1.1 About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

1.2 Glossary

TI Glossary	This glossary lists and explains terms, acronyms, and definitions.

1.4 Support Resources

TI E2E™ support forums are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

Chapter 2
Introduction

This chapter introduces the features, subsystems, and architecture of AM273x (TI Processor for Radar) Systems on Chip (SoCs).

2.1 Device Overview

The AM273x is targeted for automotive applications such as Advanced Driver Assistance System (ADAS), automotive premium audio and amplifiers, industrial and broad-market applications such as edge analytics, low-end motor drives, entry-level industrial communication gateways, and audio applications.

The device is composed of the following main subsystems:

- One Dual Core Lock-step Cortex R5F microcontroller at up to 400 MHz.
- One TI C66x variant Single Core Floating point DSP at up to 450 MHz
- Radar Hardware Accelerators running at 400 MHz
- Cortex M4-based () Hardware Security Module (HSM) for running security services in a secure island.

The device provides a rich set of peripherals, such as:

- General connectivity peripherals, including:
  - Three Inter-Integrated Circuit (I2C) interfaces
  - Four Controller/Peripheral Multi-Buffered Serial Peripheral Interfaces (MiBSPI)
  - configurable Universal Asynchronous Receiver/Transmitter (UART) interfaces
  - One General-Purpose Input/Output (GPIO) module
  - One 10-bit Analog to Digital Convertors.
- High-speed interfaces, including:
  - Two 4-Lane CSI2 receiver interface
  - One Ethernet switch (CPSW)
- Control and Communication interfaces, including:
  -
  - Three Enhanced Pulse Width Modulation (EPWM) modules
  - One Enhanced Capture (ECAP) module.
- EMIF Interface
  - One Quad-Serial Peripheral Interface (QSPI) at up to 67 MHz.
- Timers and Watchdog Module
- Interprocesser Communication (IPC) interface
  - Mailbox module for interprocessor communication between the different modules
- Sub-system Reset and control module with device top-level configurations:
  - Power distribution, reset controls, and clock management components.
  - Registers for the following functions:
    - I/O Configurations
    - PLL control and associated High-speed Dividers (HSDIV)
    - Clock Selection

    - System boot mode decoding logic
  - Up to 5 MB of on-chip memory split across DSS, MSS, and the shared memory L3 bank.
  - Debug and trace capabilities.

The AM273x device has distinguished characteristics for ADAS applications:

- High Performance Radar Processing Accelerators with the capability to offload the DSP/CPU almost all the pre-processing functions.
- Radar Hardware Accelerators running at 400 MHz capable of the 256 pt FFT for 4Rx channels in 3.2 µs.
- High Performance/Cost ratio. Highly optimized, area efficient infrastructure to support the radar data flow with maximum cost effectiveness and efficiency.
- One 4-Lane LVDS TX interface with Xilinx AURORA protocol.

The device includes different modules for functional safety requirements support:

- Logic BIST mechanism for all the CPU cores
- PBIST mechanism for all the memories
- ECC on the critical memories
- MPU on all critical shared resources – MMRs and memories
- Voltage monitor on all the primary supplies with >90% DC
- Clock monitors to monitor all the primary clocks. At least one Watchdog per each subsystem.
- PLL Lock monitors – PHASELOCK, FREQLOCK
- Temperature sensors with an accuracy of +/-5°C near DSP, R5F, HSM, and all other temperature sensitive locations.
- Separate safety island (MCU) with Lock-Step Cortex-R5F.
- Safety enabled interconnect
- Two Error Signaling Modules (ESM) to enable error monitoring, 1 each in DSS and MSS.
- Temperature monitoring sensors
- Dedicated hardware Memory Cyclic Redundancy Check (MCRC) blocks.

2.2 Device Block Diagram

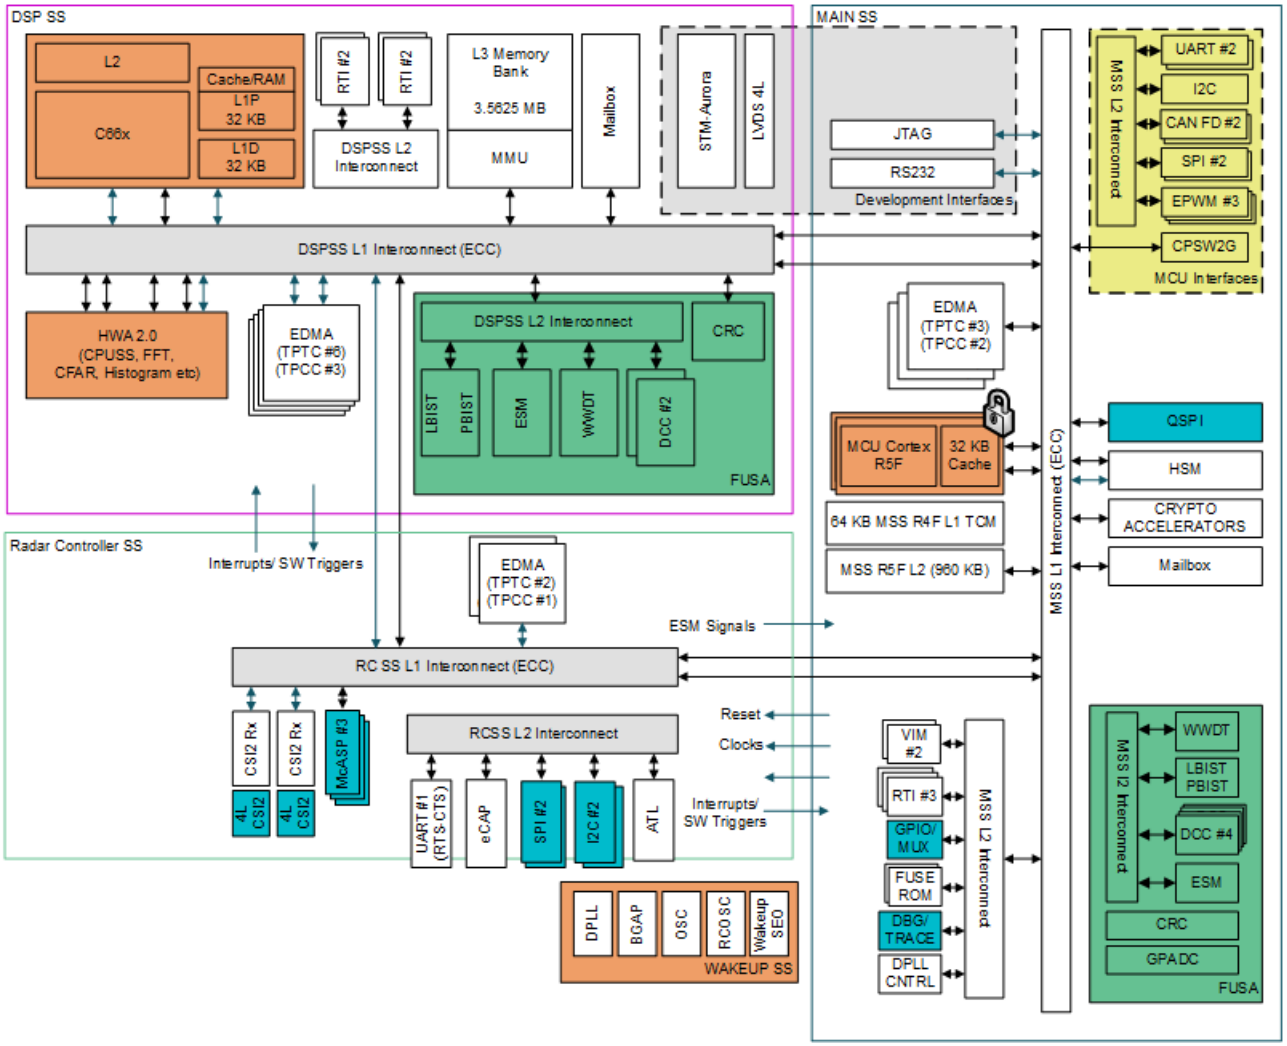

Figure 2-1. Block Diagram

Chapter 3

Memory Map

The following tables explain the memory maps.

Table 3-1. R5 Memory Map Overview

Region	Size	Notes
R5 L1 I-Cache	32 KB	L1 stands for Level 1
R5 L1 D-Cache	32 KB	D-Cache stands for Data Cache
R5 L1 TCMA ROM	128 KB	
R5 L1 TCMA RAM Lock Step Mode	32 KB	Applicable for Core A only
R5 L1 TCMA RAM Dual Core Mode	16 KB for Core A and 16 KB for Core B	
R5 L1 TCMB RAM Lock Step Mode	32 KB	Applicable for Core A Only
R5 L1 TCMB RAM Dual Core Mode	16 KB for Core A and 16 KB for Core B	

Note

There are no fundamental restrictions on access to MSS and DSS memories. The address regions (global view) must be selected appropriately. There are Memory Protection Units (MPUs) at the key memories (MSS L2, DSS L3, etc...). This allows the user application to restrict access as needed.

Table 3-2. MSS L2 Memory Map Overview

Region	Size	Notes
L2 RAM	960 KB	Also known as L2 Memory and MSS_L2

Table 3-3. DSP L1 Memory Map Overview

Region	Size	Notes
DSP L1P	32 KB	L1P stands for L1 Program
DSP L1D	32 KB	L1D stands for L1 Data

Table 3-4. DSS Memory Map Overview

Region	Size	Notes
DSS L2 RAM	384 KB	
DSS L3 Memory	1.5 - 3.5625 MB	Size depends device's memory grade. See data sheet's Device Speed and Memory Grade for details.

Note

L3 consists of banks. The below tables show example sizes and addresses. However, the banks are for PBIST and have different ways to map.

3.1 Main Subsystem Cortex R5F Memory Map

Module Name	Base Address	End Address	Size
TCMA_ROM_CR5A	0x0000 0000	0x0001 FFFC	128 KBytes

Note

TPTC-C2, TPTC-C3, TPTC-C4, and TPTC-C5 modules and their functionality are not supported in this family of devices. *Any information regarding these modules has been retained in the documentation solely for the purpose of clarifying memory map read/write attributes. Features noted as "not supported" must not be used.*

The device implements a system interconnect based on TI's common bus architecture, comprising of VBUSM and VBUSP protocols.

The system interconnect is designed for the high-performance needs of the system. The interconnect structure is a full crossbar implementation, wherein every controller has an independent communication path with every target such that transactions from each controllers have access to full interconnect bandwidth. Arbitration only happens at taget end point. It's divided into interconnect systems local to each subsystem: the Main R5F subsystem, and Radar Control subsystem.

4.1 Main Subsystem R5F Infrastructure

In the main subsystem, the primary VBUSM SCR is responsible for managing the arbitration priority between accesses from multiple controllers to each of the targets. The arbitration priority is always round-robin.

The main subsystem has PCR interconnect that manages the accesses to the peripheral registers and peripheral memories, and provides a global reset for all peripherals. It also supports the capability to selectively enable or disable the clock for each peripheral individually. The PCR also manages the accesses to the system module registers required to configure the device clocks, interrupts, and so forth.

The system module registers include status flags for indicating exception conditions – resets, aborts, errors, and interrupts.

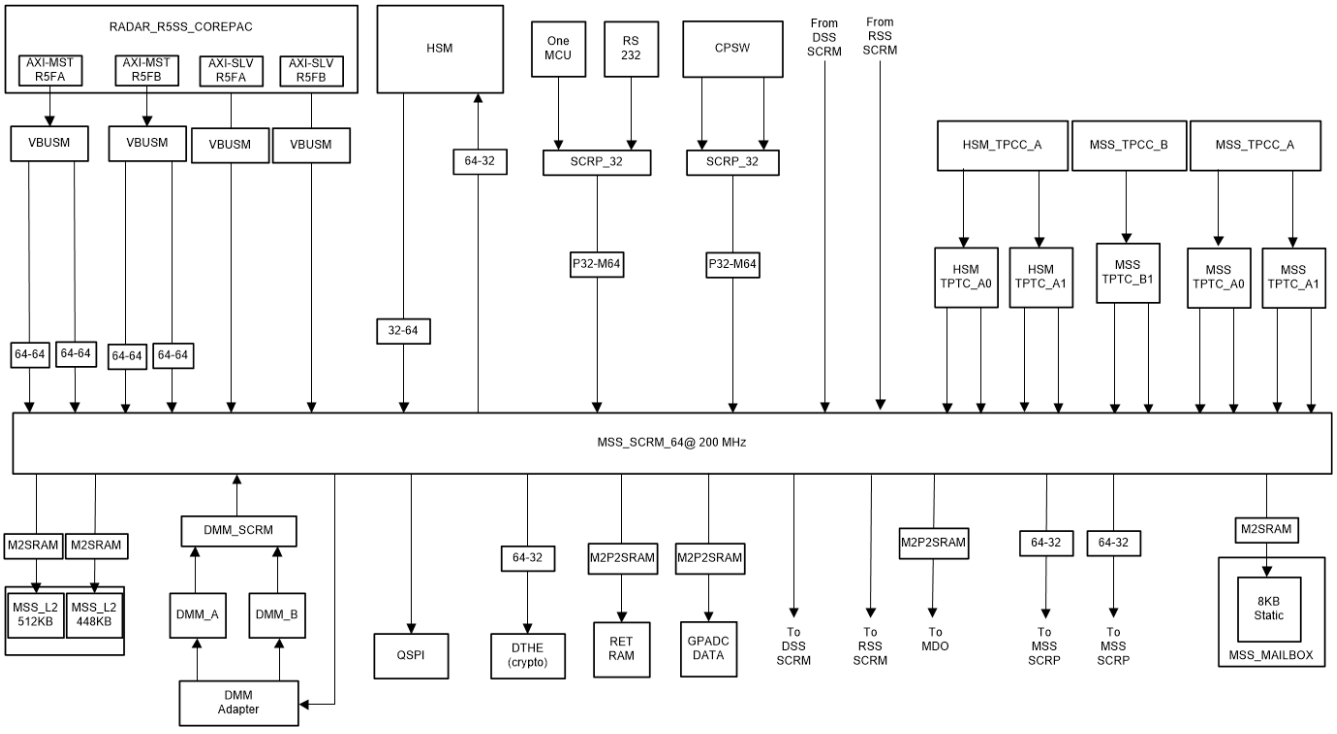

Figure 4-1. Main Subsystem R5F Infrastructure

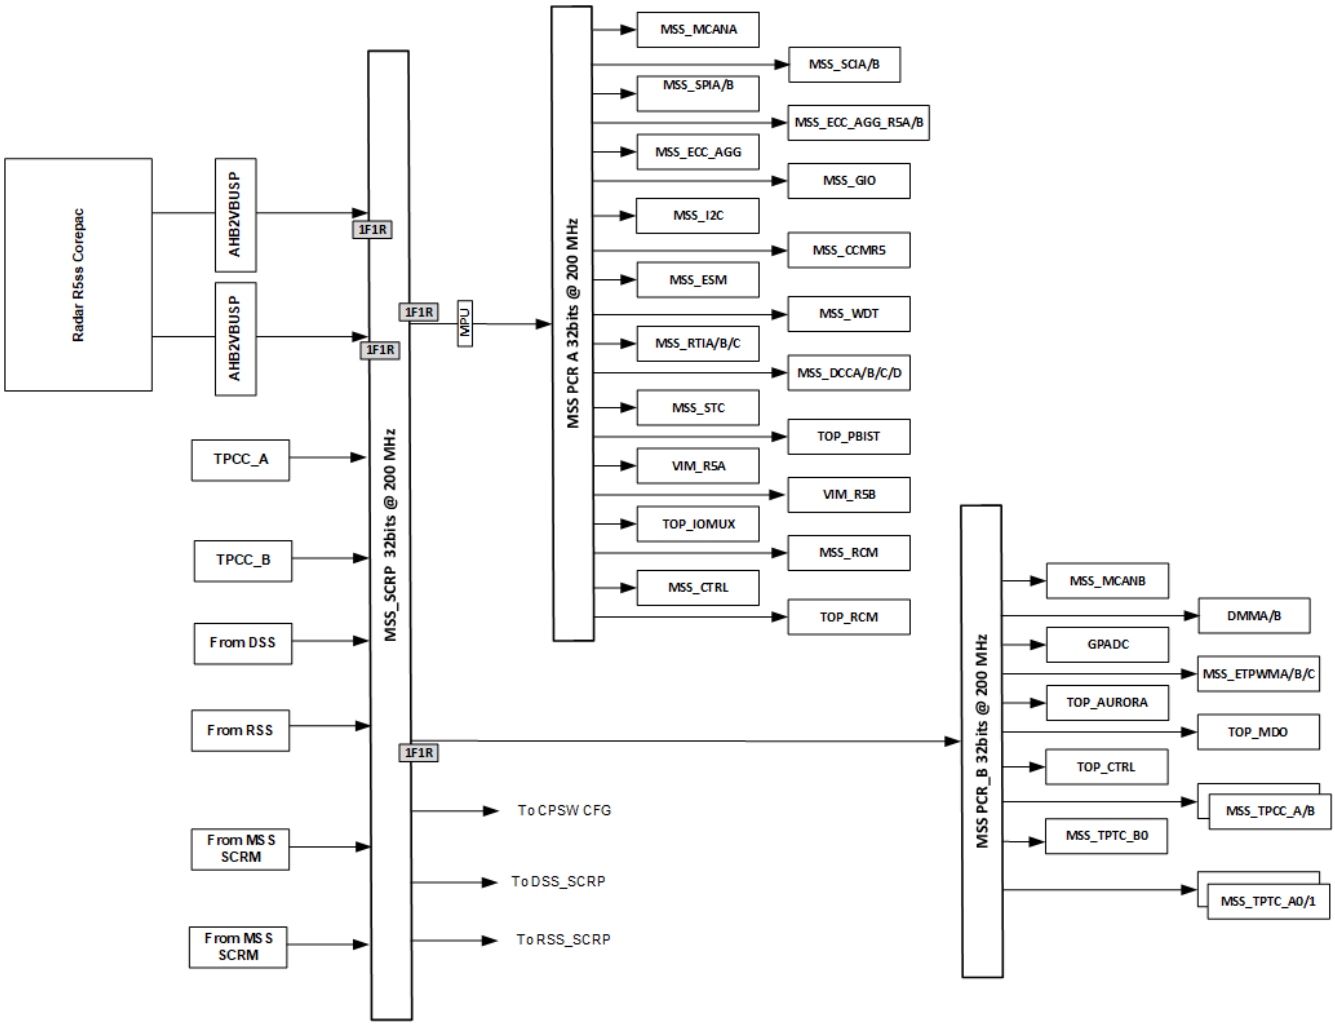

Figure 4-2. MSS Peripheral Infrastructure

4.2 DSP Subsystem C66x Infrastructure

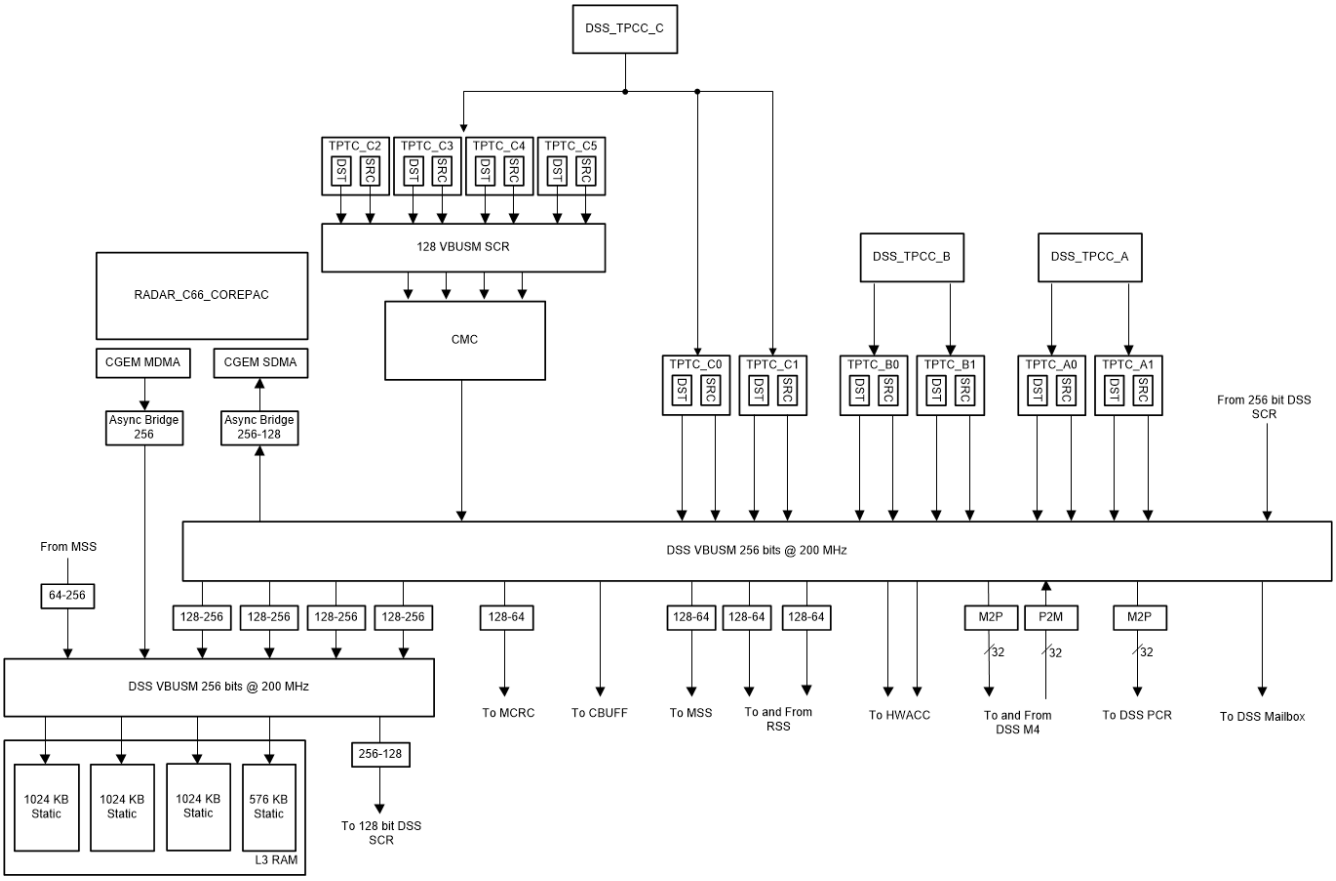

Figure 4-3. DSP Subsystem Infrastructure

The DSS has a hybrid infrastructure of 256-bit and 128-bit data SCRs. This is to match the L3 and DSP MDMA port data widths. The area overhead of hooking up all the other controllers and targets to a 256-bit SCR because the number of bridges required was too large. The MSS Controller also sits on the 256-bit SCR, so that the latency to L3 is reduced.

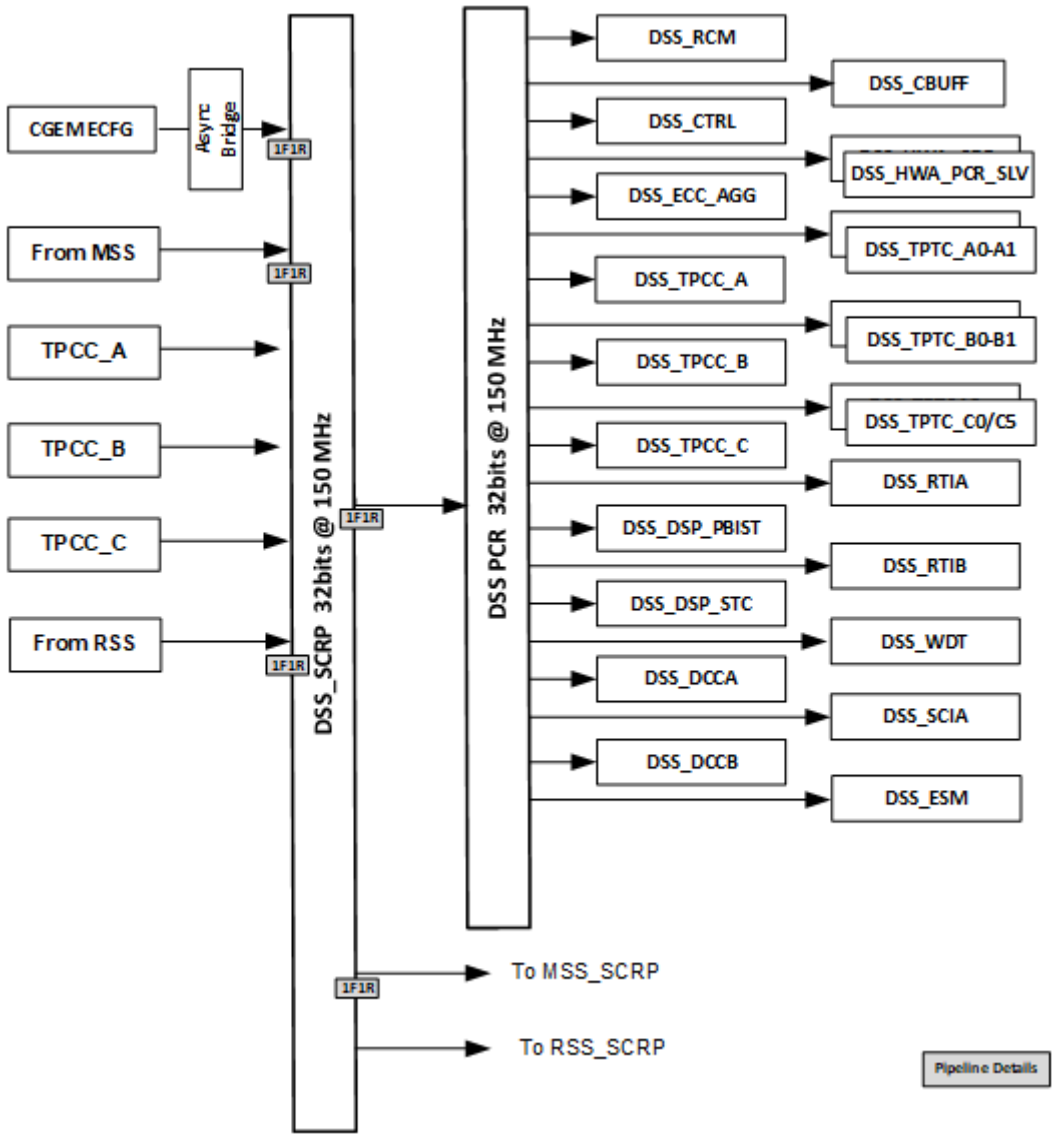

Figure 4-4. DSS Peripheral Infrastructure

Note

TPTC-C2, TPTC-C3, TPTC-C4, and TPTC-C5 modules and their functionality are not supported in this family of devices. *Any information regarding these modules has been retained in the documentation solely for the purpose of clarifying memory map read/write attributes. Features noted as "not supported" must not be used.*

4.3 Radar Control Subsystem Infrastructure

The RControlSS has a 64-bit data SCR

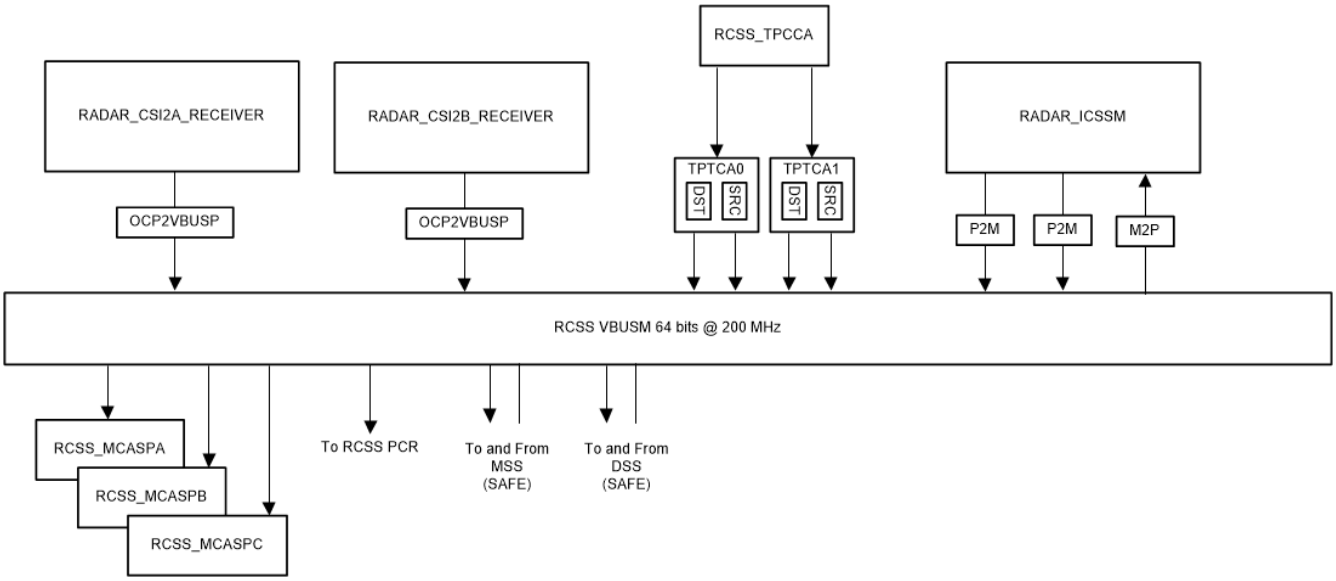

Figure 4-5. Radar Control Subsystem Infrastructure

Chapter 5

Device Initialization

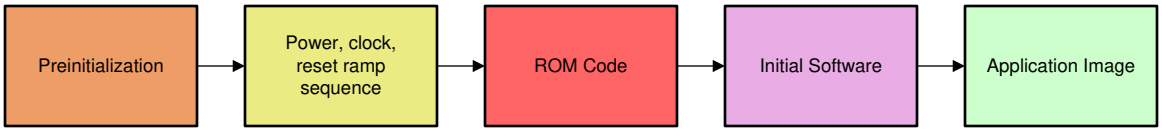

Figure 5-1. Device Initialization

The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins, the associated configuration registers, and memory structures that are vital to the correct initialization of the device.

5.2 Boot Process

5.2.1 ROM Code Overview

To accommodate various system scenarios, the ROM code supports several boot modes. These boot modes can be broadly classified as:

- Host boot modes
- Memory boot modes.

During a host boot, the device is configured to receive code from a host through the selected interface (such as UART). Either the host writes the application code directly into internal memory over UART, or the ROM code receives the application code on the selected interface and stores it in internal memory.

During a memory boot, the device transfers code from non-volatile memory to internal memory for execution.

In all boot modes, the entire boot operation can be partitioned into two sections:

- Hardware initialization phase
- Boot process

During initialization, the ROM code configures the device resources (PLLs, peripherals, pins) as needed to support the boot process. The resources used depend on the boot mode requirements. During the boot process, the boot image can be loaded into device memory and executed, depending on the boot peripheral. HSM ROM code performs code verification and allows or forbids the image execution.

The main configuration source for boot after power-up are the SOP mode pins sampled automatically after reset release and stored in device status registers. At ROM code startup, these pin values are read from the registers to create the boot peripheral list, and the boot configuration tables used later to initialize and startup the PLLs and boot peripherals.

5.2.2 Boot Modes

MCU ROM supports the functionality of loading the secondary boot loader (SBL). The SBL can be loaded through QSPI (primary/secondary SBL) and UART mode. The primary use case of QSPI programming through UART interface is to support the uniFlash utility. This mode programming may be applicable for certain use

cases, such as initial FLASH programming in volume mass production, that can also be achieved with special in-circuit gang programming tools.

Primary functional boot mode is through QSPI FLASH. MCU ROM supports managing multiple (primary and backup) QSPI SBL images. It can identify the primary image, and switch to secondary image load if primary image load fails.

Table 5-1. Boot Modes and Boot Media

Boot Mode/Peripheral	Boot Media/Host	Notes
QSPI	QSPI flash	Download and boot SBL from QSPI flash. Attempt Primary SBL, followed by Secondary SBL if primary loading fails: If above is not successful
UART	External host	Download and boot SBL from UART. Device is expected to get SBL from UART. We will support the XMODEM protocol for download over UART.
SBL Dev	Load SBL via debugger/CCS	**Only applicable for HS-FS devices**. SBL download by HSM ROM is skipped and R5 is booted. SBL developers load SBL via CCS JTAG to help development flow to be faster

For more information about various bootmode and flash device support please refer to application note.

Note

Boot ROM does not give software reset to QSPI Flash. Hence is it recommended to make sure Flash is in ready state to accept commands before ROM bootloader kicks in.

5.2.3 SOP Mode Pins

Table 5-2 lists the functional mode pin settings to be done for the SOP lines of the device to boot using different peripheral. New SOP modes will be added later.

Table 5-2. Functional Mode Pin Settings

Functional Mode	SOP Mode	PMIC_OUT	SYNC_OUT	TDO
Func Mode –QSPI	SOP_MODE4	0	0	1
Func Mode –UART	SOP_MODE5	1	0	1
Func Mode –SBL Dev	SOP_MODE6	1	1	0

5.2.4 BOOT-ROM Architecture (RBL)

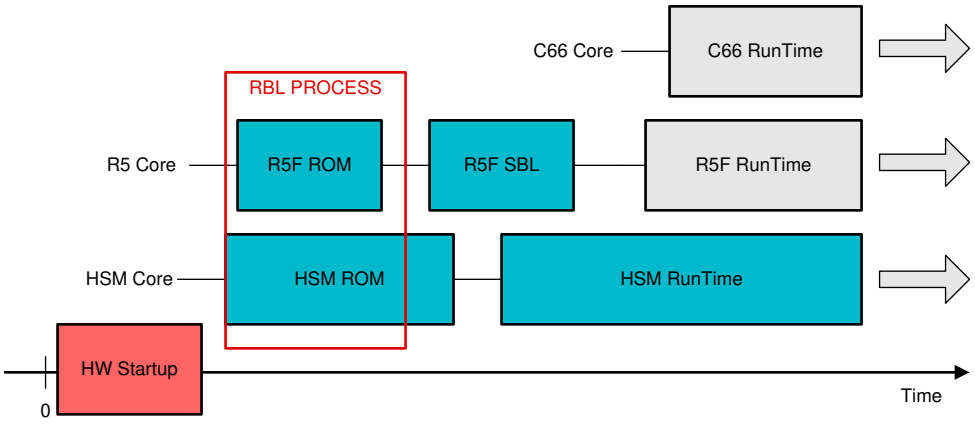

Figure 5-2. Boot Flow and Boot ROM Architecture

The RBL process goal is to load, verify, optionally decrypt, and launch an authentic R5F software image that accomplishes general-purpose/secure boot goals. The RBL process is implemented jointly by the R5F and HSM ROM as illustrated in Figure 5-2.

HSM ROM

This HSM ROM contains the first set of software instructions that is executed by any processor core on all TPR devices. All state changes in the device after the external reset is released but prior to the beginning of the HSM ROM code execution are purely a function of hardware logic. This hardware logic must perform sufficient ramp up and initialization to allow the Cortex M4 core of the HSM to leave reset and begin execution from its reset vector. The HSM ROM code is “time zero” software. The HSM ROM code is only intended to be used during the initial load of the secondary boot loader (SBL) and HSM RunTime image. HSM ROM is also responsible for providing Test/Debug capabilities when functional boot is interrupted.

MCU ROM

The MCU ROM code is only intended to be used during the initial load of the secondary boot loader (SBL). RBL can load the SBL content only to MSS_L2 area and at the end copies SBL's IVT (interrupt vector table) of 640B size to TCMA_RAM_CR5A before switching to SBL. This ROM-to-RAM (RBL to SBL) switching causes TCMA_ROM_CR5A eclipse to TCMA_RAM_CR5A i.e. 0x0000_0000 now maps to TCMA_RAM_CR5A memory area. Use of RBL at any other time in the lifecycle of a system is not supported. MCU ROM executes set of self-tests: PBIST (DATA SRAM, PROGRAM SRAM, and ROM Code Integrity) using a hardware-defined interface. If unsuccessful, the error condition is indicated, external ESM signal asserted, and boot does not proceed.

R5F SBL

This SBL can perform complete boot sequence on general purpose devices. Customers are expected to develop their own SBLs, supporting a wider range of requirements (such as different interfaces, additional protocols, different image formats, future update flow and so forth).

HSM RunTime/R5F Runtime

HSM RunTime is only applicable in case of Secured (HS) variant and out of scope of this document. R5F user developed applications and loaded/executed by SBL.

5.2.5 R5F SBL Loading

The SBL process starts with R5F executing loaded and verified R5F SBL code.

