters in low-power state even if MMCHS_SYSCONFIG[0] AUTOIDLE is cleared to 0. The functional clock is internally switched off and only interconnect read and write accesses are allowed.

18.2.4.2 Idle Mode

The clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request. The MMC/SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 1h: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 2h: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.
- 3h: Smart-idle wake-up-capable mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when in idle state (related to IRQ or DMA requests)

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the OCP and Functional clocks may be switched off whatever the value set in the MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY field.

18.2.4.3 Transition from Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 2h or 3h. The MMC/SD/SDIO host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity. The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the mmchs_dat1 signal.

As long as the MMC/SD/SDIO controller does not acknowledge the idle request, if an event occurs, the MMC/SD/SDIO host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the MMC/SD/SDIO controller acknowledges the idle request from the PRCM:

- If Smart-Idle mode: the module does not assert any new interrupt or DMA request
- If Smart-Idle wake-up-capable mode: the module may generate wake-up events related to interrupt or DMA request.

18.2.4.4 Transition from Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request. For the wake-up event, there is a corresponding interrupt status in the MMCHS_STAT register. The MMC/SD/SDIO host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the MMCHS_ISE register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the MMCHS_HCTL and MMCHS_ISE registers. The overall consistency must be ensured by software.

The interrupt status register MMCHS_STAT is updated with the event that caused the wake-up in the CIRQ bit when the MMCHS_IE[8] CIRQ_ENABLE associated bit is enabled. Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

18.2.4.5 Force-Idle Mode

Force-idle mode is enabled when the MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is cleared to 0. Force-idle mode is an idle mode where the MMC/SD/SDIO host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the MMC/SD/SDIO host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCHS_STAT register. In force-idle mode, the interrupt and DMA request lines are deasserted. Interface Clock (OCP) and functional clock (CLKADPI) can be switched off.

CAUTION

In Force-Idle mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the OCP clock is alive.

The module exits the force-idle mode when the PRCM deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

18.2.4.6 Local Power Management

Table 18-3 describes power-management features available for the MMC/SD/SDIO modules.

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMC clock PRCM control bits.

Table 18-3. Local Power Management Features

Feature	Registers	Description
Clock Auto Gating	MMCHS_SYSCONFIG AUTOIDLE bit	This bit allows a local power optimization inside module, by gating the OCP clock upon the interface activity or gating the CLKADPI clock upon the internal activity.
Slave Idle Modes	MMCHS_SYSCONFIG SIDLEMODE bit	Force-idle, No-idle, and Smart-idle modes
Clock Activity	MMCHS_SYSCONFIG CLOCKACTIVITY bit	See Table 18-4 for configuration details.
Master Standby Modes	MMCHS_SYSCONFIG STANDBYMODE bit	Force-idle, No-idle, and Smart-idle modes
Global Wake-Up Enable	MMCHS_SYSCONFIG ENAWAKEUP bit	This bit enables the wake-up feature at module level.
Wake-Up Sources Enable	MMCHS_HCTL register	This register holds one active high enable bit per event source able to generate wake-up signal.

Table 18-4. Clock Activity Settings

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available when Module is in IDLE State		Wake-Up Events
	OCP Clock	CLKADPI			
00	OFF	OFF		None	Card Interrupt
10	OFF	ON		None	
01	ON	OFF		None	
11	ON	ON		All	

18.2.5 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCHS_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCHS_IE register enable/disable the automatic update of the MMCHS_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCHS_ISE register enable/disable the transmission of an interrupt request on the interrupt line MMC_IRQ (from the MMC/SD/SDIOi host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the MMCHS_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCHS_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 1 (the MMC/SD/SDIO host controller updates the status bit) in the MMCHS_STAT register. If later a mask is applied on the interrupt in the MMCHS_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCHS_STAT register and the corresponding mask is removed from the MMCHS_ISE register, the interrupt status is not asserted again in the MMCHS_STAT register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the MMCHS_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller will wait for the service of the interrupt without updating the status MMCHS_STAT register or transmitting an interrupt request.

Table 18-5 lists the event flags, and their mask, that can cause module interrupts.

Table 18-5. Events

Event Flag	Event Mask	Map To	Description
MMCHS_STAT[29] BADA	MMCHS_IE[29] BADA_ENABLE	MMC_IRQ	Bad Access to Data space. This bit is set automatically to indicate a bad access to buffer when not allowed. This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE=0). This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_STATE[10] BWE=0)

Table 18-5. Events (continued)

Event Flag	Event Mask	Map To	Description
MMCHS_STAT[28] CERR	MMCHS_IE[28] CERR_ENABLE	MMC_IRQ	Card Error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response errors register (MMCHS_CSRE) is set. There is not card detection for auto CMD12 command.
MMCHS_STAT[25] ADMAE	MMCHS_IE[25] ADMAE_ENABLE	MMC_IRQ	ADMA error. This bit is set when the host controller detects errors during ADMA based data transfer. The stat of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.
MMCHS_STAT[24] ACE	MMCHS_IE[24] ACE_ENABLE	MMC_IRQ	Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1
MMCHS_STAT[22] DEB	MMCHS_IE[22] DEB_ENABLE	MMC_IRQ	Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode.
MMCHS_STAT[21] DCRC	MMCHS_IE[21] DCRC_ENABLE	MMC_IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status difference of a position "010" token during a block write command.
MMCHS_STAT[20] DTO	MMCHS_IE[20] DTO_ENABLE	MMC_IRQ	Data Timeout error. This bit is set automatically according to the following conditions: A) busy timeout for R1b, R5b response. B) busy timeout after write CRC status. C) write CRC status timeout, or D) read data timeout.
MMCHS_STAT[19] CIE	MMCHS_IE[19] CIE_ENABLE	MMC_IRQ	Command Index Error. This bit is set automatically when response index differs from corresponding command index previously emitted. The check is enabled through MMCHS_CMD[20] CICE bit.
MMCHS_STAT[18] CEB	MMCHS_IE[18] CEB_ENABLE	MMC_IRQ	Command End Bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
MMCHS_STAT[17] CCRC	MMCHS_IE[17] CCRC_ENABLE	MMC_IRQ	Command CRC error. This bit is set automatically when there is a CRC7 error in the command response. CRC check is enabled through the MMCHS_CMD[19] CCCE bit.
MMCHS_STAT[16] CTO	MMCHS_IE[16] CTO_ENABLE	MMC_IRQ	Command Timeout error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles, the timeout is still detected at 64 clock cycles.
MMCHS_STAT[15] ERRI	MMCHS_IE[15] ERRI_ENABLE	MMC_IRQ	Error Interrupt. If any of the bits in the Error Interrupt Status register (MMCHS_STAT[24:15]) are set, this bit is set to 1.
MMCHS_STAT[10] BSR	MMCHS_IE[10] BSR_ENABLE	MMC_IRQ	Boot Status Received interrupt. This bit is set automatically when MMCHS_CON[18] BOOT_CF0 is set to 1 or 2h and boot status is received on the dat0 line. This interrupt is only used for MMC cards.
MMCHS_STAT[8] CIRQ	MMCHS_IE[8] CIRQ_ENABLE	MMC_IRQ	Card Interrupt. This bit is only used for SD, SDIO, and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wake-up). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drive CMD line to zero during one cycle after data transmission end.
MMCHS_STAT[5] BRR	MMCHS_IE[5] BRR_ENABLE	MMC_IRQ	Buffer Read ready. This bit is set automatically during a read operation to the card when one block specified by MMCHS_BLK[10:0] BLEN is completely written in the buffer. It indicates that the memory card has filled out the buffer and the local host needs to empty the buffer by reading it.
MMCHS_STAT[4] BWR	MMCHS_IE[4] BWR_ENABLE	MMC_IRQ	Buffer Write ready. This bit is automatically set during a write operation to the card when the host can write a complete block as specified by MMCHS_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and the local host is able to write one block of data into the buffer.
MMCHS_STAT[3] DMA	MMCHS_IE[3] DMA_ENABLE	MMC_IRQ	DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer is complete.

Table 18-5. Events (continued)

Event Flag	Event Mask	Map To	Description
MMCHS_STAT[2] BGE	MMCHS_IE[2] BGE_ENABLE	MMC_IRQ	Block Gap event. When a stop at block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.
MMCHS_STAT[1] TC	MMCHS_IE[1] TC_ENABLE	MMC_IRQ	Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap requested (MMCHS_HCTL[16] SBGR). In read mode this bit is automatically set on completion of a read transfer (MMCHS_PSTATE[9] RTA). In write mode, this bit is automatically set on completion of the DAT line use (MMCHS_PSTATE[2] DLA).
MMCHS_STAT[0] CC	MMCHS_IE[0] CC_ENABLE	MMC_IRQ	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC). If a response is expected but none is received, then a Command Timeout error is detected and signaled instead of the Command Complete interrupt.

18.2.5.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCHS_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the MMCHS_STAT register to identify which event occurred.
- Write 1 into the corresponding bit of the MMCHS_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

NOTE: In the MMCHS_STAT register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.

The MMCHS_STAT[8] CIRQ status bit must be masked by disabling the MMCHS_IE[8] CIRQ_ENABLE bit (cleared to 0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR).

The MMCHS_STAT[15] ERRI bit is automatically cleared when all status bits in MMCHS_STAT[31:16] are cleared.

18.2.5.2 Polling

When the interrupt capability of an event is disabled in the MMCHS_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCHS_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCHS_STAT register clears the interrupt status and does not affect the interrupt line state.

NOTE: See the note in [Section 18.2.5.1](#) concerning CIRQ and ERRI bits clearing.

18.2.6 DMA Modes

The device supports DMA slave mode only. In this case, the controller is slave on DMA transaction managed by two separated requests (SDMAWREQN and SDMARREQN)

18.2.6.1 DMA Slave Mode Operations

The MMC/SD/SDIO controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the local host (LH) of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

The DMA request is issued if the following conditions are met:

- The MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the SD_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIO controller to write an entire block (BLEN writes).

18.2.6.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal SDMARREQN is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCHS_BLK BLEN field.

The SDMARREQN signal is deasserted to its inactive level when the sDMA has read one single word from the buffer. Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

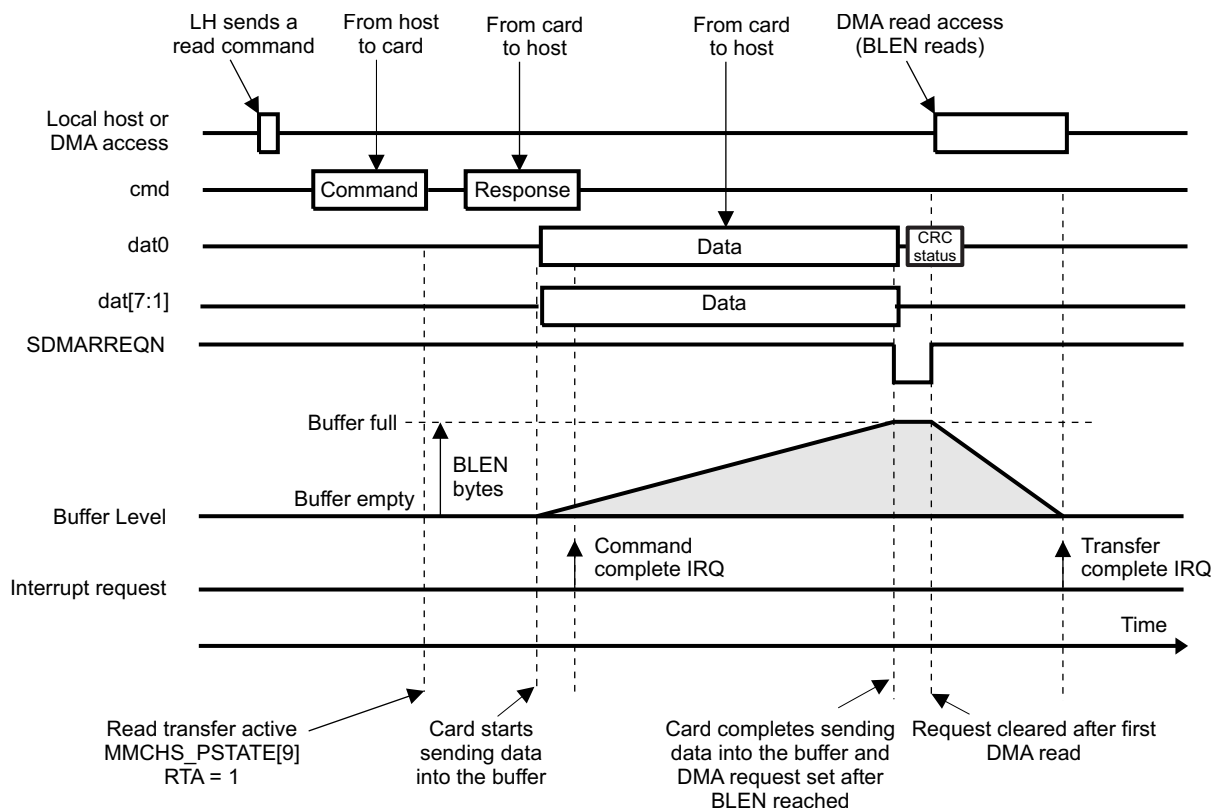

New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is $\text{Integer}(\text{BLEN}/4)+1$.

The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the MMC_CLK clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Figure 18-15 provides a summary:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 18-15. DMA Receive Mode

18.2.6.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal SDMAWREQN is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCHS_BLK BLEN field.

The SDMAWREQN signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

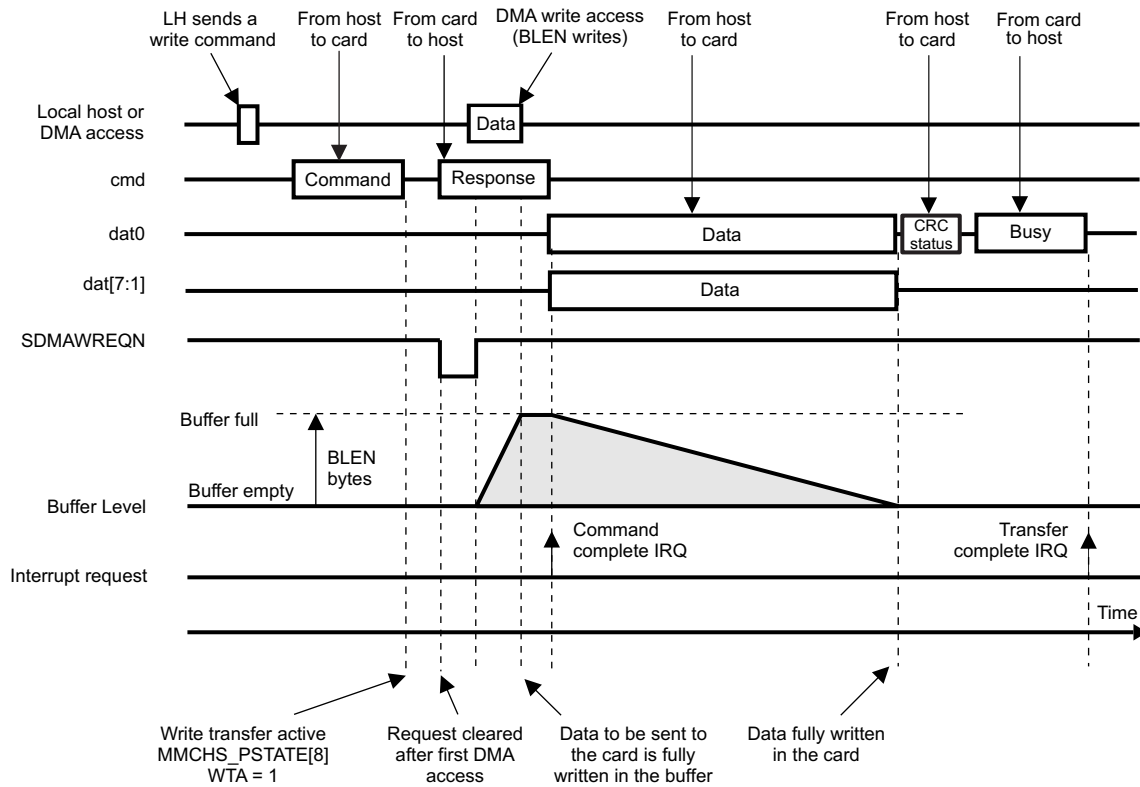

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is $\text{Integer}(\text{BLEN}/4)+1$) and if there is not enough memory space to write a complete block in the buffer.

Figure 18-16 provides a summary:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 18-16. DMA Transmit Mode

18.2.7 Mode Selection

The MMC/SD/SDIO host controller can be used in two modes, MMC and SD/SDIO modes. It has been designed to be the most transparent with the type of card. The type of the card connected is differentiated by the software initialization procedure.

Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, and the *SDIO Card Specification, Part E1* for more details.

The purpose of the module is to transfer commands and data, to whatever card is connected, respecting the protocol of the connected card. Writes and reads to the card must respect the appropriate protocol of that card.

18.2.8 Buffer Management

18.2.8.1 Data Buffer

The MMC/SD/SDIO host controller uses a data buffer. This buffer transfers data from one data bus (Interconnect) to another data bus (SD, SDIO, or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card). To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer, the prefetch buffer, and the post-write buffer is the 32-bit register MMCHS_DATA. A write access to the MMCHS_DATA register followed by a read access from the MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCHS_DATA register and the data of the read access to the MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCHS_DATA register that are needed to read (or write) a data block with a size of MMCHS_BLK_BLEN, and equals the rounded up result of BLEN divided by 4. The maximum block size supported by the host controller is hard-coded in the register MMCHS_CAPA[17:16] MBL field and cannot be changed.

A read access to the MMCHS_DATA register is allowed only when the buffer read enable status is set to 1 (MMCHS_PSTATE[11] BRE); otherwise, a bad access (MMCHS_STAT[29] BADA) is signaled.

A write access to the MMCHS_DATA register is allowed only when the buffer write enable status is set to 1 (MMCHS_PSTATE[10] BWE); otherwise, a bad access (MMCHS_STAT[29] BADA) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double buffering), two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The MMC/SD/SDIO controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa. When BLEN is less than or equal to 200h (that is, less or equal to 512Bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32-bits x BLEN div by 4). Not more than this total size of 2 times 32-bits x BLEN div by 4 can be used.
- When the size of the data block to transfer is larger than MEM_SIZE/2, only one data transfer can occur from one data bus to the other data bus at a time. The MMC/SD/SDIO host controller uses the entire data buffer as a single portion. In this mode, a bad access (MMCHS_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

CAUTION

The MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 18-17 shows the buffer management for writing and Figure 18-18 shows the buffer management for reading.

Figure 18-17. Buffer Management for a Write

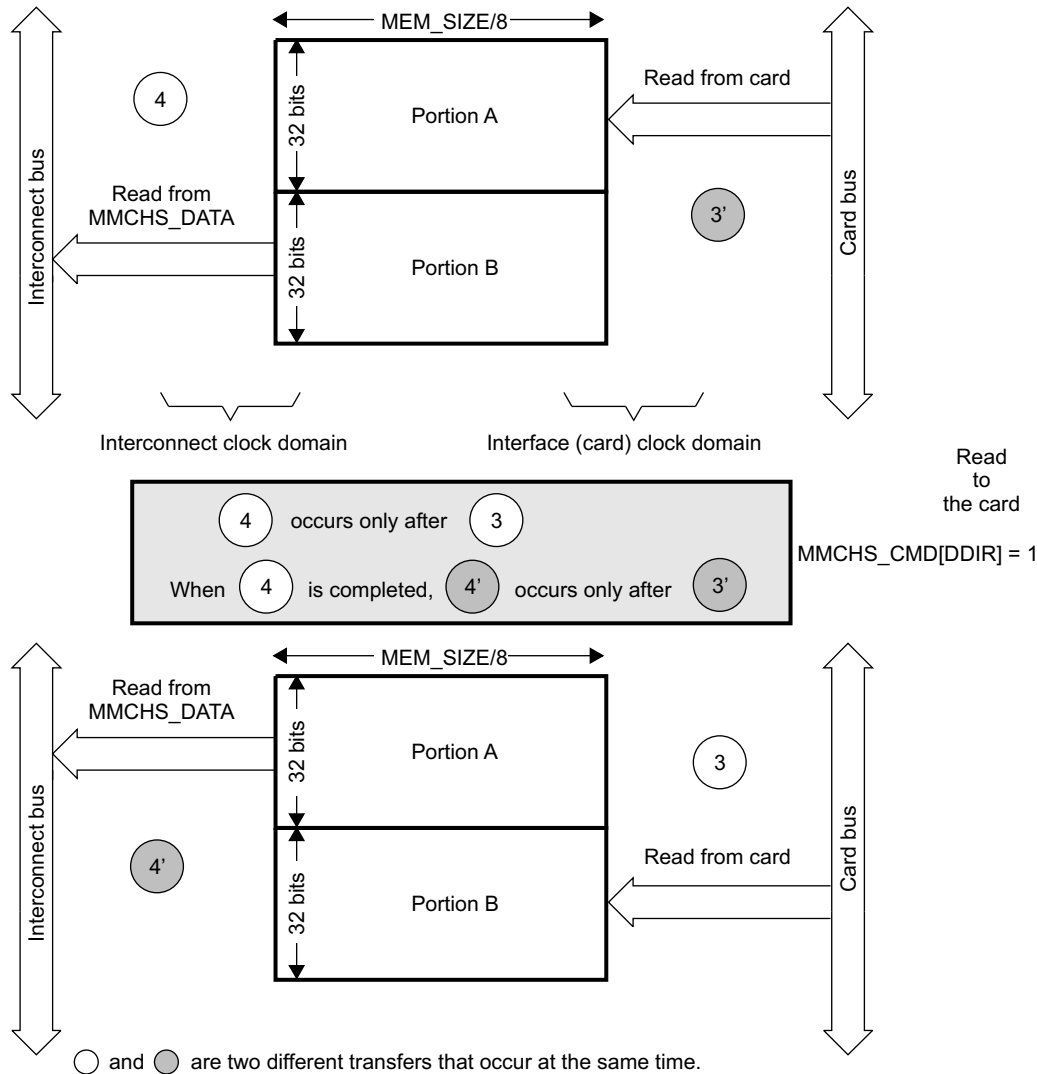

Figure 18-18. Buffer Management for a Read

18.2.8.1.1 Memory Size, Block Length, and Buffer Management Relationship

The maximum block length and buffer management that can be targeted by system depend on memory depth setting.

Table 18-6. Memory Size, BLEN, and Buffer Relationship

Memory Size([5:2] MEMSIZE in bytes)	512	1024	2048	4096
Maximum block length supported	512	1024	2048	2048
Double-buffering for maximum block length	N/A	BLEN <= 512	BLEN <= 1024	BLEN <= 2048
Single-buffering for block length	BLEN<=512	512 < BLEN <= 1024	1024 < BLEN <= 2048	N/A

18.2.8.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see [Figure 18-56](#)):
 - MMCHS_STAT[29] BADA: Bad access to data space
 - MMCHS_STAT[5] BRR: Buffer read ready
 - MMCHS_STAT[4] BWR: Buffer write ready
- Status registers (see [Figure 18-53](#)):
 - MMCHS_PSTATE[11] BRE: Buffer read enable
 - MMCHS_PSTATE[10] BWE: Buffer write enable

18.2.9 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

18.2.9.1 Different Types of Commands

Different types of commands are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, the *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification* for more details.

18.2.9.2 Different Types of Responses

Different types of responses are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, the *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification* for more details.

[Table 18-7](#) shows how the MMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 18-7. MMC, SD, SDIO Responses in the MMCHS_RSP_n Registers

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8] ⁽¹⁾	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8] ⁽¹⁾	MMCHS_RSP76[31:0]
R2	RESP[127:0] ⁽¹⁾	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

⁽¹⁾ RESP refers to the command response format described in the specifications mentioned above.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in MMCHS_RSP10 register and conversely.

18.2.10 Transfer or Command Status and Error Reporting

Flags in the MMC/SD/SDIO host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See [Table 18-8](#) and register description for more details.

Table 18-8. CC and TC Values Upon Error Detected

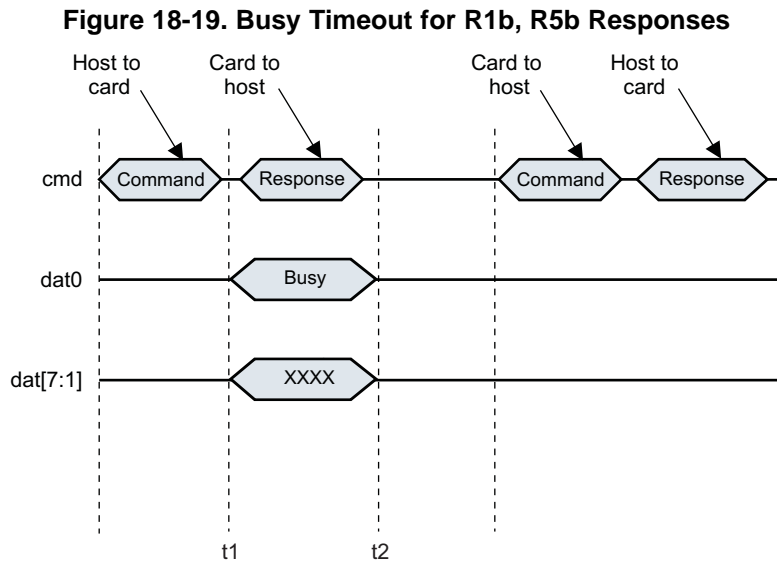

Error Hold in the MMCHS_STAT Register	CC	TC	Comments
29 BADA			No dependency with CC or TC. BADA is related to the register accesses. Its assertion is not dependent of the ongoing transfer.
28 CERR	1		CC is set upon CERR.
22 DEB		1	TC is set upon DEB.
21 DCRC		1	TC is set upon DCRC.
20 DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19 CIE	1		CC is set upon CIE.
18 CEB	1		CC is set upon CEB.
17 CCRC	1		CC can be set upon CCRC - See CTO comment
16 CTO			CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC it indicates a command abort due to a contention on CMD line. In this case no CC appears.

MMCHS_STAT[21] DCRC event can be asserted in the following conditions:

- Busy timeout for R1b, R5b response type
- Busy timeout after write CRC status
- Write CRC status timeout
- Read data timeout
- Boot acknowledge timeout

18.2.10.1 Busy Timeout for R1b, R5b Response Type

Figure 18-19 shows DCRD event condition asserted when there is a busy timeout for R1b or R5b responses.