The only service exposed to R5F SBL by HSM ROM is the API to load the HSM RunTime. All other HSM services are outside of the HSM ROM. The R5 Boot ROM and HSM Boot ROM work together to load the R5F SBL. When the R5F SBL has been successfully validated and loaded, the R5F Boot-ROM is eclipsed and the R5F SBL executes.

Figure 5-3 is the simplified sequence of the boot process. It is provided for illustration purposes only. An illustration of the SBL and HSM RunTime is similar to what is shown in Figure 5-3.

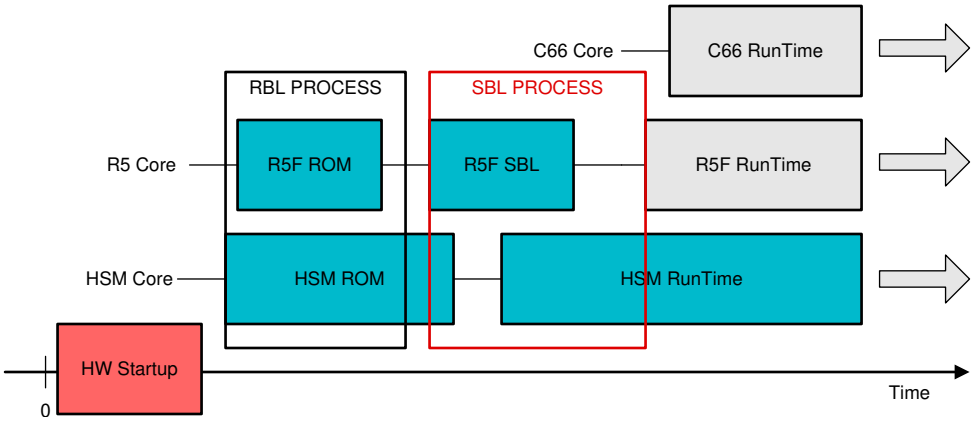

Figure 5-3. R5F SBL

The HSM ROM configures IPC mechanism, and releases R5F from reset, sends boot options message to R5F, and awaits for R5F service calls. R5F reads the boot options and configures QSPI. R5F reads the R5F SBL image. The image may or may not be integrity checked. The HSM ROM switches the memory map and restarts the R5F to SBL. The HSM-ROM for GP devices is now locked (black-boxed). SBL now runs the multicore loader to the DMA-copy image sections to R5F and C66 loading addresses. SBL loads images of R5F and C66, and restarts/jumps to R5F RunTime. R5F RunTime releases the C66 from reset.

Chapter 6

Device Configuration

6.1 Overview

PRCM manages clocks, resets, and power domain control of subsystems and modules inside the device. Additionally, configuration of certain device-level features is also performed through this module. PRCM has control and status registers to achieve this functionality. The Clock and Reset Management in AM273x is distributed. The Main subsystem TOPRCM module controls all the Subsystem Resets and Clocks. The SubSystem RCM modules control their respective subsystem IPs

The available address space of PRCM is divided as in Figure 6-1.

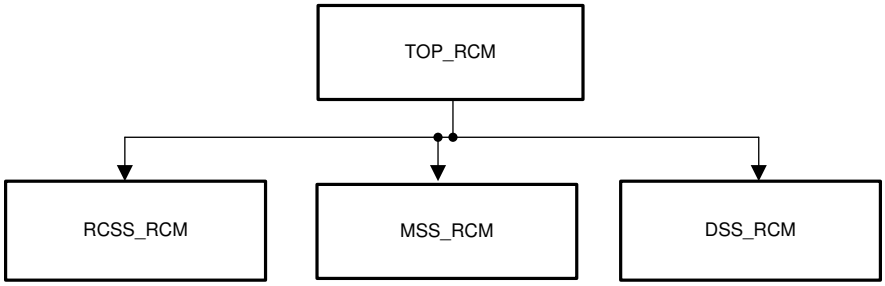

Figure 6-1. Device Configuration

Table 6-1. PRCM Space

PRCM Space	Description
MSS_TOPRCM/TOP_RCM	Top-level reset, clock management registers
MSS_RCM	Main subsystem reset, clock management registers
RCSS_RCM	Radar Control subsystem reset, clock management registers

Note

TOP_RCM and MSS_TOPRCM names are used interchangeably across this document and are pointed to same RCM space.

6.2 Control Registers

6.2.1 Kick Protection Registers

The Control MMR modules have a protection mechanism which prevents spurious writes from changing the values of its registers. The LOCKi_KICK0 and LOCKi_KICK1 registers are used for this purpose. A write is required first to the LOCKi_KICK0[31-1] KEY field and then to the LOCKi_KICK1[31-0] KEY field with exact data values to unlock the protection mechanism. Once released then all registers within Partition "i" having write permissions can be written to. The read only registers are still read only. An indication for unlocked Partition "i" is when the LOCKi_KICK0[0] UNLOCKED bit is set to 1h. When the protection mechanism is locked (indicated by LOCKi_KICK0[0] UNLOCKED = 0h) none of the registers within Partition "i" can be written to. They can only be read.

The table below shows the values that must be written to the LOCKi_KICK0 and LOCKi_KICK1 registers to unlock each partition. Writing any other data value to either of these registers locks the protection mechanism and blocks any writes to the registers that reside in Partition "i".

The MSS_IOMUX module also has kick protection registers.

Table 6-2. Kick Protection Register Unlock Values

Protected Register	Kick Register	Unlock Value
MSS_TOPRCM	LOCK0_KICK0	0x01234567
	LOCK0_KICK1	0xFEDCBA8

Table 6-50. PLL_CORE_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PONOUT	R	1h	Status of the weak power-switch 0x0 : indicates the/OFF status of the weak power-switch in digital to SOC. 0x1 : ndicates the ON status of the weak power-switch in digital to SOC.
30	PGOODOUT	R	1h	Status of the strong power-switch 0x0 : indicates the/OFF status of the strong power-switch in digital to SOC. 0x1 : ndicates the ON status of the strong power-switch in digital to SOC.
29	LDOPWDN	R	0h	1 indicates ADPLLLJ internal LDO is power down. VDDLDOOUT will be un-defined in this condition
28	RECAL_BSTATUS3	R	0h	Recalibration status flag. 1 ADPLLLJ requires recalibration
27	RECAL_OPPIN	R	0h	Recalibration status flag. 1 ADPLLLJ requires recalibration
26-12	RESERVED	R	X	
11	CLKDCOLDOACK	R	0h	Status on PHASELOCK output pin
10	PHASELOCK	R	0h	Status on PHASELOCK output pin
9	FREQLOCK	R	0h	Status on FREQLOCK output pin
8	BYPASSACK	R	0h	Status of BYPASSACK output pin
7	STBYRETACK	R	0h	Standby and retention status 0x0: indicates to SOC that all internal clocks in ADPLLLJ are active and it is starting the relock process. 0x1: indicates to SOC that all internal clocks in ADPLLLJ are gated and it is ready for retention.
6	LOSSREF	R	0h	Reference input loss
5	CLKOUTENACK	R	1h	Indicates the enable/disable condition of CLKOUTEN 0x0 = CLKOUT gating completed 0x1 = CLKOUT enabling completed
4	LOCK2	R	0h	ADPLL internal loop lock status

Table 6-50. PLL_CORE_STATUS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	M2CHANGEACK	R	0h	Acknowledge for change to M2 divider. Toggles from 1-0 or 0-1 (depending on current value) once CLKOUT frequency change has completed.
2	SSCACK	R	0h	Spread Spectrum status 0x0 : Spread-spectrum Clocking is disabled on output clocks 0x1 : Spread-spectrum Clocking is enabled on output clocks
1	HIGHJITTER	R	0h	1 indicates jitter. After PHASELOCK is asserted high, the HIGHJITTER flag is asserted high if phase error between REFCLK and FBCLK greater than 24%.
0	BYPASS	R	1h	Bypass status signal. 1 CLKOUT in bypass

6.2.2.48 PLL_CORE_HSDIVIDER Register (Offset = 428h) [reset = X]

PLL_CORE_HSDIVIDER is shown in Figure 6-49 and described in Table 6-51.

Return to the Summary Table.

Table 6-74. PLL_DSP_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PONOUT	R	1h	Status of the weak power-switch 0x0 : indicates the/OFF status of the weak power-switch in digital to SOC. 0x1 : ndicates the ON status of the weak power-switch in digital to SOC.
30	PGOODOUT	R	1h	Status of the strong power-switch 0x0 : indicates the/OFF status of the strong power-switch in digital to SOC. 0x1 : ndicates the ON status of the strong power-switch in digital to SOC.
29	LDOPWDN	R	0h	1 indicates ADPLLLJ internal LDO is power down. VDDLDOOUT will be un-defined in this condition
28	RECAL_BSTATUS3	R	0h	Recalibration status flag. 1 ADPLLLJ requires recalibration
27	RECAL_OPPIN	R	0h	Recalibration status flag. 1 ADPLLLJ requires recalibration
26-12	RESERVED	R	X	
11	CLKDCOLDOACK	R	0h	Status on PHASELOCK output pin
10	PHASELOCK	R	0h	Status on PHASELOCK output pin
9	FREQLOCK	R	0h	Status on FREQLOCK output pin
8	BYPASSACK	R	0h	Status of BYPASSACK output pin
7	STBYRETACK	R	0h	Standby and retention status 0x0: indicates to SOC that all internal clocks in ADPLLLJ are active and it is starting the relock process. 0x1: indicates to SOC that all internal clocks in ADPLLLJ are gated and it is ready for retention.
6	LOSSREF	R	0h	Reference input loss
5	CLKOUTENACK	R	1h	Indicates the enable/disable condition of CLKOUTEN 0x0 = CLKOUT gating completed 0x1 = CLKOUT enabling completed
4	LOCK2	R	0h	ADPLL internal loop lock status

Table 6-74. PLL_DSP_STATUS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	M2CHANGEACK	R	0h	Acknowledge for change to M2 divider. Toggles from 1-0 or 0-1 (depending on current value) once CLKOUT frequency change has completed.
2	SSCACK	R	0h	Spread Spectrum status 0x0 : Spread-spectrum Clocking is disabled on output clocks 0x1 : Spread-spectrum Clocking is enabled on output clocks
1	HIGHJITTER	R	0h	1 indicates jitter. After PHASELOCK is asserted high, the HIGHJITTER flag is asserted high if phase error between REFCLK and FBCLK greater than 24%.
0	BYPASS	R	1h	Bypass status signal. 1 CLKOUT in bypass

6.2.2.72 PLL_DSP_HSDIVIDER Register (Offset = 828h) [reset = X]

PLL_DSP_HSDIVIDER is shown in Figure 6-73 and described in Table 6-75.

Return to the Summary Table.

31	CYCLESLIPEN	R/W	0h	FailSafe enable to trigger re-calibration in case CycleSlip occurs between REFCLK and FBCLK.
30	ENSSC	R/W	0h	Controls Clock Spreading. SSC is not supported. Should be set to 0x0 to disable clock spreading.
29	CLKDCOLDOEN	R/W	0h	Synchronously enables/disables CLKDCOLDO 0x0 : synchronously disables CLKDCOLDO 0x1 : synchronously enables CLKDCOLDO
28-24	NWELLTRIM	R/W	9h	Trim value for the PLL
23	IDLE	R/W	1h	Sets PLL to Idle mode 0x0 : When SYSRESET = 0 and TINITZ = 1 IDLE = 0 PLL will go to Active and Locked 0x1 : When SYSRESET = 0 and TINITZ = 1 IDLE = 1 PLL will go to Idle Bypass low powe
22	BYPASSACKZ	R/W	0h	BYPASSACKZ is a special purpose input to the module. In general this input is expected to be tied to static low. For the output clocks of the module that do not have an internal bypass mux viz. CLKDCOLDO and CLKOUTLDO, a bypass mux could be implemented external to the module.
21	STBYRET	R/W	0h	Standby retention control 0x0 : prepares ADPLLLJ for relock when out of retention by removing the gating on all internal clocks. 0x1 : prepares ADPLLLJ for retention by gating all the internal clocks.
20	CLKOUTEN	R/W	1h	CLKOUT enable or disable 0x0 : synchronously disables CLKOUT 0x1 : synchronously enables CLKOUT
19	CLKOUTLDOEN	R	0h	Synchronously enables/disables CLKOUTLDO 0x0 : synchronously disables CLKOUTLDO 0x1 : synchronously enables CLKOUTLDO
18	ULOWCLKEN	R/W	0h	Select CLKOUT source in bypass 0x0: When ADPLLLJ in bypass mode, CLKOUT = CLKINP/(N2+1) 0x1: When ADPLLLJ in bypass mode, CLKOUT = CLKINPULOW.

Table 6-81. PLL_PER_CLKCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17	CLKDCOLDOPWDNZ	R/W	0h	0 Asynchronous power down for CLKDCOLDO o/p.
16	M2PWDNZ	R/W	1h	M2 divider power down mode 0x0: Asynchronous power down for M2 divider 0x1 : M2 divider is functional
15	RESERVED	R/W	X	
14	STOPMODE	R/W	1h	When in Lossclk/Stbyret 0x0 : Limp mode 0x1 : Stopmode
13	RESERVED	R/W	X	
12-10	SELFREQDCO	R/W	2h	DCO Clock (DCOCLK = CLKINP * [M/(N+1)]) frequency range selector. 0x0: Reserved 0x2: HS2 : DCOCLK range is from 500 MHz to 1000 MHz 0x3: Reserved 0x4: HS1: DCOCLK range is from 1000 MHz to 2000 MHz 0x5: Reserved
9	RESERVED	R/W	X	
8	RELAXED_LOCK	R/W	0h	Decides when FREQLOCK asserted 0x0: FREQLOCK asserted when DC frequency error less than 1% 0x1: FREQLOCK asserted when DC frequency error less than 2%
7-2	RESERVED	R/W	X	
1	SSCTYPE	R/W	0h	SSC Type
0	TINTZ	R/W	0h	PLL core soft reset

6.2.2.79 PLL_PER_TENABLE Register (Offset = 844h) [reset = X]

PLL_PER_TENABLE is shown in Figure 6-80 and described in Table 6-82.

Return to the Summary Table.

Table 6-89. PLL_PER_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PONOUT	R	1h	Status of the weak power-switch 0x0 : indicates the/OFF status of the weak power-switch in digital to SOC. 0x1 : ndicates the ON status of the weak power-switch in digital to SOC.
30	PGOODOUT	R	1h	Status of the strong power-switch 0x0 : indicates the/OFF status of the strong power-switch in digital to SOC. 0x1 : ndicates the ON status of the strong power-switch in digital to SOC.
29	LDOPWDN	R	0h	1 indicates ADPLLLJ internal LDO is power down. VDDLDOOUT will be un-defined in this condition
28	RECAL_BSTATUS3	R	0h	Recalibration status flag. 1 ADPLLLJ requires recalibration
27	RECAL_OPPIN	R	0h	Recalibration status flag. 1 ADPLLLJ requires recalibration
26-12	RESERVED	R	X	
11	CLKDCOLDOACK	R	0h	Status on PHASELOCK output pin
10	PHASELOCK	R	0h	Status on PHASELOCK output pin
9	FREQLOCK	R	0h	Status on FREQLOCK output pin
8	BYPASSACK	R	0h	Status of BYPASSACK output pin
7	STBYRETACK	R	0h	Standby and retention status 0x0: indicates to SOC that all internal clocks in ADPLLLJ are active and it is starting the relock process. 0x1: indicates to SOC that all internal clocks in ADPLLLJ are gated and it is ready for retention.
6	LOSSREF	R	0h	Reference input loss
5	CLKOUTENACK	R	1h	Indicates the enable/disable condition of CLKOUTEN 0x0 = CLKOUT gating completed 0x1 = CLKOUT enabling completed
4	LOCK2	R	0h	ADPLL internal loop lock status

Table 6-89. PLL_PER_STATUS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	M2CHANGEACK	R	0h	Acknowledge for change to M2 divider. Toggles from 1-0 or 0-1 (depending on current value) once CLKOUT frequency change has completed.
2	SSCACK	R	0h	Spread Spectrum status 0x0 : Spread-spectrum Clocking is disabled on output clocks 0x1 : Spread-spectrum Clocking is enabled on output clocks
1	HIGHJITTER	R	0h	1 indicates jitter. After PHASELOCK is asserted high, the HIGHJITTER flag is asserted high if phase error between REFCLK and FBCLK greater than 24%.
0	BYPASS	R	1h	Bypass status signal. 1 CLKOUT in bypass

6.2.2.87 PLL_PER_HSDIVIDER Register (Offset = 864h) [reset = X]

PLL_PER_HSDIVIDER is shown in Figure 6-88 and described in Table 6-90.

Return to the Summary Table.

Table 6-99. ANA_REG_CLK_CTRL_REG1_XO_SLICER Register Field Descriptions

Bit	Field	Type	Reset	Description
31	OSC_CLKOUT_EN	R/W	0h	OSC_CLKOUT Enable Enables the Slicer clock to drive the OSC_CLKOUT output buffer. It is recommended that this bit be activated as the last step after fields OSC_CLKOUT_DRV, OSC_CLKOUT_CLRZ_DIV, and OSC_CLKOUT_FREQ_SEL have been configured. 0 = Clock Disabled 1 = Clock Enabled 0x00 = Functional Reset
30-29	OSC_CLKOUT_FREQ_SEL	R/W	0h	OSC_CLKOUT Frequency Selection Selects the output frequency as a division of the XTAL (or externally driven CLKP) frequency. x0 = XTAL/2 10 = XTAL/1 11 = XTAL/4 0x00 = Functional Reset
28	OSC_CLKOUT_CLRZ_DIV	R/W	0h	OSC_CLKOUT Divider ClearZ This active low signal permits the output frequency dividers to be properly cleared before enabling. 0 = All dividers cleared 1 = Normal divider function enabled 0x1 = Functional Reset
27-24	OSC_CLKOUT_DRV	R/W	0h	OSC_CLKOUT Drive This bit controls the drive strength of the OSC_CLKOUT buffer. 4'b0000 = No Test Output, Hi-Z Output Drive Ctrl = [4/9X][2/9X][2/9X][1/9X] 0xF = Functional Reset
23-13	RESERVED	R/W	0h	Reserved Reads return 0x0 and writes have no effect. 0x0 = Functional Reset

Table 6-99. ANA_REG_CLK_CTRL_REG1_XO_SLICER Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	XTAL_DETECT_XO_SLICER	R/W	0h	XTAL Detect Enable This bit connects a pullup and sense circuitry to CLKM to detect the presence or absence of a crystal. This operation will conflict with oscillator functionality, so this bit must be asserted only when the oscillator is disabled (CTRL_CLKTOP_REG1 bit 2 must be "0"). After asserted, the internal XTAL_SENSE signal will reflect a "1" if a crystal is present (CLKM sees a high impedance) or "0" if CLKM is tied to ground. After the sense operation is detected, this bit must be cleared before the oscillator will function properly if enabled. 0 = Normal operation (pullup and sense circuitry are disconnected from CLKM, XTAL_SENSE outputs "1") 1 = XTAL sense function enabled (pullup and sense circuitry connected to CLKM, output of XTAL_SENSE reads "1" if high impedance, "0" if CLKM is tied to ground) 0x0 = Functional Reset
11	SLICER_DCCPL_XO_SLICER	R/W	0h	Slicer DC-Coupled Mode 0 = Normal operation (AC-couple CLKP to internal slicer) 1 = DC-couple CLKP to internal slicer to CLKP 0x0 = Functional Reset
10	SLICER_HIPWR_XO_SLICER	R/W	0h	Slicer High-power Mode This bit bypasses the input clock slicer current-starving/filtering circuitry to increase gain and reduce device phase-noise at the expense of power and reduced supply noise rejection. This permits the use of a high-speed external test clock (660MHz max). 0 = Normal operation (current-limiting present) 1 = High-power/high-speed test mode 0x0 = Functional Reset
9	FASTCHARGEZ_BIAS_XO_SLICER	R/W	0h	Bias Fast-charge Enable (Active Low) This bit bypasses the RC filtering on the XOSC/SLICER Bias to permit more rapid power-up. 0 = Bias fast-charge 1 = Normal operation (filtering present) 0x1 = Functional Reset
8-4	XOSC_DRIVE_XO_SLICER	R/W	0h	Crystal Oscillator Output Drive Binary-weighted oscillator drive control 0x0 = Functional Reset
3-0	RTRIM_BIAS_XO_SLICER	R/W	0h	Crystal Oscillator and Slicer Bias RTrim Binary-weighted bias control 0x0 = Functional Reset

6.2.2.97 ANA_REG_CLK_CTRL_REG1_CLKTOP Register (Offset = C04h) [reset = 7h]

ANA_REG_CLK_CTRL_REG1_CLKTOP is shown in Figure 6-98 and described in Table 6-100.

R/W-X			R/W-1h	R/W-X			R/W-1h

Table 6-296. DSP_PD_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	RESERVED	R/W	X	
4	proc_halt	R/W	1h	Controls the unhalting on the processor during the power-up sequence Write 1 : The DSP is kept in halt state at the end of the power up sequence. The L2 memories can now be initialised and loaded before setting this bit to 0, unhalting the processor and begin execution Write 0 : The processor is unhalted at the end of the power up sequence. Here the assumption is the code is already downloaded in L2 and the processor can immediatey being execution on power up.
3-1	RESERVED	R/W	X	
0	interrupt_mask	R/W	1h	Masks interrupts to the DSP. Write 1 : Mask interrupts to the DSP before powering off the DSP. When masked, any interrupts are now stored in the Missed event register. Write 0 : Send the interrupts to the DSP after power on.

6.2.4.3 DSP_PD_TRIGGER_WAKUP Register (Offset = 18h) [reset = X]

DSP_PD_TRIGGER_WAKUP is shown in Figure 6-293 and described in Table 6-297.

Return to the Summary Table.

R/W-X					R/W-0h		
7	6	5	4	3	2	1	0
RESERVED					lock_step		
R/W-X					R/W-7h		

Table 6-1355. R5_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-27	RESERVED	R/W	X	
26-24	rom_wait_state	R/W	0h	writing '111' enables a single cycle wait state with respect to CR5A_clk for rom access. This needs to be set when R5 clock is at 400MHZ and Interconnect-clk is at 200MHZ. (because it is a timing issue in this scenario)
23-19	RESERVED	R/W	X	
18-16	reset_fsm_trigger	R/W	0h	Write pulse bit field: writing 3'b111 will trigger the reset FSM. Reset FSM ensures reset to R5SS and inturn ensures the latching of lock_step and also mem_swap bit
15-11	RESERVED	R/W	X	
10-8	lock_step_switch_wait	R/W	0h	writing 3'b111 ensures switch happens only after R5SS reset. Orelse it will be a immediate switch.
7-3	RESERVED	R/W	X	
2-0	lock_step	R/W	7h	writing 3'b000 ensures R5 to be in Dual-Core mode. Note: The change happens after the R5SS reset assertion if R5_CONTROL_lock_step_switch_wait is set. Or else the switiching to Dual-core happens on the fly.

6.2.7.434 R5_ROM_ECLIPSE Register (Offset = 804h) [reset = X]

R5_ROM_ECLIPSE is shown in Figure 6-1349 and described in Table 6-1356.

Return to the Summary Table.

RESERVED					memswap		
R/W-X					R/W-0h		

Table 6-1356. R5_ROM_ECLIPSE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RESERVED	R/W	X	
10-8	memswap_wait	R/W	0h	writing 3'b111 ensures ROM-Eclipsing happens only after R5SS reset. Orelse it will be a immediate change.
7-3	RESERVED	R/W	X	
2-0	memswap	R/W	0h	writing '111' ensures eclipsing of CR5A_ROM immediately if memswap_wait is not set. If memswap_wait is set then ROM is eclipsed after R5SS reset assertion.

6.2.7.435 R5_COREA_HALT Register (Offset = 808h) [reset = X]

R5_COREA_HALT is shown in Figure 6-1350 and described in Table 6-1357.

Return to the Summary Table.

Table 6-1678. IOCFGKICK1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	IOCFGKICK1	R/W	0h	Kicker 1 Register. The value 95A4 F1E0h must be written to the KICK1 as part of the process to unlock the CPU write access to above PINMUX registers (excluding IOCFGKICK0). IOCFGKICK0 has to be written with 83E70B13h to enable access to IOCFGKICK1.

6.3 Device Clock Architecture

6.3.1 Clock Overview

Figure 6-1670 shows a high-level overview of the device clock architecture. The figure and the table captures the key clock sources and the configuration options available to select the appropriate clock source. The detailed structure is captured under each PLL clocking section.

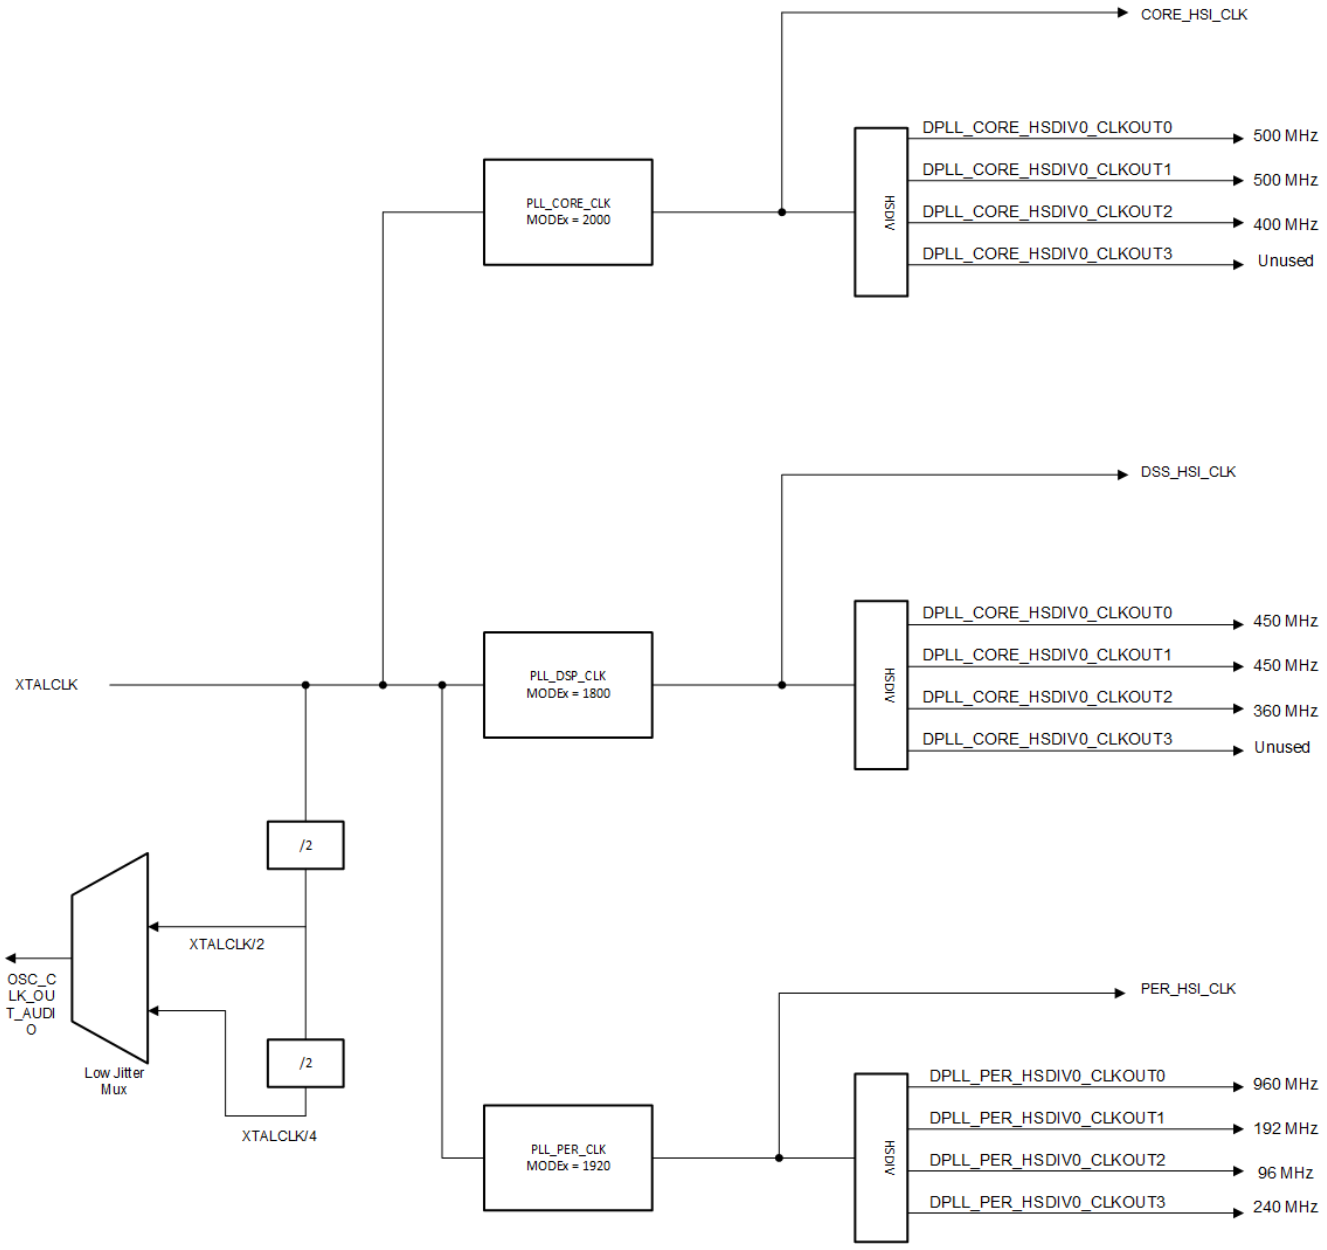

Figure 6-1670. Clock Tree Configuration

Table 6-1679. Clock Tree Configuration Table

PLL	Frequency (MODEx)	Output Line	Div Value (MODEx)	Clock Name	Frequency
PLL_CORE_CLK	2000	0	4	DPLL_CORE_HSDIV0_CLKOUT0	500 MHz
		1	4	DPLL_CORE_HSDIV0_CLKOUT1	500 MHz
		2	5	DPLL_CORE_HSDIV0_CLKOUT2	400 MHz

Table 6-1679. Clock Tree Configuration Table (continued)

PLL	Frequency (MODEx)	Output Line	Div Value (MODEx)	Clock Name	Frequency
PLL_DSP_CLK	1800	0	4	DPLL_DSP_HSDIV_CLKOUT0	450 MHz
		1	4	DPLL_DSP_HSDIV_CLKOUT1	450 MHz
		2	5	DPLL_DSP_HSDIV_CLKOUT2	360 MHz
PLL_PER_CLK	1920	0	2	DPLL_PER_HSDIV0_CLKOUT0	960 MHz
		1	10	DPLL_PER_HSDIV0_CLKOUT1	192 MHz
		2	20	DPLL_PER_HSDIV0_CLKOUT2	96 MHz
		3	8	DPLL_PER_HSDIV0_CLKOUT3	240 MHz

6.3.2 External Clocks

The clocks in the AM273x device to the supported peripherals are as depicted in Figure 6-1671.

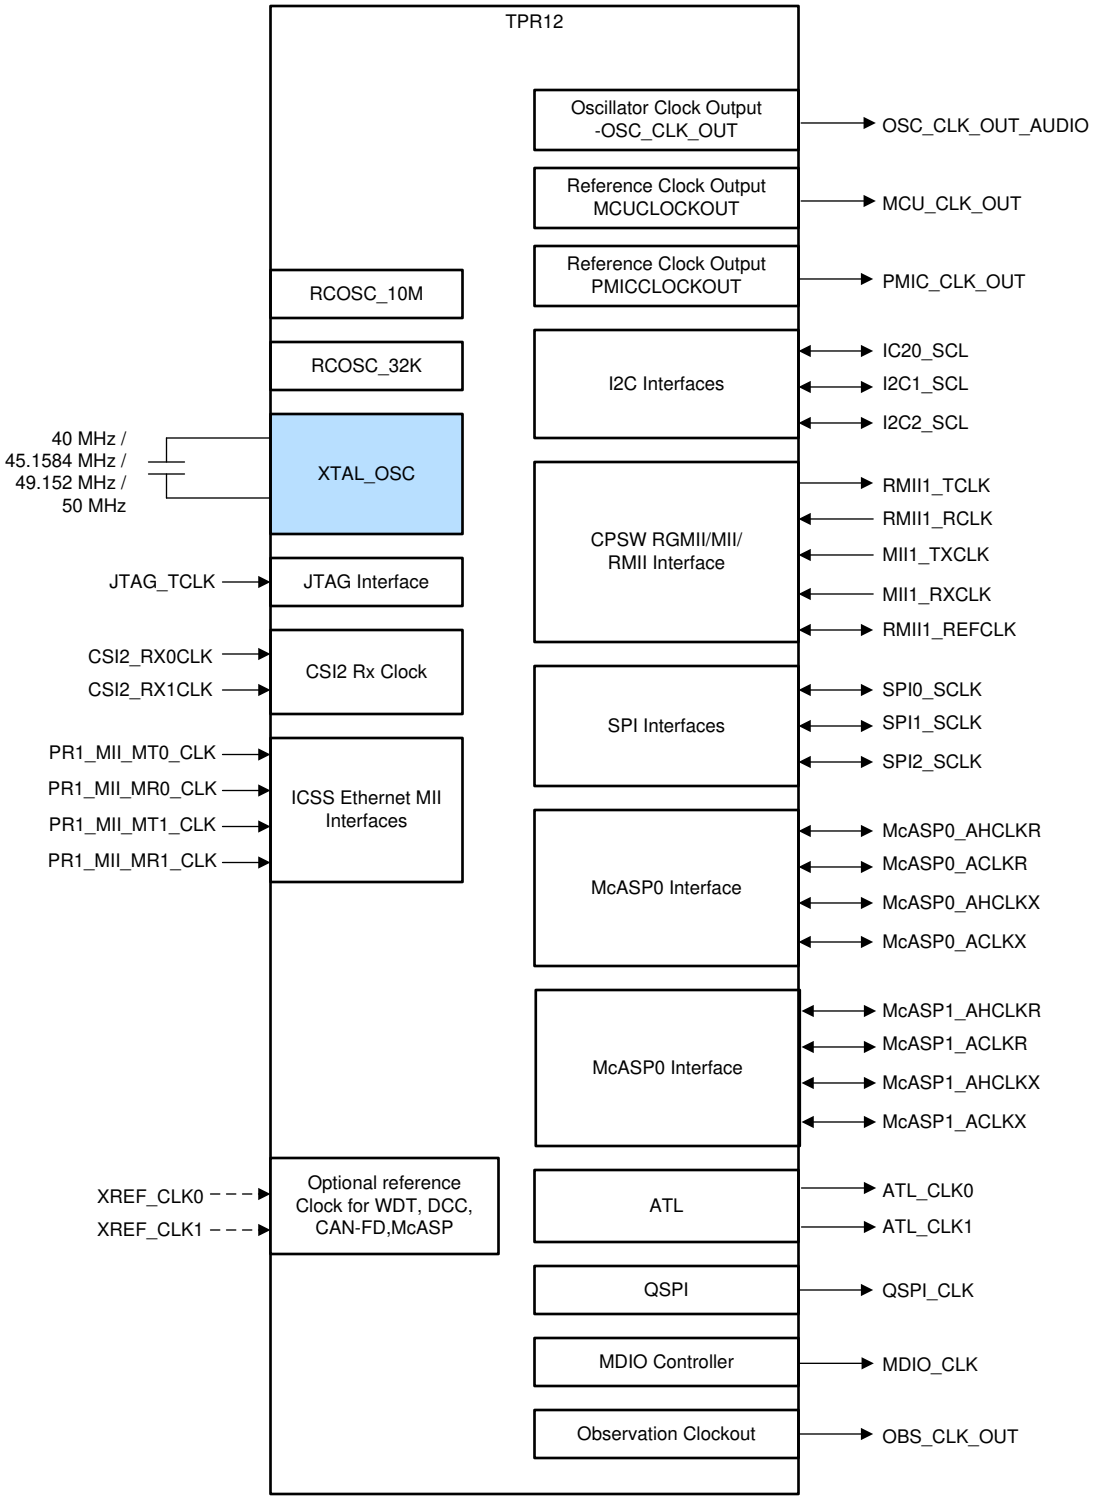

Figure 6-1671. External Clocks

Note

RCOSC_10M , RCOSC_32K : these two clocks are internal and not available for application.

Note

The ATL_CLK in the image is referring to RCSS_ATL_CLK

6.3.3 Clock Selection

Table 6-1680 lists the configuration options for the clock source, divider, and gating selections for different peripheral clocks.