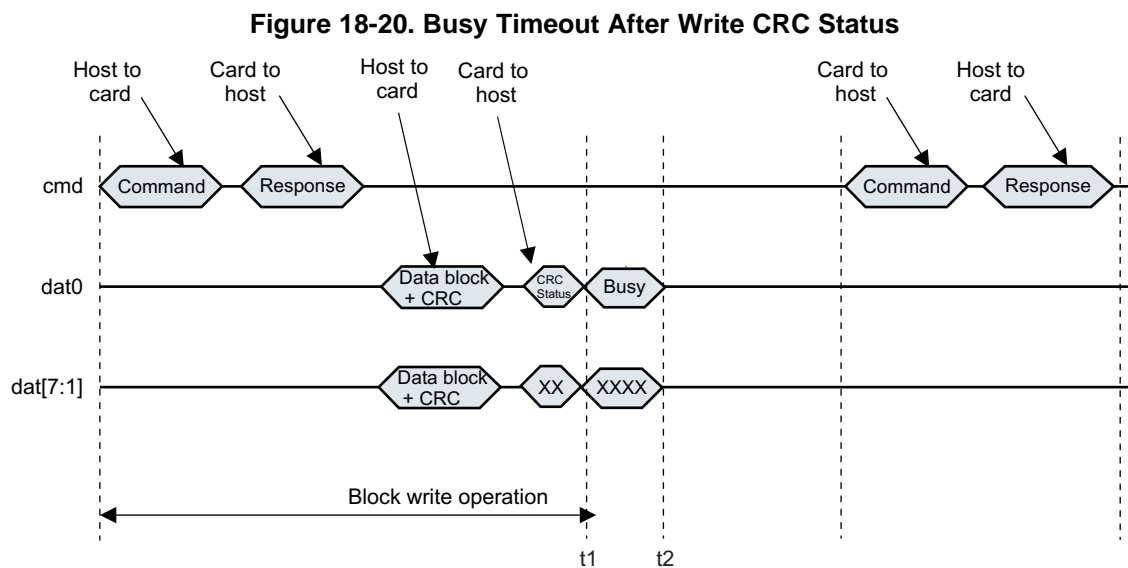

t1 - Data timeout counter is loaded and starts after R1b, R5b response type.

t2 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.

18.2.10.2 Busy Timeout After Write CRC Status

Figure 18-20 shows DCRC event condition asserted when there is busy timeout after write CRC status.

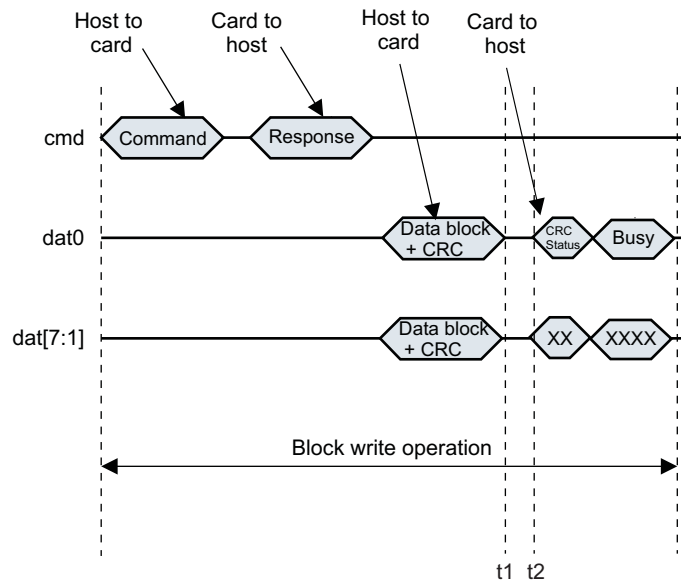

t1 - Data timeout counter is loaded and starts after CRC status.

t2 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.

18.2.10.3 Write CRC Status Timeout

Figure 18-21 shows DCRC event condition asserted when there is write CRC status timeout.

Figure 18-21. Write CRC Status Timeout

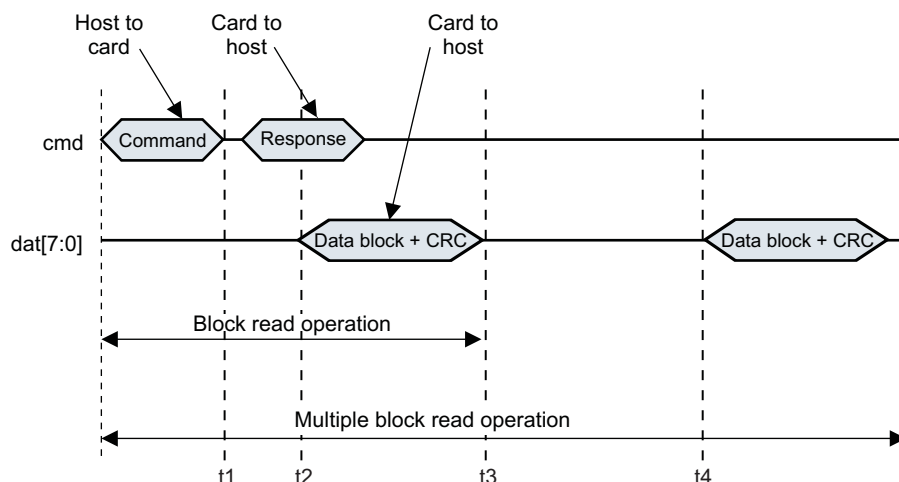

t1 - Data timeout counter is loaded and starts after Data block + CRC.

t2 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.

18.2.10.4 Read Data Timeout

Figure 18-22 shows DCRC event condition asserted when there is read data timeout.

Figure 18-22. Read Data Timeout

t1 - Data timeout counter is loaded and starts after Command transmission.

t2 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.

t3 - Data timeout counter is loaded and starts after Data block + CRC transmission.

t4 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.

18.2.10.5 Boot Acknowledge Timeout

Figure 18-23 shows DCRC event condition asserted when there is boot acknowledge timeout and CMD0 is used.

Figure 18-23. Boot Acknowledge Timeout When Using CMD0

* Refer to MMC Specification for correct argument.

- t1 - Data timeout counter is loaded and starts after CMD0.
- t2 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.
- t3 - Data timeout counter is loaded and starts.
- t4 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.
- t5 - Data timeout counter is loaded and starts after Data + CRC transmission.
- t6 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.

Figure 18-24 shows DCRC event condition asserted when there is boot acknowledge timeout and CMD line is held low.

Figure 18-24. Boot Acknowledge Timeout When CMD Held Low

- t1 - Data timeout counter is loaded and starts after cmd line is tied to 0.
- t2 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.
- t3 - Data timeout counter is loaded and starts.
- t4 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.
- t5 - Data timeout counter is loaded and starts after Data + CRC transmission.
- t6 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.

18.2.11 Auto Command 12 Timings

With the UHS definition of SD cards with higher frequency for MMC clocks up to 208, SD standard imposes a specific timing for Auto CMD12 "end bit" arrival.

18.2.11.1 Auto Command 12 Timings During Write Transfer

A margin named Nrcr in range of 2 to 8 cycles has been defined for SDR50 and SDR104 card components for write data transfers, as auto command 12 'end bit' shall arrive after the CRC status "end bit".

Figure 18-25 shows auto CMD12 timings during write transfer.

Figure 18-25. Auto CMD12 Timing During Write Transfer

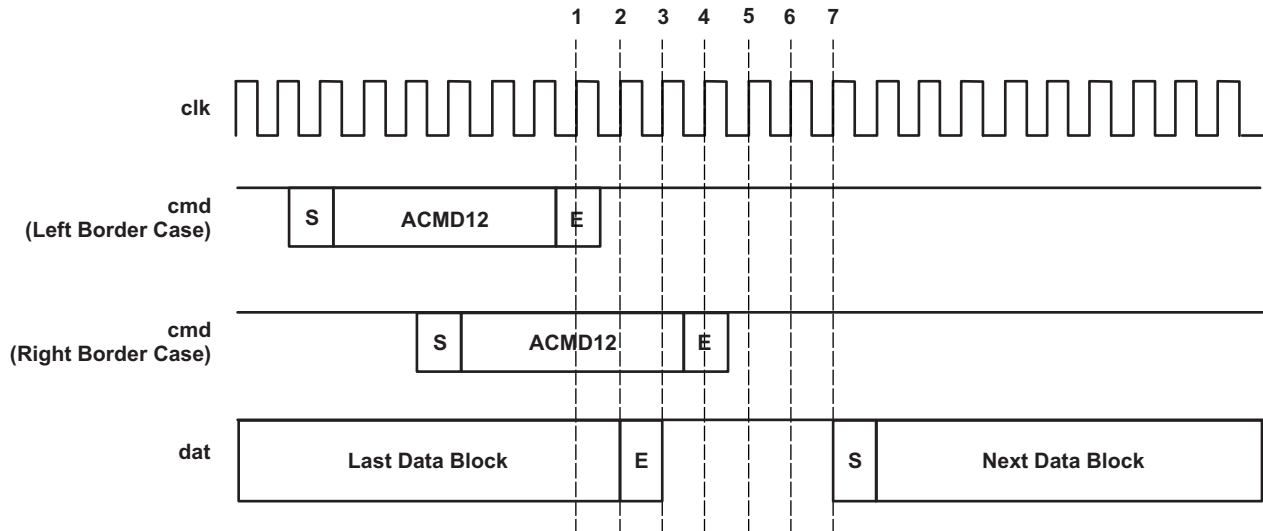

The Host controller has a margin of 18 clock cycles to make sure that auto CMD12 'end bit' arrives after the CRC status. This margin does not depend on MMC bus configuration, DDR or standard transfer, 1,4 or 8 bus width.

18.2.11.2 Auto Command 12 Timings During Read Transfer

With UHS very-high speed cards gap timing between 2 successive cards has been extended to 4 cycles instead of 2. By the way, it gives more flexibility for Host Auto CMD12 arrival in order to receive the last complete and reliable block. SD controller only follows the 'Left Border Case' defined by SD UHS specification.

Figure 18-26 shows ACMD12 timings during read transfer.

Figure 18-26. Auto Command 12 Timings During Read Transfer

The Auto CMD12 arrival sent by the Host controller is not sensitive to the MMC bus configuration whether it is DDR or standard transfer and whether it is a 1, 4, or 8 bit bus width transfer.

18.2.12 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

NOTE: Since the MMC/SD/SDIO controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIO controller includes two features which make a transfer stop more convenient and easier to manage:

- Auto CMD12 (for MMC and SD only).

This feature is enabled by setting the MMCHS_CMD[2] ACEN bit to 1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the MMC/SD/SDIO controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.

- Stop at block gap

This feature is enabled by setting the MMCHS_HCTL[16] SBGR bit to 1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

Table 18-9 shows the common ways to stop a transfer, indicating command to send and features to enable.

Table 18-9. MMC/SD/SDIO Controller Transfer Stop Command Summary

		WRITE Transfer		READ Transfer	
		MMC/SD	SDIO	MMC/SD	SDIO
Single block		Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC
Multi blocks (finite or infinite)	Before the programmed block boundary	Send CMD12 Wait TC	Send CMD52 Wait TC	Send CMD12 Wait TC	Send CMD52 Wait TC
	Stop at the end of the transfer (finite transfer only)	Auto CMD12 active Transfer ends automatically Wait TC	Set MMCHS_HCTL[16] SBGR bit to 1. Send CMD52 Wait TC	Auto CMD12 active Transfer ends automatically Wait TC	If READ_WAIT supported Stop at block gap Wait TC If READ_WAIT not supported Send CMD52 Wait TC

NOTE: The MMC/SD/SDIO controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

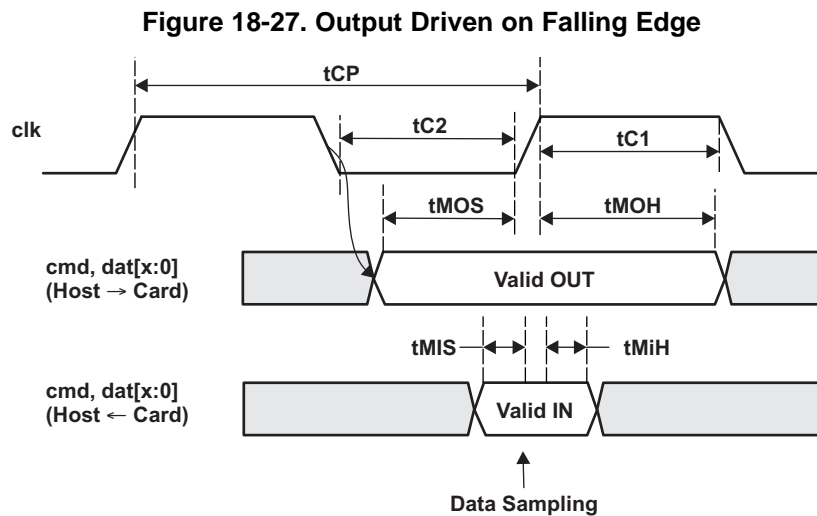

18.2.13 Output Signals Generation

The MMC/SD/SDIO output signals can be driven on either falling edge or rising edge depending on the MMCHS_HCTL[2] HSPE bit. This feature allows to reach better timing performance, and thus to increase data transfer frequency.

18.2.13.1 Generation on Falling Edge of MMC Clock

The controller is by default in this mode to maximize hold timings. In this case, MMCHS_HCTL[2] HSPE bit is cleared to 0.

Figure 18-27 shows the output signals of the module when generating from the falling edge of the MMC clock.

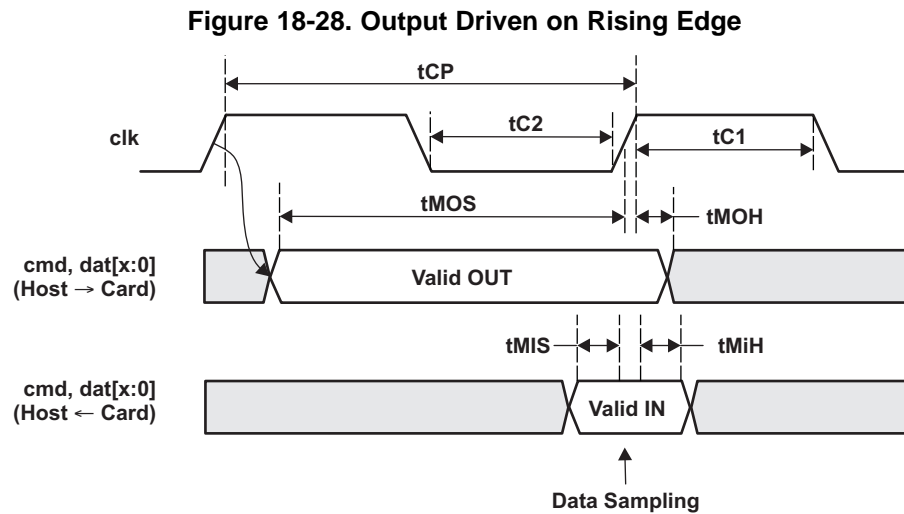

18.2.13.2 Generation on Rising Edge of MMC Clock

This mode increases setup timings and allows reaching higher bus frequency. This feature is activated by setting MMCHS_HCTL[2] HSPE bit to 1. The controller shall be set in this mode to support SDR transfers.

NOTE: Do not use this feature in Dual Data Rate mode (when MMCHS_CON[19] DDR is set to 1).

Figure 18-28 shows the output signals of the module when generating from the rising edge of the MMC clock.

18.2.14 Card Boot Mode Management

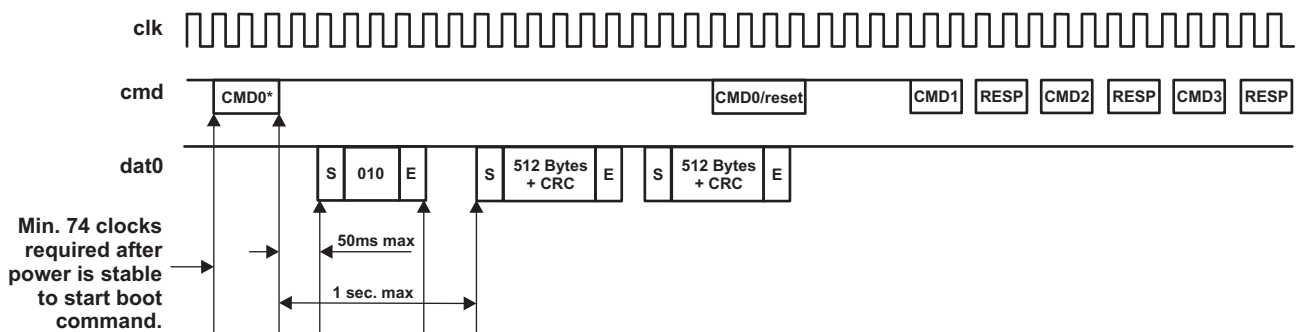

Boot Operation Mode allows the MMC/SD/SDIO host controller to read boot data from the connected slave (MMC device) by keeping CMD line low after power-on (or sending CMD0 with specific argument) before issuing CMD1. The data can be read from either boot area or user area, depending on register setting. Power-on boot defines a way for the boot-code to be accessed by the MMC/SD/SDIO host controller without an upper-level software driver, speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (either issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

18.2.14.1 Boot Mode Using CMD0

Figure 18-29 shows the timing diagram of a boot sequence using CMD0.

Figure 18-29. Boot Mode With CMD0

* Refer to MMC Specification for correct argument.

18.2.14.2 Boot Mode With CMD Held Low

Figure 18-30 shows the timing diagram of a boot sequence with CMD line tied to 0.

Figure 18-30. Boot Mode With CMD Line Tied to 0

For more information on how to configure the MMC/SD/SDIO host controller, see the section titled Boot with CMD line tied to 0.

18.2.15 CE-ATA Command Completion Disable Management

The MMC/SD/SDIO controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal (MMCHS_CON[12] CEATA and MMCHS_CMD[2] ACEN set to 1) is launched, the host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token follow:

- MMCHS_CON[12] CEATA is set to 1.
- MMCHS_CON[2] HR set to 1.
- Clear the MMCHS_ARG register.
- Write into MMCHS_CMD register with value 0000 0000h.

When a command completion disable token was emitted (that is, MMCHS_STAT[0] CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

- CCS is receive just before CCSD is emitted:
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:
The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:
Only the interrupt CIRQ is generated when CCS is detected.

18.2.16 Test Registers

Test registers are available to be compliant with SD Host controller specification. This feature is useful to generate interrupts manually for driver debugging. The Force Event register (MMCHS_FE) is used to control the Error Interrupt Status and Auto CMD12 Error Status. The System Test register (MMCHS_SYSTEST) is used to control the signals that connect to I/O pins when the module is configured in system test (MMCHS_CON[4] MODE = 1) mode for boundary connectivity verification.

18.2.17 MMC/SD/SDIO Hardware Status Features

Table 18-10 summarizes the MMC/SD/SDIO hardware status features.

Table 18-10. MMC/SD/SDIO Hardware Status Features

Feature	Type	Register/Bit Field/Observability Control	Description
Interrupt flags		See Section 18.2.5 .	
CMD line signal level	Status	[24] CLEV	Indicates the level of the cmd line
DAT lines signal level	Status	[23:20] DLEV	Indicates the level of the data lines
Buffer read enable	Status	[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	[9] RTA	This status is used for detecting completion of a read transfer.
Write transfer active	Status	[8] WTA	This status indicates a write transfer active.
Data line active	Status	[2] DLA	Indicates whether the data lines are active
Command Inhibit (data lines)	Status	[1] DATI	Indicates whether issuing of command using data lines is allowed
Command inhibit (CMD line)	Status	[0] CMDI	Indicates whether issuing of command using CMD line is allowed

18.3 Low-Level Programming Models

18.3.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the module has to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMC/SD/SDIO modules.

Table 18-11. Global Init for Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information, see Power, Reset, and Clock Management (PRCM) chapter
Control module	Module-specific pad muxing and configuration must be set in the control module. See Control Module chapter.
(optional) MPU INTC	MPU INTC configuration must be done to enable the interrupts from the MMCHS module. See Interrupt Controller chapter
(optional) sDMA (or dDMA)	DMA configuration must be done to enable the module DMA channel requests. See SDMA chapter
(optional) Interconnect	For more information about the interconnect configuration, see Interconnect chapter

NOTE: The MPU interrupt controller and the sDMA/dDMA configurations are necessary, if the interrupt and DMA based communication modes are used.

18.3.2 MMC/SD/SDIO Controller Initialization Flow

The next sections outline the four steps to initialize the MMC/SD/SDIO controller:

- Initialize Clocks
- Software reset of the controller
- Set module's hardware capabilities
- Set module's Idle and Wake-Up modes

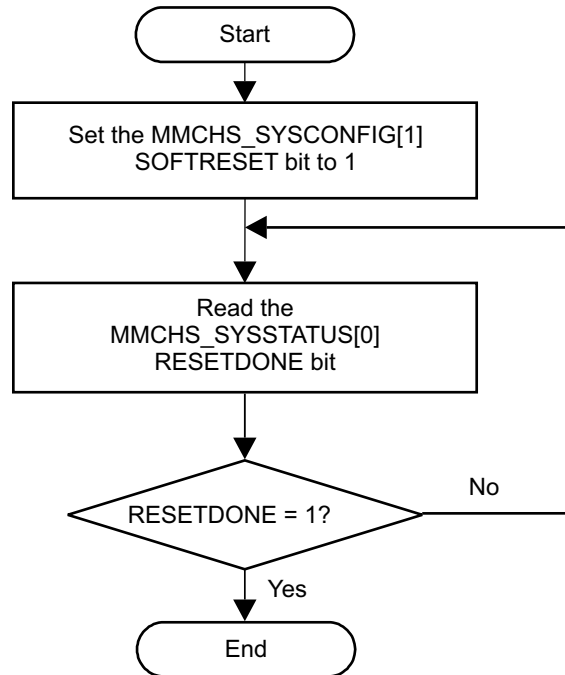

18.3.2.1 Enable OCP and CLKADPI Clocks

Prior to any MMCHS register access, you must enable the OCP clock and CLKADPI clock in PRCM module registers. Refer to the *Power, Reset, and Clock Management* chapter.

18.3.2.2 SD Soft Reset Flow

Figure 18-31 shows the soft reset process of MMC/SD/SDIO controller.

Figure 18-31. MMC/SD/SDIO Controller Software Reset Flow

18.3.2.3 Set SD Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) MMCHS_CAPA[26:24] before the MMC/SD/SDIO host driver is started.

18.3.2.4 Wake-Up Configuration

Table 18-12 details SD controller wake-up configuration.

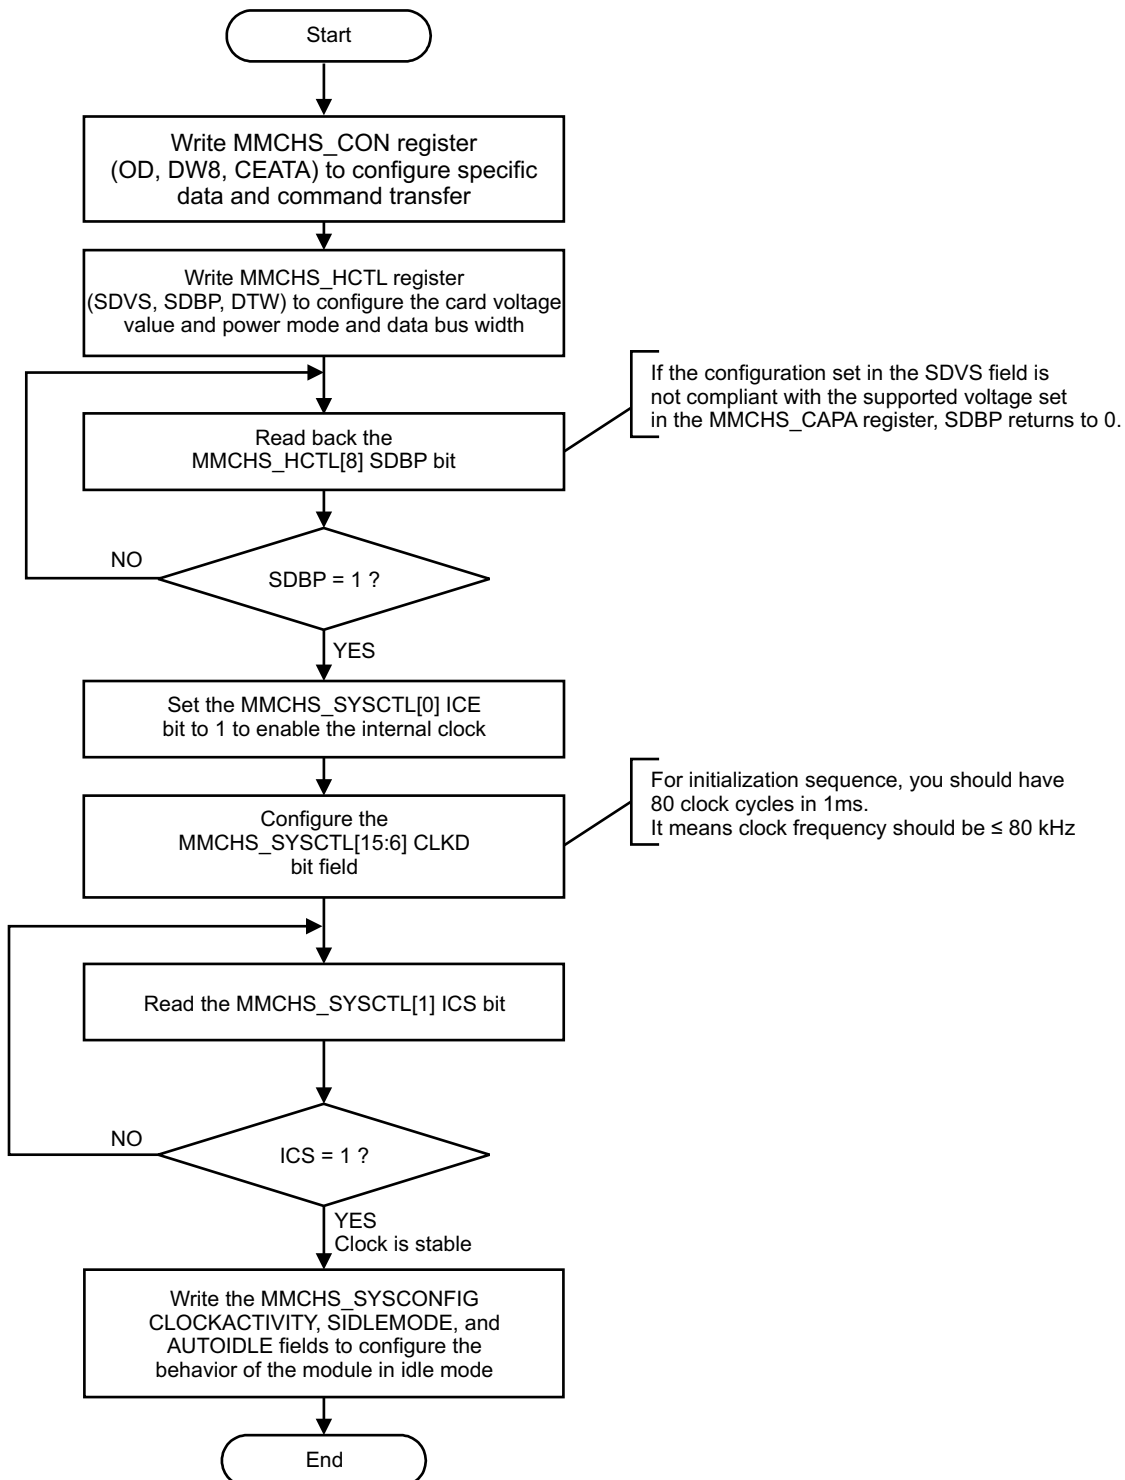

Table 18-12. MMC/SD/SDIO Controller Wake-Up Configuration

Step	Access Type	Register/Bit Field/Programming Model	Value
Configure wake-up bit (if necessary).	W	MMCHS_SYSCONFIG[2] ENAWAKEUP	1
Enable wake-up events on SD card interrupt (if necessary).	W	MMCHS_HCTL[24] IWE	1
SDIO Card only Enable card interrupt (if necessary).	W	MMCHS_IE[8] CIRQENABLE	1

18.3.2.5 MMC Host and Bus Configuration

Figure 18-32 details the MMC bus configuration process.