Table 6-1680. Configuration Options

Note

Note that MII100 is 5 MHz and MII10 is 50 MHz

6.3.4 Analog Modules

6.3.4.1 ADPLL

General features of the ADPLL-J module are:

- Low Jitter Phase-Locked Loop
- RHEA, OCP, and Direct Access interface
- Programmable 8-bit input divider: N
- Programmable 12-bit integer, 18-bit fractional loop multiplier: M
- Programmable 7-bit post divider: M2
- Digital control and loop filter
- User-selectable multiple in-built oscillators for power-jitter optimization
- Primary output clock on digital core domain: CLKOUT = (M / (N+1))*CLKINP*(1/M2)
- Additional output clock on internal LDO domain: CLKOUTLDO = (M / (N+1))*CLKINP*(1/M2)
- Internal oscillator clock on internal LDO domain: CLKDCOLDO = (M / (N+1))*CLKINP
- Output clock gating control: CLKOUTEN / CLKOUTLDOEN / CLKOUTDCOLDOEN
- Digital LOCK indicators for frequency and phase lock
- Fast re-lock
- Input to output bypass on CLKOUT
- Bypass programmable 4-bit divider: N2: CLKOUT = CLKINP / (N2 + 1)
- Optional low frequency bypass clock control: ULOWCLKEN CLKOUT = CLKINPULOW
- Power management modes:
- Power down
- Idle bypass
- Stop Clock-input Bypass
- Retention
- Output clock Spread spectrum clocking supported

The ADPLLLJ is a low jitter PLL with a 2-GHz maximum output. ADPLLLJ has a predivide feature which allows user to divide, for instance, a 24-MHz or 26-MHz reference clock to 1 MHz and then multiply up to 2 GHz maximum. All PLLs will come-up in bypass mode at reset. SW needs to program all the PLL settings appropriately and then wait for PLL to be locked.

Spread Spectrum Clocking

The module supports spread spectrum clocking (SSC) on its output clocks. SSC is used to spread the spectral peaking of the clock to reduce any electromagnetic interference (EMI) that may be caused due to the clock's

fundamental or any of its harmonics. When SSC is enabled the clock's spectrum is spread by the amount of frequency spread, and the attenuation is given by the ratio of the frequency spread (Δf) and the modulation frequency (fm), i.e., 10*log10(Δf/fm) dB.

Note

Please refer MMWAVE-MCUPLUS-SDK for reference implementation of this feature.

6.3.4.2 ADPLLJ Programming Model

6.3.4.2.1 ADPLLJ Programming Sequence

The following sequence is for PLL_PER. Similar registers exist for PLL_CORE and PLL_DSP.

1. Program the values M and N2 in TOP_RCM: PLL_PER_MN2DIV.
2. Program the values of N and M2 in TOP_RCM:PLL_PER_M2NDIV.
3. Program the Fractional M in TOP_RCM:PLL_PER_FRACDIV_FRACTIONALM.
4. Program the Sigma Delta Divider (SD) in TOP_RCM:PLL_PER_FRACDIV_REGSD.
5. Copy the NWELL TRIM from EFUSE to TOP_RCM:PLL_PER_CLKCTRL_NWELLTRIM.
6. Write 0x0 to TOP_RCM:PLL_PER_CLKCTRL_IDLE.
7. Write 0x1 to TOP_RCM:PLL_PER_TENABLE.
8. Write 0x1 to TOP_RCM:PLL_PER_CLKCTRL_TINTZ.
9. Write 0x0 to TOP_RCM:PLL_PER_TENABLE.
10. Write 0x1 to TOP_RCM: PLL_PER_TENABLEDIV.
11. Write 0x0 to TOP_RCM: PLL_PER_TENABLEDIV.
12. Poll Lock Status by reading TOP_RCM:PLL_PER_STATUS_PHASELOCK until it is 0x1.

6.3.4.2.2 HS Divider Programming Sequence

1. Program the CLKOUT0 Divider value in TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT0_DIV.
2. Program the CLKOUT0 Divider value in TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT1_DIV.
3. Program the CLKOUT0 Divider value in TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT2_DIV.
4. Program the CLKOUT0 Divider value in TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT3_DIV.
5. Write 0x1 to TOP_RCM:PLL_PER_HSDIVIDER_TENABLEDIV.
6. Write 0x0 to TOP_RCM:PLL_PER_HSDIVIDER_TENABLEDIV.
7. Enable the CLKOUT0 by write 0x1 to TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT0_GATE_CTRL.
8. Enable the CLKOUT0 by write 0x1 to TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT1_GATE_CTRL.
9. Enable the CLKOUT0 by write 0x1 to TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT2_GATE_CTRL.
10. Enable the CLKOUT0 by write 0x1 to TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT3_GATE_CTRL.

6.3.4.2.3 ADPLLLJ (Low Jitter DPLL)

The ADPLLLJ is a low jitter PLL with a 2-GHz maximum output. ADPLLLJ has a predivide feature which allows user to divide, for instance, a 24-MHz or 26-MHz reference clock to 1 MHz and then multiply up to 2 GHz maximum.

All PLLs will come-up in bypass mode at reset. SW needs to program all the PLL settings appropriately and then wait for PLL to be locked. For more details, see the configuration procedure for each PLL.

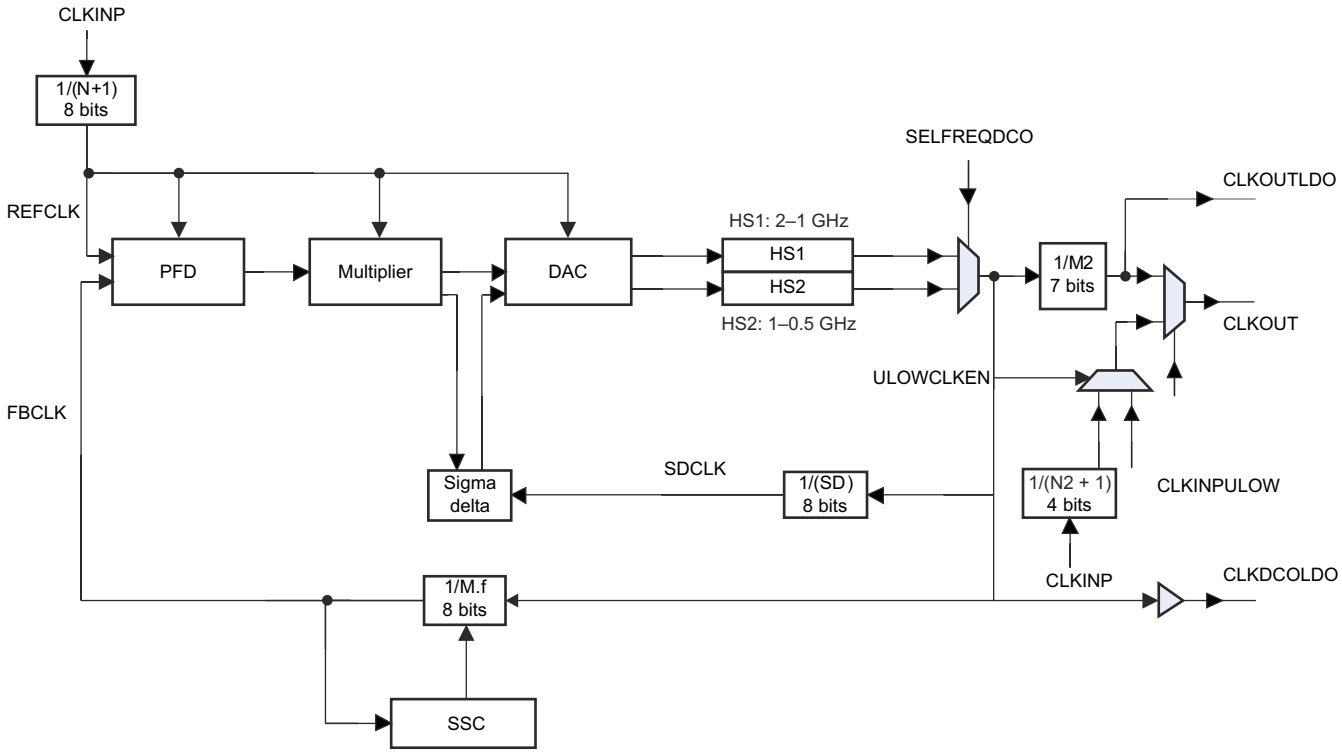

Figure 6-1672. Basic Structure of the ADPLLLJ

The peripheral PLL and EXTDEV PLL belong to type ADPLLLJ:

The DPLL has two input clocks:

- CLKINP: Reference input clock
- CLKINPULOW: Bypass input clock.

The DPLL has two internal clocks:

- REFCLK (Internal reference clock): This is generated by dividing the input clock CLKINP by the programmed value N+1. The entire loop of the PLL runs on the REFCLK.

  Here, REFCLK = CLKINP/(N+1).
- CLKDCO (Internal Oscillator clock.):This is the raw clock directly out of the digitally controlled oscillator (DCO) before the post-divider. The PLL output clock is synthesized by an internal oscillator which is phase locked to the refclk. There are two oscillators built within ADPLLLJ. The oscillators are user selectable based on the synthesized output clock frequency requirement. In locked condition, CLKDCO = CLKINP *[M/(N+1)].

The ADPLLLJ lock frequency is defined as follows: f_{DPLL} = CLKDCOOUT

The DPLL has three external output clocks:

- CLKOUTLDO: Primary output clock in VDDLDOOUT domain. Bypass option not available on this output.

  CLKOUTLDO = (M / (N+1))*CLKINP*(1/M2)
- CLKOUT:

  Primary output clock on digital core domain

  CLKOUT = (M / (N+1))*CLKINP*(1/M2)
- CLKDCOLDO:

Oscillator (DCO) output clock before post-division in VDDLDOOUT domain. Bypass option is not available on this output.

CLKDCOLDO = (M / (N+1))*CLKINP.

All clock outputs of the DPLL can be gated. The Control module provides the DPLL with a clock gating control signal to enable or disable the clock, and the DPLL provides the PRCM module with a clock activity status signal to let the PRCM module hardware know when the clock is effectively running or effectively gated. Output clock gating control for various clockouts: CLKOUTEN/CLKOUTLDOEN/CLKDCOLDOEN.

6.3.4.2.3.1 Clock Functions

Table 6-1681. Output Clocks in Locked Condition

Pin Name	Frequency
CLKOUT	[M /(N+1)] * CLKINP * [1/M2]
CLKOUTLDO	[M /(N+1)] * CLKINP * [1/M2]
CLKDCOOUT	[M /(N+1)] * CLKINP

Table 6-1682. Output Clocks Before Lock and During Relock Modes

Pin Name	Frequency	Comments
CLKOUT	CLKINP/(N2+1)	ULOWCLKEN='0'
	CLKINPLOW	ULOWCLKEN='1'
CLKDCOLDO	LOW	
CLKOUTLDO	LOW	

6.3.4.2.4 M2 and N2 Change On-the-Fly

The dividers M2 and N2 are designed to change on the fly and provide a glitch-free frequency switch from the old to new frequencies. In other words, they can be changed while the PLL is in a locked condition, without having to switch to bypass mode. A status toggle bit will give an indication if the new divisor was accepted. These dividers can also be changed in bypass mode, and the new divisor value will be reflected on output after the PLL relocks. For more details, see the PLL configuration procedures for each PLL.

6.4 Power Domains

The device has two power domains:

- Always-on power domain: This power domain supplies power to entire device except for the DSP core. This domain cannot be switched off dynamically within the device.
- DSP power domain: The DSP core inside the DSP subsystem is placed on switchable power domain. This feature can be used to reduce power consumption of the device when the DSP core is not in use. By default, the state of this power domain is OFF.

The DSP power domain provides a way to lower power consumption. Other system level power states or modes are not supported by the device.

6.4.1 DSP Power Domain

The C66x DSP is off by default on bootup. The DSS_RCM controls the power cycling of the DSP. Software can trigger a power on/off sequence by writing to the DSP_PD registers in DSS_RCM space.

6.4.1.1 Software Sequence To Power On DSP

1. Unmask the wakeup trigger related to DSS_DSP_WAKEUP. This is DSP interrupt number 16. Thus, unmask the 16th bit in the register DSS_RCM.DSP_PD_WAKEUP_MASK0 by writing 0xFFFEFFFF
2. Trigger DSP wakeup by writing 0x1 to register DSS_RCM.DSP_PD_TRIGGER_WAKU.
3. Poll DSS_RCM.DSP_PD_STATUS.STATE for the value 13. This indicates that the L2 memory can now be written to or preloaded with code.
4. Download the DSP code into L2.

5. Write 0x0 to DSS_RCM.DSP_PD_CTRL.PROC_HALT to unhalt the processor and begin execution.

6.4.1.2 Software Sequence To Power OFF DSP

1. Ensure that all previous registered events during the previous power down are cleared.
2. Set up the DSP interrupt routine for DSS_DSP_PDC_INT (Gem event number : 118) as below:
   a. Set the bit DSP_ICFG.PDCCMD.GEMPD.
   b. Execute the idle instruction
3. If DSP powers up in autonomous mode without the program download, set the DSS_REG.GEMPWRSMCFG4.PWRSMLRSTHALT bit to 0x0.
4. Unmask the events to use as wakeup events in DSS_RCM:DSP_PD_WAKEUP_MASK[0-2].
5. Unmask the events to receive as hardware event pulses after the next power up in DSS_RCM:DSP_PD_MISSED_EVENT_MASK [0-2].
6. Mask all interrupts from DSP by setting the DSS_RCM:DSP_PD_CTRL:DSP_PD_CTRL_INTERRUPT_MASK field to 0x1.
7. Trigger a power down by setting the DSS_RCM:DSP_PD_TRIGGER_SLEEPfield to 0x1, and wait in a while loop. This triggers the interrupt DSS_DSP_PDC_INT, followed by the power-down of the DSP core by the control module.
8. The state of the DSP power domain can be polled by other main subsystem R5F cores to ensure the DSP power down. DSS_RCM:DSP_PD_STATUS_PD_STATUS field

6.4.2 DSP Subsystem L3 Power Domain

The DSS L3 memory can be controlled from DSS_RCM registers by the software.

By default, all the L3 memory is Power ON.

When partially switching off banks, it is the software's responsibility to ensure that the banks are disabled from the last 256 KB bank, that is, DSS L3 BANK D3. A bank should not be powered off if all its higher banks are not powered off. For example, if DSS L3 BANK D1 is powered down, BANK D2 and D3 are also powered down.

Table 6-1683. Banks

Bank 256 KB	Bank Name	Control Registers
0	DSS L3 BANK A0	DSS_L3_BANKA0_PD_CTRL_AGOODINDSS_L3_BANKA0_PD_CTRL_AONINDSS_L3_BANKA0_PD_CTRL_ISO

6.5 Resets

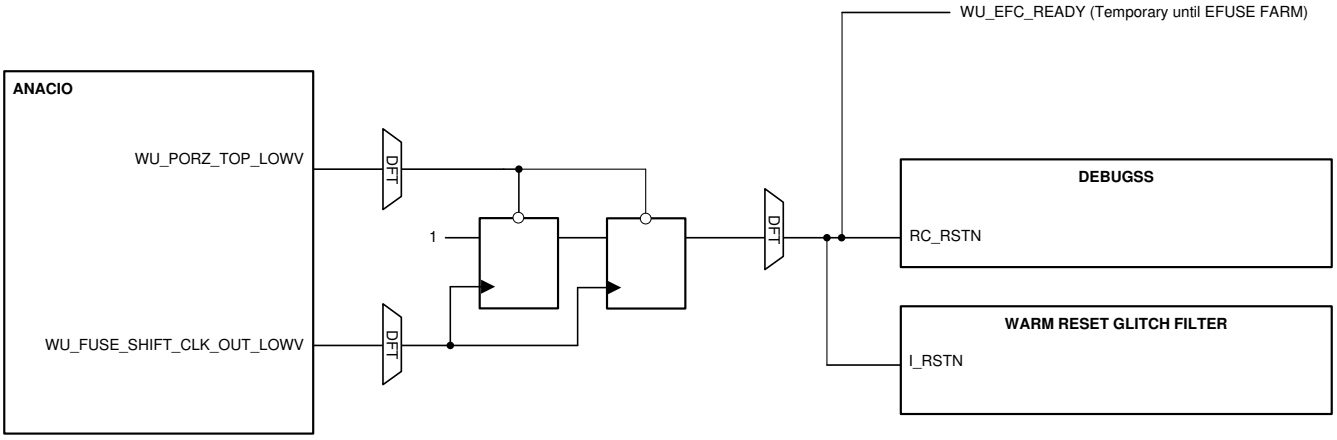

Figure 6-1673. Resets

Two device resets are available that can be controlled from the device pins: the power-on reset pin NRESET and the bidirectional WARM_RESET signal. The warm reset signal is implemented as an I/O, so that an external monitor can be used to detect changes to the state of the internal warm reset control signal.

Device registers can capture recent reset events, and can be used by software to manage failure recovery. Certain registers in the device are immune to WARM_RESET, and can only be reset by power-on reset.

The registers immune to WARM_RESET are:

- Reset Cause Registers in TOPRCM and MSSRCM
  - MSS_RST_STATUS
  - SYS_RST_CAUSE
- SOP and Clock Status registers in TOPRCM
  - SYS_RST_CAUSE
  - ANA_REG_CLK_STATUS_REG
  - ANA_REG_WU_MODE_REG_LOWV
  - ANA_REG_WU_STATUS_REG_LOWV
  - ANA_REG_WU_SPARE_OUT_LOWV
- BOOT INFO Registers in MSS_CTRL: MSS_BOOT_INFO_REG0-7
- All Efuse Registers in TOP CTRL

In addition to WARM_RESET and power-on reset, there are some local resets. This table summarizes the available local reset sources that are supported.

Table 6-1684. Available Reset Registers

Reset Register	Subsystem	Description
DSS_RST_CTRL	DSP Subsystem	Reset control for DSP Subsystem Data should be loaded as multibit. Write 3'b000: Reset is not asserted by SW Write 3'b111 : Reset is asserted by SW See Section 7.2.2.30 for more details
MSS_CR5SS_POR_RST_CTRL	R5SS	Software needs to ensure the state of the Device/IP before configuring. Writing '111' will assert por reset to R5SS. See Section 7.2.3.76 for details
MSS_CR5SSA_RST_CTRL	CR5A and MSS_CR5A_VIM	Software needs to ensure the state of the Device/IP before configuring. Writing' 111' will reset CR5A and MSS_CR5A_VIM. See Section 7.2.3.77 for more details.
MSS_CR5SSB_RST_CTRL	CR5B and MSS_CR5B_VIM	Software needs to ensure the state of the Device/IP before configuring. Writing '111' will reset CR5B and MSS_CR5B_VIM. See Section 7.2.3.78 for details
MSS_CR5A_RST_CTRL	CR5A	Software needs to ensure the state of the Device/IP before configuring. Writing '111' will reset CR5A only. See Section 7.2.3.79 for details.
MSS_CR5B_RST_CTRL	CR5B	Software needs to ensure the state of the Device/IP before configuring. Writing 111' will reset CR5B only. See Section 7.2.3.80 for details.
MSS_VIMA_RST_CTRL	MSS_CR5A_VIM	Software needs to ensure the state of the Device/IP before configuring. Writing '111' will reset MSS_CR5A_VIM. See Section 7.2.3.81 for more details.
MSS_VIMB_RST_CTRL	MSS_CR5B_VIM	Software needs to ensure the state of the Device/IP before configuring. Writing '111' will reset MSS_CR5B_VIM. See Section 7.2.3.82 for more details.
DSS_DSP_RST_CTRL	DSS DSP Data	Write to bits 10-8 for Local Reset control for DSS DSP Data. Write 3'b000: Reset is not asserted by SW. Write 3'b111 : Reset is asserted by SW See Section 7.2.4.56 for details.

Device includes the following processor core and accelerators:

- MCU Subsystem ARM Cortex dual core lockstep R5F
- DSP Subsystem TI C66x DSP
- Radar Processing Hardware Accelerators
- Radar Processing M4 Subsystem

7.1 Main Subsystem Cortex R5F

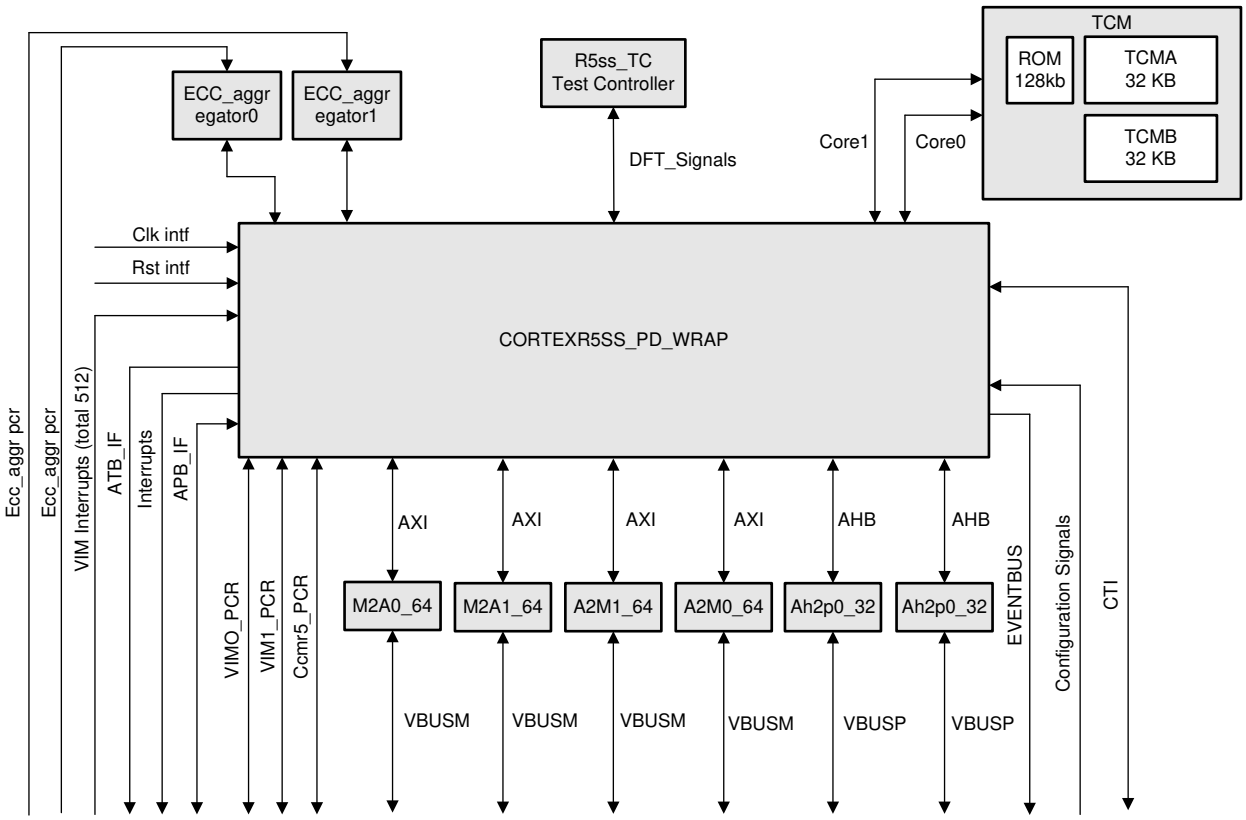

Figure 7-1. Main Subsystem

The Main SubSystem is a dual-core implementation of the Arm Cortex-R5F processor configured for split/lock operation. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm® CoreSight™ debug and trace architecture, integrated Vectored Interrupt Manager (VIM), ECC Aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

7.1.1 Main ARM SubSystem Features

The MSS supports the following features:

- ARMv7-R architecture with the following extensions:
  - Basic SIMD extension for integer and floating-point vector operations
  - Vector Floating Point Version 3 (VFPv3) with Single/Double Precision
  - Dynamic branch prediction with a global history buffer, and a 4-entry return stack
- Lock step and dual core modes are supported:
  - Switching to dual core mode is possible by the application (if switching to performance mode is enabled by EFUSE), even if the boot has happened in lock step mode – using a CPU reset triggered by application software.
- L1 memory architecture (per each CPU in split mode, or single lock-step CPU):
  - 16KByte I-Cache with 64-bit ECC
  - 16Kbyte D-cache with 32-bit ECC
- L2 Interface
  - 64-bit Controller interface for peripheral access
  - 64-bit Target interface for cache and TCM access
  - 32-bit Controller interface for MCU peripherals
  - ECC on data. Redudancy on Control bus
- Vectored Interrupt Manager with ECC protection on Vector Table RAM
  - VIM1 and VIM2 in lockstep pair when CPU cores are in lock step mode
- Static (boot time) configuration for either lockstep mode or dual-CPU mode
- Mechanism to clock gate the CPU and comparator logic in a non-Lockstep mode.
- CPU Self-Test Controller for CPU core, VIM, and Comparator modules
- PBIST controller for test of all the RAMs
- Support to test ECC functionality in safety-critical applications
- Built in debug features
  - Up to 8 hardware breakpoints per CPU
  - Up to 8 watch points per CPU
- 32-bit Target Debug interface to access Debug components (CTI, ETM, ATB)
- Trace interface to a Core Sight ETM-R5
- Performance Monitoring Unit (PMU)

7.1.2 TCM Initialization

Auto-init module has been implemented for initializing the TCMs. Paths from TCMA and TCMB are timing-critical, so the initialization of these memories occur through the test path. Initialization of TCMA and TCMB occurs in parallel.

Below are the registers used for the TCM initialization

- Writing 1 to MSS_CTRL:MSS_<A/B>TCM_MEM_INIT:MSS_<A/B>TCM_MEM_INIT_MEM_INIT starts the mem-init for MSS_TCM<A/B>_CR5A/B.
- Reading 1 from MSS_CTRL: MSS_<A/B>TCM_MEM_INIT_DONE: MSS_<A/B>TCM_MEM_INIT_DONE_MEM_INIT_DONE confirms the end of initialization for MSS_TCM<A/B>_CR5A/B.
- Writing 1 to MSS_CTRL: MSS_<A/B>TCM_MEM_INIT_DONE: MSS_<A/B>TCM_MEM_INIT_DONE_MEM_INIT_DONE clears the field.
- Reading 1 from MSS_CTRL: MSS_<A/B>TCM_MEM_INIT_STATUS: MSS_<A/B>TCM_MEM_INIT_STATUS_MEM_STATUS confirms progress of initialization for MSS_TCM<A/B>_CR5A/B.

7.1.3 TCM ROM-RAM SWAP

7.1.3.1 R5 as Master

Sequence for Swapping for ROM with RAM:

1. Write ‘3’b111’ to “MSS_CTRL: R5_ROM_ECLIPSE: R5_ROM_ECLIPSE_MEMSWAP_WAIT”. This ensures swapping happens only on CR5A/B reset.
2. Write ‘3’b111’ to to “MSS_CTRL: R5_ROM_ECLIPSE: R5_ROM_ECLIPSE_MEMSWAP”. This decides whether to swap or not.
3. Write ‘0xFFFFFFFF’ to “MSS_RCM:RST_WFICHECK” to ensure Reset-Sequencer would look for ‘WFI’ state of CR5A/B before asserting the reset.
4. Write ‘3’b111’ to to “MSS_CTRL: R5_CONTROL: R5_CONTROL_RESET_FSM_TRIGGER”. This will trigger the reset sequencer which will be waiting for WFI from CR5A/B as we are ensuring step-3 is done.
5. Go to “WFI” with arm-command “asm(wfi)”.
6. R5 goes through a reset-cycle and starts booting.
7. Read bit9 of “MSS_RCM: MSS_RST_STATUS:MSS_RST_STATUS_CAUSE”. That being ‘1’ will ensure reset is happened because of Reset-Sequencer.
8. Write ‘3’b111’ to “MSS_RCM: MSS_RST_CAUSE_CLR:MSS_RST_CAUSE_CLR_CLR” will the clear the “MSS_RCM: MSS_RST_STATUS:MSS_RST_STATUS_CAUSE” register.

7.1.3.2 HSM as Master

HSM can only follow the below sequence before unhalting CR5A. HSM will never know the state of CR5A after unhalting it.

Sequence for Swapping for ROM with RAM:

1. Write ‘3’b000’ to “MSS_CTRL: R5_ROM_ECLIPSE: R5_ROM_ECLIPSE_MEMSWAP_WAIT”. This ensures swapping happens immediately after changing the “MSS_CTRL: R5_ROM_ECLIPSE: R5_ROM_ECLIPSE_MEMSWAP”.
2. Write ‘3’b111’ to to “MSS_CTRL: R5_ROM_ECLIPSE: R5_ROM_ECLIPSE_MEMSWAP”. This decides whether to swap or not.
3. Swapping is done. So now HSM can unhalt the CR5A by writing ‘3’b000’ to MSS_CTRL: R5_COREA_HALT: R5_COREA_HALT_HALT”

7.1.3.3 Address Information

For use cases where the devices will be operating in lockstep mode, the TCMA and TCMB ROM sizes are 32KB.

Before Eclipsing, the addresses are as follows in Table 7-1.

Table 7-1. Address Information

Address	Region	Details
0x0	TCMA_ROM (128KB)	Dedicated Rom for R5 CORE-A
0x1FFFF		
0x20000	TCMA0_RAM (16KB)	Dedicated-Ram for R5 CORE-A
0x23FFF		
0x24000	TCMA1_RAM (16KB)	Gives an TCM_ERROR during Dual core mode
0x27FFF		
0x80000	TCMB0_RAM (16KB)	Dedicated-Ram for R5 CORE-A
0x83FFF		
0x84000	TCMB1_RAM (16KB)	Gives an TCM_ERROR during Dual core mode
0x87FFF		

After eclipsing, TCMA RAM address is relocated to start at 0x0, (up to 32KB). TCMB, L2, and L3 addresses do not change.

7.1.4 Lock-Step to Dual Core Switching

1. Write 3’b111 to MSS_CTRL: R5_CONTROL: R5_CONTROL_LOCK_STEP_SWITCH_WAIT. This ensures switching happens only on CR5A/B reset.

2. Write 3'b000 to MSS_CTRL: R5_CONTROL: R5_CONTROL_LOCK_STEP. This decides whether to switch or not.
3. Write 0xFFFFFFFF to MSS_RCM:RST_WFICHECK to ensure the Reset-Sequencer looks for WFI state of CR5A/B before asserting the reset.
4. Write 3'b111 to MSS_CTRL: R5_CONTROL: R5_CONTROL_RESET_FSM_TRIGGER. This triggers the reset sequencer, which is waiting for WFI from CR5A/B as it ensures step-3 is done. Go to WFI with arm-command asm(wfi).
5. R5F goes through a reset-cycle and starts booting.
6. Read bit9 of MSS_RCM: MSS_RST_STATUS:MSS_RST_STATUS_CAUSE. That being '1' ensures the reset has happened because of the Reset-Sequencer.
7. Write 3'b111 to MSS_RCM: MSS_RST_CAUSE_CLR:MSS_RST_CAUSE_CLR_CLR to clear the MSS_RCM: MSS_RST_STATUS:MSS_RST_STATUS_CAUSE register.

Note

The switch can only be performed from Lock Step mode to Dual core mode and not vice versa. This switch cannot be done multiple times; it is allowed only once.

7.1.5 Vectored Interrupt Manager (VIM) Module

This chapter describes the behavior of the vectored interrupt manager (VIM) module of the device family.

7.1.5.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU(s). It can be used in either split or lockstep configuration. In split, it has two independent interrupt cores, one per CPU. In lockstep, CPU1 acts as a diagnostic on CPU0; only CPU0's outputs are used but all outputs are compared to CPU1 to provide diagnostic coverage.

The VIM module supports the following features:

- 256 interrupt inputs per R5F core
- Each interrupt has its own 4-bit programmable priority
  - Defined via the INTPRIORITY_j register
  - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
  - Interrupt enable is done via the INTR_EN_SET_j register
  - Interrupt disable is done via the INTR_EN_CLR_j register
- Each interrupt can be programmed as either an IRQ or FIQ
  - Defined via the INTMAP_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
  - Defined via the INTVECTOR_j register
  - Protected with SECDED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
  - Compatible with R5F VIC port
- Default vector provided when a double-bit error is detected
- Split or lockstep capable
  - In lockstep mode, only interrupts connected to VIM interrupt core 0 are available
- Software interrupt generation

7.1.5.2 VIM Interrupt Inputs

The VIM supports 256 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the two R5F cores can be found in Chapter 9, *Interrupts*.

7.1.5.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- *CoreN_IRQn*: This is a normal interrupt for core *N* (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the INTMAP_j register) and is enabled (via the INTR_EN_SET_j register), then it will cause an IRQ to assert
- *CoreN_FIQn*: This is a fast (or non-maskable) interrupt for core *N* (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

7.1.5.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (INTVECTOR_j). Hence, the interrupt vector table is organized in 256 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

Note

The lower two bits of the 32-bit interrupt vector are always 0s.

Figure 7-2 shows the VIM RAM interrupt vector map.

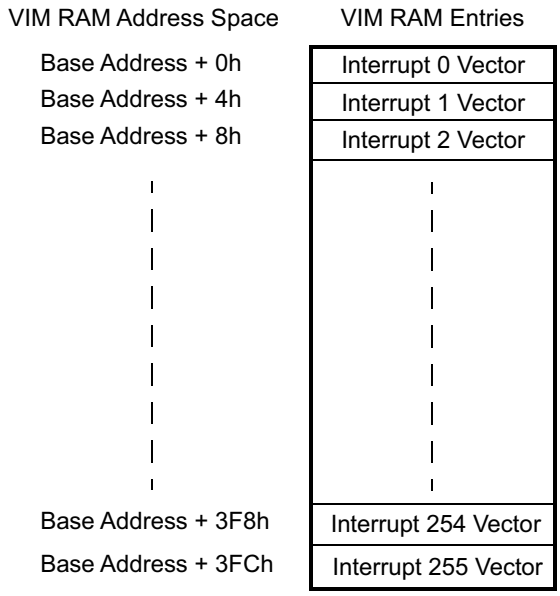

Figure 7-2. VIM RAM Interrupt Vector Map

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. Refer to the ECC aggregator map for the VIM RAM ID.

7.1.5.5 VIM Interrupt Prioritization

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the FIQVEC register; IRQ: reading the IRQVEC register, then the interrupt is loaded into the corresponding active register (ACTFIQ / ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to theFIQVEC register, or IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. If the CPU switches this interrupt to active (by reading the FIQVEC / IRQVEC register), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by reading the FIQVEC / IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the ACTFIQ / ACTIRQ register, so that software may continue where it left off.

7.1.5.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the DEDVEC register is used to provide the default vector for the *coreN_IRQADDRV* signal, the IRQVEC register, and the FIQVEC register. The DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
   a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device
4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt . This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by the ECC aggregator.

7.1.5.7 VIM Lockstep Mode

In lockstep mode, CPU1 is used as a diagnostic for CPU0. In this mode, only the interrupt inputs for CPU0 are used. Besides to CPU0, these interrupt inputs are also internally routed to CPU1 (through the level-sync / edge-detect logic dedicated to CPU1, and additionally through some delay circuits). The outputs from both VIM interrupt cores are then sent to the MSS CCMR5 module through dedicated compare buses (with CPU0's outputs delayed). The CCMR5 module is responsible for comparing the two sets of output signals and for reporting any mismatches by generating an interrupt (MSS_CCMR5_ERR).

Note

In lockstep mode, only the RAM dedicated to CPU0 is used, so software *must not* do anything with the ECC interface on the RAM dedicated to CPU1.

7.1.5.8 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

7.1.5.9 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in Section 7.1.5.9.1, but the procedures in Section 7.1.5.9.2 or Section 7.1.5.9.3 (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

For FIQs, it is recommended to use the procedure in Section 7.1.5.9.4, but the procedure in Section 7.1.5.9.5 may be used as an alternative.

Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

7.1.5.9.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
   a. CPU asserts *coreN_IRQACK* high
   b. VIM asserts *coreN_IRQADDRV* to indicate that the *coreN_IRQADDR* bus is stable with the correct vector address
   c. CPU reads *coreN_IRQADDR*, jumps to that address, and de-asserts *coreN_IRQACK* low
   d. VIM de-asserts *coreN_IRQn* and *coreN_IRQADDRV*, VIM masks (discards) all IRQs with the same or lower priority
   e. VIM loads the value from the PRIIRQ[9:0] NUM bit field (which corresponds to the vector address) into the ACTIRQ[9:0] NUM bit field, which causes the ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the ACTIRQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the INTTYPE_j register to determine type)
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the IRQSTS_j register, or STS_j register
      ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the IRQSTS_j register, or STS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the IRQVEC register
   a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
   b. This will also clear the ACTIRQ[31] VALID bit

7.1.5.9.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the IRQVEC register and jump to that address to service the ISR
   a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN_IRQn* will re-assert, allowing priority interruption of an interrupt
   b. Reading this register will cause the value from the PRIIRQ[9:0] NUM bit field to be loaded into the ACTIRQ[9:0] NUM bit field, and the ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse

i. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or IRQSTS_j register
ii. Clear the interrupt at the source

b. Level
i. Clear the interrupt at the source
ii. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or IRQSTS_j register

4. Write any value to the IRQVEC register
a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
b. This will also clear the ACTIRQ[31] VALID bit

7.1.5.9.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the IRQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
a. Read the PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
b. Optionally read the IRQGSTS register to determine which groups have IRQs pending, then read the IRQSTS_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
a. Pulse
i. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or IRQSTS_j register
ii. Clear the interrupt at the source.

b. Level
i. Clear the interrupt at the source
ii. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or IRQSTS_j register

7.1.5.9.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the FIQVEC register and jump to that address to service the ISR
a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN_FIQn* will re-assert, allowing priority interruption of an interrupt.
b. Reading this register will cause the value from the PRIFIQ[9:0] NUM bit field to be loaded into the ACTFIQ[9:0] NUM bit field, and the ACTFIQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the INTTYPE_j register to determine type)
a. Pulse
i. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or FIQSTS_j register
ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt

b. Level
i. Clear the interrupt at the source
ii. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or FIQSTS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt

4. Write any value to the FIQVEC register
a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
b. This will also clear the ACTFIQ[31] VALID bit

7.1.5.9.5 Servicing FIQ (Alternative)

If a user does not want to use the FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
   a. Read the PRIFIQ register to determine which interrupt is the highest priority FIQ currently asserted, OR
   b. Optionally read the FIQGSTS register to determine which groups have IRQs pending, then read the FIQSTS_j register and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
   a. Pulse
      i. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or FIQSTS_j register
      ii. Clear the interrupt at the source.
   b. Level
      i. Clear the interrupt at the source
      ii. Clear the status by writing a '1' to the appropriate bit in the STS_j register, or FIQSTS_j register.

7.1.5.10 MSS_VIM Registers

Table 7-3 lists the memory-mapped registers for the MSS_VIM registers. All register offset addresses not listed in Table 7-3 should be considered as reserved locations and the register contents should not be modified.

Table 7-2. VIM Instances

Instance	Base Address
MSS_VIM_R5A	0x02080000
MSS_VIM_R5B	0x020A0000

Table 7-3. MSS_VIM Registers

Offset	Acronym	Register Name	Section

Table 7-62. INTTYPE_5 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	VAL	R/W	0h	This field is used to indicate whether the source of an interrupt is a level (default) or a pulse for event group M. This is informational so that an ISR may query this register and know whether it has to clear a pulse event or a level event (see 3.4 Interrupt Handling). The value has no effect on how the VIM hardware functions. The input interrupts are agnostic as to whether they are pulse or level. Each bit corresponds to event Q where Q = Mx32+Bit 0 Level (default) 1 Pulse

7.1.5.10.60 RAW_6 Register (Offset = 4C0h) [Reset = 0h]

RAW_6 is shown in Figure 7-62 and described in Table 7-63.

Return to the Summary Table.

Group M Interrupt Raw Status/Set Register (M is 0 to 7) h400 + M x h20 + h00

Table 7-80. INTVECTOR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	ADDR	R/W	0h	This is the 32-bit Vector Address associated with interrupt Q. It is the address that will be reflected in the IRQ Vector Address (Base Address + 0x18) or FIQ Vector Address (Base Address + 0x1C) and the VECADDR pin when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new Vector Address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.

Table 7-80. INTVECTOR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	RES20	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. Vector addresses must be 32-bit aligned.

7.1.6 Resets

AM273x supports the following resets:

- CR5SS_POR_RST: This is the full MCU R5F subsystem reset. It is also the Power On Reset.
- CR5ASS_RST: This reset is only for the Cortex R5F and the Vectored Interrupt Manager of the CoreA. None of the other logics are reset.
- CR5A_RST: This only reset the cortex of the R5F of the CoreA.
-
-
- VIMA_RST: This only reset the vectored interrupt manager of the CoreA.
-

7.1.6.1 R5F Subsystem Reset Trigger

For the safe reset of the R5F subsystem, follow this reset sequence:

1. Write 3’b111 to MSS_CTRL: R5_CONTROL: R5_CONTROL_RESET_FSM_TRIGGER starts the sequencer.
2. The sequencer is waiting for WFI from only CR5A if WFI_CHECKEN for corresponding resets is programmed. The sequencer isolates CR5SS when it receives WFI from CR5A.
3. The sequencer triggers CR5SS_POR_RST, which triggers resets to all resets mentioned in resets-table.
4. The intent is to reset CR5SS when it is in isolation. Thus, before Step 1, ensure MSS_RCM:RST2ASSERTDLY is programmed to 0;.
5. Reset is asserted for RST_ASSERDLY: RST_ASSERDLY_COMMON number of clock cycles, and released.

7.2 TI C66x DSP Subsystem (DSS)Overview

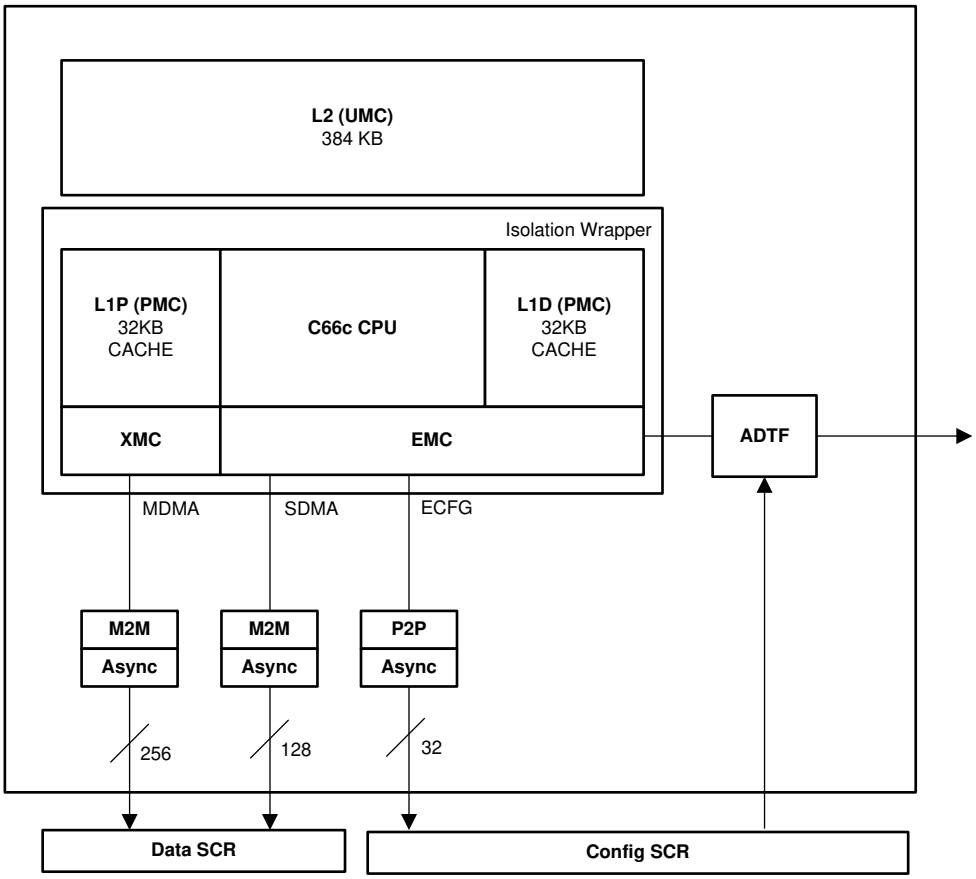

Figure 7-80. DSP C66x Subsystem

7.2.1 C66x DSP Subsystem

The purpose of this section is to provide an overview of the DSP subsystem (C66x CorePac) along with some integration details.

7.2.1.1 DSP Subsystem Overview

The DSP subsystem (C66x CorePac) supports the following key features:

- Fixed/Floating-point C66x CPU based on a superset of the C64x+ and C67x+ ISA
- Program Memory Controller (PMC):
  - 32KB Level 1 Program (L1P) Cache/SRAM
- Data Memory Controller (DMC):
  - 32KB L1 Data (L1D) Cache/SRAM
- L2 Memory Controller:
  - 384KB L2 RAM with up to 256KB of configurable into cache
- External Memory Controller (EMC):
  - Internal DMA (IDMA) engine
  - One 128-bit VBUSM slave port from DMA access at Div-by-2 clock
  - One 32-bit VBUSP master port to CFG access at Div-by-2 clock
- XMC (Extended Memory Controller):
  - One 256-bit port to L3 memory at Div-by-2 clock
- Multistream prefetch buffer
- Address extension/translation (32-bit to 36-bit)
- Memory protection for multiple segments
- Memory protection for all internal L1/L2 RAM
- Error Detection for L1P
- Error Detection and Correction for L1D
- Error Detection and Correction for all L2
- Integrated C66x CorePac interrupt controller (INTC) that works in conjunction with Chip-level Interrupt Controller (CIC) for distribution of system interrupts to the C66x core. Interrupts can be routed directly to the C66x core or through the CIC module in a flexible manner
- Integrated leakage and dynamic power management
- Debug/emulation capabilities:
  - Support for halt mode, real time and monitor mode debug capabilities
  - Support for processor instruction trace and system trace (**printf**-style debug)
- Error Detection for L1P Data and Tag RAMs
- Error Detection and Correction for L1D Data and Tag RAMs
- Error Detection and Correction for all L2 Data and Tag RAMs

Figure 7-81 shows an overview of the C66x CorePac.

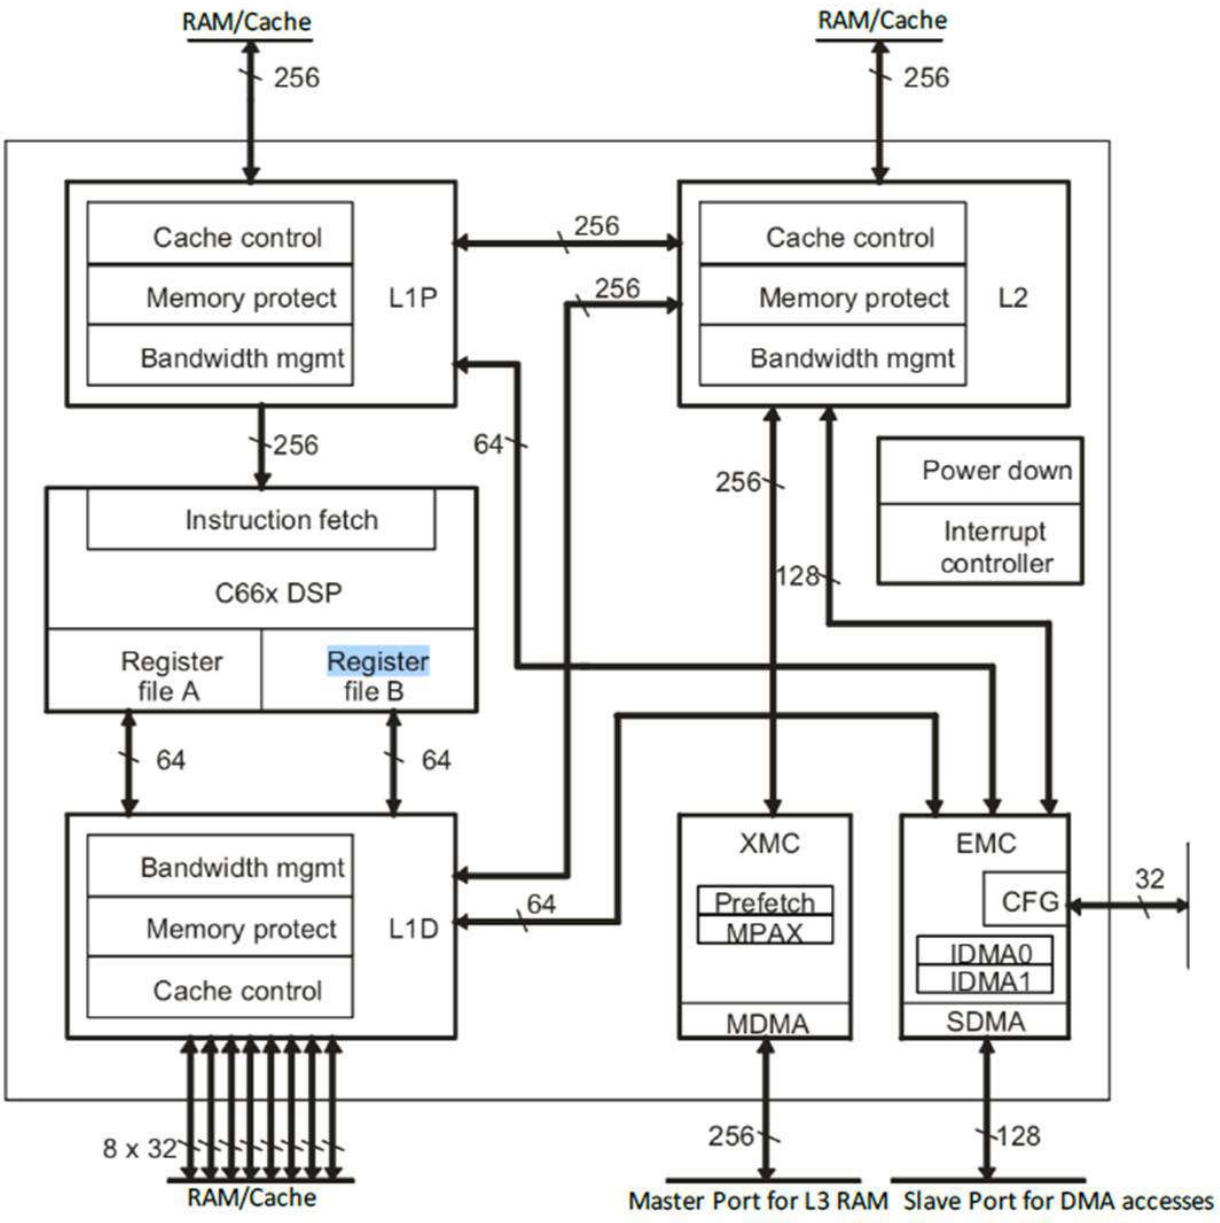

Figure 7-81. C66x CorePac Overview

For more information about:

- C66x CorePac, see the *TMS320C66x DSP CorePac User Guide* (SPRUGW0).
- C66x CPU core, see the *TMS320C66x DSP CPU and Instruction Set Reference Guide* (SPRUGH7).
- C66x cache memory system, see the *TMS320C66x DSP Cache User Guide* (SPRUGY8).
- C66x debug/trace support, see Section 12.1.

7.2.1.2 DSP Subsystem Integration

To turn on DSP power, please follow DSP power domain for details. To configure the DSP clock, please refer to section 1.5.3.3, DSS_DSP_CLK for clock source, divider, and gating selections details.

7.2.1.3 DSP Interrupt Sources

Refer to Section 9.2

7.2.1.4 DSP Subsystem Functional Description

For detailed DSP subsystem functional description, see the documents referenced in Section 8.2.1.1 .

7.2.1.5 DSP Subsystem Registers

Table 7-81 lists the memory-mapped registers for the C66x CorePac. All register offset addresses not listed in Table 7-81 should be considered as reserved locations and the register contents should not be modified. For base addresses of the DSP subsystem internal modules, see #unique_91.

The C66x CorePac registers (DSP_ICFG) are described in detail in the *TMS320C66x DSP CorePac User Guide* (SPRUGW0).

Table 7-81. C66x CorePac Registers

Address	Acronym	Register Name

7.2.2 DSP Subsystem Integration

The DSP C66x Corepac integrates the following IPs :

- Improved C66x Core and CGEM Megamodule with ECC
- 32-kB L1P Cache/SRAM
- 32-kB L1D Cache/SRAM
- 384-kB L2 Cache/SRAM
- ECC and EDC wherever supported
- L1P - 4-bit parity per 256-b location (1-b parity per 64-b line quadrant)
- L1D – no protection
- L2 – Distance-3 “detect 2, correct 1” Hamming code based error correction/detection

7.2.2.1 DSP Memory Overview

The L1P 32kB memory and L1D 32kB memory can be independently configured as part cache and part mapped to SRAM. The cache size can be 0KB, 4KB, 8KB, 16KB, or 32KB (where the mapped SRAM size is 32KB minus the cache size).

The L2 memory 384 kB memory can also be configured as part SRAM and part Cache. 128kB is always mapped as SRAM. The remaining 256kB can be configured to cache sizes of 0, 32k, 64k, 128k, or 256kB. The additional mapped SRAM available is 256-kB minus the cache size.

7.2.2.2 C66x Cache Subsystem

The purpose of this section is to provide an overview of the C66x cache memory architecture and to specify its configuration in this device. Details on the C66x cache functionality can be found in the *TMS320C66x DSP Cache User Guide* (SPRUGY8).

The device contains a 384KB level-2 memory (L2), a 32KB level-1 program memory (L1P), and a 32KB level-1 data memory (L1D). Each memory has a unique location in the memory map (see #unique_91).

After device reset, L1P and L1D cache are configured as all cache, by default. The L1P and L1D cache can be reconfigured via software through the L1PMODE field of the L1P Configuration Register (L1PMODE) and the L1DMODE field of the L1D Configuration Register (L1DCFG) of the C66x CorePac. L1D is a two-way set-associative cache, while L1P is a direct-mapped cache.

7.2.2.2.1 L1P Memory

The L1P memory configuration for this device is as follows:

- Region 0 size is 0K bytes (disabled)
- Region 1 size is 32K bytes with no wait states

Figure 7-82 shows the available SRAM/cache configurations for L1P.

Note

L1P can only be configured as cache.

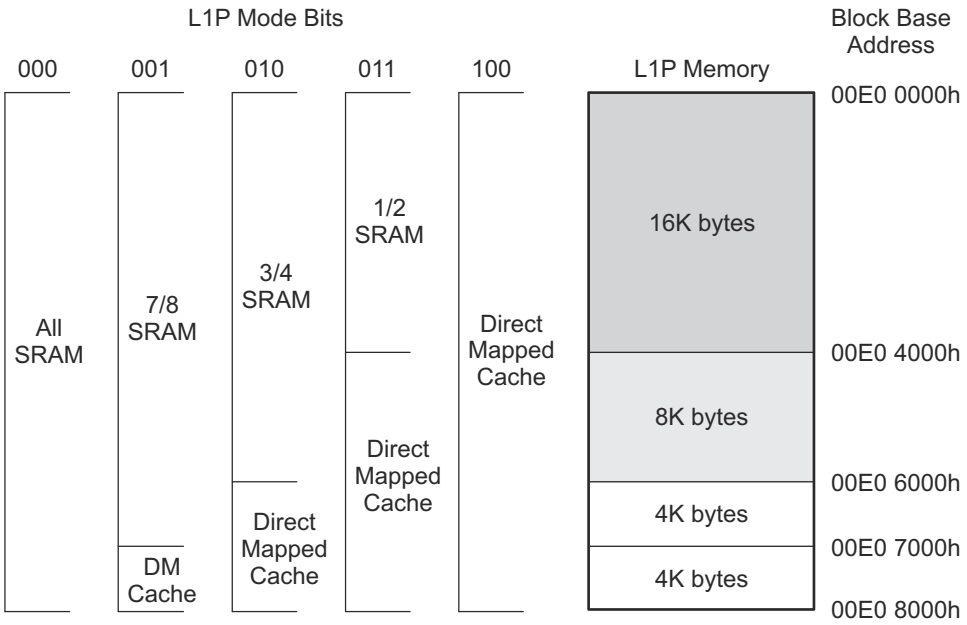

Figure 7-82. L1P Memory Configurations

7.2.2.2.2 L1D Memory

The L1D memory configuration for this device is as follows:

- Region 0 size is 0K bytes (disabled)
- Region 1 size is 32K bytes with no wait states.

Figure 7-83 shows the available SRAM/cache configurations for L1D.

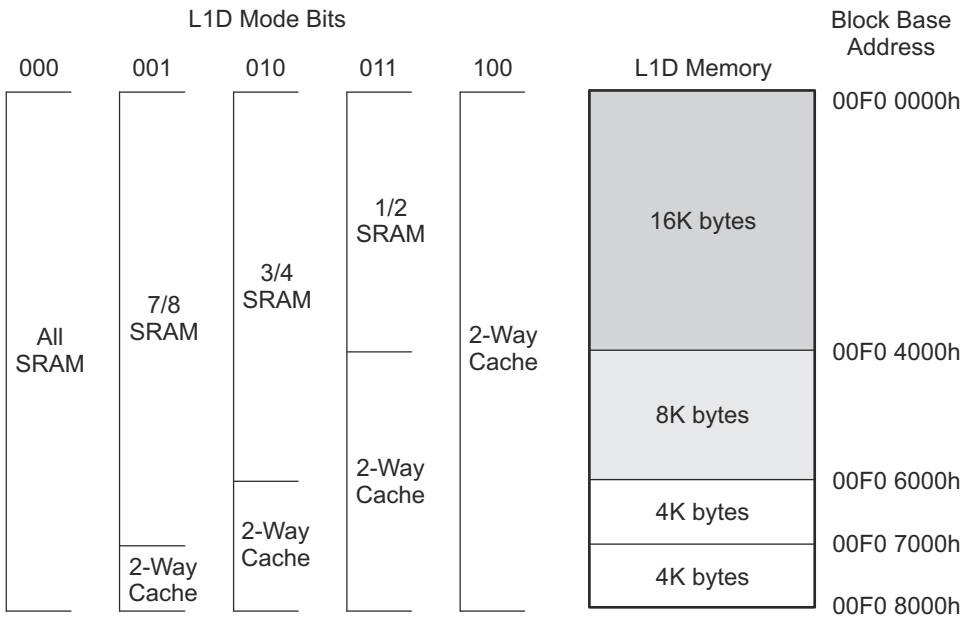

Figure 7-83. L1D Memory Configurations

7.2.2.2.3 L2 Memory

The L2 memory configuration for this device is as follows:

- 384KB of memory
- Local starting address is 0080 0000h.

L2 memory can be configured as all SRAM, all 4-way set-associative cache, or a mix of the two. The amount of L2 memory that is configured as cache is controlled through the L2MODE field of the L2 Configuration Register (L2CFG) of the C66x CorePac. Figure 7-84 shows the available SRAM/cache configurations for L2. By default, L2 is configured as all SRAM after device reset.

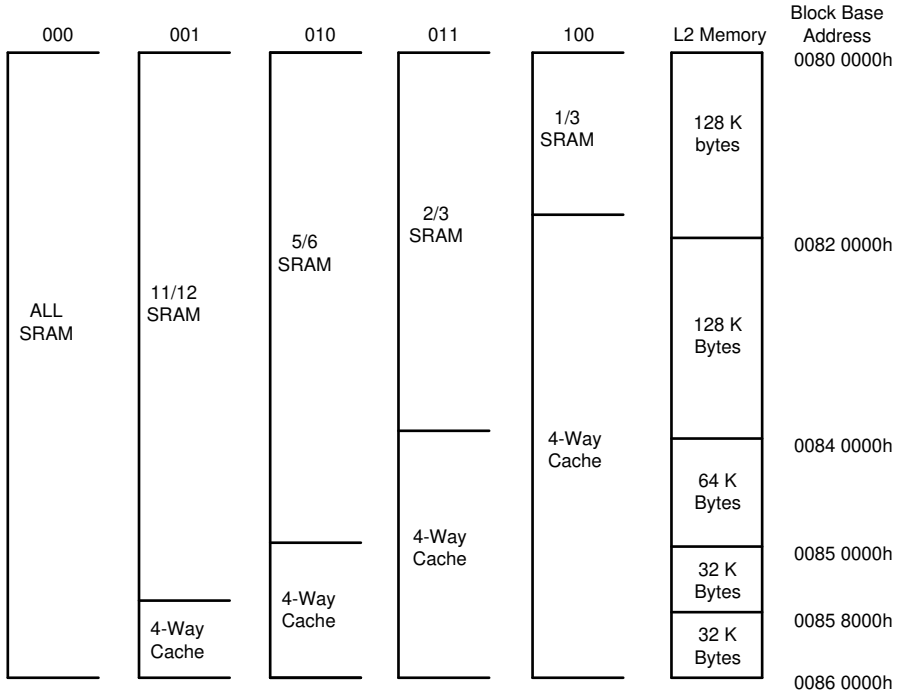

Figure 7-84. L2 Memory Configurations

7.2.2.2.4 DSP ECC Configuration

The device supports ECC/parity on all DSP internal SRAMs. All the ECC/parity features are enabled by default (that is, after device reset). Software can disable the features per SRAM type if not required.

Table 7-82 summarizes the ECC/parity support in DSP.

Table 7-82. DSP ECC/Parity Support

DSP Memory	ECC/Parity Support
L1P Data RAM	Parity
L1P Tag	Parity
L1D Data RAM	ECC-SECDED (Single Error Correction, Double Error Detection)
L1D Tag	ECC-SECDED
L2 Data RAM	ECC-SECDED
L2 Tag	ECC-SECDED

7.3 Radar Processing Hardware Accelerator

In addition to the DSP cores, the AM273x device incorporates Radar Hardware Accelerators HWA2.0 to offload the DSP from pre-processing computations.

7.3.1 Radar Accelerator Features Overview

- Flexible enough to offload almost all the operations from the initial compensation (DC estimation-correction, interference mitigation, and so forth) on raw ADC data before first dimension FFT until point cloud detection, with the least possible intervention from the DSP.
- Operating clock frequency is 400 MHz
- Data path bit-width of 24-bits (24-bit I, 24-bit Q)
- Input and output data formatter: scaling, truncation, head/tail sample skipping, zero padding/insertion of data, sample access pattern for DDMA use case.
- Capability to do all these operations in a single iteration: DC correction, interference zeroing out, complex multiplication, windowing, FFT, log, magnitude, stats computation with a capability of selecting/enabling or disabling/bypassing each of these computation blocks individually.
- 128KB local buffer/RAM split into eight 16KB banks, with each bank configurable as input or output for any compute/data transfer functionality.
- Flexible data flow and data sample arrangement to support efficient multi-dimensional operations and transpose accesses as required.
- Processing for inline (range FFT) and inter-frame (Doppler FFT, angle FFT, detection) threads simultaneously
- Support for CSI2 data input either in Rx interleaved or in serial manner
- Support for DC estimation and correction
- Support for interference mitigation
  - Estimation and zeroing out of the interference samples by estimating the average of the magniture of sudden spikes of vector elements, and applying scaled values as a threshold.
- Support for complex vector/scalar multiplications
- Support for a synthesizer channel combining and MIMO demodulation for DDMA
- Complex windowing – 2K samples window RAM with a capability to split 1KB ping- 1KB pong to allow programming new coefficients while older ones are used.
- Up to 2K point FFT with efficiency of 1 sample output per cycle and possibility to go higher in size until 4K/8K, with stitching (reduced efficiency).
- Doppler de-rotation of the FFT output
- Support for magnitude (absolute value) and Log-Magnitude computation.
- Nested loop support in PARAM sets
- Compression/decompression engine with block floating and exponential Golomb modes with performance of 1 complex sample processing per cycle
- Detection algorithm-specific accelerators (for example: CFAR CA/OS and other variants)

- 2D Local Maxima/Peak search algorithm with efficiency of 1 cell processing per cycle
- Lock-step state machine
- ECC on the PARAM RAMs and parity on local buffers

7.3.2 Radar Accelerator Architecture

The Radar accelerator details are covered in Section 7.4, which consists of 2 parts.

The first part covers the high-level architecture and key features such as windowing, FFT, and log-magnitude. The (optional) second part covers additional features such as CFAR, complex multiplication, advanced statistics, radar data compression engine, and so forth.

7.4 Radar Hardware Accelerator 2.0

This chapter describes the Radar Hardware Accelerator architecture, features, and operation of various blocks and their register descriptions. The purpose is to enable the user to understand the capabilities offered by the Radar Hardware Accelerator and to program it appropriately to achieve the desired functionality.

This chapter provides an overview of the overall architecture and features available in the Radar Hardware Accelerator. The main features, such as, windowing, FFT, and log-magnitude are covered in this chapter.

The chapter also covers additional features like CFAR and other advanced usage possibilities, which can be skipped if the user is interested only in the FFT computation capability.

This chapter covers the introduction and high-level architecture, the state machine, trigger mechanisms, input/output formatting, and general framework for using the accelerator. Later sections describe the primary computational unit features, namely, windowing, FFT, and log-magnitude.

7.4.1 Radar Hardware Accelerator – Overview

This section provides an overview of the Radar Hardware Accelerator 2.0. The section covers the key features of the accelerator and overall architecture.

7.4.1.1 Introduction

The Radar Hardware Accelerator 2.1 is a hardware IP that enables off-loading the burden of certain frequently used computations in FMCW radar signal processing from the main processor. It is well known that FMCW radar signal processing involves the use of FFT and log-magnitude computations to obtain a radar image across the range, velocity, and angle dimensions. Some of the frequently used functions in FMCW radar signal processing can be done within the Radar Hardware Accelerator, while still retaining the flexibility of implementing other proprietary algorithms in the main processor.

7.4.1.2 Key Features

The main features of the Radar Hardware Accelerator 2.1 are as follows.

- Fast FFT computation, with programmable FFT sizes (2, 4, 8…, 2048-pt, and 3, 6, 12, …, 1536-pt) complex FFT.
- Internal FFT bit width of 24 bits (for each I and Q) for good SQNR performance, with fully programmable butterfly scaling at every stage for user flexibility.
- Built-in capabilities for pre-FFT processing – specifically DC estimation and removal, interference localization and mitigation, channel equalization, channel combination, zero insertion, and programmable windowing.
- Magnitude (absolute value) and log-magnitude computation capability.
- Flexible data flow and data sample arrangement to support efficient multidimensional FFT operations and transpose accesses as required.
- Chaining, looping and context switching mechanisms to sequence a set of accelerator operations one-after-another with minimal intervention from the main processor
- CFAR-CA and CFAR-OS detector support (linear and logarithmic), Local Maxima engine
- Statistics including 2D maxima, Histogram and CDF
- Radar data compression / decompression capability
- Miscellaneous other capabilities of the accelerator:
  - Stitching two or four 2K-point FFTs to get the equivalent of 4096-point or 8192-point FFT for industrial level sensing applications where large FFT sizes are required
  - Slow DFT mode, with resolution equivalent to 16K size FFT, for FFT peak interpolation purposes (for example, range interpolation)
  - Complex vector multiplication and Dot product capability for vectors up to 1024 in size

This chapter covers the high-level architecture and key features such as windowing, FFT, and log-magnitude. It also covers additional features such as CFAR, complex multiplication, advanced statistics, radar data compression engine, and so forth.

7.4.1.3 High Level Architecture

The Radar Hardware Accelerator module is loosely coupled to the main processor (eg. C6x DSP). The accelerator is connected to a 128-bit bus that is present in the main processor system, as shown in Figure 7-85.

The Radar Hardware Accelerator module comprises an accelerator engine and four memories, each of 16KB size, which are used to send input data to and pull output data from the accelerator engine. These memories are referred to as *local memories* of the Radar Accelerator (ACCEL_MEM). For convenience, these eight local memories are referred to as ACCEL_MEM0, ACCEL_MEM1, ACCEL_MEM2, ACCEL_MEM3, ACCEL_MEM4, ACCEL_MEM5, ACCEL_MEM6 and ACCEL_MEM7.

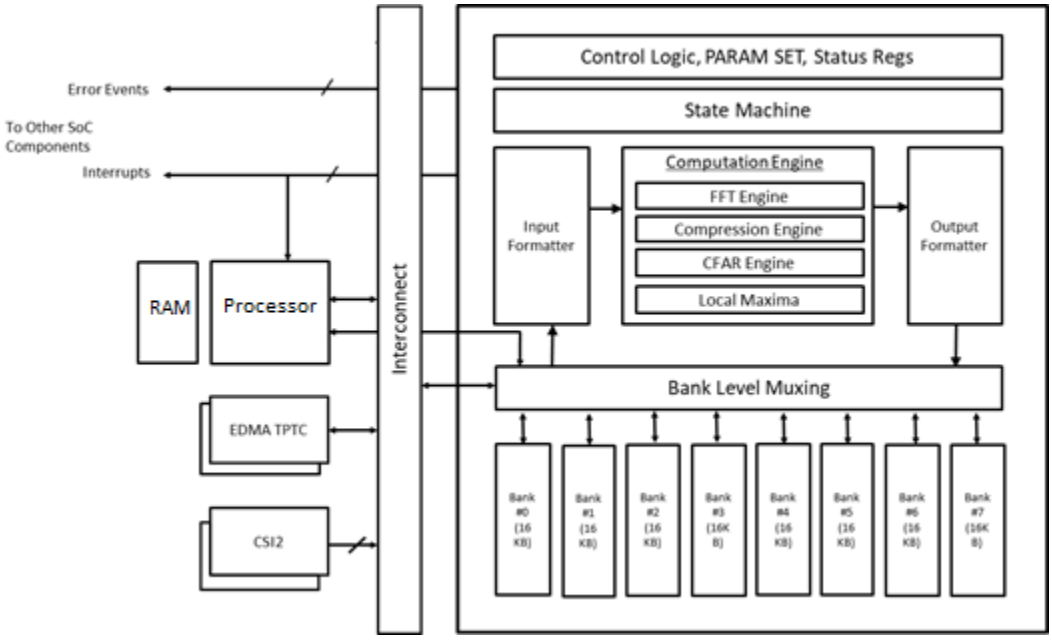

Figure 7-85. Radar Hardware Accelerator

7.4.1.3.1 High-Level Data Flow

The typical data flow is that the DMA module is used to bring samples (for example, FFT input samples) into the local memories of the Radar Hardware Accelerator, so that the main accelerator engine can access and process these samples. Once the accelerator processing is done, the DMA module reads the output samples from the local memories of the Radar Hardware Accelerator and stores them back in the Radar data memory for further processing by the main processor.

The purpose behind the eight separate local memories (16KB each) inside the Radar Hardware Accelerator is to enable the *ping-pong* mechanism, for both the input and output, such that the DMA write (and read) operations can happen in parallel to the main computational processing of the accelerator. The presence of four memories enables such parallelism. For example, the DMA can be configured to write FFT input samples (ping) into ACCEL_MEM0 and read FFT output samples (ping) from ACCEL_MEM2. At the same time, the accelerator engine can be working on FFT input samples (pong) from ACCEL_MEM1 and writing FFT output samples (pong) into ACCEL_MEM3. However, both the DMA and the accelerator cannot access the same 16KB memory at the same time. This would lead to an error (referto the MEM_ACCESS_ERR_STATUS register description in TBD-Table 3). As will be explained in later sections, the accelerator engine can perform multiple computational steps one after another autonomously. In each step, the input samples are read from one of the eight local memories and the output samples are written into another one of the eight local memories.

The Radar Hardware Accelerator operates on a single clock domain and the operating clock frequency is 400MHz.

The accelerator local memories are 128-bits wide, for example, each of the 16KB banks is implemented as 1024 words of 128 bits each. This allows the DMA to bring data into the accelerator local memories efficiently (up to a maximum throughput of 128 bits per clock cycle, depending upon the DMA configuration). Two ports for accessing the HWA local memories are available and these map the same 128KB into two different address spaces, thus allowing simultaneous efficient to and from DMA transfers.

It is important to note that any of the eight local memories can be the *source* of the input samples to the accelerator engine and any of the eight local memories can be the *destination* for the output samples from the accelerator engine – with the important restriction that the source and destination memories cannot be the same 16KB bank. Note also that the accelerator local memories do not necessarily need to be used in ping-pong mode and can instead be used as larger 32KB input and output memories, if the use case requires. The address space for the four 16KB memories is contiguous (including a wrap-around form the end of ACCEL_MEM7 to the start of ACCEL_MEM0). Therefore the source as well as destination memory addresses can span beyond 16KB.

7.4.1.3.2 Configuration

The operations of the Radar Hardware Accelerator are configured using registers, which are of two types – *parameter sets* and *common* (common for all parameter sets) registers. The purpose of the parameter sets is to enable a complete sequence of various accelerator operations to be preprogrammed (with appropriate source and destination memory addresses and other configurations specified for each operation in that sequence), such that the accelerator can perform them one after the other, with minimal intervention from the main processor.

The parameter-set register configurations are programmed into a separate 4KB *parameter-set configuration memory*. A state machine built into the accelerator handles the loading of one parameter-set configuration at a time and sequences the preprogrammed operations one after another. This process is further explained in later sections of this user's guide.