Figure 18-32. MMC/SD/SDIO Controller Bus Configuration Flow

18.3.3 Operational Modes Configuration

18.3.3.1 Basic Operations for MMC/SD/SDIO Host Controller

The MMC/SD/SDIO controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

18.3.3.2 Card Detection, Identification, and Selection

Figure 18-33 and Figure 18-34 show the card identification and selection process.

Figure 18-33. MMC/SD/SDIO Controller Card Identification and Selection - Part 1

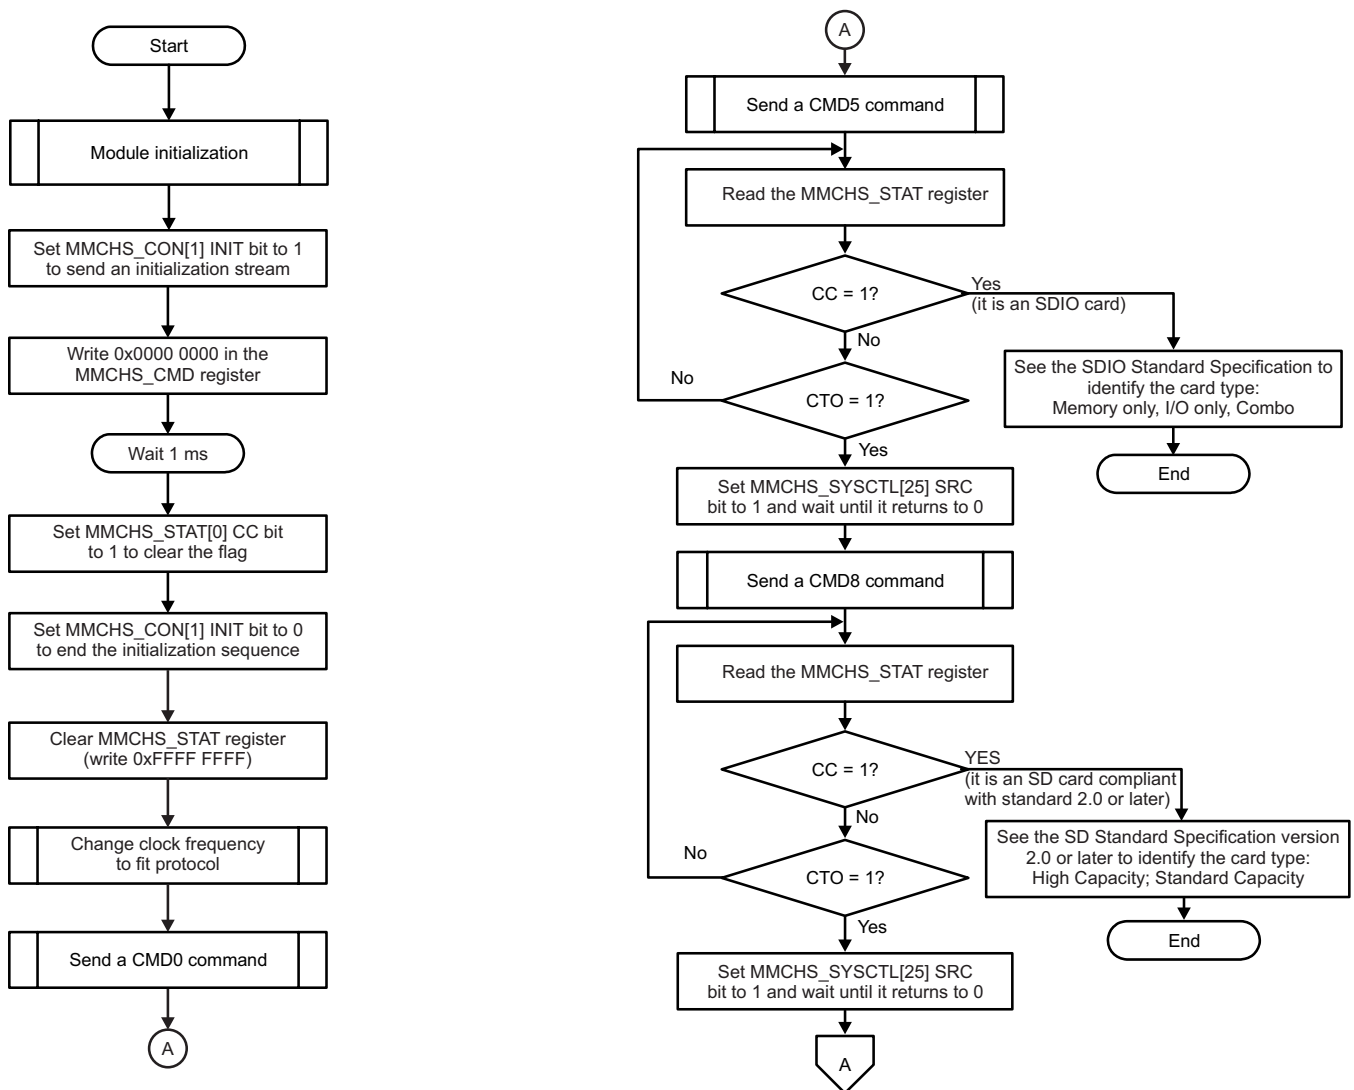

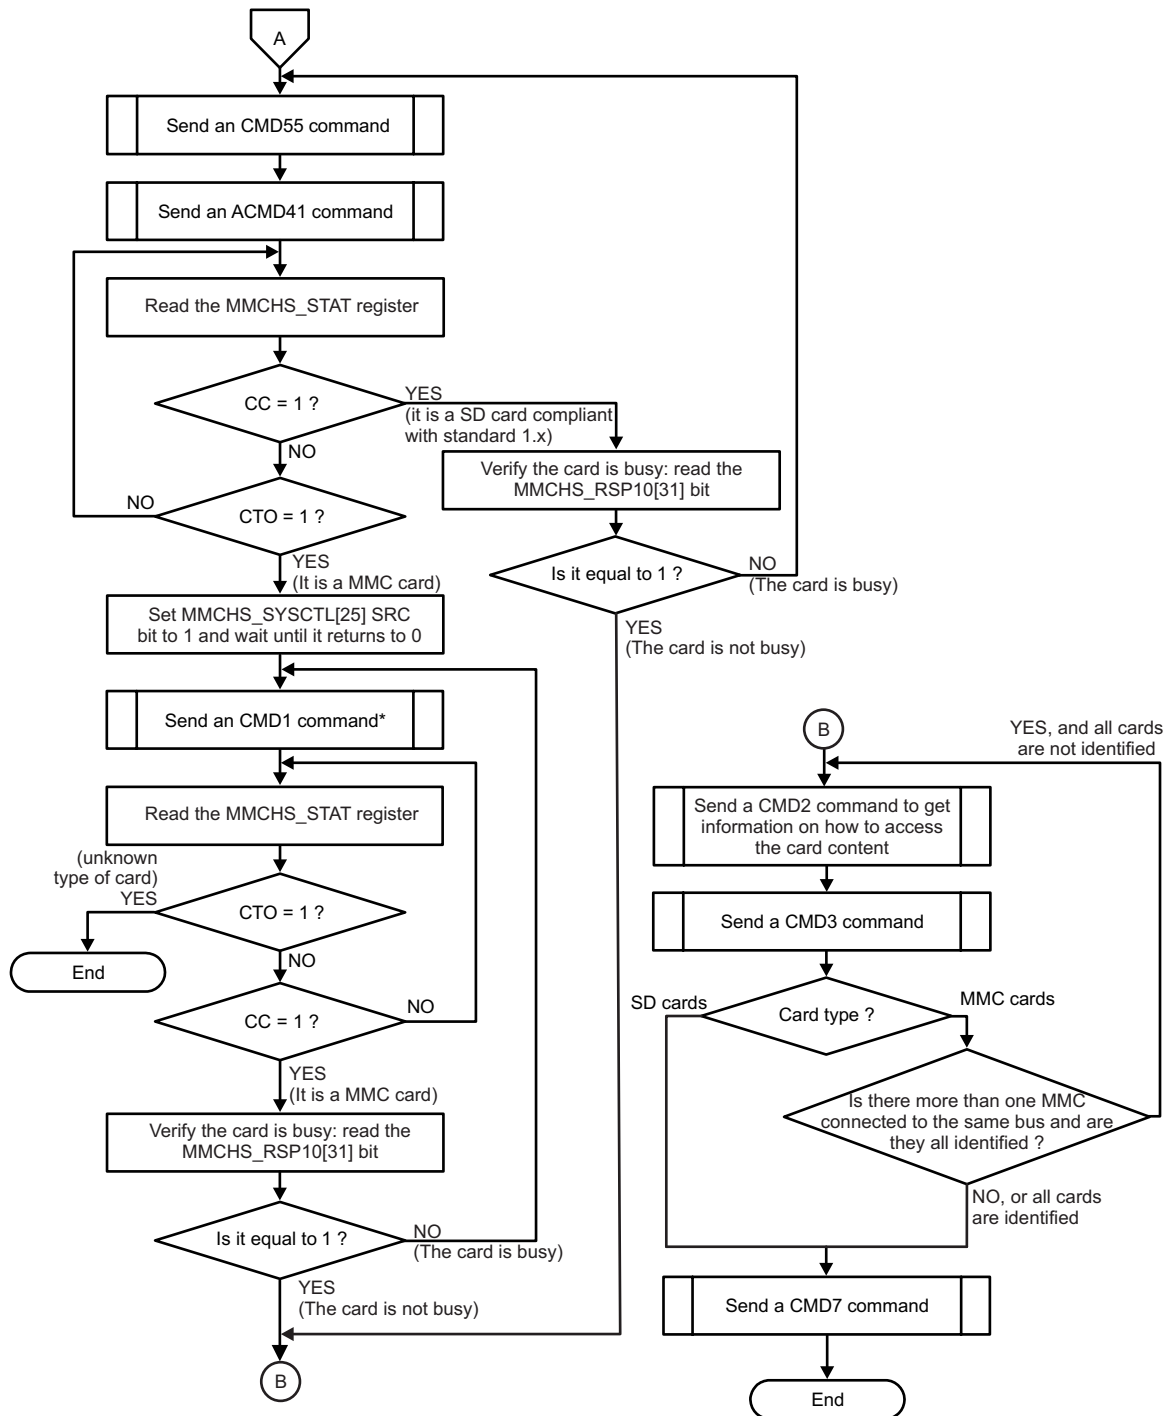

Figure 18-34. MMC/SD/SDIO Controller Card Identification and Selection - Part 2

*With OCR 0.

18.4 MMC/SD/SDIO Registers

Table 18-13 lists the MMC/SD/SDIO registers.

CAUTION

The MMC/SD/SDIO registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

Table 18-13. MMC/SD/SDIO Registers

Address Offset	Acronym	Register Name	Section
0	MMCHS_HL_REV	IP Revision Identifier	Section 18.4.1
4h	MMCHS_HL_HWINFO	Hardware Configuration	Section 18.4.2
10h	MMCHS_HL_SYSCONFIG	Clock Management Configuration	Section 18.4.3
110h	MMCHS_SYSCONFIG	System Configuration	Section 18.4.4
114h	MMCHS_SYSSTATUS	System Status	Section 18.4.5
124h	MMCHS_CSRE	Card status response error	Section 18.4.6

18.4.1 IP Revision Identifier Register (MMCHS_HL_REV)

This register holds the IP Revision Identifier (X.Y.R) information.