7.4.1.4 Accelerator Engine Block Diagram

As previously mentioned, the Radar Hardware Accelerator module consists of eight local memories of 16KB each (ACCEL_MEM) and the main accelerator engine. The accelerator engine has the following five components (as shown in Figure 7-86) – a state machine, input formatter block, output formatter block, core computational unit, and the 4KB parameter-set configuration memory.

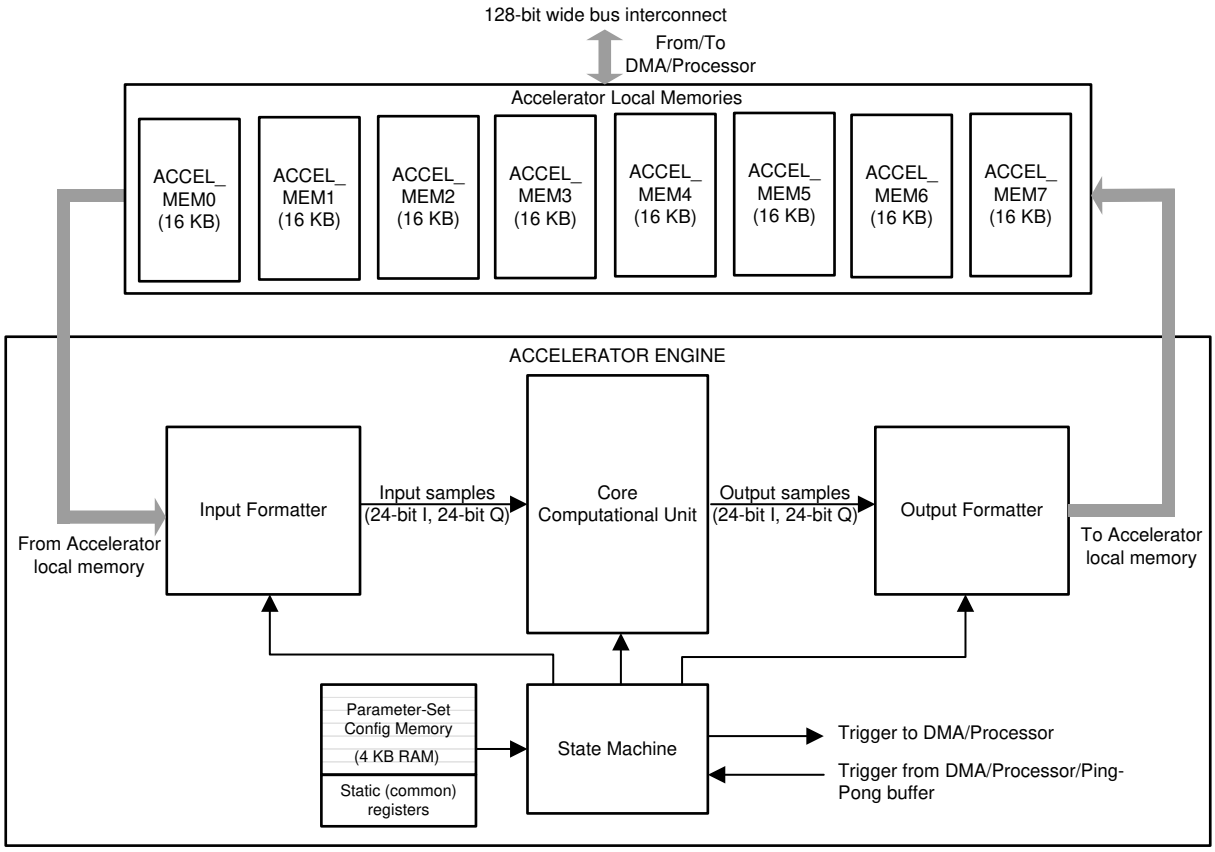

Figure 7-86. Accelerator Engine Block Diagram

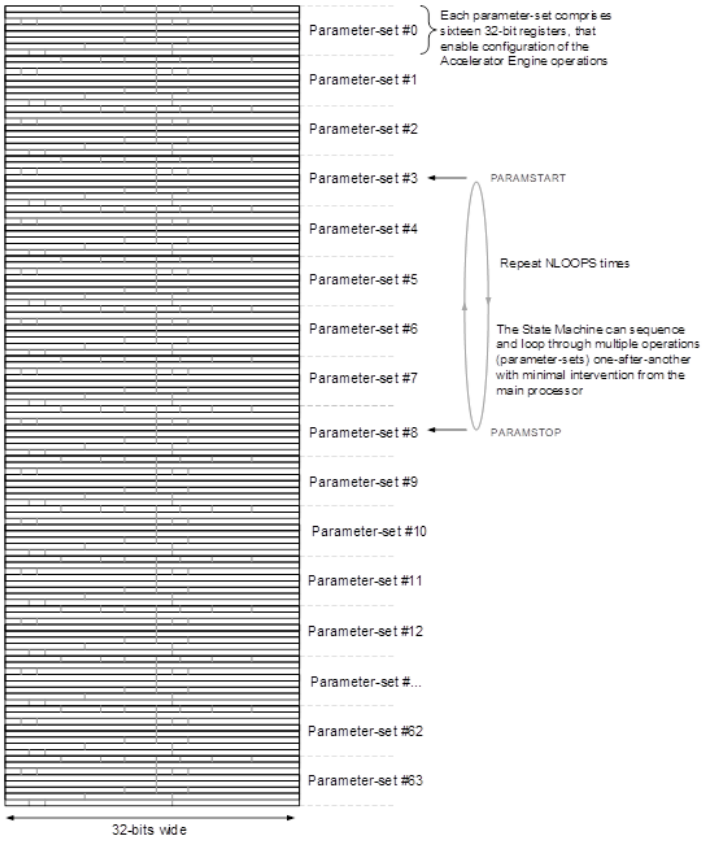
The purpose of these components is as follows.

- State machine: the state machine is responsible for controlling the overall operation of the accelerator – specifically, the starting, looping, stopping, as well as triggering and handshake mechanisms between the accelerator, DMA, and main processor. The state machine is also closely connected to the parameter-set configuration memory and takes care of sequencing and chaining a sequence of multiple accelerator operations as programmed in the parameter-set configuration memory.
- Input formatter: the input formatter block is responsible for reading the input samples from any one of the local memories and feeding them into the core computational unit. In this process, this block provides flexible ways of accessing the input samples, in terms of 16-bit versus 32-bit aligned input samples, transpose read-out, flexible scaling, and sign extension to generate internal bit-width of 24 bits, and so on. Lastly the input formatter block provides 24-bit complex samples as input to the core computational unit. The local memory (memories) from which the input formatter reads the input samples is called the *source* memory.
- Output formatter: the output formatter block is responsible for writing the output samples from the core computational unit into the local memories. This block also provides flexible ways of formatting the output samples, in terms of 16-bit versus 32-bit aligned output samples, transpose write, flexible scaling from internal bit-width of 24 bits, to 16-bit or 32-bit aligned output samples, sign-extension, and so on. The local memory (memories) to which the output formatter writes the output samples is called the *destination* memory.
- Core computational unit: the core computational unit contains the main computational logic for various operations, such as windowing, FFT, magnitude, log2, and CFAR calculations. The unit accepts a streaming input from the input formatter block (at the rate of one input sample per clock cycle), performs computations, and produces a streaming output to the output formatter block (typically at the rate of one output sample per clock cycle), with some initial latency depending on the nature of the computations involved.
- Parameter-set configuration memory: this is a 4096-byte RAM that is used to preconfigure the sets of parameters (register settings) for a chained sequence of accelerator operations, which can then be executed

by the state machine in a loop. This allows the accelerator to perform a preprogrammed sequence of operations in a loop without frequent intervention from the main processor.

Figure 7-87. Parameter-Set Configuration Memory (4KB)



The number of parameter sets that can be preconfigured and sequenced (chained) is 64. This means that up to 64 accelerator operations can be chained together and these can then be looped as well, with minimal intervention from the main processor. For example, operations like FFT, log-magnitude, and CFAR detection can be preconfigured in the parameter-set configuration memory and the state machine can be made to sequence them one after another and run them in a loop for specified number of times. There is a provision available to interrupt the main processor and/or trigger a DMA channel at the end of each parameter set if required. This allows various ways by which the accelerator, DMA, and the main processor can work together to establish a data and processing flow. As shown in Figure 7-87, each parameter set contains the equivalent of sixteen 32-bit registers, which corresponds to total RAM size of 64 ×16 × 32 bits = 4KB for the parameter-set configuration memory.

The layout of the parameter-set register map is provided in Section 7.4.6. Note that the parameter-set RAM must be programmed using 32-bit word writes only (i.e., byte-writes and half-word writes are not supported). The detailed descriptions of the registers is provided in the various sections, as and when the functionality of each component is presented.

Typically, all necessary parameter sets can be pre-configured before triggering execution by the accelerator. If needed, the parameter sets can be modified on-the-fly but without modifying the parameter set being executed at that time. If parameter sets are being overwritten after execution, it is recommended to re-program all the fields for particular set, i.e., avoid partial over-writing.

7.4.1.5 Accelerator Engine Operation

The accelerator engine and the local memories run on a single clock domain. The overall operation of the accelerator can be summarized as follows. The accelerator engine is configured by the main processor through

common configuration registers (common for all parameter sets), as well as the parameter-set configuration memory. As explained earlier, the former comprises common register settings for overall control of the accelerator engine, and the latter comprises the 64 parameter-set specific settings which control the functioning of the accelerator for each of its *chained* sequence of operations.

When the accelerator engine is enabled, the state machine kicks off and controls the overall operation of the accelerator, which involves loading the parameter sets one at a time from the parameter-set configuration memory into various internal registers of the accelerator engine and running the accelerator as per the programmed configuration for each parameter set one after another. The entire procedure then repeats in a loop for a programmed number of times (NUMLOOPS described later).

Each parameter set includes various configuration details such as the accelerator mode of operation (FFT, Log2, and so on), the source memory address, number of samples, the destination memory address, input formatting, output formatting, trigger mode for controlling the start of computations to ensure proper handshake with the DMA, and so on.

7.4.1.5.1 Data Throughput

Once the state machine has loaded the registers corresponding to the current parameter set to be executed, the data flow happens as follows: at each clock cycle, one sample from the source memory is read by the input formatter and fed into the core computational unit with appropriate scaling and formatting as configured. The data interface between the input formatter and the core computational unit is a 24-bit complex bus (24-bit for each I and Q) which streams one input sample every clock cycle. The core computational unit processes this streaming sequence of input samples and in general, produces a streaming output also at one sample every clock cycle, after an initial latency period. Thus for most operations (FFT, log-magnitude, CFAR, and so on), in steady state the core computational unit maintains a streaming data rate of one sample per clock cycle. The data interface between the core computational unit and the output formatter is also a 24-bit complex bus (24-bit for each I and Q) and the output formatter is responsible for writing into the destination memory, with appropriate scaling and formatting as configured.

The next section provides more details regarding the state machine, including its detailed operation, registers, trigger mechanisms, and so on.

7.4.2 Accelerator Engine – State Machine

This section describes the state machine block present in the accelerator engine (see Figure 7-88). This block, together with the input formatter and output formatter blocks described in the next two sections, provides the overall framework for establishing the data flow and using the accelerator for various computations.

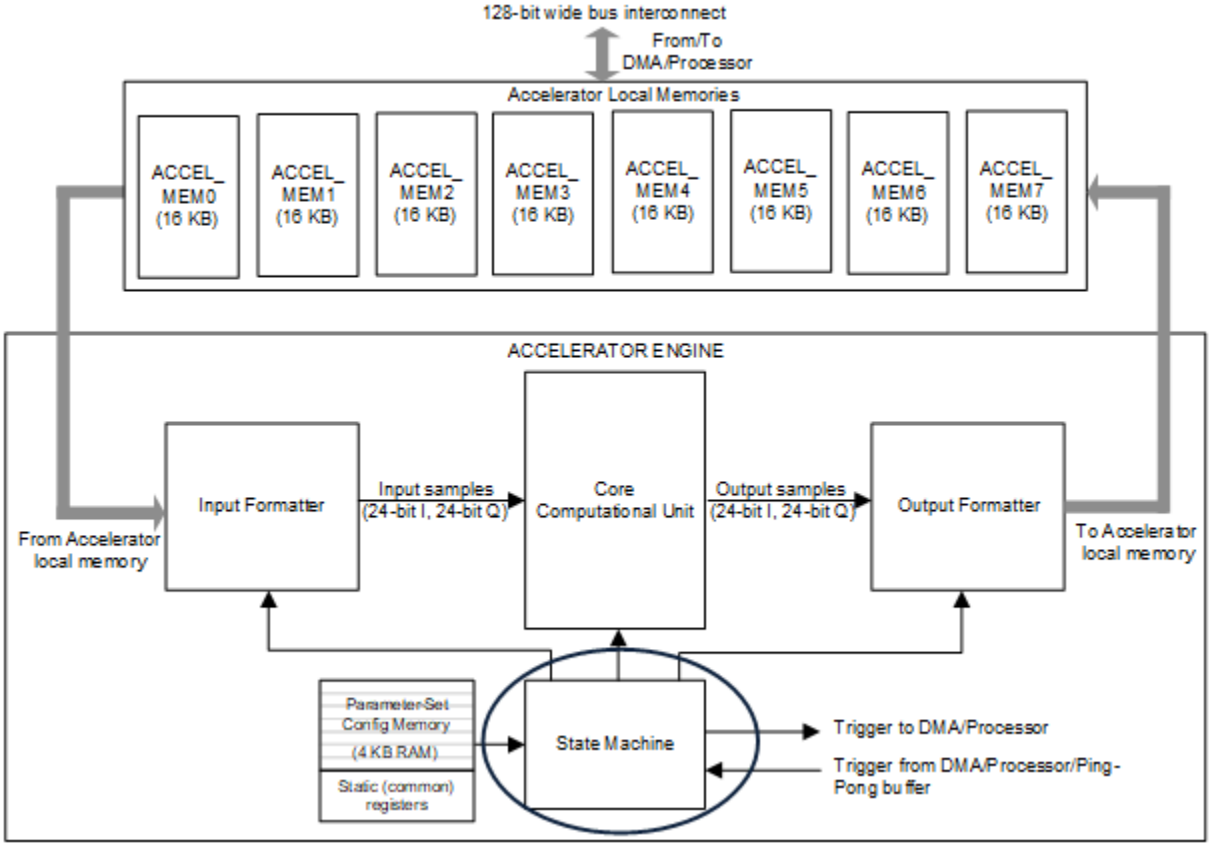


Figure 7-88. State Machine

7.4.2.1 State Machine

The state machine controls the overall functioning of the Radar Hardware Accelerator. The state machine controls the enabling and disabling of the accelerator, as well as supports sequencing an entire set of operations (configured using parameter-set configuration memory), and looping through those operations one after another without needing frequent intervention from the main processor.

7.4.2.1.1 State Machine – Operation

The state machine block and the entire accelerator remain in reset and disabled state by default. The state machine (and hence the accelerator in general) is enabled by setting the HWA_CLK_EN register bit, followed by writing 111b into the HWA_EN register.

Note that a complete list of registers pertaining to the state machine is provided in Section 7.4.2.1.4. Some of the registers are common (common for all parameter sets) registers, whereas some other registers are parameter-set registers, which as explained in the previous section means that they can be uniquely programmed for each of the 64 parameter sets. For each register, Table 7-83 lists whether it is part of the parameter set or not. Table 7-83 also provides a brief description of each register.

When enabled, the state machine steps through (one after another) the parameter sets programmed in the parameter-set configuration memory and executes the computations as per the configuration of each parameter set. The registers PARAM_START_IDX andPARAM_END_IDX define the starting index and ending index within

the 64 parameter sets, so that only those parameter sets between the start and end indices are executed by the accelerator, as shown in TBD. The state machine also loops through these parameter sets for a total of NUMLOOPS times (unless NUMLOOPS is programmed as 0 or 4095, in which case the loop does not run or runs infinite times respectively). As an example, if the state machine needs to be configured to run the first four parameter sets in a loop 64 times, then the registers should be programmed as follows: PARAM_START_IDX =0, PARAM_END_IDX = 3, and NUMLOOPS = 64.

For each parameter set, there is a TRIGMODE register, which is used to control when the state machine starts executing the computations for that parameter set. This control is useful, for example, to ensure that the input data is ready in the accelerator local memory (source memory) before the computations are started. Specifically, it is possible to trigger the start of computations after completion of a DMA transfer, or after a CSI2 line is received, and so on. The TRIGMODE register setting thus controls when the accelerator operation is triggered for the current parameter set and there are four trigger mechanisms supported as listed in the next subsection. Once triggered, the state machine loads all the registers from the parameter-set configuration memory for the current parameter set into corresponding internal registers of the accelerator and starts the actual computations for that parameter set. After completion of computations of the current parameter set, it moves to the next parameter set. . In general, once the parameter set registers are configured and the state machine is enabled, it is recommended to avoid dynamically changing any of the register values. In particular, note that the loading of parameter set (N+1)'s registers happens soon after the completion of parameter set N's execution, and this loading can happen even while the state machine is waiting for the parameter set (N+1)'s trigger to arrive. This means that parameter set configuration registers of parameter set (N+1) cannot be reliably changed while parameter set N is already executing.

After a sequence of operations as programmed in the parameter set(s) for the specified number of loops is complete, the accelerator provides a completion interrupt (DSS_HWA_THREAD1_LOOP_INT) to the processor. The accelerator can be reconfigured as desired. For reconfiguration, the following procedure must be followed. The accelerator must be disabled by writing 000b to the HWA_EN register. Then, a reset must be asserted by writing 111b followed by 000b to the HWA_RESET register. The new configurations can now be written in to the accelerator, and then the accelerator can be enabled again by writing 111b to HWA_EN. Note that any spare/reserved bits should be kept as 0.

7.4.2.1.2 State Machine – Trigger Mechanisms (Incoming)

As mentioned in the previous subsection, for each parameter set, the start of the computations can be triggered based on specific events. Four trigger mechanisms are supported as follows.

- Immediate trigger (TRIGMODE = 000b): In this case, the state machine does not wait for any trigger and starts the accelerator computations immediately for the current parameter set. This mode is applicable when chaining (sequencing) a set of operations one after another in the accelerator without any need for control handshake or data exchange outside the accelerator (for example, when chaining FFT and log-magnitude operations) with no need to wait for a trigger in between.
- Wait for processor-based software trigger (TRIGMODE = 001b, TRIGMODE = 111b): This is a software-triggered mode that is useful when the main processor must directly control the data flow and start or stop of accelerator computations. In this trigger mode, the state machine waits for a software-based trigger, which involves the main processor setting a separate self-clearing bit in a FW2HWA_TRIGGER_0 or FW2HWA_TRIGGER_1 register (single-bit register). The state machine keeps monitoring that register bit and waits as long as the value is zero. When the value becomes 1 (set), the state machine gets triggered to start the accelerator operations for the current parameter set. FW2HWA_TRIGGER_0 register bit corresponds to TRIGMODE = 001b and FW2HWA_TRG_1 corresponds to TRIGMODE = 111b.
- TRIGMODE= 010b : mode is reserved.
- Wait for the DMA-based trigger (TRIGMODE = 011b): This trigger mode is useful when a DMA transfer completion must be used to trigger the start of the accelerator computations for the current parameter set. The primary purpose of this trigger mode is as follows; when performing second dimension FFT, the DMA is used to bring the FFT input samples from the Radar data memory to the local memory of the accelerator. Upon completion of each DMA transfer, it is useful to automatically trigger the accelerator to perform the FFT.

To achieve this, the state machine of the accelerator has a 32-bit register called the DMA2HWA_TRIGGER register, where each register bit maps to one of 32 DMA channels that are associated with the accelerator. To use the DMA-based trigger mode, the HWA_TRIGSRCregister in the current parameter set must be programmed to the DMA channel whose completion we wish to monitor. The state machine then monitors the corresponding register bit in the DMA2HWA_TRIGGER register, and triggers the execution of the current parameter set only when that register bit gets set. For e.g. if HWA_TRIGSRC is programmed to 5, then the current parameter set will execute only once the register bit #5 gets set in DMA2HWA_TRIGGER.

The user may utilize the EDMA's linking capability to set the appropriate register bit in DMA2HWA_TRIGGER. Linking is a programmable feature of the EDMA, where the completion of a DMA transfer can automatically trigger a second DMA transfer. In the present context, the DMA transfer that moves data to the local memory of the accelerator can be linked to a second DMA whose purpose is to write a one-hot signature into DMA2HWA_TRIGGER to set a specific register bit and trigger the accelerator. Note that there are 32 read-only, one-hot, signature registers (SIG_DMACH1_DONE, SIG_DMACH2_DONE, and more) that are available. These registers are simply read-only registers which contain hard-coded values (each register is a one-hot signature – 0x0001, 0x0002, 0x0004, 0x0008, and so on). For convenience, these hard-coded 32 read-only signatures can be used, so that the second DMA can simply copy from one of these SIG_DMACHx_DONE registers into the DMA2HWA_TRIGGER register to set the appropriate register bit.

In case of multiple DMA triggers waiting on multiple HWA paramset operation, each time the DMA transfer is completed, the corresponding one-hot signature is copied to DMA2HWA_TRIGGER (self-clearing bit) register and this value gets internally latched and is serviced only on DMA transfer completion. For example, assume there are two parallel DMA's (DMA-0 and DMA-1) which are about to trigger paramset-0 and paramset-1 respectively. So in this case even if DMA-1 completes transfer first, the HWA will only start execution once DMA-0 is over and also note that DMA2HWA_TRIGGER register is not overwritten but the values get internally latched as mentioned above.

- Wait for hardware trigger (TRIGMODE = 0b100): These trigger modes are useful when a hardware signal such as CSI interrupt needs to be used to trigger the start of the accelerator computations for the current parameter set. The hardware trigger sources can be either CSI #1 frame start, CSI #1 lineend, or CSI #2 frame start, or CSI #2 line end. The HWA_TRIG_SRC register in the parameter-set decides which of these trigger sources is selected. . The valid range for HWA_TRIG_SRC register is 0 to 19, and these values correspond to different trigger sources – specifically, a value of 0 selects the right most trigger and 19 selects left most trigger in the following trigger sources: RCSS_CSI2A_SOF_INT[0,1] RCSS_CSI2A_EOL_CNTX[0..7]_INT, RCSS_CSI2B_SOF_INT[0,1], RCSS_CSI2B_EOL_CNTX[0..7]_INT. Please refer to the device TRM for more details.

7.4.2.1.3 State Machine – Trigger Mechanisms (Outgoing)

After the accelerator computations for the current parameter set are triggered (using one of the four incoming trigger mechanisms mentioned in the previous subsection), it performs the actual computation operations for that parameter set. These computations typically take several tens or hundreds of clock cycles, depending on the nature of the configuration programmed. Once the accelerator completes its computation operations for the current parameter set, the state machine advances to the next parameter set and repeats the same process. But before advancing to the next parameter set, it can interrupt the main processor and/or trigger a DMA channel. This provision is useful if the main processor is required to read or write registers or memory locations at the end of the current parameter set. Also, this provision is useful for triggering a DMA channel, so that the output of the accelerator can be copied out of the accelerator local memories.

There are two trigger mechanisms provided as follows:

- Interrupt(s) to main processor (CPU_INTR1_EN = 1, CPU_INTR2_EN = 1): The accelerator interrupts the main processor(s) at the end of completion of computations for the current parameter set, if the register bit CPU_INTR1_EN or CPU_INTR2_EN is set. Two interrupt signals are available and they are enabled or disabled for each parameter-set by these two register bits. Setting CPU_INTR1_EN in a parameter-set enables DSS_HWA_PARAM_DONE_INTR1 interrupt to be generated at the end of that parameter-set. Setting CPU_INTR2_EN in a parameter-set enables DSS_HWA_PARAM_DONE_INTR2 interrupt to be generated at the end of that parameter-set.

- Trigger to DMA (DMATRIG_DMATRIG_ENEN = 1): The accelerator gives a trigger to a DMA channel at the end of completion of computations for the current parameter set, if the register bit DMATRIG_EN is set. If DMATRIG_EN is set, then the particular DMA channel as specified in a separate HWA2DMA_TRIGDST register (valid values are 0 to 31, for the 32 DMA channels dedicated for the accelerator) is triggered. Thus, it is possible to preconfigure up to 32 DMA channels and trigger the appropriate one at the end of the computations of the current parameter set. The trigger from accelerator to the DMA channels can also be emulated by the processor, by writing to a FW2DMA_TRIGGER register. This can be used by the processor to kick-start a full/repetitive chain of operations, that are then subsequently managed between the DMA and the accelerator without further processor involvement – for example, the processor writes to the FW2DMA_TRIGGER register to trigger a DMA channel for the first time, and this kicks off a series of back-to-back data transfers and accelerator computations, with the DMA and accelerator hand-shaking with each other.

7.4.2.1.4 State Machine – Register Descriptions

Table 7-83 lists all the registers of the state machine block. As explained previously, some of the registers are common (common for all parameter sets) registers, whereas some others are *part of each parameter set*. For each register, this distinction is captured as part of the register description in Table 7-83.

Table 7-83. State Machine Registers

Register.Field	Width	Parameter Set	Description
HWA_ENABLE.hwa_en	3	No	Enable and Disable Control: This register enables or disables the entire Radar Hardware Accelerator. The reason for a 3-bit register (instead of 1-bit) is to avoid an accidental bit-flip (for example, transient error caused by a neutron strike) from unintentionally turning on the accelerator engine. A value of HWA_EN = 111b enables the Radar Hardware Accelerator and any other value of the register keeps the accelerator engine in disabled state.
HWA_ENABLE.hwa_clk_en	3	No	Clock-gating Control: This register bit controls the enable/ disable for the clock of the Radar Accelerator. This register bit can be set to 0 to clock-gate the accelerator when not using the accelerator. Before enabling the accelerator or before configuring the accelerator's registers, this register bit should be set first, so that the clock is available.
HWA_ENABLE.hwa_reset	3	No	Software Reset Control: This register provides software reset control for the Radar Hardware Accelerator. The assertion of these register bits by the main processor will bring the accelerator engine to a known reset state. This is mostly applicable for resetting the accelerator in case of unexpected behavior. Under normal circumstances, it is expected that whenever the accelerator is enabled (from disabled state), it always comes up in a known reset state automatically. The recommended sequence to be followed in case software reset is desired is to write 111b to this register and then a 000b, before the clock is enabled to the accelerator.
PARAM_RAM_LOOP.numloops	12	No	Number of loops: This register controls the number of times the state machine will loop through the parameter sets (from a programmed start index till a programmed end index) and run them. The maximum number of times the loop can be made is run is 4094. A value of 4095 (0xFFF) programmed in this register should be considered as a special case and it should be interpreted as an infinite loop mode, for example, keep looping and never stop the accelerator engine unless reset by the main processor. A value of zero programmed in this register means that the looping mechanism is disabled. In this case, the accelerator engine can still be used under direct control of the main processor (without the state machine looping provision coming into the picture).

Table 7-83. State Machine Registers (continued)

PARAM_RAM_IDX. param_start_idx	4	No	Parameter-set Start Index: These registers are used to control the start and stop index of the parameter set through which the state machine loops through. The state machine starts at the parameter set specified by PARAM_START_IDX and loads each parameter set one after another and runs the accelerator as per that configuration. When the state machine reaches the parameter set specified by PARAM_END_IDX, it loops back to the start index as specified by PARAM_START_IDX.
PARAM_RAM_IDX. param_end_idx	4	No	Parameter-set Stop Index: Refer register description for PARAM_START_IDX
HWA_ENABLE. hwa_dyn_clk_en	1	No	Dynamic Clock-gating Control: Setting this register bit to '1' enables the capability to clock gate the unused computation engines (i.e., from the four computation engines, namely FFT, CFAR, Memory compression, Local Maxima) to save power consumption, based on the specific parameter-set being executed.
TRIGMODE	4	Yes	Trigger mode select: 0000b – Immediate trigger 0001b – Software trigger 0010b – Reserved 0011b – DMA-based trigger 0100b – Hardware based trigger 0101b – Reserved 0110b – Reserved 0111b – M4 Micro-controller based trigger (equivalent to software trigger, differentiating trigger source between external and HWA CPU.
FW2HWA_TRIG_0.fw2hwa_trigger_0	1	No	Software trigger bit: This register bit is relevant whenever software triggered mode is used (TRIGMODE = 001b). Whenever this software triggered mode is configured for a parameter set, the state machine keeps monitoring this register bit and waits as long as the value is zero. The main processor software can set this register bit, so that the state machine gets triggered and starts the accelerator operations for that parameter set.
FW2HWA_TRIG_1.fw2hwa_trigger_1	1	No	Software trigger bit: This register bit is similar to FW2HWA_TRIGGER_0, except that this register bit corresponds to TRIGMODE = 111b.
DMA2HWA_TRIG.dma2hwa_trigger	32	No	DMA trigger register: This register is relevant whenever DMA triggered mode is used (for example, TRIGMODE = 011b). Whenever a DMA channel has finished copying input samples into the local memory of the accelerator and wants to trigger the accelerator, the procedure to follow is to use a second linked DMA channel to write a 32-bit one-hot signature into this register to trigger the accelerator. In DMA triggered mode, the state machine keeps monitoring this 32-bit register and waits as long as a specific bit (see DMA2HWA_TRIGSRC) in this register is zero. The second linked DMA channel writes a one-hot signature that sets the specific bit, so that the state machine gets triggered and starts the accelerator operations for that parameter set.
DMA2HWA_TRIGSRC	5	Yes	DMA channel select for DMA completion trigger: This parameter-set register is relevant whenever DMA triggered mode is used (for example, TRIGMODE = 011b). This register selects the bit number in DMA2HWA_TRIGGER for the state machine to monitor to trigger the operation for that parameter set.

Table 7-83. State Machine Registers (continued)

CPU_INTR1_EN	1	Yes	Completion interrupt to main processor: This parameter-set register is used to enable/disable interrupt to the main processor upon completion of the accelerator operation for that parameter set. If enabled, the main processor receives an interrupt from the Radar Hardware Accelerator at the end of operations for that parameter set, so that the main processor can take any necessary action. Two interrupts are available, and this register bit enables or disables the first interrupt.
CPU_INTR2_EN	1	Yes	Completion interrupt to main processor: Similar to CPU_INTR1_EN. This register bit enables or disables the second interrupt to the main processor.
PARAM_DONE_SET_STATUS_0 . param_done_set_status_0 PARAM_DONE_SET_STATUS_1. param_done_set_status_1	32	No	Parameter-set done status: These read-only status registers can be used by the main processor to see which parameter sets are complete that led to the interrupt to the main processor. The individual bits in these 32-bit status register indicate which of the 64 parameter sets have completed. These status bits are not automatically cleared, but they can be individually cleared by writing to another set of 32-bit registers (PARAM_DONE_STATUS_CLR)
PARAM_DONE_STATUS_CLR_0 PARAM_DONE_STATUS_CLR_1	32	No	Refer register description for PARAM_DONE_SET_STATUS
DMATRIG_EN	1	Yes	Completion trigger to DMA: This parameter-set register is used to enable DMA channel trigger upon completion of the accelerator operation for that parameter set. This trigger mechanism enables the accelerator to hand-shake with the DMA so that output data samples are copied out of the accelerator local memory. If enabled, the accelerator triggers a specified DMA channel, so that the output samples can be shipped from the local memory to Radar data memory.
HWA2DMA_TRIGDST	5	Yes	DMA channel select for accelerator completion trigger: This parameter-set register is used to select which of the 32 DMA channels allocated to the accelerator should be triggered upon completion of the accelerator operation for that parameter set. This register is to be used in conjunction with DMATRIG_EN.
FW2DMA_TRIGGER. fw2dma_trigger	32	No	Trigger from processor to DMA: This register can be used by the processor to trigger a DMA channel for the first time, so that a full sequence of repeated operations between the DMA and the accelerator gets kick-started.
PARAMADDR.paramaddr	6	No	Debug register for current parameter-set index: This read-only status register indicates the index of the current parameter set that is under execution. This is useful for debug, where parameter sets can be executed in single-step manner (one-by-one) using SW trigger mode for each of them. In such a debug, this register indicates which parameter set is currently waiting for the SW trigger.
LOOP_CNT.loop_cnt	12	No	Debug register for current loop count: This read-only status register indicates what is the loop count that is presently running. When the state machine is programmed for NUMLOOPS loops, this register shows the current loop count that is running.
TRIGGER_SET_STATUS_0. Trigger_set_status_0	32	No	Debug register for trigger status: This is a read-only status register, which indicates the trigger status of the accelerator, for example, whether a DMA trigger was ever received (refer TRIGMODE). The 32 bits in this register correspond to the 32 DMA trigger bits (refer DMA2HWA_TRIGGER).
TRIGGER_SET_STATUS_1. Trigger_set_status_1	32	No	Debug register for trigger status: This is a read-only status register, which indicates the trigger status of the accelerator, for example, whether a specific hardware trigger or software trigger or context switch trigger has even been received.

Table 7-83. State Machine Registers (continued)

TRIGGER_SET_IN_CLR_0. Trigger_set_in_clr_0	1	No	Clear trigger status read-only register: This register-bit when set clears the trigger status register TRIGGER_SET_STATUS_0 described above.
TRIGGER_SET_IN_CLR_1 Trigger_set_in_clr_1	1	No	Clear trigger status read-only register: This register-bit when set clears the trigger status register TRIGGER_SET_STATUS_1 described above.
FORCED_CONTEXTSW_EN	**1**	Yes	Force context switch: This register bit is useful in Context Switching. If this bit is set, the state machine switches the context to other thread after the completion of the current parameter-set. Refer the Context Switching section 28.11 of TRM for details.
CONTEXTSW_EN	1	Yes	Enable context switch: This register bit is useful in Context Switching. If this bit is set, the state machine is allowed to switch context at the end of execution of this parameter-set. Refer the Context Switching section 28.11 of TRM for details
PARAM_RAM_IDX_ALT.param_start_idx	10	No	Refer Context Switching section in section 28.11 of TRM
PARAM_RAM_IDX_ALT.param_end_idx	10	No	Refer Context Switching section in section 28.11 of TRM
PARAM_RAM_IDX_ALT.numloops	12	No	Refer Context Switching section in section 28.11 of TRM

The next two sections cover the Input Formatter and Output Formatter blocks, including their detailed operation, registers and usage procedure.

7.4.3 Accelerator Engine – Input Formatter

This section describes the input formatter block present in the accelerator engine (see Figure 7-89).

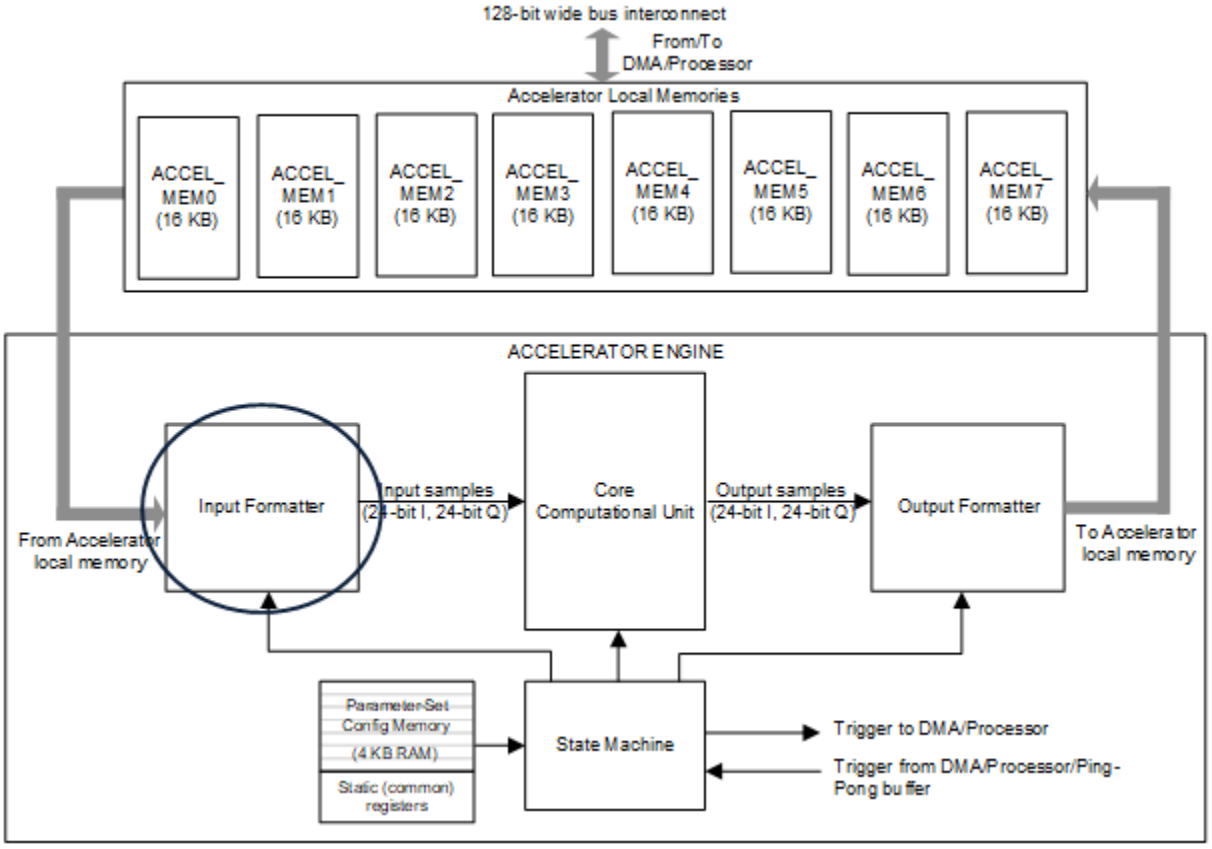

Figure 7-89. Input Formatter

7.4.3.1 Input Formatter

The input formatter is used to access, format, and feed the data from the local memories of the accelerator as 24-bit I and 24-bit Q samples into the core computational unit. The input formatter provides various capabilities to access and format the samples from the local memories – especially, various multidimensional access patterns (for example transpose access), 16-bit or 32-bit aligned word access, scaling using bit-shifts to generate 24-bit wide samples from 16-bit or 32-bit words, real versus complex input, sign extension, conjugation, and more.

7.4.3.1.1 Input Formatter – Operation

The input formatter block is responsible for reading the input samples from the accelerator local memory and feeding them into the core computational unit (see Figure 7-89). The data flow from the input formatter, through the core computational unit, to the output formatter is designed to sustain a steady-state throughput of one complex sample per clock cycle. The input formatter thus feeds one sample (24-bit I and 24-bit Q) into the core computational unit every clock cycle.

To make the best use of the capabilities of the core computational unit and to allow meaningful chaining of radar signal processing operations with minimal intervention from the processor, the input formatter supports flexibility in how the input samples are accessed from the memory and how they are formatted and fed into the core computational unit.

The memory from which the input formatter picks up the data is referred to as *source memory*. Note that any of the eight accelerator local memories can be the source memory. However, as will be described in a subsequent

section, there is an important restriction which explains that the source memory cannot be the same as the destination memory (which is the memory to which the output formatter writes the output data).

7.4.3.1.2 Input Formatter – 2D Indexed Addressing for Source Memory Access

The parameter-set register SRCADDR specifies the start address at which the input samples must be accessed. This register is a byte-address, and a value of 0x00000 corresponds to the first memory location of ACCEL_MEM0 memory. The SRCADDR register maps to the entire 128 KB address space of the eight accelerator local memories (8x16KB). Note that even though SRCADDR register is a 20-bit register, only the 17 LSB bits are used. The 3 MSB bits are reserved for future extension purpose.

The input data can be read from the memory as either 16-bit wide samples or 32-bit wide samples. Also, they can be read as real samples or complex samples. These two aspects are configured using register bits SRC16b32b and SRCREAL. See Section 7.4.3.1.5 for a description of these and other registers pertaining to the input formatter block. As an example, if SRC16b32b = 0 and SRCREAL = 0, then the input samples are read from the memory as 16-bit complex samples (16-bit I and 16-bit Q), shown in Figure 7-90.

An important feature of the input formatter block is that it supports flexible access pattern to fetch data from the source memory, which makes it convenient when the data corresponding to multiple RX channels are interleaved or when performing multi-dimensional (FFT) processing. This feature is facilitated through the SRCAINDX, SRCACNT, SRCBINDX, and BCNT registers, which are part of each parameter-set configuration.

The register SRCAINDX specifies how many bytes separate successive samples to be fetched from the source memory and the register SRCACNT specifies how many samples need to be fetched per iteration. An iteration is typically one computational routine, such as one FFT operation. It is possible to perform multiple iterations back-to-back – for example, four FFT operations corresponding to four RX channels. The register SRCBINDX specifies how many bytes separate the start of input samples for successive iterations and BCNT specifies how many iterations to perform back-to-back. These registers can be better understood using the example given in Figure 7-90.

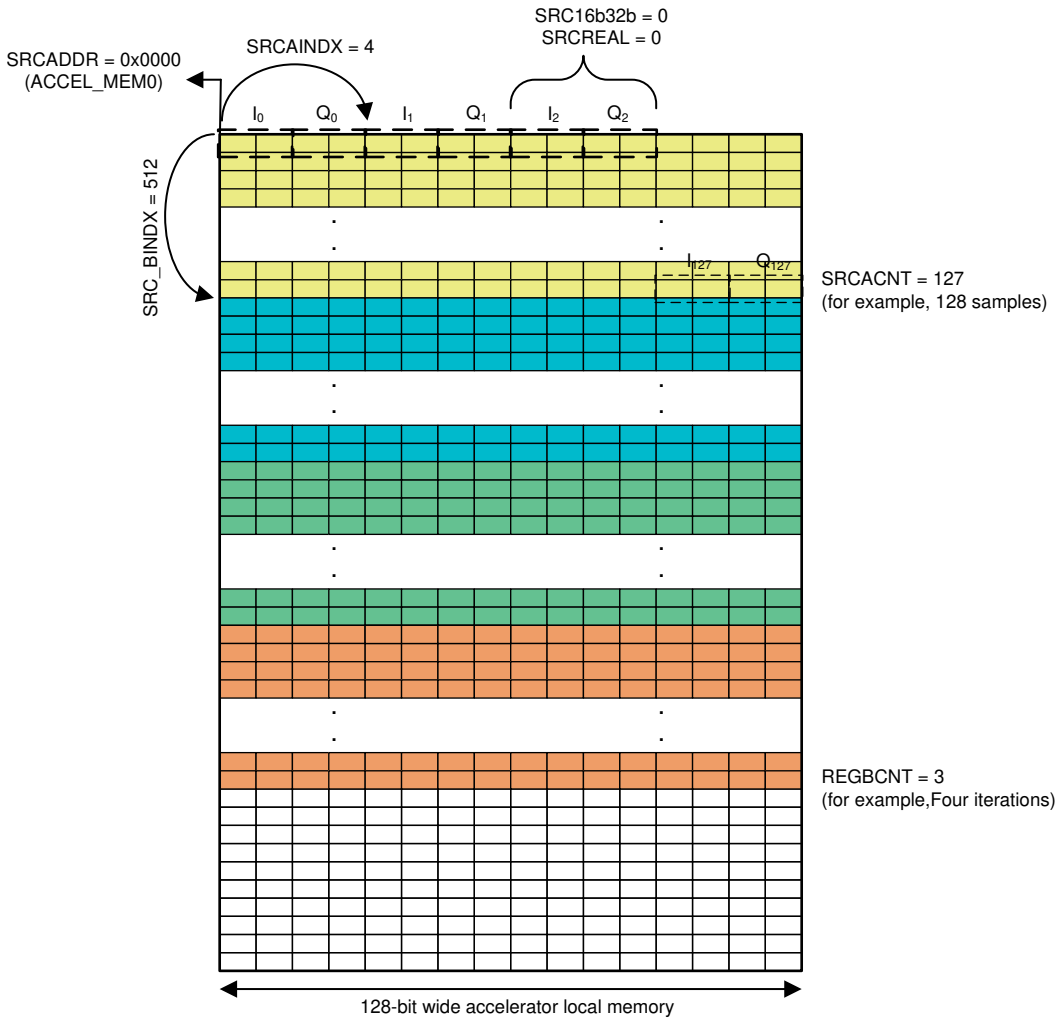

Figure 7-90. Input Formatter Source Memory Access Pattern (Example)

In Figure 7-90, the input data consists of complex data (16-bit I and 16-bit Q) that is contiguously present in ACCEL_MEM0. The data in memory consists of four sets of 128 samples each (say, corresponding to four RX antennas) and these are shown in four different colors. Because each sample occupies 4 bytes and the samples are contiguously placed in the memory starting at the beginning of ACCEL_MEM0, values of SRCADDR = 0x0000 and SRCAINDX = 4 are used to fetch these samples.

In each clock cycle, the input formatter fetches one complex sample from the memory and feeds it into the core computational unit (with appropriate scaling, as described later). Because there are 128 samples to be fed for the first iteration (computational routine), a value of SRCACNT = 127 is used. For the second iteration, the samples are fetched starting from a memory location that is SRCBINDX (=128 × 4 = 512) bytes away from SRCADDR.

This process repeats for the programmed number of iterations as per the BCNT register. For example, the value of BCNT = 3 used in this example corresponds to four iterations. Note that the registers shown here are part of parameter-set configuration registers and the four iterations described here can be performed using a single parameter set. Thus, A-dimension is used to run through samples of a given vector, and B-dimension is used to repeat (iterate) the same operation for multiple vectors.

In addition to A and B dimensions, the Input Formatter also includes a provision for C-dimension. The C-dimension is only available in a certain restricted mode of operation called the Local Maxima Engine and its usage is explained in the section 28.10 of the TRM.

An important restriction in programming the registers related to source memory access pattern is that the input formatter can only read data from one memory row (128-bit memory location) in a clock cycle. Therefore, if a sample is placed in memory such that the real-part (I value) is at the end of one memory location and the imaginary part (Q value) is at the beginning of the next memory location, then that would be an invalid configuration (see Figure 7-91). Further, although the accelerator supports byte-addresses, only even values are allowed for SRCADDR, SRCAINDX, SRCBINDX and SRCCINDX.

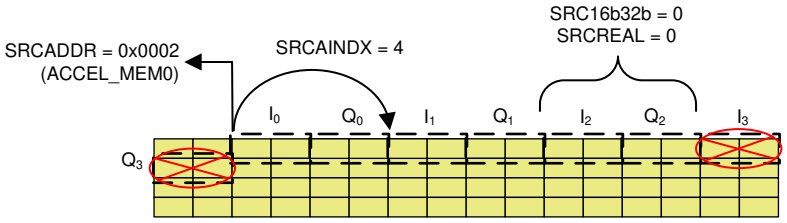

Figure 7-91. Invalid Configuration Example

7.4.3.1.3 Input Formatter – Circular and Shuffled Addressing

The input formatter additionally supports circular addressing in each of the A, B and C dimensions. For the A dimension, the register, SRCA_CIRCSHIFT controls the initial offset, while the registers, SRCA_CIRCSHIFTWRAP and SRC_CIRCSHIFTWRAP3X (bit 0) indicate the circular modulus at which the wrap-around happens.

For example, if SRCA_CIRCSHIFT is programmed as 7, then the input formatter skips sample indices 0 to 6 and reads samples from the source memory starting directly from index 7 (i.e., the 8th sample). Then, for wrap-around, if SRCA_CIRCSHIFTWRAP is programmed with a non-zero value and the LSB bit (bit 0) of SRC_CIRCSHIFTWRAP3X is 0, then the sample index wraps around (i.e., resets to 0) at 2^SRCA_CIRCSHIFTWRAP. Continuing the previous example, if SRCA_CIRCSHIFT = 7, SRCA_CIRCSHIFTWRAP = 9, and the LSB bit of SRC_CIRCSHIFTWRAP3X = 0, then the sample indices will be in the following order: 7, 8, 9, 10, 11, …, 510, 511, 0, 1, 2, 3, 4, 5, 6. On the other hand, in the same example, if the LSB bit (bit 0) of SRC_CIRCSHIFTWRAP3X is set equal to 1, then the sample index wraps around at 3*2^SRCA_CIRCSHIFTWRAP, and then the sample indices will be in the following order: 7, 8, 9, 10, 11, …, 1534, 1535, 0, 1, 2, 3, 4, 5, 6. Circular shifting is generally useful in CFAR and Local Maxima engines. Its usage is explained in more detail in the CFAR engine section in the scetion 28.10 of the TRM.

Circular shifting is also supported in B-dimension with registers SRCB_CIRCSHIFT, SRC_CIRCSHIFTWRAP and SRC_CIRCSHIFTWRAP3X (bit 1).

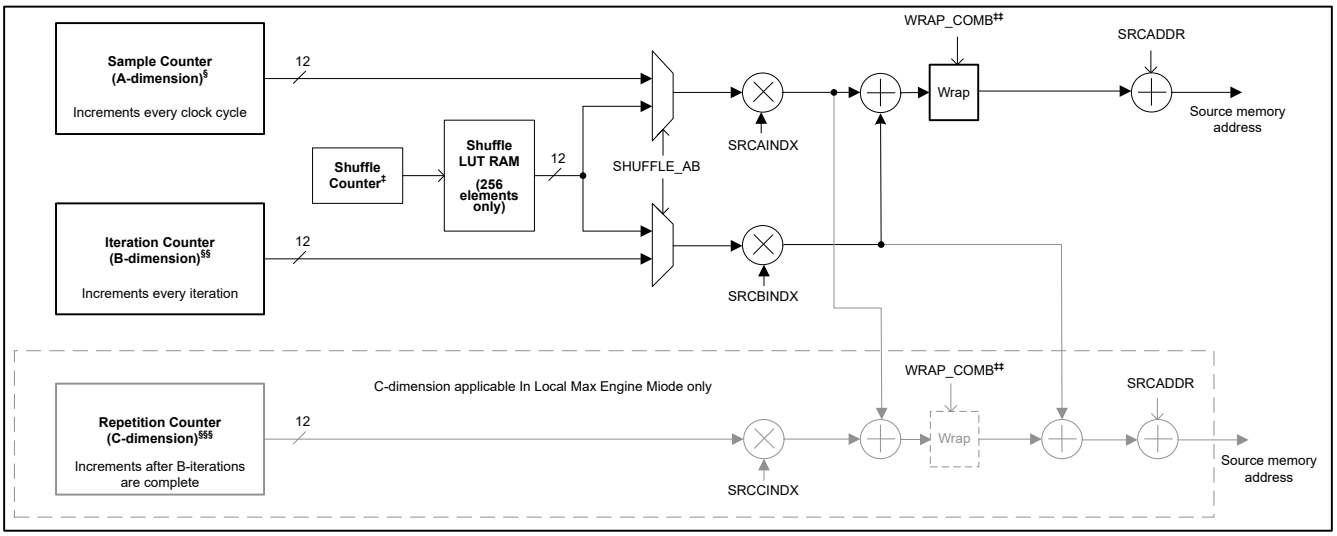
In addition to linear and circular addressing, the input formatter allows a shuffled access, in either the A-dimension or the B-dimension (selectable through the register SHUFFLE_AB). When engaged in A-dimension, the A-dimension's sample index is remapped (or shuffled) through a programmable look up table, Shuffle LUT. The Shuffle LUT is a 256 element vector (RAM) storing 12-bit numbers and this LUT can be programmed by the user with the shuffled index pattern that is desired. This feature is useful in rearranging angle dimension input samples for FFT. Note that the Shuffle LUT can hold only 256 elements atmost, and therefore the shuffled access is only supported for a maximum count of 256 (eg. SRCACNT of 255). Since Angle dimension FFT is usually small in size, this limitation is acceptable.

The start index within the Shuffle LUT (RAM) is also configurable in the parameter-set using the 4-bit register SHUFFLE_INDX_START_OFFSET. This 4-bit register value along with 4 LSBs padded as zeros becomes the 8-bit start index for the 256-element look-up table RAM. This feature allows multiple small shuffle patterns to be pre-stored in the Shuffle LUT, so that any of those patterns can be selected by appropriately setting this start index register in the parameter-set. For example, if SHUFFLE_INDX_START_OFFSET = 0010b, then the shuffled indices are picked up starting from index 32 (i.e., 00100000b) of the Shuffle LUT, and these shuffled indices in turn are used to pick up appropriate input samples from the source memory.

While A- and B-dimension have independent circular wrap around capabilities through the registers explained above, some use cases may need a combined (A, B) wrap around capability. A limited wrap around capability

in the combined (A, B) dimension is provided through the register WRAP_COMB (see Figure 7-92). If shuffling is enabled, it is possible that after combining (A, B) dimension, the combined value attempts to access an address outside the valid range. The register WRAP_COMB can be programmed to overcome this, and the input formatter wraps back any access outside the range [0, WRAP_COMB) to fall within this range.

Figure 7-92 shows how the sample count value (A-dimension sample index) and the iteration count value (B-dimension count) are used to calculate the address of the input sample to be fetched from the source memory. The exact addressing calculation is indicated in the schematic of the below figure. The bottom section of the figure showing C-dimension is only applicable in the case of a Local Max Engine mode of operation, which will be introduced later.



§ Starts at SRCA_CIRCSHIFT. If SRCA_CIRCSHIFTWRAP is non-zero, then wraps around at $2^{SRCA\_CIRCSHIFTWRAP}$, or at $3*2^{SRCA\_CIRCSHIFTWRAP}$

§§ Starts at SRCB_CIRCSHIFT. If SRCB_CIRCSHIFTWRAP is non-zero, then wraps around at $2^{SRCB\_CIRCSHIFTWRAP}$, or at $3*2^{SRCA\_CIRCSHIFTWRAP}$

§§§ Starts at SRCC_CIRCSHIFT. If SRCC_CIRCSHIFTWRAP is non-zero, then wraps around at $2^{SRCC\_CIRCSHIFTWRAP}$, or at $3*2^{SRCA\_CIRCSHIFTWRAP}$. Only applicable for Local Maxima Engine.

‡ Starts at SHUFFLE_INDX_START_OFFSET * 16. Increments every clock cycle if engaged in A-dim, or every iteration if engaged in B-dim.

‡‡ Wrap around based on WRAP_COMB register applies after combining A and B dimension address offsets. In local maxima engine mode, the WRAP_COMB register applies after combining A and C dimension address offsets.

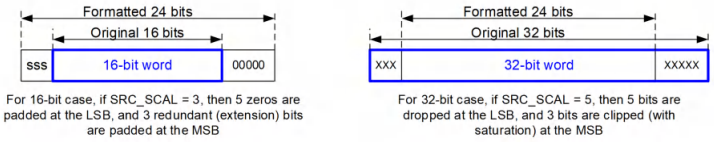
Figure 7-92. Input Formatter's Source Memory Address Generation

7.4.3.1.4 Input Formatter – Scaling and Formatting

The input formatter allows the input samples read from the source memory to be scaled and formatted before feeding them as 24-bit complex samples into the core computational unit.

Even though the data read from the source memory is initially 16-bits or 32-bits wide (for each I and Q), the samples expected by the core computational unit are 24-bit complex samples (24-bits each for I and Q). There is a SRCSCAL register which provides scaling options using bit-shift to generate 24-bit samples from the original 16- or 32-bit data (see Figure 7-93).

For the 16-bit case, the 24-bit sample is generated by padding (8-SRCSCAL) zeros at the LSB and SRCSCAL redundant MSBs. For the 32-bit case, the 24-bit sample is generated by dropping SRCSCAL bits at the LSB and clipping (8-SRCSCAL) bits at the MSB. Note that the register bit SRCSIGNED is used to indicate whether the input samples are signed or unsigned. When this register bit is set, the input samples are treated as signed numbers and hence any extra MSB bits are sign- extended and any clipping of MSB bits takes care of signed saturation. In most cases of interest in this TRM (for example, when performing FFT operation), the input samples would be signed and hence SRCSIGNED should be set (i.e., equal to 1).



A. 16- or 32-bit words to 24-bit samples

Figure 7-93. Input Formatter Data Scaling

When the input samples are complex (for example, SRCREAL = 0), there is a provision to conjugate the input samples. Setting the register bit SRCCONJ conjugates the input samples before feeding them to the core computational unit. This feature (together with a corresponding DSTCONJ register bit in the output formatter block) enables an IFFT mode from the FFT engine. Note that conjugating the input and output of an FFT block is equivalent to an IFFT function.

There is also provision for swapping I and Q samples read from memory. This can be controlled using SRCIQSWAP register bit. If SRCIQSWAP = 0, then the I sample is located at the LSB bits, and the Q sample is located at the MSB bits.

There are other registers in the input formatter, such as BPM_EN, BPMPATTERNLSB and BPMPATTERNMSB, BPMRATE, and so on, which are beyond the scope of part one of this user's guide and these registers are described section 28.7.10 of the TRM. For the immediate purpose, of the first part of the TRM, it is important to note that BPM_EN and unused dimension (C) registers must be kept 0.

7.4.3.1.5 Input Formatter – Register Descriptions

Table 7-84 lists all the registers of the input formatter block.

Table 7-84. Input Formatter Registers

Register	Width	Parameter Set	Description
SRCADDR	20	Yes	Source start address: This register specifies the starting address of the input samples, for example, it specifies the source memory start address from which input samples have to be fetched by the input formatter. This is a byte-address but only even values are valid. This register covers the entire address space of the eight local memories (8 × 16KB = 128 KB). Only the 17 LSB bits of this register are relevant for this device, and the 3 MSB bits are reserved for future use. The eight accelerator local memories are contiguous in the memory address space and any of them can act as the source memory (as long as the same memory bank is not configured to be used as destination memory at the same time).
SRCACNT	12	Yes	Source sample count: This register specifies the number of samples (minus 1) from the source memory to process for every iteration. The sample count is in number of samples, not number of bytes. For example, the sample count can be specified as 255 (SRCACNT = 0x0FF) in a case where a 256-point FFT is required to be performed. Note however that the sample count register does not always match the FFT size. This can happen when zero-padding of input samples is required. For example, a sample count of 192 could be used with an FFT size of 256, in which case, the input formatter will automatically append 64 zeros.
SRCAINDX	20	Yes	Source sample index increment: This register specifies the number of bytes separating successive samples in the source memory. For example, a value of SRCAINDX = 16 means that successive samples are separated by 16 bytes in memory. Only even values are allowed for this register. The maximum value allowed for this register is 65534.

Table 7-84. Input Formatter Registers (continued)

BCNT	12	Yes	Number of iterations: This register specifies the number of times (minus 1) the processing should be repeated. This register can be used to process the four RX chains back-to-back – for example, a value of BCNT = 3 means that the processing (say first dimension FFT processing) is repeated four times. Note the distinction between the NUMLOOPS register of the state machine block and the BCNT register of the input formatter block. The NUMLOOPS register specifies how many times the state machine loops through all the configured parameter sets (with each time possibly awaiting a trigger), whereas the register BCNT specifies how many times the input formatter and the computational processing of the accelerator is iterated back-to-back for the current parameter set (without any intermediate triggers). Non-zero BCNT should be used only with non-zero ACNT.
SRCBINDX	20	Yes	Source offset per iteration: This register specifies the number of bytes separating the starting address of input samples for successive iterations. For example, when using four iterations to process the four RX chains, this register can be used to specify the offset in the starting address between the successive RX chains. Note the distinction that SRCAINDX specifies the number of bytes separating successive samples for a particular iteration, whereas SRCBINDX specifies the number of bytes separating the starting address of the first sample for successive iterations. Only even values are allowed for this register. The maximum value allowed for this register is 65534.
CCNT	12	Yes	C-dimension count – i.e., Number of times (minus 1) that the B dimension iterations are performed. This register specifies the C-dimension count. C-dimension is applicable only to Local Maxima Engine. Non-zero CCNT should be used only with non-zero BCNT.
SRCCINDX	20	Yes	Source offset in C-dimension: This register specifies the number of bytes separating the starting address of input samples for successive sets of B-dimension iterations. Only even values are allowed for this register. Refer to the description section for details on the address generation logic.
SRCREAL	1	Yes	Complex or Real Input: This register-bit specifies whether the input samples are real or complex. A value of SRCREAL = 0 implies complex input and a value of SRCREAL = 1 implies real input. When real input is selected, the input formatter block automatically feeds zero for the imaginary part into the core computational unit.
SRCA_CIRCSHIFT	12	Yes	Start index for circular shift in A-dimension. Input Formatter reads samples from the source memory with this start offset to the sample index.
SRCB_CIRCSHIFT	12	Yes	Start index for circular shift in B-dimension (similar to A-dimension circular shift).
SRCA_CIRCSHIFTWRAP	4	Yes	Circular shift wrap-around point for A-dimension: This register, when set to a non-zero value, specifies the wrap-around point for A-dimension sample counter. If SRC_CIRCSHIFTWRAP3X (A-dimension bit) is set to 0, the A-dimension sample index counter wraps around (i.e., resets to 0) when the counter exceeds (2^SRCA_CIRCSHIFTWRAP-1). When that bit is 1, the A-dimension sample index counter wraps around when the counter exceeds (3*2^SRCA_CIRCSHIFTWRAP-1).

Table 7-84. Input Formatter Registers (continued)

SRCB_CIRCSHIFTWRAP	4	Yes	Circular shift wrap-around point for B-dimension: This register, when set to a non-zero value, specifies the wrap-around point for B-dimension iteration counter. Functionality is similar to SRCA_CIRCSHIFTWRAP.
SRC_CIRCSHIFTWRAP3X	2	Yes	3X enable for circular shift wrap-around: This register is used in conjunction with SRCA_CIRCSHIFTWRAP and SRCB_CIRCSHIFTWRAP to specify the wrap-around point when circular shift is used. Bit 0 of this register corresponds to A-dimension, and bit 1 corresponds to B-dimension. Refer description of SRCA_CIRCSHIFTWRAP for details.
SHUFFLE_AB	2	Yes	Shuffled addressing: If this register is set to 0b01, the Shuffle LUT is used for sample index re-ordering in A-dimension. If it is set to 0b10, it is used in B-dimension. If this register is set to 0b00, the Shuffle LUT is bypassed / ignored.
SHUFFLE LUT RAM[256] DSS_HWA_SHUFFLE_RAM	12	No	This RAM stores the Shuffle LUT contents
SHUFFLE_INDX_START_OFFSET	4	Yes	Start index for the Shuffle LUT: This register together with 4 zeros padded at the LSB becomes the 8-bit starting index for the 256-element Shuffle LUT (RAM).
WRAP_COMB	20	*Yes*	Combined wrap around for A and B dimension: This is applicable in Shuffled addressing mode. The combined A & B dimension based address offset is wrapped around this number.
SRC16b32b	1	Yes	16-bit or 32-bit input word alignment: This register-bit specifies whether the input samples fetched from source memory are to be read as 16-bits or 32-bits wide. A value of SRC16b32b = 0 implies that the input samples are 16-bits wide each (in case of complex input, real and imaginary parts are each 16 bits wide). A value of SRC16b32b = 1 implies that the input samples are 32-bits wide each.
SRCSIGNED	1	Yes	Input sign-extension mode: This register-bit, when set, specifies that the input samples are signed numbers and hence, sign-extension or signed-saturation at the MSB is required when converting 16- bit or 32-bit input words to the 24-bit wide samples to be fed into the core computational unit.
SRCCONJ	1	Yes	Input conjugation: This register-bit specifies whether the input samples should be conjugated before feeding them into the core computational unit. If SRCCONJ is set, then the input samples are conjugated. Setting this register-bit only makes sense if the samples are complex numbers (for example, SRCREAL = 0). This register, together with its counterpart in the output formatter block, enable an IFFT mode for the FFT engine. Note that conjugating the input and output of an FFT block is equivalent to an IFFT function.
SRCSCAL	4	Yes	Input scaling: This register specifies a programmable scaling using bit-shift, when converting the 16-bit or 32-bit wide input data to 24-bit wide samples before feeding into the core computational unit. See Figure 8 and its description for more details regarding this register.
SRCIQSWAP	1	Yes	Swap the I & Q samples drawn from memory. LSB bits drawn from memory is used as I, and the MSB bits are used a Q of input
IP_OP_FORMATTER_CLIP_STATUS. ip_formatter_clip_status	1	No	Read-only register that indicates clip status for input formatter (during scaling).

Table 7-84. Input Formatter Registers (continued)

CLR_CLIP_MISC.clr_clip_status	1	No	Below clip status read-registers will be cleared upon writing to this self-clearing register bit: channel_comb_clip_status, dc_acc_clip_status, dc_est_clip_status, intf_stats_mag_accumulator_clip_status, intf_stats_magdiff_accumulator_clip_status, intf_stats_thresh_mag_clip_status, intf_stats_thresh_magdiff_clip_status, twid_incr_delta_frac_clip_status, ip_formatter_clip_status, op_formatter_clip_status
BPM_PATTERN_0, BPMPATTERN_1, … BPMPATTERN_7	–	–	Described in part two of this user's guide. For the immediate purposes relevant to part one of this user's guide, all of these registers must be kept as 0.
BPMRATE	–	–	Described in section 28.7.7 of the TRM.
BPMPHASE	–	–	Described in section 28.7.7 of the TRM.

7.4.4 Accelerator Engine – Output Formatter

This section describes the output formatter block present in the accelerator engine (see Figure 7-94).

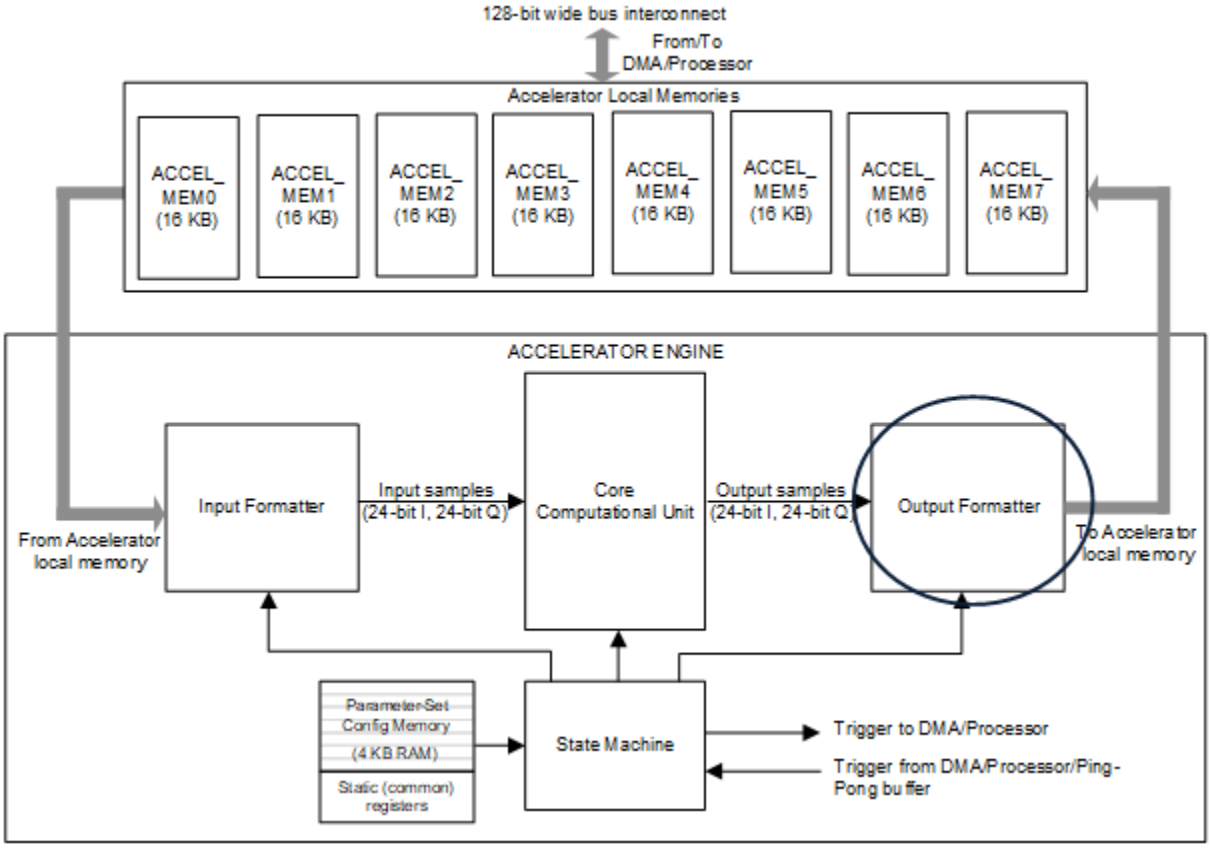


Figure 7-94. Output Formatter

7.4.4.1 Output Formatter

The output formatter is used to format and write the data coming out of the core computational unit into the accelerator local memory. Similar to the input formatter block discussed in the previous section, the output formatter block also provides various capabilities to format and write the samples written to the local memory – especially, various multidimensional access patterns (for example, transpose writes), 16-bit or 32-bit aligned word writes, scaling using bit-shifts to generate 16-bit or 32-bit words from 24-bit wide samples, real versus complex output write, and more.

7.4.4.1.1 Output Formatter – Operation

The output formatter block is responsible for storing the samples coming out of the core computation unit into the accelerator local memory (see Figure 7-94). As mentioned in the previous section, the data flow from the input formatter, through the core computational unit, to the output formatter, is designed to sustain a steady-state throughput of one complex sample per clock cycle. Thus, typically, the output formatter accepts one sample (24-bit I and 24-bit Q) from the core computational unit every clock cycle and writes it to the accelerator local memory. Just like the input formatter, the output formatter also supports lot of flexibility in how the samples are formatted and written into the memory.

The memory into which the output formatter writes the data is referred to as *destination memory*. Note that any of the four accelerator local memories can be the destination memory, with the important restriction that the source memory cannot be same as the destination memory. In other words, each of the eight 16KB memory banks can either function as source memory, or as destination memory at any time (for example, in any given parameter set).

7.4.4.1.2 Output Formatter – 2-D Indexed Addressing for Destination Memory Access

The parameter-set register DSTADDR specifies the start address at which the output samples must be written into the accelerator local memory. Similar to the SRCADDR register of the input formatter, the DSTADDR register of the output formatter is a byte-address and a value of 0x0 corresponds to the first memory location of ACCEL_MEM0 memory. The DSTADDR register maps to the entire 128KB address space of the eight accelerator local memories (each 16KB). As mentioned in the previous paragraph, in a given parameter set, SRCADDR and DSTADDR cannot be configured such that the input samples being fetched and the output samples being written out are accessing the same memory bank.

Even though the core computational unit produces a 24-bit complex output stream, this output data can be written to the memory as either 16-bit wide samples or 32-bit wide samples. Also, they can be written out as complex samples or real samples (for example, drop imaginary part – applicable when performing log-magnitude computation). These two aspects are configured using register bits DST16b32b and DSTREAL. See Section 7.4.4.1.4 for a description of these and other registers pertaining to the output formatter block. As an example, if DST16b32b = 0 and DSTREAL = 0, then the output samples are written to the memory as 16-bit complex samples (16-bit I and 16-bit Q), shown in Figure 7-95.

Similar to the input formatter block, the output formatter block also supports flexible patterns to write multidimensional data to the destination memory and this makes it convenient when the data corresponding to multiple RX channels must be interleaved, or when performing multidimensional (FFT) processing. This feature is facilitated through the DSTAINDX, DSTACNT, DSTBINDX, and BCNT registers, which are part of each parameter-set configuration.

The register DSTAINDX specifies how many bytes separate successive samples to be written to the destination memory and the register DSTACNT specifies how many samples must be written per iteration. Note that DSTACNT can be different from SRCACNT – this is useful when only a subset of the output samples need to be stored in the output memory (for example, if some FFT output bins must be discarded). The register DSTBINDX specifies how many bytes separate the start of output samples for successive iterations and BCNT specifies the number of iterations. The BCNT register is common for input formatter and output formatter. These registers can be better understood using the example given in Figure 7-95.