Figure 18-35. IP Revision Identifier Register (MMCHS_HL_REV)

LEGEND: R = Read only; -n = value after reset

Table 18-14. IP Revision Identifier Register (MMCHS_HL_REV) Field Descriptions

Bit	Field	Value	Description
31-30	SCHEME	1	Used to distinguish between old Scheme and current. 1: Current scheme
29-28	Reserved	0	Reserved
27-16	FUNC	20h	Function indicates a software compatible module family. A new Function number is assigned when there is no level of software compatibility. 20h: MMCHS
15-11	R_RTL	5h	RTL version. 5h: Current RTL Version.
10-8	X_MAJOR	3h	Major Revision. 3h: Current Major Revision
7-6	CUSTOM	0	Indicates a special version for a particular device.
5-0	Y_MINOR	1	Minor Revision 1: Current Minor Revision

18.4.2 IP Module Hardware Configuration Register (MMCHS_HL_HWINFO)

This register provides information about the IP module's hardware configuration, typically the module's HDL generics (if any).

Figure 18-36. IP Module Hardware Configuration Register (MMCHS_HL_HWINFO)

LEGEND: R = Read only; -n = value after reset

Table 18-15. IP Module Hardware Configuration Register (MMCHS_HL_HWINFO) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	RETMODE	0	Indicates whether the retention mode is supported using the pin PIRFFRET. 0: Retention mode disabled.
5-2	MEM_SIZE	2h	Memory size for FIFO buffer. 2h: Memory of 1024 bytes, max block length is 1024 bytes.
1	MERGE_MEM	1	Memory merged for FIFO buffer. 1: A single memory is used with multiplexed addresses, data, and clocks.
0	MADMA_EN	0	Master DMA enabled generic parameter. 0: No Master DMA (ADMA) management supported.

18.4.3 Clock Management Configuration (MMCHS_HL_SYSCONFIG)

This register provides information about the clock management configuration.

Figure 18-37. Clock Management Configuration (MMCHS_HL_SYSCONFIG)

31	Reserved					16	
R-0							
15	6	5	4	3	2	1	0
Reserved		STANDBYMODE	IDLEMODE	FREEEMU	SOFTRESET		
R-0		R/W-2h	R/W-2h	R/W-0	R/W-0		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-16. Clock Management Configuration (MMCHS_HL_SYSCONFIG Field Descriptions)

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5-4	STANDBYMODE	0	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state.
		0	Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only.
		1h	No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only.
		2h	Smart-standby mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator.
		3h	Smart-standby wakeup-capable mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module shall not generate (initiator-related) wakeup events.
		3h	Smart-standby wakeup-capable mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module may generate (master-related) wakeup events when in standby state. Mode is only relevant if the appropriate IP module "mwakeup" output is implemented.
3-2	IDLEMODE	0	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state.
		0	Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, that is, regardless of the IP module's internal requirements. Backup mode, for debug only.
		1h	No-idle mode: local target never enters idle state. Backup mode, for debug only.
		2h	Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements.
		3h	Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events.
		3h	Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA request- related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.
1	FREEEMU	0	Sensitivity to emulation (debug) suspend input signal. Functionality NOT implemented in MMCHS.
		0	IP module is sensitive to emulation suspend
		1	IP module is not sensitive to emulation suspend
0	SOFTRESET	Read 0	Software reset.
		Write 0	Reset done, no pending action
		Read 1	No action
		Write 1	Reset (software or other) ongoing
		Write 1	Initiate software reset

18.4.4 System Configuration Register (MMCHS_SYSCONFIG)

This register allows controlling various parameters of the OCP interface. The system configuration register (MMCHS_SYSCONFIG) is shown in Figure 18-38 and described in Table 18-17.

Figure 18-38. System Configuration Register (MMCHS_SYSCONFIG)

	Reserved						
	R-0						
15	14	13	12	11	10	9	8
Reserved	STANDBYMODE	Reserved	CLOCKACTIVITY				
R-0	R/W-2h	R-0	R/W-0				
7	5	4	3	2	1	0	
Reserved	SIDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE			
R-0	R/W-2h	R/W-1	R/W-0	R/W-1			

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-17. System Configuration Register (MMCHS_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
13-12	STANDBYMODE	0	Master interface power Management, standby/wait control. The bit field is only useful when generic parameter MMCHS_HL_HWINFO[0] ADMA_EN bit is set as active; otherwise, it is a read only register read a 0.
		1h	Force-standby: Mstandby is forced unconditionally.
		2h	No-standby: Mstandby is never asserted.
		3h	Smart-standby mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module shall not generate (initiator-related) wake-up events.
		3h	Smart-Standby wake-up-capable mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module can generate (master-related) wake-up events when in standby state. Mode is only relevant if the appropriate IP module "mwake-up" output is implemented. Functional clock is maintained. Interface clock may be switched off.
11-10	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
9-8	CLOCKACTIVITY	0	Clocks activity during wake up mode period.
		Bit 8	Interface clock
		Bit 9	Functional clock
		0	Interface and Functional clock may be switched off.
		1h	Interface clock is maintained. Functional clock may be switched-off.
		2h	Functional clock is maintained. Interface clock may be switched-off.
		3h	Interface and Functional clocks are maintained.
7-5	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
4-3	SIDLEMODE	0	Power management
		0	If an idle request is detected, the MMC/SD/SDIO host controller acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally deasserted.
		1h	If an idle request is detected, the request is ignored and the module keeps on behaving normally.
		2h	If an idle request is detected, the module will switch to wake up mode based on its internal activity, and the wake up capability can be used if the wake up capability is enabled (bit MMCHS_SYSCONFIG[2] ENAWAKEUP bit is set to 1).
		3h	Smart-idle Wake-up capable mode: local target's idle state eventually acknowledges the system's idle requests, depending on the IP modules internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in idle state. Mode is only relevant if the appropriate IP module "swake-up" output(s) is (are) implemented.

Table 18-17. System Configuration Register (MMCHS_SYSCONFIG) Field Descriptions (continued)

Bit	Field	Value	Description
2	ENAWAKEUP	0	Wake-up feature control Wake-up capability is disabled.
		1	Wake-up capability is enabled.
1	SOFTRESET		Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0.
		Read 0	Normal mode
		Write 0	No effect
		Read 1	The module is reset.
Write 1	Trigger a module reset.		
0	AUTOIDLE	0	Internal Clock gating strategy Clocks are free-running.
		1	Automatic clock gating strategy is applied, based on the interconnect and MMC interface activity.

18.4.5 System Status Register (MMCHS_SYSSTATUS)

This register provides status information about the module excluding the interrupt status information. The system status register (MMCHS_SYSSTATUS) is shown in [Figure 18-39](#) and described in [Table 18-18](#).

Figure 18-39. System Status Register (MMCHS_SYSSTATUS)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-18. System Status Register (MMCHS_SYSSTATUS) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved bit field. Do not write any value.
0	RESETDONE		Internal Reset Monitoring. Note the debounce clock, the interface clock and the functional clock shall be provided to the MMC/SD/SDIO host controller to allow the internal reset monitoring.
		Read 0	Internal module reset is on-going
		Read 1	Reset completed

18.4.6 Card Status Response Error (MMCHS_CSRE)

This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCHS_CSRE[i] is set to 1, if the corresponding bit at the same position in the response MMCHS_RSP10[i] is set to 1, the host controller indicates a card error (MMCHS_STAT[28] CERR bit) interrupt status to avoid the host driver reading the response register (MMCHS_RSP10).

NOTE: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCHS_RSP76) for possible card errors.

The card status response error (MMCHS_CSRE) is shown in [Figure 18-40](#) and described in [Table 18-19](#).

Figure 18-40. Card Status Response Error (MMCHS_CSRE)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-19. Card Status Response Error (MMCHS_CSRE) Field Descriptions

Bit	Field	Value	Description
31-0	CSRE	0-FFFF FFFFh	Card status response error

18.4.7 System Test Register (MMCHS_SYSTEST)

This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification.

NOTE: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCHS_BLK[10:0] BLEN bits) and the Blocks count for current transfer (MMCHS_BLK[31:16] NBLK bits) are needed to generate a Buffer write ready interrupt (MMCHS_STAT[4] BWR bit) or a Buffer read ready interrupt (MMCHS_STAT[5] BRR bit) and DMA requests if enabled.

The system test register (MMCHS_SYSTEST) is shown in [Figure 18-41](#) and described in [Table 18-20](#).

Figure 18-41. System Test Register (MMCHS_SYSTEST)

31							17	16

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-20. System Test Register (MMCHS_SYSTEST) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved bit field. Do not write any value. Reads return 0.
16	OBI	0	Out-of-band interrupt (OBI) data value. The out-of-band interrupt pin is driven low.
		1	The out-of-band interrupt pin is driven high.
15	SDCD	0	Card detect input signal (SDCD) data value The card detect pin is driven low.
		1	The card detect pin is driven high.
14	SDWP	0	Write protect input signal (SDWP) data value The write protect pin SDWP is driven low.
		1	The write protect pin SDWP is driven high.
13	WAKD	Read 0	Wake request output signal data value No action. Returns 0.
		Write 0	The pin SWAKEUP is driven low.
		Read 1	No action. Returns 1.
		Write 1	The pin SWAKEUP is driven high.
12	SSB	Read 0	Set status bit. This bit must be cleared prior attempting to clear a status bit of the interrupt status register (MMCHS_STAT). No action. Returns 0.
		Write 0	Clear this SSB bit field. Writing 0 does not clear already set status bits.
		Read 1	No action. Returns 1.
		Write 1	Force to 1 all status bits of the interrupt status register (MMCHS_STAT) only if the corresponding bit field in the Interrupt signal enable register (MMCHS_ISE) is set.

Table 18-20. System Test Register (MMCHS_SYSTEST) Field Descriptions (continued)

Bit	Field	Value	Description
11	D7D	Read 0	DAT7 input/output signal data value If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT7 line (low). If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT7 line is driven low. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT7 line (high) If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT7 line is driven high. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
10	D6D	Read 0	DAT6 input/output signal data value If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT6 line (low). If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT6 line is driven low. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT6 line (high) If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT6 line is driven high. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
9	D5D	Read 0	DAT5 input/output signal data value If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT5 line (low). If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT5 line is driven low. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT5 line (high) If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT5 line is driven high. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
8	D4D	Read 0	DAT4 input/output signal data value If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT4 line (low). If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT4 line is driven low. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT4 line (high) If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT4 line is driven high. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
7	D3D	Read 0	DAT3 input/output signal data value If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT3 line (low). If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT3 line is driven low. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT3 line (high) If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT3 line is driven high. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.

Table 18-20. System Test Register (MMCHS_SYSTEST) Field Descriptions (continued)

Bit	Field	Value	Description
6	D2D	Read 0	DAT2 input/output signal data value If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT2 line (low). If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT2 line is driven low. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT2 line (high) If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT2 line is driven high. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
5	D1D	Read 0	DAT1 input/output signal data value If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT1 line (low). If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT1 line is driven low. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT1 line (high) If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT1 line is driven high. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
4	D0D	Read 0	DAT0 input/output signal data value If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT0 line (low). If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT0 line is driven low. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT0 line (high) If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT0 line is driven high. If MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
3	DDIR	Read 0	Control of the DAT[7:0] pins direction No action. Returns 0.
		Write 0	The DAT lines are outputs (host to card).
		Read 1	No action. Returns 1.
		Write 1	The DAT lines are inputs (card to host).
2	CDAT	Read 0	CMD input/output signal data value If MMCHS_SYSTEST[1] CDIR bit = 1 (input mode direction), returns the value on the CMD line (low). If MMCHS_SYSTEST[1] CDIR bit = 0 (output mode direction), returns 0 .
		Write 0	If MMCHS_SYSTEST[1] CDIR bit = 0 (output mode direction), the CMD line is driven low. If MMCHS_SYSTEST[1] CDIR bit = 1 (input mode direction), no effect.
		Read 1	If MMCHS_SYSTEST[1] CDIR bit = 1 (input mode direction), returns the value on the CMD line (high) If MMCHS_SYSTEST[1] CDIR bit = 0 (output mode direction), returns 1 .
		Write 1	If MMCHS_SYSTEST[1] CDIR bit = 0 (output mode direction), the CMD line is driven high. If MMCHS_SYSTEST[1] CDIR bit = 1 (input mode direction), no effect.
1	CDIR	Read 0	Control of the CMD pin direction No action. Returns 0.
		Write 0	The CMD line is an output (host to card).
		Read 1	No action. Returns 1.
		Write 1	The CMD line is an input (card to host) .

Table 18-20. System Test Register (MMCHS_SYSTEST) Field Descriptions (continued)

Bit	Field	Value	Description
0	MCKD		MMC clock output signal data value
		Read 0	No action. Returns 0.
		Write 0	The output clock is driven low.
		Read 1	No action. Returns 1.
		Write 1	The output clock is driven high.

18.4.8 Configuration Register (MMCHS_CON)

This register is used:

- To select the functional mode or the SYSTEST mode for any card
- To send an initialization sequence to any card
- To enable the detection on the mmc_dat[1] signal of a card interrupt for SDIO cards only

It also configures:

- The parameters related to the card detect and write protect input signals

The configuration register (MMCHS_CON) is shown in [Figure 18-42](#) and described in [Table 18-21](#).