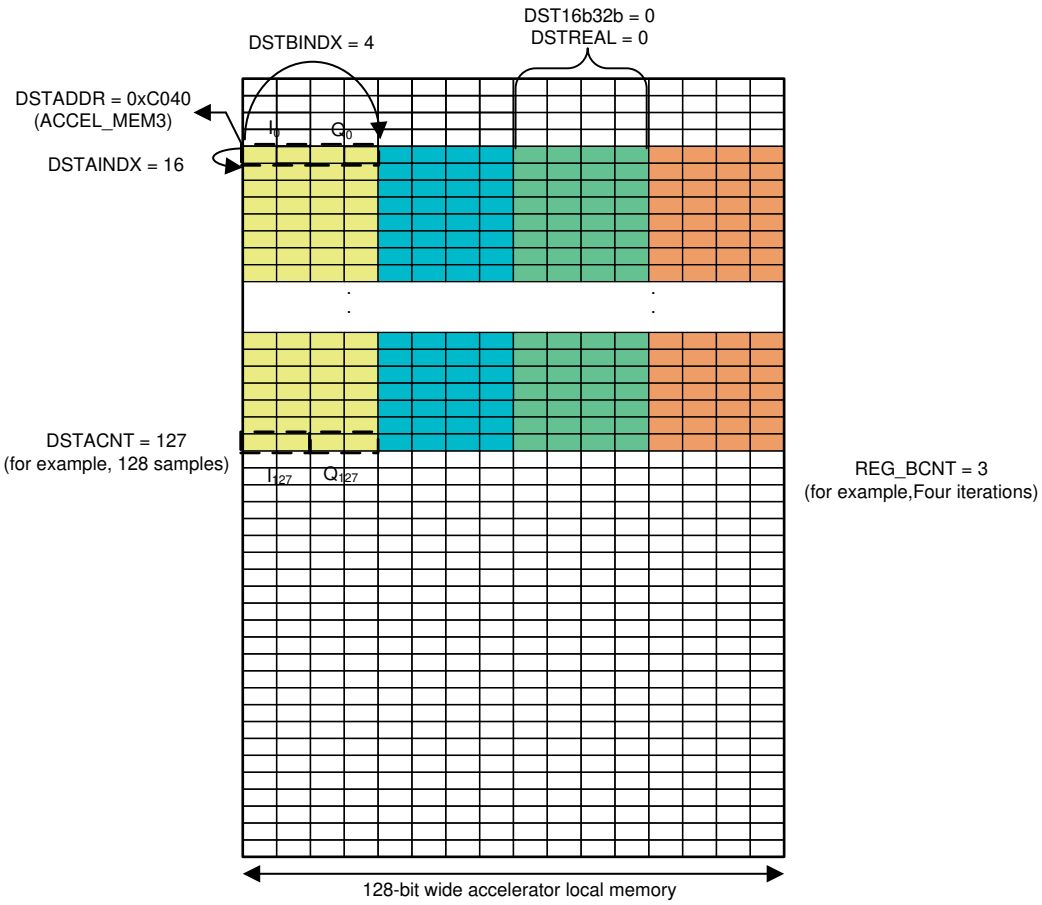

Figure 7-95. Output Formatter Destination Memory Access Pattern (Example)

In the example shown in Figure 7-95, the output data consists of complex data (16-bit I and 16-bit Q) that is written to ACCEL_MEM3. The output data consists of four sets of 128 samples each (say, corresponding to FFT output of four RX antennas) and these are shown in four different colors. Each sample occupies 4 bytes and the samples are written to the output memory at a specific start address inside ACCEL_MEM3, as shown in Figure 7-95. The samples for the four RX antennas are written to the memory in an interleaved manner. Thus, for this example, a value of DSTADDR = 0xC040, DSTAINDX = 16, DSTACNT = 127, and DSTBINDX = 4 are used. The register BCNT (common for input formatter and output formatter) is configured with a value of 3, corresponding to the four iterations required (for the four RX antennas). In steady state, for each clock cycle, the output formatter accepts one complex sample from the core computational unit and writes it into the memory as per the 2-D indexed addressing pattern programmed.

The register DSTACNT, which corresponds to the number of samples written to the destination memory for each iteration does not need to be equal to SRCACNT. This is useful in cases where some of the output samples (for example, some FFT bins at the end) can be dropped and do not need to be written into the destination memory. Another register, DST_SKIP_INIT is also available, which can be used to skip some samples in the beginning as well. The number of samples written to the destination memory for each iteration is equal to (DSTACNT + 1) – DST_SKIP_INIT.

Note that when performing FFT operations, internally the core computational unit sends out FFT output data in bit-reversed addressing order, but this is automatically handled in the output formatter, such that when the FFT output samples are written into the destination memory, they are written out in the correct normal order. Therefore, no special procedure is required on the part of the main processor to read the FFT output samples in the right sequence.

Similar to the input formatter, the output formatter can write data into only one memory row (128-bit memory location) in a clock cycle. Therefore DSTADDR, DSTAINDX, and DSTBINDX should be programmed such that no sample needs to be partially written in one memory row and the next (e.g. if DST16b32b=1). Also, these address parameters should be restricted to even values.

7.4.4.1.3 Output Formatter – Scaling and Formatting

The output formatter allows the 24-bit output samples from the core computational unit to be scaled and formatted before writing them to the destination memory as 16-bit or 32-bit words. There is a DSTSCAL register which provides scaling options using bit-shift, to take the 24-bit samples and convert them to 16-bit or 32-bit data.

For the 16-bit case (see Figure 7-96), the 24-bit sample (24-bits for each I and Q) is converted to 16-bit word by dropping DSTSCAL bits at the LSB and by clipping with saturation (8-DSTSCAL) bits at the MSB. For the 32-bit case, the 24-bit sample is padded with DSTSCAL extra bits at the MSB and with (8-DSTSCAL) extra zeros at the LSB. Note that the register bit DSTSIGNED is used to indicate whether the output samples are signed or unsigned. When this register bit is set, the output samples are treated as signed numbers and therefore any extra MSB bits are sign-extended and any clipping of MSB bits handles signed saturation. In most cases of interest in the TRM (for example, when performing FFT operation), the output samples would be signed and therefore DSTSIGNED should be set (for example, equal to 1). However, if the log-magnitude operation in the core computational unit is enabled, then the output samples are unsigned and therefore DSTSIGNED is cleared (for example, equal to zero).

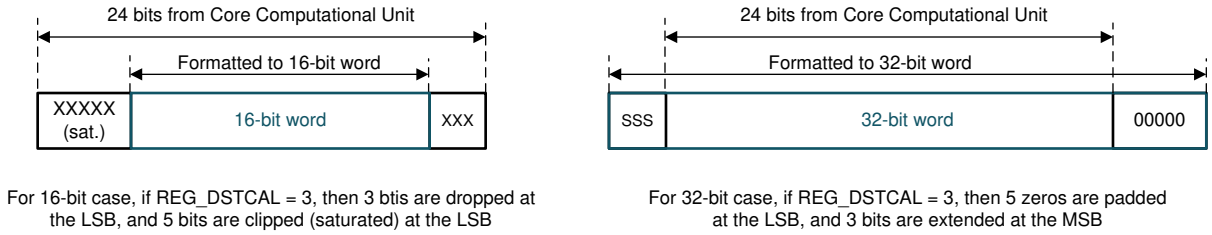

Figure 7-96. Output Formatter Data Scaling

When the output samples are complex (for example, DSTREAL = 0), there is a provision to conjugate the output samples. Setting the register bit DSTCONJ conjugates the output samples before writing them to the destination memory. This feature (together with a corresponding SRCCONJ register bit in the input formatter block) enables an IFFT mode from the FFT engine.

In addition, there is provision for swapping I and Q samples written into the destination memory. This is controlled using DSTIQSWAP register bit.

7.4.4.1.4 Output Formatter – Register Descriptions

Table 7-85 lists all the registers of the output formatter block.

Table 7-85. Output Formatter Registers

Register	Width	Parameter Set	Description

Table 7-85. Output Formatter Registers (continued)

DSTADDR	20	Yes	Destination start address: This register specifies the starting address of the output samples, for example, it specifies the destination memory start address at which the output samples have to be written by the output formatter. This is a byte-address but only even values are valid. This register covers the entire address space of the eight local memories (8 × 16KB = 128 KB). Only the 17 LSB bits of this register are relevant for this device, and the 3 MSB bits are reserved for future use. The eight accelerator local memories are contiguous in the memory address space and any of them can act as the destination memory (as long as the same memory bank is not configured to be used as source memory at the same time).
DSTACNT	12	Yes	Destination sample count: This register specifies the number of samples (minus 1) to be written to the destination memory for every iteration. The sample count is in number of samples, not number of bytes. For example, the sample count can be specified as 191 (DSTACNT = 0x0BF) in a case where 192 samples must be written. Note that the DSTACNT register can be different from SRCACNT or even the FFT size. This is useful when only a part of the FFT bins must be written to memory and the remaining (far-end FFT bins) can be discarded. This register description is true when the DST_SKIP_INIT register value is zero (see further for more information related to DST_SKIP_INIT).
DSTAINDX	20	Yes	Destination sample index increment: This register specifies the number of bytes separating successive samples to be written to the destination memory. For example, a value of DSTAINDX = 16 means that successive samples written to the destination memory should be separated by 16 bytes. Only even values are allowed for this register. The maximum value allowed for this register is 65534.
DSTBINDX	20	Yes	Destination offset per iteration: This register specifies the number of bytes separating the starting address of output samples for successive iterations. For example, when using four iterations to process four RX chains, this register can be used to specify the offset in the starting address between the successive RX chains. Note the distinction that DSTAINDX specifies the number of bytes separating successive samples for a particular iteration, whereas SRCBINDX specifies the number of bytes separating the starting address of the first sample for successive iterations. Only even values are allowed for this register. The maximum value allowed for this register is 65534.
DST_SKIP_ INIT	10	Yes	Destination skip sample count: This register specifies how many output samples should be skipped in the beginning, before starting to write to the destination memory. This is useful if only a certain part of the FFT output (skipping the first several bins) need to be stored in memory. The total number of samples written to destination memory is equal to DSTACNT+1-DST_SKIP_INIT.

Table 7-85. Output Formatter Registers (continued)

DSTREAL	1	Yes	Complex or real output: This register-bit specifies whether the output samples are real or complex. A value of DSTREAL = 0 implies complex output and a value of DSTREAL = 1 implies real output. When real output is selected, the output formatter block automatically stores only the real part into the destination memory. This is useful when the core computational unit is configured to output magnitude or log-magnitude values.
DST16b32b	1	Yes	16-bit or 32-bit output word alignment: This register-bit specifies whether the output samples are to be written as 16-bits or 32- bits wide in the destination memory. A value of DST16b32b = 0 implies that the output samples are to be written as 16-bit words (in case of complex output, real and imaginary parts are each 16 bits wide). A value of DST16b32b = 1 implies that the output samples are 32-bits wide each.
DSTSIGNED	1	Yes	Output sign-extension mode: This register-bit, when set, specifies that the output samples are signed numbers and therefore, sign-extension or signed-saturation at the MSB is required when converting the 24-bit wide samples coming from the core computational unit into 16-bit or 32-bit output words to be written to the destination memory.
DSTCONJ	1	Yes	Output conjugation: This register-bit specifies whether the output samples must be conjugated before writing them into the destination memory. If DSTCONJ is set, then the output samples are conjugated. Setting this register-bit only makes sense if the samples are complex numbers (for example, DSTREAL = 0). This register, together with its counterpart in the output formatter block, enables an IFFT mode for the FFT engine.
DSTSCAL	4	Yes	Output scaling: This register specifies a programmable scaling using bit-shift, when converting the 24-bit samples coming from the core computational unit into 16-bit or 32-bit wide words to be written to the destination memory. See Figure 11and its description for more details regarding this register.
DSTIQSWAP	1	Yes	IQ Swapping : Swap the I & Q samples written out to memory.
IP_OP_FORMATTER_CLIP_STATUS. op_formatter_clip_status	1	No	Read-only register that indicates clip status for output formatter (during scaling).
MEM_INIT_START. MEM_INIT_START_PARAM_RAM	1	No	Writing 1'b1 would start the memory initialization for the Param memory. Self-clearing bit.
MEM_INIT_START.MEM_INIT_START_DMEM7, MEM_INIT_START_DMEM6, .. MEM_INIT_START_DMEM0	1	No	Writing 1'b1 would start the memory initialization for the DMEM7, DMEM6.. DMEM0. Self-clearing bit
DMEM0, DMEM1… DMEM7 (MEM_ACCESS_ERR_STATUS) MEM_ACCESS_ERR_STATUS.dmem0..7	1	No	Memory access error: This set of 8 1-bit read-only registers indicates if there is a memory access error caused by incorrect configuration or usage of the accelerator, where both the DMA and the accelerator are attempting to access the same 16KB memory at the same time. The composite 8- bit register indicates the error status for the 8 16KB memories (DMEM0 bit corresponds to ACCEL_MEM0).

7.4.5 Accelerator Engine – Core Computational Unit

This section describes the core computational unit present in the accelerator engine (see Figure 7-97).

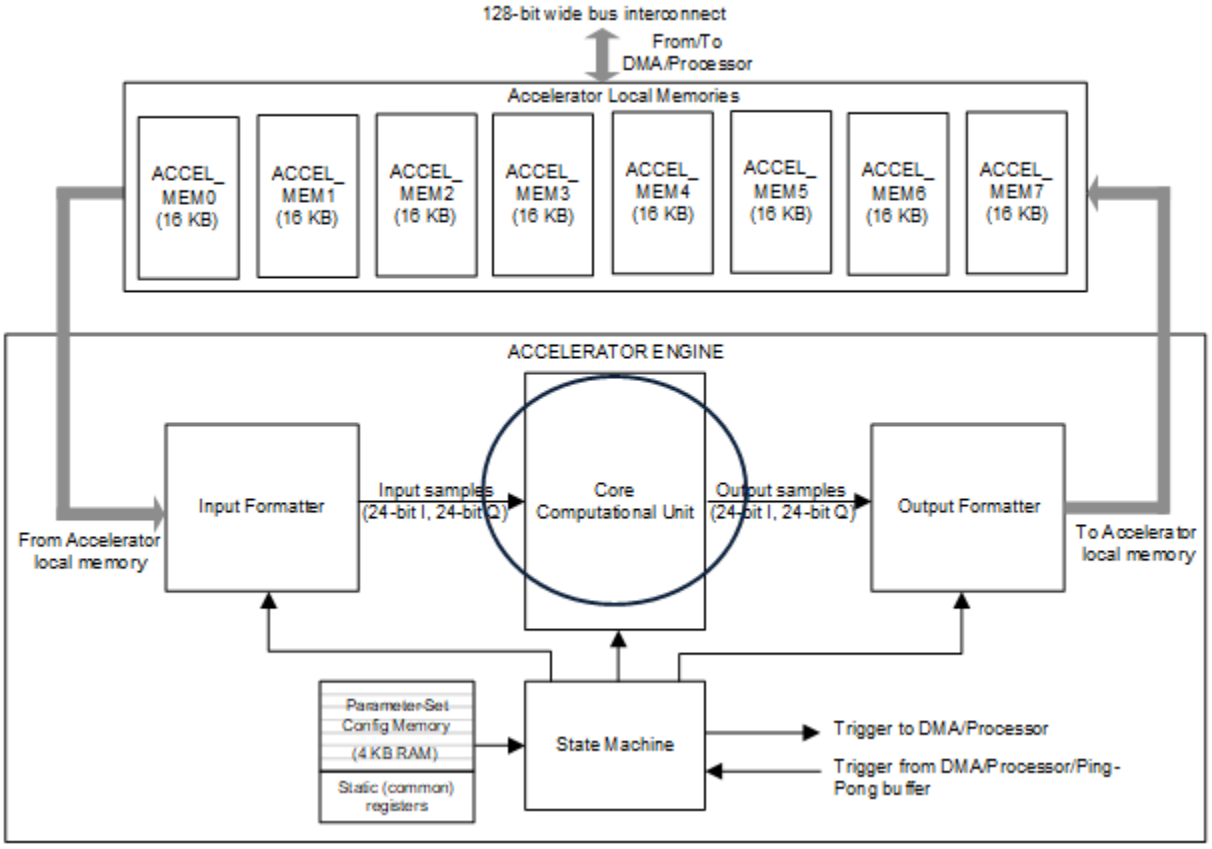

Figure 7-97. Core Computational Unit

7.4.5.1 Core Computational Unit

The core computational unit performs the mathematical operations required for the key functions, such as FFT, log-magnitude, CFAR detection, and so on. The core computational unit accepts a streaming 24-bit complex input (24 bits for each I and Q) from the input formatter block and it outputs a streaming 24-bit complex output (24 bits for each I and Q) to the output formatter block.

Figure 7-98 shows the block diagram of the core computational unit. The core computational unit has four main computation engines, namely:

- FFT Engine: Performs Pre-processing, Windowing, FFT and Log-magnitude.
- CFAR Engine: Performs CFAR detection using CFAR-CA or CFAR-OS method.
- Local Maxima Engine: Performs threshold and local maxima based peak identification.
- Compression Engine: Used for compression and decompression of radar data.

Only one of these four engines can be operational at any given instant. However, in separate parameter sets, different engines can be configured and used, so that multiple parameter sets executing one after another can accomplish a sequence of computational operations as desired. The register ACCEL_MODE controls which engine gets used in a given parameter set.

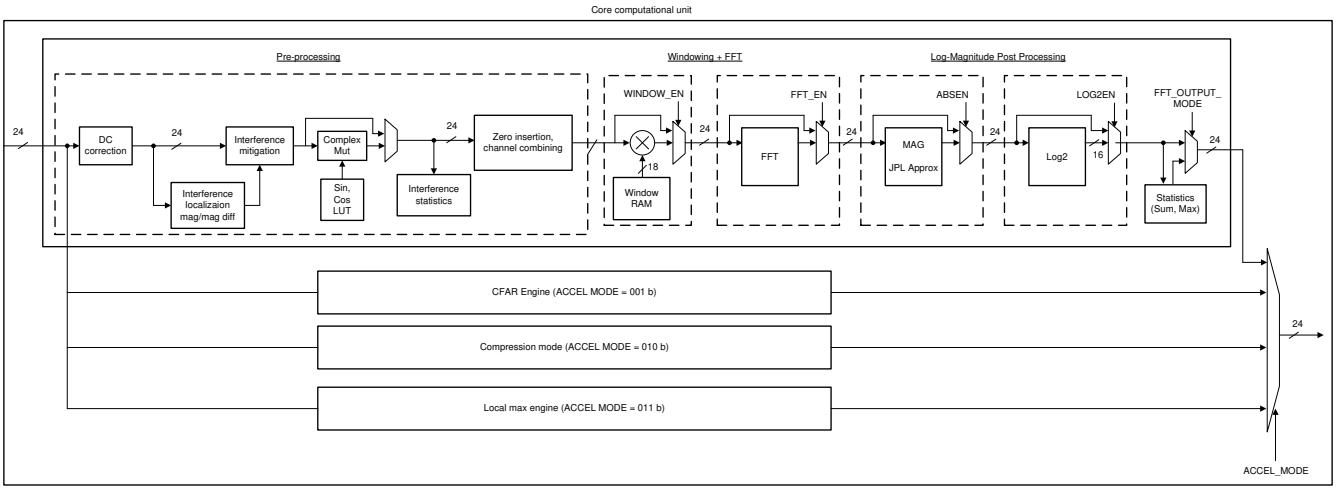

Figure 7-98. Core Computational Unit Block Diagram

7.4.5.1.1 Core Computational Unit – FFT Engine – Operation

The core computational unit operates on the streaming input of samples coming from the input formatter block, and in general outputs a stream of samples (after an initial latency in some cases) to the output formatter block. In general, at steady-state, one input sample is processed and one output sample is produced every clock.

The FFT Engine in the core computational unit has the ability to perform pre-processing, windowing, FFT, and log-magnitude computations. Each of these computational subblocks operate on a streaming input and produce a streaming output at the throughput of one sample per clock. These computational subblocks are stitched together one after the other in a series, as shown in Figure 7-98. This architecture allows multiple operations to be done in a streaming manner (for example, windowing and FFT can be done together), while at the same time, providing the user flexibility to choose one operation at a time.

The parameter-set registers WINDOW_EN, FFT_EN, ABS_EN, and LOG2_EN control the multiplexers (see Figure 7-98), which decide what operations are performed on the input samples for that parameter set.

Note that for the purpose of FFT engine operation in this section, the registers ACCEL_MODE and FFTOUT_MODE must be kept at zero. The purpose of these registers is covered in following sections of the TRM.

7.4.5.1.2 Core Computational Unit – FFT Engine – Windowing

The incoming samples from the input formatter to the core computational unit are passed through the (optional) windowing operation (see Figure 7-99). Windowing operation is often required prior to performing FFT, to mitigate the sinc roll-off leakage from one strong FFT bin to the adjacent bins.

As the incoming samples from the input formatter stream in, each sample is multiplied by the appropriate window coefficient read from a Window RAM. Because the incoming samples are complex 24-bits wide (24-bits for each I and Q), the windowing operation involves multiplying the 24-bit I and 24-bit Q of the incoming sample with the

window coefficient (see Figure 7-99). The output of this multiplication is rounded back to 24-bit I and 24-bit Q by dropping excess LSBs. Note that windowing can be enabled by setting the register bit WINDOW_EN to 1.

The window RAM can hold up to 2048 32-bit words. The window coefficients can be stored in these words in one of the following three formats:

1. 18-bit real coefficients: If WINDOW_MODE = 0b00, the window coefficients are assumed to be 18-bit signed real values. Up to 2048 real coefficients can be stored in the window RAM in this mode (one 32-bit word in the RAM stores one 18-bit coefficient).
2. 16-bit real coefficients: If WINDOW_MODE = 0b01, the window coefficients are assumed to be 16-bit signed real values. Up to 4096 real coefficients can be stored in the window RAM in this mode (one 32-bit word in the RAM stores two successive 16-bit coefficients: the 16LSBs store coefficients 0, 2, 4, etc. and 16MSBs store coefficients 1, 3, 5, etc.).
3. 16-bit complex coefficients: If WINDOW_MODE = 0b10, the window coefficients are assumed to be 16-bit I and 16-bit Q complex values. Up to 2048 complex coefficients can be stored in the window RAM in this mode (one 32-bit word in the RAM stores the real part of the coefficient in the 16 LSBs of the word and the imaginary part in the 16 MSBs of the word).

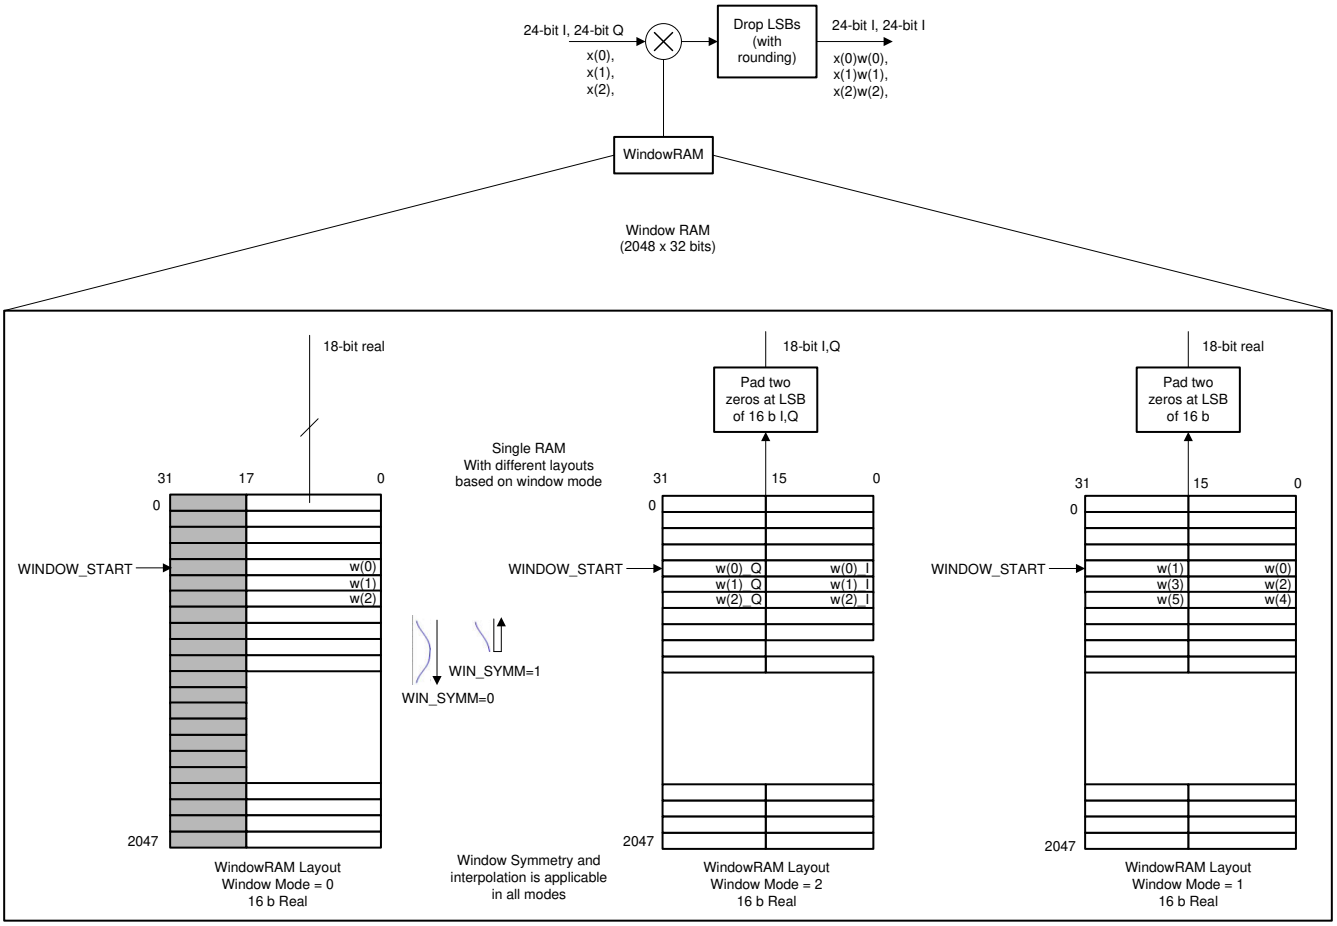

Figure 7-99. Window RAM Layout for 18b Real, 16b Complex and 16b Real Modes

The start location (32-bit word index) in the window RAM is programmed in a 11-bit register WINDOW_START as part of the parameter set, so that the windowing computation can pick the appropriate window coefficients starting from that index. For each incoming sample, the index keeps incrementing, so that each successive sample is multiplied by the successive window coefficient. At the end of each iteration (for example, when SRCACNT number of samples have been processed), the index resets back to the starting coefficient index programmed for the parameter set, so that the next iteration can be performed. At the end of all the iterations

of the current parameter set, the next parameter set can use a different window if desired. For example, when performing second- and third-dimension FFTs one after another (in two parameter sets), the window functions for both these FFTs can be pre-stored in the Window RAM and appropriate start index can be provided for each of the FFT operation dimensions.

If the window function is symmetric, the user may store only one half of the window coefficients in the Window RAM. The register bit WINSYMM, when set, indicates that after SRCACNT / 2 samples (or, if SRCACNT is odd, (SRCACNT + 1) / 2 samples) are processed, the window coefficients read-indexing must be reversed, so that the same set of coefficients used for the first SRCACNT / 2 samples are reused in the reverse order for the next SRCACNT / 2 samples. (See Figure 7-99). If SRCACNT is odd, then the last window coefficient is read only once, when the direction is reversed. If SRCACNT is even, then the last window coefficients is read twice, when the direction is reversed. In the dynamic window mode, the coefficients are read from the corresponding bank only.

The output of the windowing computation is 24-bit I and 24-bit Q, which is streamed into the FFT subblock.

7.4.5.1.3 Core Computational Unit – FFT Engine – FFT

The FFT subblock performs FFT on the incoming 24-bit I and 24-bit Q data stream. The FFT size is programmable, in the range, 2 to 2048. FFTs of length 2N for N = 0 to 11, and 3x2N for N = 0 to 9 are supported. Advanced features such as direct computation of two-dimensional FFTs, as well as an FFT *stitching* feature that realizes FFTs of larger lengths using a two-step process, are also supported. But their description is deferred to section 28.7.6 of the TRM.

The lowest FFT size of 2 is mostly useful as a *complexadd-subtract* feature or while using the *FFT*stitchingfeature. FFT sizes of 4, 8, 16, and 32 can be used for third dimension (angle estimation) FFT.

The FFT operation can be enabled or disabled by using the register bit FFT_EN. When enabled, the FFT subblock computes the FFT of the input data stream and produces a 24-bit I and 24-bit Q output stream. This output stream is initially in bit-reversed order, but the output formatter handles appropriately writing the output to the destination memory in the correct order.

The FFT implementation comprises a series of butterfly stages. Depending on the FFT size needed, an appropriate number of butterfly stages are employed.The FFT size is programmed using the registers, FFTSIZE and FFTSIZE_3X_EN.

For power-of-2 FFT sizes, the register bit FFTSIZE_3X_EN should be kept 0. The FFT size is configured using the register FFTSIZE and the actual FFT size in this case is 2^FFTSIZE. When an FFT size of the form (3 * power-of-2) is needed, then the register bit FFTSIZE_3X_EN should be set to 1. In this case, the actual FFT size is 3 * 2^FFTSIZE.

For example, if FFTSIZE_3X_EN is 0, then FFTSIZE = 5 means 32-point FFT, FFTSIZE = 7 means 128-point FFT, and so on. In this case, the FFT is realized using a series of FFTSIZE number of radix-2 butterfly stages. On the other hand, if FFTSIZE_3X_EN is set to 1, then FFTSIZE = 5 means a 96-point FFT, FFTSIZE = 7 means 384-point FFT. In these cases, an additional radix 3 butterfly stage is engaged before feeding to the original series of radix-2 butterfly stages.

Note that the FFT size must be equal to or larger than SRCACNT, and the input formatter block automatically zero-pads extra samples to account for the difference between FFT size and SRCACNT.

7.4.5.1.4 Core Computational Unit – FFT Engine – FFT – Zero Padding

The FFT engine has provision for *zeropadding*, which is important when performing FFT of a set of samples whose length doesn’t match a supported FFT size. The FFT engine automatically feeds the required number of zeros into the core computational unit, whenever the FFT size (as programmed using the FFTSIZE register, which is described in a later section) does not match the SRCACNT setting.

For example, if the number of input samples read by the input formatter is 56 (for example, SRCACNT = 55) and the FFT size is programmed to be 64 (FFTSIZE = 6, FFTSIZE_3X_EN = 0), then the FFT engine feeds 8 zeros at the end of each iteration, before starting to read the input samples for the next iteration from the

source memory. This zero-padding provision enables the core computational unit to perform 64-point FFT with the correct set of zero-padded input samples.

The zero padding is effective only when performing FFT operation in the core computational unit (i.e., when FFT_EN = 1) and not otherwise. Advanced features such as zero insertion (at programmable locations) and channel combining are described in section 28.7.9 of the TRM.

7.4.5.1.5 Core Computational Unit – FFT Quantization and Speed Performance

As is well known, a butterfly stage typically consists of add-subtract and twiddle multiplication operations. At the output of each add-subtract structure, the bit-width would increase by 1 bit (for example, 24-bit input would grow to 25-bit output). To handle this one-bit growth due to add-subtract operation, there is a provision at the output of each butterfly add-subtract stage to scale the result back to 24 bits, by either dividing the output by 2 (round off one LSB) or by saturating one MSB, shown in Figure 7-100.

The multi-bit register BFLY_SCALING is used to control this divide-by-2 scaling operation at each stage, so that the user has full flexibility to control the signal level through the different butterfly stages. If BFLY_SCALING = 0 for a particular stage, then the 25-bit output is saturated at the MSB to get back to 24 bits. Otherwise, it is convergent-rounded at the LSB to get back to 24 bits. The user can thus control the scaling at each of the butterfly stages. The LSB of this multi-bit register corresponds to the last stage and the MSB of this register corresponds to the first stage. For an FFT size of 64, only the LSB 6 bits are relevant. Similarly, for an FFT size of 3*64, the LSB 6 bits are relevant. Additionally the register, BFLY_SCALING_FFT3X indicates the scaling option for the single radix-3 stage (i.e., it supports removing 0 or 1 or 2 LSBs).

There is a multi-bit read-only register FFTCLIP which indicates whether there was any clipping in any of the butterfly stages. This register is a sticky register that gets set when a clipping event occurs and remains set until it is cleared using the CLR_FFTCLIP register bit. See the register description of FFTCLIP in Section 7.4.5.1.9.

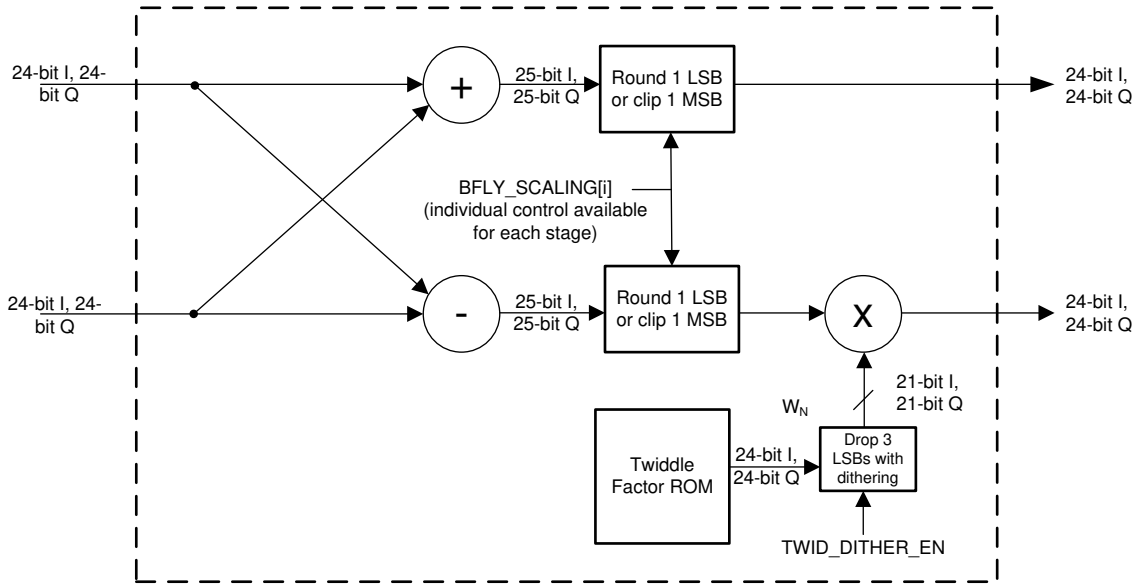

Figure 7-100. Butterfly Stage Fixed-Point

The twiddle factors are stored as 24-bit I and 24-bit Q coefficients. Prior to twiddle factor multiplication, the coefficients are reduced to 21-bit I and 21-bit Q by dropping three LSBs (with optional dithering). The purpose of dithering is to eliminate any repetitive quantization noise patterns from degrading the SFDR of the FFT. The use of dithering here is optional. For dithering, an LFSR is used to generate a random pattern, for which the LFSR seed must be loaded with a non-zero value (see LFSRSEED in the register descriptions).

The SFDR performance of the FFT, with dithering enabled, is better than –140 dBc, as shown in Figure 7-101.

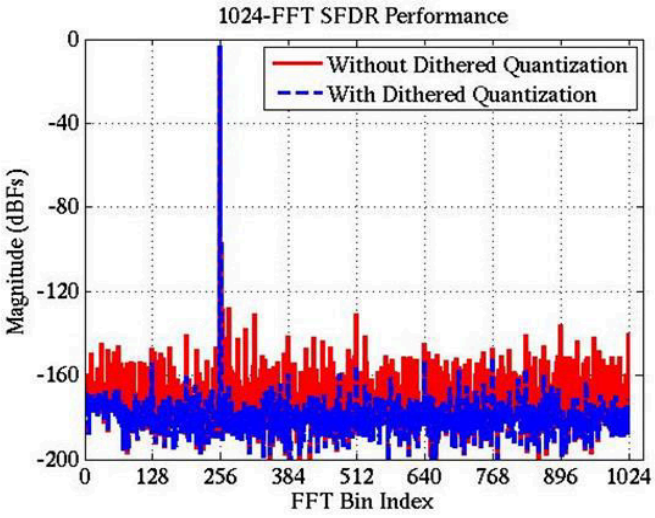

Figure 7-101. FFT SFDR Performance With and Without Dithering

The architecture of the FFT is such that it can take a streaming input (one sample per clock) and produce a streaming FFT output (one sample per clock), in steady-state. There is an initial latency of approximately *FFT size* number of clocks. This latency only comes into picture once for a given parameter set. Within a parameter set, multiple FFT iterations can be performed back-to-back (for example, for four RX) with no additional latency between iterations.

Because the implementation uses 400MHz clock in the device, a 256-point complex FFT for four RX chains would take 256 + 256 × 4 clock cycles to complete, which corresponds to 3.2 µs (plus a few clocks of implementation latencies, which are not accounted here since it is negligible). Table 7-86 lists the approximate computation time needed for various FFT sizes.

Table 7-86. FFT Computation Time

Example	FFT Size	Number of Back-to-Back Iterations	Number of Clock Cycles (Initial latency + Computation)	Total Duration
1	256	4	256 + (256 × 4)	3.2 µs
2	128	4	128 + (128 × 4)	1.6 µs
3	8	64	8 + (64 × 8)	1.3 µs

The output of the FFT can be fed to the output formatter or it can be sent to the magnitude/log-magnitude computation subblock.

Note

The FFT is a complex FFT implementation. If the input samples are real-only, then the SRCREAL register bit can be set, such that the imaginary part (Q-part) will be forced to zero by the input formatter block.