Figure 18-42. Configuration Register (MMCHS_CON)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-21. Configuration Register (MMCHS_CON) Field Descriptions

Bit	Field	Value	Description
31-22	Reserved	0	Reserved bit field. Do not write any value.
21	SDMA_LnE	0 1	Slave DMA Level/Edge Request. The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to MMCHS_DATA register or late de-assertion, request remains active until last allowed data written into MMCHS_DATA. 0 Slave DMA edge sensitive. 1 Slave DMA level sensitive.
20	DMA_MnS	0 1	DMA Master or Slave selection. When this bit is set and the controller is configured to use the DMA, Ocp master interface is used to get datas from system using ADMA2 procedure (direct access to the memory). This option is only available if generic parameter MADMA_EN is asserted to 1. 0 The controller is slave on data transfers with system. 1 Not available on this device.
19	DDR	0 1	Dual Data Rate mode. When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of MMCHS_SYSCTL[CLKD], it is insensitive to MMCHS_HCTL[HSPE] setting 0 Standard mode: Data are transmitted on a single edge. 1 Data Bytes and CRC are transmitted on both edges.

Table 18-21. Configuration Register (MMCHS_CON) Field Descriptions (continued)

Bit	Field	Value	Description
18	BOOT_CF0	Read 0 Read 1 Write 0 Write 1	Boot Status Supported. This register is set when the CMD line needs to be forced to 0 for a boot sequence. CMD line is driven to 0 after writing in MMCHS_CMD. The line is released when this bit field is de-asserted and aborts data transfer in case of a pending transaction. CMD line not forced. CMD line is released when it was previously forced to 0 by a boot sequence. CMD line forced to 0 is enabled. CMD line forced to 0 is enabled and will be active after writing into MMCHS_CMD register.
17	BOOT_ACK	0 1	Book acknowledge received. When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated. No acknowledge to be received. A boot status will be received on DAT0 line after issuing a command.
16	CLKEXTFREE	0 1	External clock free running. This register is used to maintain card clock out of transfer transaction to enable slave module (for example to generate a synchronous interrupt on mmc_dat[1]). The Clock will be maintain only if MMCHS_SYSCTL[2] CEN bit is set. External card clock is cut off outside active transaction period. External card clock is maintain even out of active transaction period only if MMCHS_SYSCTL[2] CEN bit is set.
15	PADEN	0 1	Control power for MMC lines. This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for mmc_dat[1], the signal is also combine outside the module with the dedicated power control MMCHS_CON[11] CTPL bit. ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms. ADPIDLE module pin is forced to active state
14-13	Reserved	0	Any writes to these bits will result in 0.
12	CEATA	0 1	CE-ATA control mode (MMC cards compliant with CE-ATA). By default, this bit is cleared to 0. It is used to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features. Standard MMC/SD/SDIO mode. CE-ATA mode. Next commands are considered as CE-ATA commands.
11	CTPL	0 1	Control Power for mmc_dat[1] line (SD cards). By default, this bit is cleared to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards. When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of mmc_dat[1] outside of a transaction in order to detect asynchronous card interrupt on mmc_dat[1] line and minimize the leakage current of the buffers. Disable all the input buffers outside of a transaction. Disable all the input buffers except the buffer of mmc_dat[1] outside of a transaction.
10-9	DVAL	0 1h 2h 3h	Debounce filter value (all cards). This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 33 us debounce period 231 us debounce period 1 ms debounce period 8.4 ms debounce period
8	WPP	0 1	Write protect polarity (SD and SDIO cards only). This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. Active high level Active low level

Table 18-21. Configuration Register (MMCHS_CON) Field Descriptions (continued)

Bit	Field	Value	Description
7	CDP	0 1	Card detect polarity (all cards). This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. Active-high level Active-low level
6	MIT	0 1	MMC interrupt command (MMC cards only). This bit must be set to 1, when the next write access to the command register (MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. Command timeout enabled. Command timeout disabled.
5	DW8	0 1	8-bit mode MMC select (MMC cards only). For SD/SDIO cards, this bit must be cleared to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification. 1-bit or 4-bit data width 8-bit data width
4	MODE	0 1	Mode select (all cards). This bit selects the functional mode or SYSTEST mode. 0 Functional mode: Transfers to the MMC/SD/SDIO cards follow the card protocol. The MMC clock is enabled. MMC/SD transfers are operated under the control of the MMCHS_CMD register. 1 SYSTEST mode: The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.
3	STR	0 1	Stream command (MMC cards only). This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20WRITE_DAT_UNTIL_STOP). Block oriented data transfer Stream oriented data transfer
2	HR	0 1	Broadcast host response (MMC cards only). This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core. In order to have the host response to be generated in open drain mode, the register MMCHS_CON[0] OD bit must be set to 1. When MMCHS_CON[12] CEATA bit is set to 1 and MMCHS_ARG cleared to 0, when writing 0000 0000h into MMCHS_CMD register, the host controller performs a 'command completion signal disable' token (that is, mmchs_cmd line held to 0 during 47 cycles followed by a 1). The host does not generate a 48-bit response instead of a command. The host generates a 48-bit response instead of a command or a command completion signal disable token.
1	INIT	0 1	Send initialization stream (all cards). When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the mmchs_cmd line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCHS_SYSCCTL[15:6] CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms. Note that in this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. MMCHS_STAT[0] CC bit can be polled. The host does not send an initialization sequence The host sends an initialization sequence

Table 18-21. Configuration Register (MMCHS_CON) Field Descriptions (continued)

Bit	Field	Value	Description
0	OD		Card open drain mode (MMC cards only). This bit must be set to 1 for MMC card commands 1, 2, 3, and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is in idle, ready, or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCHS_CON[2] HR bit)
		0	No open drain
		1	Open drain or broadcast host response

18.4.9 Power Counter Register (MMCHS_PWCNT)

This register is used to program a mmc counter to delay command transfers after activating the PAD power, this value depends on PAD characteristics and voltage. The power counter register (MMCHS_PWCNT) is shown in [Figure 18-43](#) and described in [Table 18-22](#).

Figure 18-43. Power Counter Register (MMCHS_PWCNT)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-22. Power Counter Register (MMCHS_PWCNT) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
15-0	PWCNT	0	No additional delay added
		1h	TCF delay (card clock period)
		2h	TCF × 2 delay (card clock period)
		:	
		FFFEh	TCF × 65534 delay (card clock period)
		FFFFh	TCF × 65535 delay (card clock period)

18.4.10 SDMA System Address (MMCHS_SDMASA)

This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (that is, after a transaction has stopped). The SDMA System address (MMCHS_SDMASA) is shown in [Figure 18-40](#) and described in [Table 18-19](#).

Figure 18-44. Card Status Response Error (MMCHS_SDMASA)

LEGEND: R = Read only; -n = value after reset

Table 18-23. Card Status Response Error (MMCHS_SDMASA) Field Descriptions

Bit	Field	Value	Description
31-0	SDMA_SYSADDR		<p>Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register.</p> <p>The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register.</p>

18.4.11 Transfer Length Configuration Register (MMCHS_BLK)

This register shall be used for any card. MMCHS_BLK[BLN] is the block size register. MMCHS_BLK[NBLK] is the block count register.

The transfer length configuration register (MMCHS_BLK) is shown in [Figure 18-45](#) and described in [Table 18-24](#).

Figure 18-45. Transfer Length Configuration Register (MMCHS_BLK)

31	16	15	12	11	0
NBLK		Reserved		BLN	
R/W-0		R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-24. Transfer Length Configuration Register (MMCHS_BLK) Field Descriptions

Bit	Field	Value	Description
31-16	NBLK	0 1h 2h : FFFFh	Blocks count for current transfer. This register is enabled when Block Count Enable (MMCHS_CMD[1] BCE bit) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count. Stop count 1 block 2 blocks 65535 blocks
15-12	Reserved	0	Reserved bit field. Do not write any value.
11-0	BLN	0 1h 2h 3h 1FFh 200h 7FFh 800h	Transfer block size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLN field after transfer completion (MMCHS_STAT[1] TC bit set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched. No data transfer 1 byte block length 2 bytes block length 3 bytes block length 511 bytes block length 512 bytes block length 2047 bytes block length 2048 bytes block length

18.4.12 Command Argument Register (MMCHS_ARG)

This register contains command argument specified as bit 39-8 of Command-Format. These registers must be initialized prior to sending the command itself to the card (write action into the register MMCHS_CMD register). Only exception is for a command index specifying stuff bits in arguments, making a write unnecessary.

The command argument register (MMCHS_ARG) is shown in [Figure 18-46](#) and described in [Table 18-25](#).

Figure 18-46. Command Argument Register (MMCHS_ARG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-25. Command Argument Register (MMCHS_ARG) Field Descriptions

Bit	Field	Value	Description
31-0	ARG	0-FFFF FFFFh	Command argument bits [31:0] .

18.4.13 Command and Transfer Mode Register (MMCHS_CMD)

- MMCHS_CMD[31:16] = the command register
- MMCHS_CMD[15:0] = the transfer mode

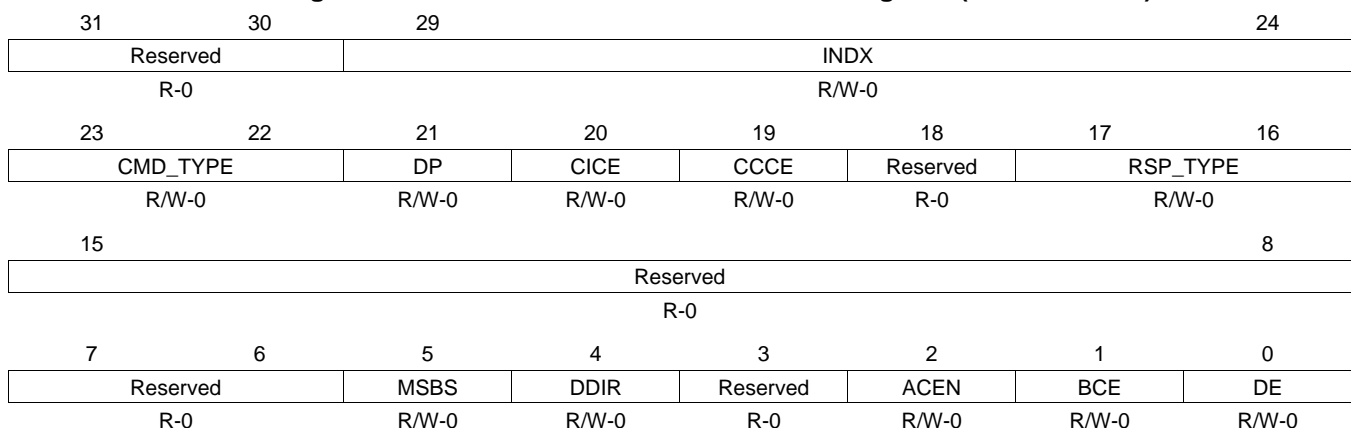

This register configures the data and command transfers. A write into the most significant byte send the command. A write into MMCHS_CMD[15:0] registers during data transfer has no effect.

This register can be used for any card.

NOTE: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer.

The command and transfer mode register (MMCHS_CMD) is shown in [Figure 18-47](#) and described in [Table 18-26](#).

Figure 18-47. Command and Transfer Mode Register (MMCHS_CMD)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-26. Command and Transfer Mode Register (MMCHS_CMD) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reserved bit field. Do not write any value.
29-24	INDX	0	Command index binary encoded value from 0 to 63 specifying the command number send to card.
		1h	CMD1 or ACMD1
		2h	CMD2 or ACMD2
		3h	CMD3 or ACMD3
		4h	CMD4 or ACMD4
		5h	CMD5 or ACMD5
		6h	CMD6 or ACMD6
		7h	CMD7 or ACMD7
		8h	CMD8 or ACMD8
		9h	CMD9 or ACMD9
		Ah	CMD10 or ACMD10
		Bh	CMD11 or ACMD11
		Ch	CMD12 or ACMD12
		Dh	CMD13 or ACMD13
		Eh	CMD14 or ACMD14
		Fh	CMD15 or ACMD15
		10h	CMD16 or ACMD16
		11h	CMD17 or ACMD17

		23h	CMD35 or ACMD35
		24h	CMD36 or ACMD36
		25h	CMD37 or ACMD37
		26h	CMD38 or ACMD38
		27h	CMD39 or ACMD39
		28h	CMD40 or ACMD40
		29h	CMD41 or ACMD41
		2Ah	CMD42 or ACMD42
		2Bh	CMD43 or ACMD43
		2Ch	CMD44 or ACMD44
		2Dh	CMD45 or ACMD45

Table 18-26. Command and Transfer Mode Register (MMCHS_CMD) Field Descriptions (continued)

Bit	Field	Value	Description
		2Eh	CMD46 or ACMD46
		2Fh	CMD47 or ACMD47
		30h	CMD48 or ACMD48
		31h	CMD49 or ACMD49
		32h	CMD50 or ACMD5
		33h	CMD51 or ACMD5
		34h	CMD52 or ACMD5
		35h	CMD53 or ACMD5
		36h	CMD54 or ACMD5
		37h	CMD55 or ACMD5
		38h	CMD56 or ACMD5
		39h	CMD57 or ACMD5
		3Ah	CMD58 or ACMD5
		3Bh	CMD59 or ACMD5
		3Ch	CMD60 or ACMD60
		3Dh	CMD61 or ACMD61
		3Eh	CMD62 or ACMD62
		3Fh	CMD63 or ACMD63
23-22	CMD_TYPE	0 1h 2h 3h	Command type. This register specifies three types of special command Suspend, Resume and Abort. These bits shall be cleared to 0b00 for all other commands. Others commands Upon CMD52 "Bus Suspend" operation Upon CMD52 "Function Select" operation Upon CMD12 or CMD52 "I/O Abort" command
21	DP	0 1	Data present select. This register indicates that data is present and mmc_dat line shall be used. It must be cleared to 0 in the following conditions: <ul style="list-style-type: none"> • Command using only mmchs_cmd line • Command with no data transfer but using busy signal on mmc_dat0 • Resume command Command with no data transfer Command with data transfer
20	CICE	0 1	Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCHS_STAT[19] CIE bit set to 1). Note The CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. Index check disable Index check enable
19	CCCE	0 1	Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCHS_STAT[17] CCRC bit set to 1). Note The CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. CRC7 check disable CRC7 check enable
18	Reserved	0	Reserved bit field. Do not write any value.
17-16	RSP_TYPE	0 1h 2h 3h	Response type. This bits defines the response type of the command. No response Response Length 136 bits Response Length 48 bits Response Length 48 bits with busy after response

Table 18-26. Command and Transfer Mode Register (MMCHS_CMD) Field Descriptions (continued)

Bit	Field	Value	Description
15-6	Reserved	0	Reserved bit field. Do not write any value.
5	MSBS	0	Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be cleared to 0.
		0	Single block. If this bit is 0, it is not necessary to set the register MMCHS_BLK[31:16] NBLK bits.
		1	Multi block. When Block Count is disabled (MMCHS_CMD[1] BCE bit is cleared to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer.
4	DDIR	0	Data transfer Direction. Select This bit defines either data transfer will be a read or a write.
		0	Data Write (host to card)
		1	Data Read (card to host)
3	Reserved	0	Reserved bit field. Do not write any value.
2	ACEN	0	Auto CMD12 Enable (SD cards only). When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. In particular, secure commands do not require CMD12.
		0	Auto CMD12 disable
		1	Auto CMD12 enable or CCS detection enabled.
1	BCE	0	Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (MMCHS_BLK[31:16] NBLK bits). When Block Count is disabled (MMCHS_CMD[1] BCE bit is cleared to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS bits is set to 1), the module can perform infinite transfer.
		0	Block count disabled for infinite transfer.
		1	Block count enabled for multiple block transfer with known number of blocks
0	DE	0	DMA Enable. This bit is used to enable DMA mode for host data access.
		0	DMA mode disable
		1	DMA mode enable

18.4.14 Command Response[31:0] Register (MMCHS_RSP10)

This 32-bit register holds bits positions [31:0] of command response type R1, R1b, R2, R3, R4, R5, R5b, or R6. The command response[31:0] register (MMCHS_RSP10) is shown in [Figure 18-48](#) and described in [Table 18-27](#).

Figure 18-48. Command Response[31:0] Register (MMCHS_RSP10)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-27. Command Response[31:0] Register (MMCHS_RSP10) Field Descriptions

Bit	Field	Value	Description
31-16	RSP1	0-FFFFh	Command Response [31:16]
15-0	RSP0	0-FFFFh	Command Response [15:0]

18.4.15 Command Response[63:32] Register (MMCHS_RSP32)

This 32-bit register holds bits positions [63:32] of command response type R2. The command response[63:32] register (MMCHS_RSP32) is shown in [Figure 18-49](#) and described in [Figure 18-49](#).

Figure 18-49. Command Response[63:32] Register (MMCHS_RSP32)

15-0	RSP4	0-FFFFh	Command Response [79:64]

18.4.17 Command Response[127:96] Register (MMCHS_RSP76)

This 32-bit register holds bits positions [127:96] of command response type R2. The command response[127:96] register (MMCHS_RSP76) is shown in [Figure 18-51](#) and described in [Table 18-30](#).

Figure 18-51. Command Response[127:96] Register (MMCHS_RSP76)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-30. Command Response[127:96] Register (MMCHS_RSP76) Field Descriptions

Bit	Field	Value	Description
31-16	RSP7	0-FFFFh	Command Response [127:112]
15-0	RSP6	0-FFFFh	Command Response [111:96]

18.4.18 Data Register (MMCHS_DATA)

This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bitsx256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput.

Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer.

Example 1Byte or 16-bit access

- Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK
- Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK
- Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad

The data register (MMCHS_DATA) is shown in [Figure 18-52](#) and described in [Table 18-31](#).

Figure 18-52. Data Register (MMCHS_DATA)

LEGEND: R/W = Read/Write; -n = value after reset

Table 18-31. Data Register (MMCHS_DATA) Field Descriptions

Bit	Field	Value	Description
31-0	DATA	0-FFFF FFFFh	<p>Data register [31:0]. In functional mode (MMCHS_CON[4] MODE bit set to the default value 0):</p> <p>A read access to this register is allowed only when the buffer read enable status is set to 1 (MMCHS_PSTATE[11] BRE bit), otherwise a bad access (MMCHS_STAT[29] BADA bit) is signaled.</p> <p>A write access to this register is allowed only when the buffer write enable status is set to 1 (MMCHS_PSTATE[10] BWE bit), otherwise a bad access (MMCHS_STAT[29] BADA bit) is signaled and the data is not written.</p>

18.4.19 Present State Register (MMCHS_PSTATE)

The Host can get the status of the Host controller from this 32-bit read only register. The present state register (MMCHS_PSTATE) is shown in [Figure 18-53](#) and described in [Table 18-32](#).

Figure 18-53. Present State Register (MMCHS_PSTATE)

31	Reserved				25	24	23	20		19	18	17	16

LEGEND: R = Read only; -n = value after reset

Table 18-32. Present State Register (MMCHS_PSTATE) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved bit field. Do not write any value.
24	CLEV	Read 0 Read 1	mmchs_cmd line signal level. This status is used to check the mmchs_cmd line level to recover from errors, and for debugging. The value of this register after reset depends on the mmchs_cmd line level at that time. The mmchs_cmd line level is 0. The mmchs_cmd line level is 1.
23-20	DLEV		mmc_dat[3:0] line signal level <ul style="list-style-type: none"> mmc_dat3 => bit 23 mmc_dat2 => bit 22 mmc_dat1 => bit 21 mmc_dat0 => bit 20 This status is used to check mmc_dat line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from mmc_dat0 . The value of these registers after reset depends on the mmc_dat lines level at that time.
19	WP	Read 0 Read 1	Write Protect Status. MMC/SD/SDIO1 only. SDIO cards only. This bit reflects the write protect input pin (SDWP) level. The value of this register after reset depends one the protect input pin (SDWP) level at that time. The card is write protected. The card is not write protected.
18	CDPL	Read 0 Read 1	Card Detect Pin Level. This bit reflects the inverse value of the card detect input pin (SDCD). Debouncing is not performed on this bit and is valid only when Card State is stable. (MMCHS_PSTATE[17] is set to 1). This bit must be debounced by software. The value of this register after reset depends on the card detect input pin (SDCD) level at that time. The value of the card detect input pin (SDCD) is 1. The value of the card detect input pin (SDCD) is 0.
17	CSS	Read 0 Read 1	Card State Stable. This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (MMCHS_PSTATE[18] CPDL). Debouncing is performed on the card detect input pin (SDCD) to detect card stability. This bit is not affected by software reset. Reset or Debouncing. No card or card inserted.
16	CINS	Read 0 Read 1	Card inserted. This bit is the debounced value of the card detect input pin (SDCD). An inactive to active transition of the card detect input pin (SDCD) will generate a card insertion interrupt (MMCHS_STAT[CINS]). A active to inactive transition of the card detect input pin (SDCD) will generate a card removal interrupt (MMCHS_STAT[CREM]). This bit is not affected by a software reset. If MMCHS_CON[CDP] is cleared to 0 (default), no card is detected. The card may have been removed from the card slot. If MMCHS_CON[CDP] is set to 1, the card has been inserted. If MMCHS_CON[CDP] is cleared to 0 (default), the card has been inserted from the card slot. If MMCHS_CON[CDP] is set to 1, no card is detected. The card may have been removed from the card slot.
15-12	Reserved	0	Reserved bit field. Do not write any value.

Table 18-32. Present State Register (MMCHS_PSTATE) Field Descriptions (continued)

Bit	Field	Value	Description
11	BRE	Read 0 Read 1	Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCHS_BLK[10:0] BLEN bits has been written in the buffer and is ready to be read. It is cleared to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCHS_STAT[5] BRR bit). Read BLEN bytes disable Read BLEN bytes enable. Readable data exists in the buffer.
10	BWE	Read 0 Read 1	Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data. There is no room left in the buffer to write BLEN bytes of data. There is enough space in the buffer to write BLEN bytes of data.
9	RTA	Read 0 Read 1	Read transfer active. This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is cleared to 0 when all data have been read by the local host after last block or after a stop at block gap request. No valid data on the mmc_dat lines. Read data transfer on going.
8	WTA	Read 0 Read 1	Write transfer active. This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is cleared to 0 when CRC status has been received after last block or after a stop at block gap request. No valid data on the mmc_dat lines. Write data transfer on going.
7-3	Reserved	0	Reserved bit field. Do not write any value.
2	DLA	Read 0 Read 1	mmc_dat line active. This status bit indicates whether one of the mmc_dat lines is in use. In the case of read transactions (card to host) This bit is set to 1 after the end bit of read command or by activating continue request MMCHS_HCTL[17] CR bit. This bit is cleared to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card) This bit is set to 1 after the end bit of write command or by activating continue request MMCHS_HCTL[17] CR bit. This bit is cleared to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request. mmc_dat line inactive mmc_dat line active
1	DATI	Read 0 Read 1	Command inhibit (mmc_dat). This status bit is generated if either mmc_dat line is active (MMCHS_PSTATE[2] DLA bit) or Read transfer is active (MMCHS_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCHS_STAT[1] TC bit). Issuing of command using the mmc_dat lines is allowed Issuing of command using mmc_dat lines is not allowed
0	CMDI	Read 0 Read 1	Command inhibit (mmchs_cmd). This status bit indicates that the mmchs_cmd line is in use. This bit is cleared to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is cleared to 0 in either the following cases: <ul style="list-style-type: none"> • After the end bit of the command response, excepted if there is a command conflict error (MMCHS_STAT[17] CCRC bit or MMCHS_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (MMCHS_AC12[0] ACNE bit). • After the end bit of the command without response (MMCHS_CMD[17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (MMCHS_STAT[19] CTO bit set to 1), this register is not automatically cleared. Issuing of command using mmchs_cmd line is allowed Issuing of command using mmchs_cmd line is not allowed

18.4.20 Control Register (MMCHS_HCTL)

This register defines the host controls to set power, wake-up and transfer parameters.

- MMCHS_HCTL[31:24] = Wake-up control
- MMCHS_HCTL[23:16] = Block gap control
- MMCHS_HCTL[15:8] = Power control
- MMCHS_HCTL[7:0] = Host control

NOTE: If your device does not support MMC cards, then those bits in this register which are meant for MMC card use should be assumed to be reserved.

The control register (MMCHS_HCTL) is shown in [Figure 18-54](#) and described in [Table 18-33](#).

Figure 18-54. Control Register (MMCHS_HCTL)

31		28	27	26	25	24	23		20	19	18	17	16	
Reserved			OBWE	REM	INS	IWE	Reserved			IBG	RWC	CR	SBGR	
R-0			R/W-0	R/W-0	R/W-0	R/W-0	R-0			R/W-0	R/W-0	R/W-0	R/W-0

R-0			R/W-0		R/W-0	R/W-0	R/W-0	R-0	R/W-2h	R/W-0	R/W-0	R-0		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-33. Control Register (MMCHS_HCTL) Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Reserved bit field. Do not write any value.
27	OBWE	0 1	Wake-up event enable for 'out-of-band' Interrupt. This bit enables wake-up events for 'out-of-band' assertion. Wake-up is generated if the wake-up feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP bit). The write to this register is ignored when MMCHS_CON[14] OBIE bit is not set. Disable wake-up on 'out-of-band' Interrupt Enable wake-up on 'out-of-band' Interrupt
26	REM	0 1	Wake-up event enable on SD card removal. This bit enables wake-up events for card removal assertion. Wake-up is generated if the wake-up feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP bit). Disable wake-up on card removal Enable wake-up on card removal
25	INS	0 1	Wake-up event enable on SD card insertion. This bit enables wake-up events for card insertion assertion. Wake-up is generated if the wake-up feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP bit). Disable wake-up on card insertion Enable wake-up on card insertion
24	IWE	0 1	Wake-up event enable on SD card interrupt. This bit enables wake-up events for card interrupt assertion. Wake-up is generated if the wake-up feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP bit) and enable status bit is set (MMCHS_IE[8] CIRQ_ENABLE bit). Disable wake-up on card interrupt Enable wake-up on card interrupt
23-20	Reserved	0	Reserved bit field. Do not write any value.
19	IBG	0 1	Interrupt block at gap. This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be cleared to 0. Disable interrupt detection at the block gap in 4-bit mode Enable interrupt detection at the block gap in 4-bit mode

Table 18-33. Control Register (MMCHS_HCTL) Field Descriptions (continued)

Bit	Field	Value	Description
18	RWC	0 1	<p>Read wait control. The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCHS_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on mmc_dat line.</p> <p>0 Disable read wait control. Suspend/resume cannot be supported.</p> <p>1 Enable read wait control</p>
17	CR	0 1	<p>Continue request. This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCHS_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically cleared to 0 by the host controller when transfer has restarted, that is, mmc_dat line is active (MMCHS_PSTATE[2] DLA bit) or transferring data (MMCHS_PSTATE[8] WTA bit). The Stop at block gap request must be disabled (MMCHS_HCTL[16] SBGR bit =0) before setting this bit.</p> <p>0 No affect</p> <p>1 Transfer restart</p>