7.4.5.1.6 Advanced FFT Features – FFT Stitching

FFT Engine additionally allows the computation of 4096 & 8192-point FFTs by using FFT stitching. This is done in two-passes. In the first pass, 2 or 4 sets of 2048-point FFT are computed. In the next pass, 2048 sets of 2-point or 4-point FFTs are computed with appropriate twiddle pre-multiplications using the complex multiplier in mode 3 (described in part 2 of user guide) yielding the final 4096 or 8192-point FFT. The relevant register (CMULT_MODE, TWIDINCR, WINDOW_INTERP) settings are indicated in table below A detailed example of FFT stitching along with window interpolation is provided in HWA 2.0 Examples document.

Table 7-87. FFT Stitching Registers

FFT Size	CMULT_MODE	TWIDINCR	WINDOW_INTERP
4096	3	1	2
8192	3	2	1

7.4.5.1.7 Advanced FFT Features – 2D FFT

The traditional approach for realizing an M×N point 2-D FFT involves two passes: first pass computing M number of N-point FFTs on the input arrays, and then a second pass computing N number of M-point FFTs on the result of the first pass. HWA instead supports a direct and faster computation of M×N 2-D FFT, for small M×N sizes (M×N≤2048, N being a power of 2).

The following illustrates the necessary programming for an example with M=16 and N=4. The register FFT_SIZE should be set to , and the register FFT_SIZE_DIM2 should be set to . Further the M×N samples of input data should be placed in the memory and fed sequentially to the FFT engine in an interleaved manner as follows. If A is the 2-D 16×4 size input array for the 2-D FFT, then the data placement should ensure that the FFT engine's input order is $A_{0,0}$, $A_{0,1}$, $A_{0,2}$, $A_{0,3}$, $A_{1,0}$, $A_{1,1}$, $A_{1,2}$, $A_{1,3}$, $A_{2,0}$, $A_{2,1}$, …, $A_{15,0}$, $A_{15,1}$, $A_{15,2}$, $A_{15,3}$. The FFT engine computes the 2-D FFT results, and automatically stores them in the destination memory in the right order. The output memory contents would be linear order: $B_{0,0}$, $B_{0,1}$, $B_{0,2}$, $B_{0,3}$, $B_{1,0}$, $B_{1,1}$, $B_{1,2}$, $B_{1,3}$, $B_{2,0}$, $B_{2,1}$, …, $B_{15,0}$, $B_{15,1}$, $B_{15,2}$, $B_{15,3}$, where B represents the 2D FFT of A.

If zero padding is required in one or both dimensions, it can be achieved through the accelerator's zero insertion feature. It can be done by adding zeros at right locations in the M×N long linear array streaming into the FFT engine (subject to the 256 element limit in zero insertion feature). If 2-D windowing is required before the 2-D FFT, then the 2-D M×N window coefficients can be unrolled into one long linear array and placed in the window RAM. This is illustrated in the below figure for a 32×16 2-D FFT case. If 2-D FFT feature is enabled in any parameter set, it is recommended that the advanced 2D statistics feature be disabled in that parameter set.

This 2-D FFT feature can be used in performing small sized 2-D FFTs, repeatedly over several iterations (e.g. Azimuth × Elevation 2-D FFTs using A dimension, performed for multiple Doppler or Range bins using B dimension). The computation time for B iterations of M×N 2-D FFTs would be (B+1)×(MN) = BMN+MN. In comparison, the traditional two pass approach mentioned earlier, uses (BM+1)×N cycles for first pass (if first passes of all B iterations are performed together) and (BN+1)×M cycles for second pass, in total 2BMN+M+N.

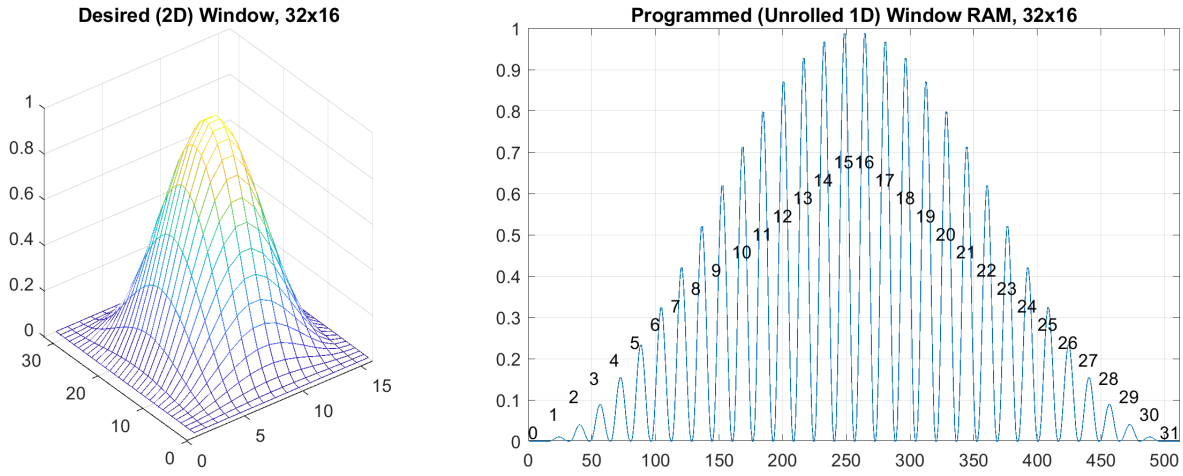

Figure 7-102. Unrolling 32x16 2D Array Window Coefficients to a 512 1D Vector for Placement in Window RAM

7.4.5.1.8 Core Computational Unit – FFT Engine – Magnitude and Log-Magnitude Post-Processing

The magnitude and log-magnitude post-processing block computes absolute value or log2 of the absolute value of its input. Because this block is connected to the output of the FFT engine, the computation of absolute value (and log2) can be directly performed on the streaming FFT output. Alternately, the FFT block can be bypassed and only the magnitude and log-magnitude block can be employed.

The processing in this block first involves computation of magnitude (absolute value) of the input samples in the magnitude subblock (using JPL approximation in HWA 2.0). The result of the magnitude computation is fed into a Log2 computation subblock, which uses a look-up table-based approximation to compute logarithm- base-2 of the magnitude.

As shown in Figure 7-98, if the register-bit ABS_EN is set, the magnitude computation subblock is enabled. In addition, if the register-bit LOG2_EN is set, then the Log2 computation subblock is also enabled. Note that setting LOG2_EN makes sense only when ABSEN is also set.

(1)

Figure 7-103.

In HWA 2.0, the magnitude computation uses JPL (Levitt and Morris) approximation. This approximation for magnitude of a complex number (I + jQ) is defined as follows, let U = max(|I|,|Q|) and V = min(|I|,|Q|). Then, the magnitude can be approximated as follows in Figure 7-104.

$$\text{Magnitude} \approx \max(U + V / 8, 7U / 8 + V / 2) \quad (2)$$

Figure 7-104.

The magnitude output is 24-bits wide (real number).

Next,the log2 computation of the magnitude value is achieved as follows. Any unsigned input number N can be written as N = 2k(1 + f) and the log2(N) can then be written as follows in Figure 7-105.

$$\log2(N) = k + \log2(1+f) \quad (3)$$

Figure 7-105.

The implementation of log2 computation uses the previous formula, where a look-up table approximation is used to generate the second term, for example, log2(1 + f). The accuracy of the log2 computation for HWA 2.0 is shown in #unique_143/unique_143_Connect_42_GUID-7ECD2969-36A1-45C6-8FA0-BF6818BB303F. The log2 output is 16-bits wide. The 16-bit logarithm output consists of 5 bits of integer part and 11 bits of fractional part.

Dependingon the settings of ABS_EN and LOG2_EN, either the magnitude or the log-magnitude is sent as the final output of the core computational unit. The final output of the core computational unit going to the output formatter is 24-bits I and 24-bits Q. Thus, if either magnitude or log-magnitude is enabled, the Q- values are just made zeros. Similarly, when log2 is enabled, because the output is 16-bits, 8 MSBs are filled as zero.

The outputformatter handles writing the samples to the destination memory as per the configured destination memory access pattern described in a previous section.

7.4.5.1.9 Core Computational Unit – FFT Engine – Register Descriptions

Table 7-88 lists all the registers of the FFT Engine within the core computational unit.

Table 7-88. FFT Engine Registers

Register	Width	Parameter Set	Description
WINDOW_EN	1	Yes	Windowing Enable: This register-bit enables or disables the pre-FFT windowing operation. If this register is set to 1, then the windowing is enabled, otherwise, it is disabled. The exact window function (coefficients) to be applied is specified in a dedicated Window RAM, which is 2048 × 32 bits in size.
FFT_EN	1	Yes	FFT Enable: This register-bit is used to enable the FFT computation. If FFT_EN = 1, then the FFT computation is enabled. Otherwise, it is disabled (bypassed).
ABS_EN	1	Yes	Magnitude Enable: This register-bit is used to enable the magnitude calculation. If this register bit is set, then the magnitude calculation is enabled, else it is bypassed. When enabled, the magnitude (absolute value) of the input complex samples are calculated using JPL approximation and the resulting magnitude value is sent on the I-arm of the output. The Q-arm is made zeros.
LOG2_EN	1	Yes	Log2 Enable: This register-bit is used to enable the Log2 computation. If this register bit is set, then the Log2 computation is enabled, else it is bypassed. Note that setting this register bit only makes sense if the inputs to the Log2 computation are unsigned real numbers, such as when the Magnitude Enable bit (ABS_EN) is also set. When enabled, the Log2 of the magnitude of the input samples is calculated and sent out on the I-arm of the output. The Q-arm is made zeros.
WINDOW_START	11	Yes	Windowing coefficients start location in Window RAM: This register specifies the starting location (32-bit word index) of the window coefficients within the Window RAM. The purpose of this register is to allow multiple windows (for example, one window of 512 coefficients and another window of 256 coefficients) to be stored in the Window RAM and one of these windows can be used by programming this start location register appropriately in the current parameter set.
WINSYMM	1	Yes	Window symmetry: This register-bit indicates whether the complete set of window coefficients are stored in the Window RAM or whether one half of the coefficients are stored. If this register bit is set, it means that the window function is symmetric and therefore, only one half of the window function coefficients are stored in the Window RAM. See the description section related to Windowing computation for more details.
WINDOW_MODE	2	Yes	Window Mode: 00b : 18-bit signed real coefficients, 01b: 16-bit signed real coefficients, 10b: 16-bit I, 16-bit Q complex coefficients
FFTSIZE	4	Yes	FFT size: This register indicates the number of FFT radix-2 butterfly stages employed. Refer detailed description section for more details on this register.
FFTSIZE3X_EN	1	Yes	FFT size 3X enable: This register indicates whether to engage the additional FFT radix-3 butterfly stage. Together with FFTSIZE, this register specifies the FFT size. This can be used to realize FFTs of length 3x2N point FFTs..
FFTSIZE_DIM2	4	Yes	2D FFT dimension specification: This register can be used to realize 2 dimensional FFTs. If this register is set to 0 (default), the FFT engine computes the usual one dimensional FFT. Otherwise, it computes a two dimensional FFT of size 2^(FFTSIZE–FFTSIZE_DIM2) x 2^FFTSIZE_DIM2.
BFLY_SCALING	12	Yes	Butterfly scaling for radix-2 stages: This register is used to control the butterfly scaling at each of the radix-2 butterfly stages. If the Nth bit in this register is set to 0, then the 25-bit output of the Nth radix-2 stage from the last is saturated to 24-bit. Otherwise it is scaled down by 2 and rounded to produce a 24-bit output.

Table 7-88. FFT Engine Registers (continued)

Register	Width	Parameter Set	Description
BFLY_SCALING_FFT3X	2	Yes	Butterfly scaling for radix-3 stage: This register is applicable only if FFTSIZE3X_EN is set to 1. This register is used to control the butterfly scaling in the 3-point FFT structure that precedes the powers-of-2 FFT structure. If this register is set to 0, then that 26-bit output after radix-3 stage is saturated at the MSB to get back to 24 bits. If it is 2, it is rounded to remove 2 LSBs to get back to 24 bits. A middle option exists by setting this to 1. In this case, the 26 bit temporary output is convergent-rounded to remove 1 LSB and the 25-bit output thus obtained is saturated to 24 bits.
DITHER_TWID_EN. dither_twid_en	1	No	Twiddle factor dithering enable: This register-bit is used to enable and disable dithering of twiddle factors in the FFT. The twiddle factors are 24-bits wide (24-bits for each I and Q), but they are quantized to 21-bits before twiddle factor multiplication. This quantization is implemented with dithering on the LSB, to avoid periodic quantization pattern affecting SFDR performance of the FFT. It is recommended to keep this register bit set to 1 (dithering enabled), with appropriate LSFR seed loaded.
LFSR_SEED. lfsr_seed	29	No	Seed for LFSR (random pattern): For twiddle factor dithering, there is an LFSR that is used, whose seed value is loaded by writing to this 29-bit LFSRSEED register. The LFSRSEED register should be set to any non-zero value, say 0x1234567. To load the LFSR seed, a pulse signal needs to be provided, by writing a 1 followed by a 0 (i.e., by setting and clearing) the LFSRLOAD register-bit.
LFSR_LOAD. lfsr_load	1	No	For twiddle factor dithering, there is an LFSR that is used, whose seed value is loaded by writing to this 29-bit LFSRSEED register. The LFSRSEED register should be set to any non-zero value, say 0x1234567. To load the LFSR seed, a pulse signal needs to be provided, by writing a 1 followed by a 0 (i.e., by setting and clearing) the LFSRLOAD register-bit.
FFT_CLIP.fft_clip	13	No	FFT Clip Status (read-only): This is a read-only status register, which indicates any saturation/clipping events that have happened in the FFT butterfly stages. Note that each of the individual butterfly stages in the FFT can be programmed to either saturate the MSB or round the LSB. Whenever saturation of MSB is used in any stage, there is a possibility that that stage can saturate or clip samples. In that case, this saturation event is indicated in the corresponding bit in this status register, so that the processor can read it. If multiple FFTs are performed, this status register includes any saturation events happening in any of them. This status register can only be cleared by any processor, by setting another single-bit register CLR_FFTCLIP, so that the saturation status indication gets cleared back to 0 and any subsequent saturation events can be freshly monitored. The MSB of this register indicates clip status corresponding to the radix 3 butterfly (note: it is the MSB, independent of the number of radix-2 stages engaged).
CLR_FFTCLIP.clr_fftclip	1	No	Clear FFT Clip Status register: This register bit, when set, clears the FFTCLIP register.
WINDOW_RAM[2048] DSS_HWA_WINDOW_RAM	32b each	No	This RAM stores the window co-efficients. Note that there is only one RAM and based on WINDOW_MODE, the samples are accordingly chosen as illustrated in Fig. 15
MEM_INIT_START. MEM_INIT_START_WINDOW_RAM	1	N	Writing 1'b1 would start the memory initialization for the window memory. This bit is self-clearing.

Table 7-88. FFT Engine Registers (continued)

Register	Width	Parameter Set	Description
ACCEL_MODE	3	Yes	Select Core Computational Unit Data Path: This register selects the data-path of the accelerator's core computational unit – for example, it selects which of the paths: the FFT engine path, or the CFAR engine path, or the compression/decompression path, or the local maxima engine path, or none is active. Value = 0b000: FFT engine path Value = 0b001: CFAR engine path Value = 0b010: Compression / decompression engine path Value = 0b011: Local Maxima engine path Value = 0b111: No Operation. The No Operation setting can be used together with an appropriate trigger mode to cause the state machine to wait for an event before moving to the next parameter-set.
WINDOW_INTERP_FRACTION CMULT_MODE TWIDINCR FFT_OUTPUT_MODE FFTSUMDIV MAX<n>_VALUE ISUM<n>, QSUM<n>	–	–	Described in sections starting from 28.7 of the TRM. For the immediate purposes relevant to this ection and above sections of HWA chapter, all of these registers should be kept as 0.

7.4.6 Parameter Set Layouts

The parameter-set register layout is provided below for all the accelerator modes. Note that the parameter-set RAM must be written using 32-bit word writes only (i.e., byte-writes and half-word writes are NOT supported).

7.4.7 FFT Engine – Pre-Processing

As explained in Part 1 of this chapter, the FFT Engine comprises pre-processing, windowing, FFT and Log-magnitude subblocks and these are stitched together one after the other in series (refer to Figure 7-110). This architecture allows multiple operations to be done in a streaming manner (for example, windowing and FFT can be done together), while at the same time, providing the user flexibility to choose one operation at a time. This section provides an overview of the pre-processing subblock inside the FFT engine of the core computational unit.

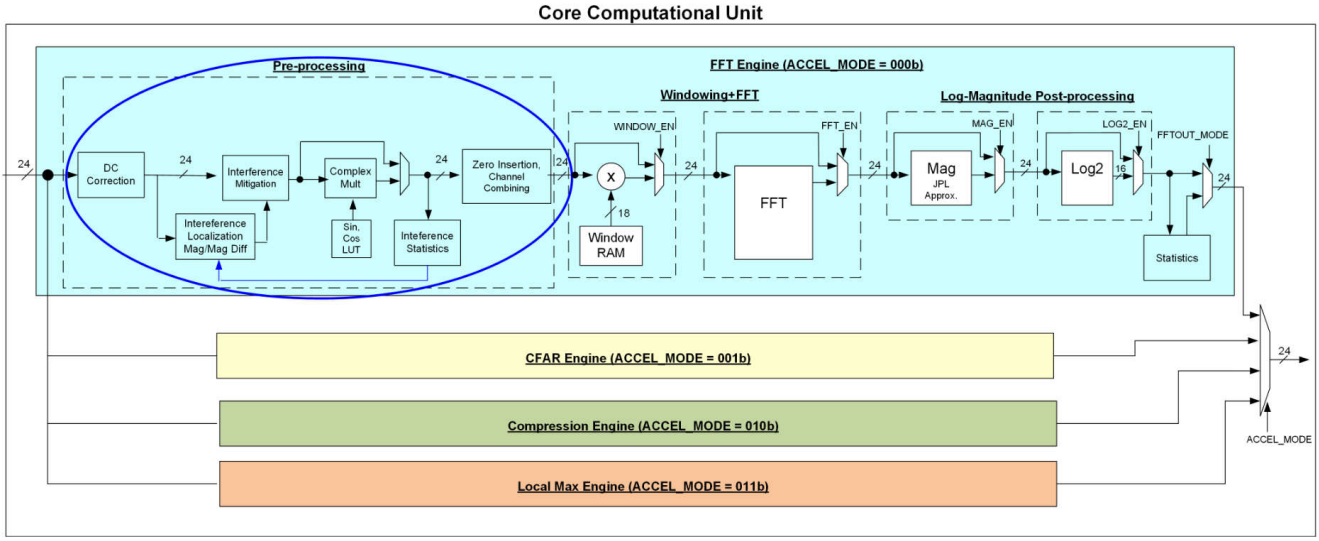

Figure 7-110. Core Computational Unit

The pre-processing subblock provides capability for DC estimation and correction, Interference localization and mitigation, complex multiplication, channel combining and zero-insertion.

7.4.7.1 DC Estimation

The DC estimation block estimates the time-domain average of the stream of samples along the A dimension. The stream can be one chirp, or set of chirps, i.e., frame. The DC is estimated on a per-iteration basis (i.e., along A dimension for each B iteration) for I & Q samples. Up-to 12 estimates corresponding to up to 12 iterations are available.

DC estimation is based on accumulation followed by a fine scaling and a programmable right shift. The fine scaling is configured as 1.8 value, via the 9-bit DCEST_SCALE register. The subsequent programmable right shift is configurable from 6 to 20 bits. Therefore, the DC estimation is well suited for cases where the number of samples per iteration is between 2^6 and 2^20. The fixed point details are captured in Figure 7-111. The internal accumulator reset supports several modes as shown in Table 7-89. For example, when DCEST_RESET_MODE = 2, the internal DC accumulators are reset at the beginning of the current parameter-set execution. Therefore, this mode estimates DC value for each set of SRCACNT samples along the A-dimension for up to 12 iterations along B-dimension within the current parameter-set. This mode is useful for per-chirp DC estimation. In this mode, the estimated DC values per iteration are latched at the end of current param-set and the accumulators are reset at the start. On the other hand, when DCEST_RESET_MODE = 3, the internal DC accumulators are reset only when the state machine executes the first loop of the parameter-set. As the state machine loops through various parameter-sets multiple times as programmed via NLOOPS register, the DC accumulators are not reset in between these loops. This mode is useful for per-frame DC estimation, where each loop corresponds to one chirp and the NLOOPS loops (chirps) correspond to a complete frame. The estimated DC values per iteration are latched at the end of last execution of the param-set.

The processor can read the DC estimates through the read-only registers – DCESTI_0VAL, .., DCESTI_11VAL & DCESTQ_0VAL, .., DCESTQ_11VAL. The DC estimates can also be used for DC subtraction described next.

Table 7-89. DC Estimation – Reset Modes

DCEST_RESET_MODE	Comments
0	Hold the DC internal accumulators without updating (bypass DC estimation).
1	DC estimation enabled, but free-running without automatic reset (i.e., not reset at the start of this parameter-set). In this mode, the software can reset the DC accumulators by writing to DC_EST_RESET_SW register bit.
2	Reset the DC internal accumulators at the start of this parameter-set. This mode is applicable for per-chirp DC estimation.
3	Reset the DC internal accumulators at the start of this parameter-set only if the loop-counter is 0. This mode is applicable for per-frame DC estimation.

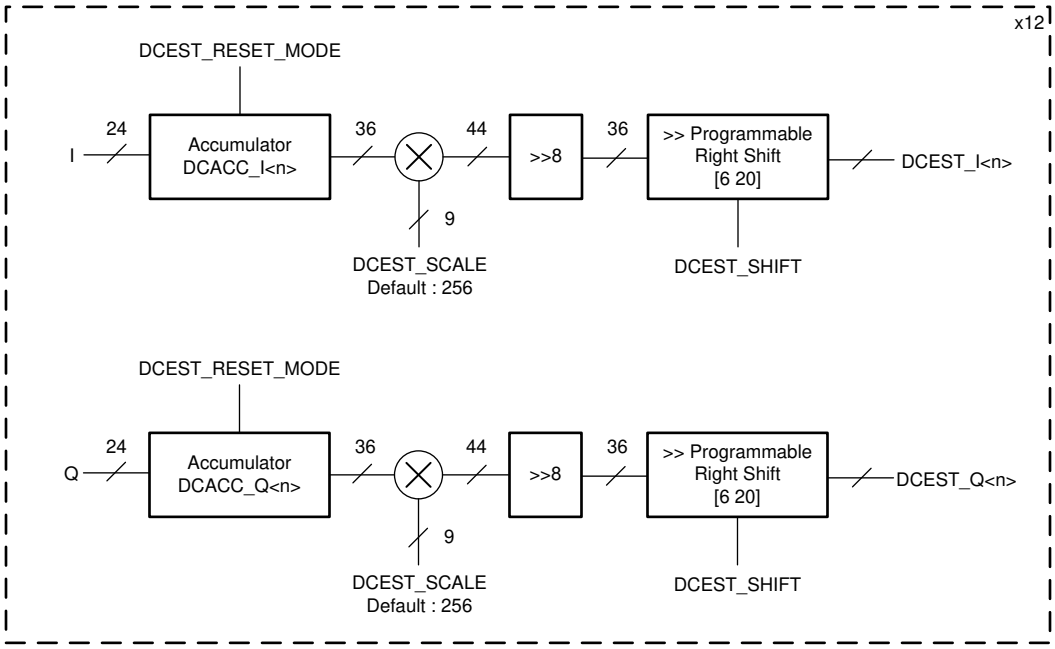

Figure 7-111. DC Estimation

7.4.7.2 DC Subtraction

The DC subtraction feature is enabled if the register DCSUB_EN is set to 1.

DC subtraction (see Figure 7-112) can use the output from the built-in DC estimation accumulators, or a user-programmed value, based on the register bit, DCSUB_SELECT. If DCSUB_SELECT is 1, the DC estimation based on the internal accumulators is used. If DCSUB_SELECT is 0, the software override values are used (they are given by DC_SW_I_<n> and DC_SW_Q_<n> for the nth iteration).

When using the built-in DC estimation accumulators, DC subtraction is performed on 12 individual streams corresponding to 12 RX on a per-iteration basis. Note that in a typical usage, for performing per-chirp DC estimation and DC subtraction, a two-pass approach is needed, where the first pass is configured for DC estimation via one parameter-set, and the second pass is configured for DC subtraction in the next parameter-set. Alternately, if a previous DC estimate (eg. From the previous chirp) is desired to be used for DC subtraction for the current chirp, then DC subtraction can be directly accomplished in one pass.

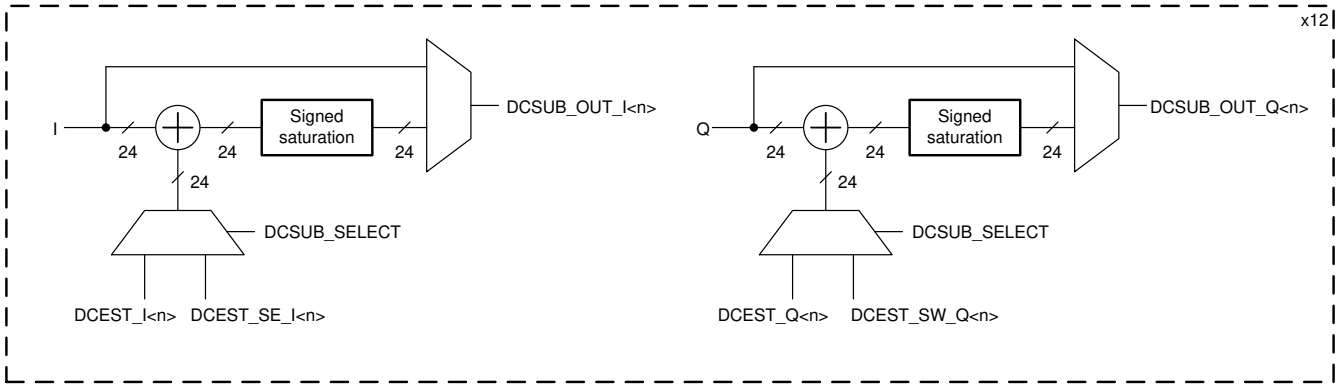

Figure 7-112. DC Subtraction

7.4.7.3 Interference Localization

In an FMCW radar transceiver, interference from another radar typically manifests itself as a time-domain spike in a few samples. This spike corresponds to the time duration when the chirping frequency of both radars overlap with each other. Such a time-domain spike caused by interference can lead to degradation in the noise floor at the FFT output, causing degradation in detection performance.

In order to mitigate the impact of interference, the pre-processing block provides capability to perform interference localization to identify samples corrupted by interference, followed by interference mitigation to repair those samples.

The INTF_LOC_THRESH_EN register is provided as part of the parameter-set to control when the interference localization should be enabled. When enabled, the input samples are fed through a magnitude calculation (based on JPL approximation), which computes a 24-bit magnitude of the 24-bit input complex sample. For definition of this approximation, see 28.5.1.8 of the TRM. Similarly, magnitude of the backward difference between adjacent samples is also computed, which is another useful metric for interference (glitch) detection.

Any sample whose magnitude and/or magnitude of backward difference exceeds thresholds THRESH_MAG<n> and THRESH_MAGDIFF<n> is considered as affected by interference and is marked by a corresponding Interference indicator Bit (IIB). This is supported individually for up to 12 iterations. Note that the IIB bit is just an internal signal that is set by the interference localization module, in order to mark samples for the interference mitigation module (described later). The register, INTF_LOC_THRESH_MODE determines the logic to set the IIB bit using the magnitude and/or magnitude of difference estimates. Based on this register, samples are marked with IIB if they exceed the THRESH_MAG<n>, or THRESH_MAGDIFF<n>, a logical AND of both, a logical OR of both as shown in Figure 7-113.

This applies across all iterations.

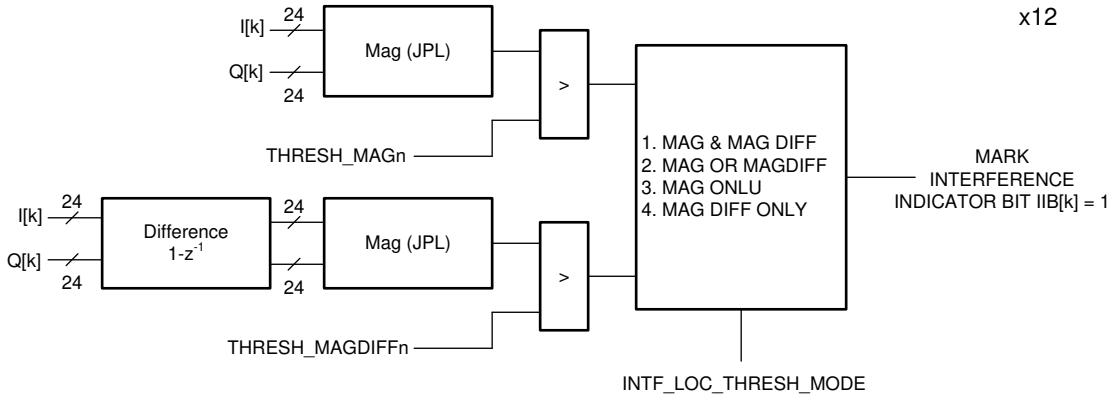

Figure 7-113. Interference Localization

The threshold values of THRESH_MAG<n> and THRESH_MAGDIFF<n> applied on a per-channel basis can derived from SW – INTF_LOC_THRESH_MAG<n>_SW, INTF_LOC_THRESH_MAGDIFF<n>_SW or from a built-in Interference statistics block – INTF_LOC_THRESH_MAG<n>, INTF_LOC_THRESH_MAGDIFF<n> as described in the next section. The user can also choose to sum the built-in interference statistics estimates across all channels to derive a common interference threshold across all iterations– INTF_STATS_SUM_MAG, INTF_STATS_SUM_MAGDIFF. The register, INTF_LOC_THRESH_SELECT is used to select these threshold options.

The number of samples marked with IIB across the iterations is recorded in the read-only registers, INTF_LOC_COUNT_ALL_CHIRP and INTF_LOC_COUNT_ALL_FRAME. This can be read after every chirp or after the completion of a frame (when the state machine completes all the programmed parameter-set loops and enters idle state).

7.4.7.4 Interference Statistics

This block (see Figure 7-114) provides the thresholds for interference localization. In order to obtain the interference statistics and derive the thresholds, the magnitude and magnitude of backward difference of the incoming samples are accumulated per iteration and up to 12 such independent accumulations are supported. These registers can be reset on a per-chirp or per-frame basis, and the behavior can be controlled using the register INTF_STATS_RESET_MODE. These reset modes are similar to DCEST_RESET_MODE previously explained (refer to Table 7-89). The interference statistics accumulators can be reset by software via writing the INTF_STATS_RESET_SW register bit. This reset also clears the INTF_LOC_COUNTS.

The determination of interference threshold for interference localization is based on taking the above accumulator values and applying a programmable fine scaling, followed by a programmable right shift. The fine scaling is configured via 8-bit registers, INTF_STATS_MAG_SCALE and INTF_STATS_MAGDIFF_SCALE in 5.3 format. The fine scaling value is interpreted as an unsigned 8-bit number with 5 integer bits and 3 fractional bits giving a scale in range [0 to 31.875]. The default value of this register is 8, applying a scaling of 1.0. The programmable right-shift in the range of 6 to 12 is applied via the registers, INTF_STATS_MAG_SHIFT and INTF_STATS_MAGDIFF_SHIFT respectively. Note that if the sum mode of threshold selection is made, then the shift values have to include the extra division based on number of iterations being summed.

The resulting values INTF_LOC_THRESH_MAGn and INTF_LOC_THRESH_MAGDIFFn are used as thresholds in the interference localization block as described in the previous section.

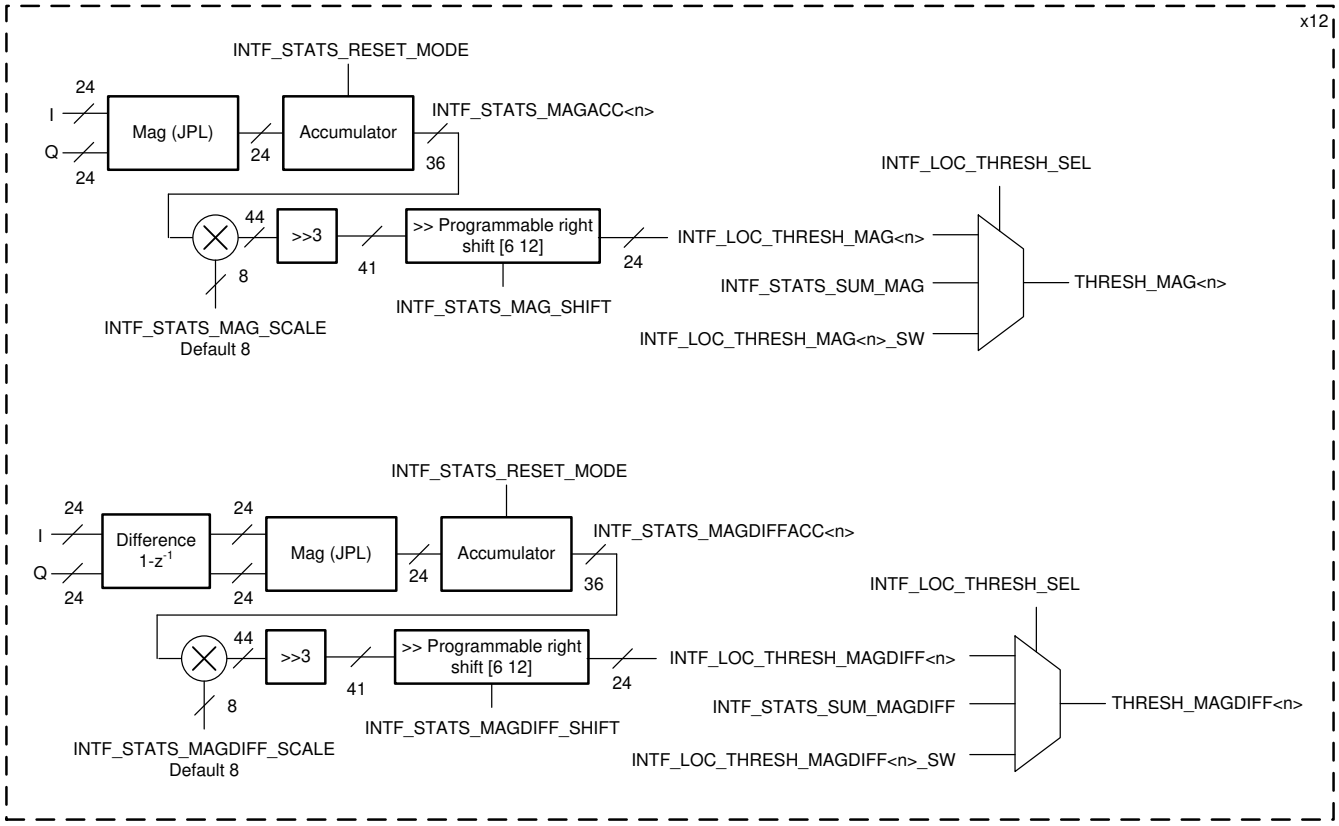

Figure 7-114. Interference Statistics

7.4.7.5 Interference Mitigation

Interference mitigation block (Figure 7-115) uses the results of Interference Localization block and mitigates the interference affecting the input samples which are marked as interference-corrupted through the Interference Indicator Bit. Interference mitigation is applicable for max. 12 iterations

The interference mitigation feature can be enabled by setting the INTF_MITG_EN bit in the parameter-set.

The first sub-module of the Interference Mitigation Block is a hysteresis module, which provides de-bouncing logic. For each incoming sample, its own IIB bit, as well as INTF_MITG_RIGHT_HYST_ORD number of right IIB bits and INTF_MITG_LEFT_HYST_ORD number of left IIB bits are considered in order to decide whether that particular sample is actually affected by interference. If the number of IIB bits in that interval is greater than or equal to INTF_MITG_CNTTHRESH, then that sample is assumed to be affected by interference. Thus, the hysteresis module outputs a filtered version of the IIB bit stream, which is then used for interference mitigation.

There are three different options (Figure 7-116) for interference mitigation and one of these can be selected using the INTF_MITG_PATH_SEL register. If INTF_MITG_PATH_SEL = 0, then the interference mitigation block simply zeros out samples that are marked with the IIB bit. This is a simple form of interference mitigation.

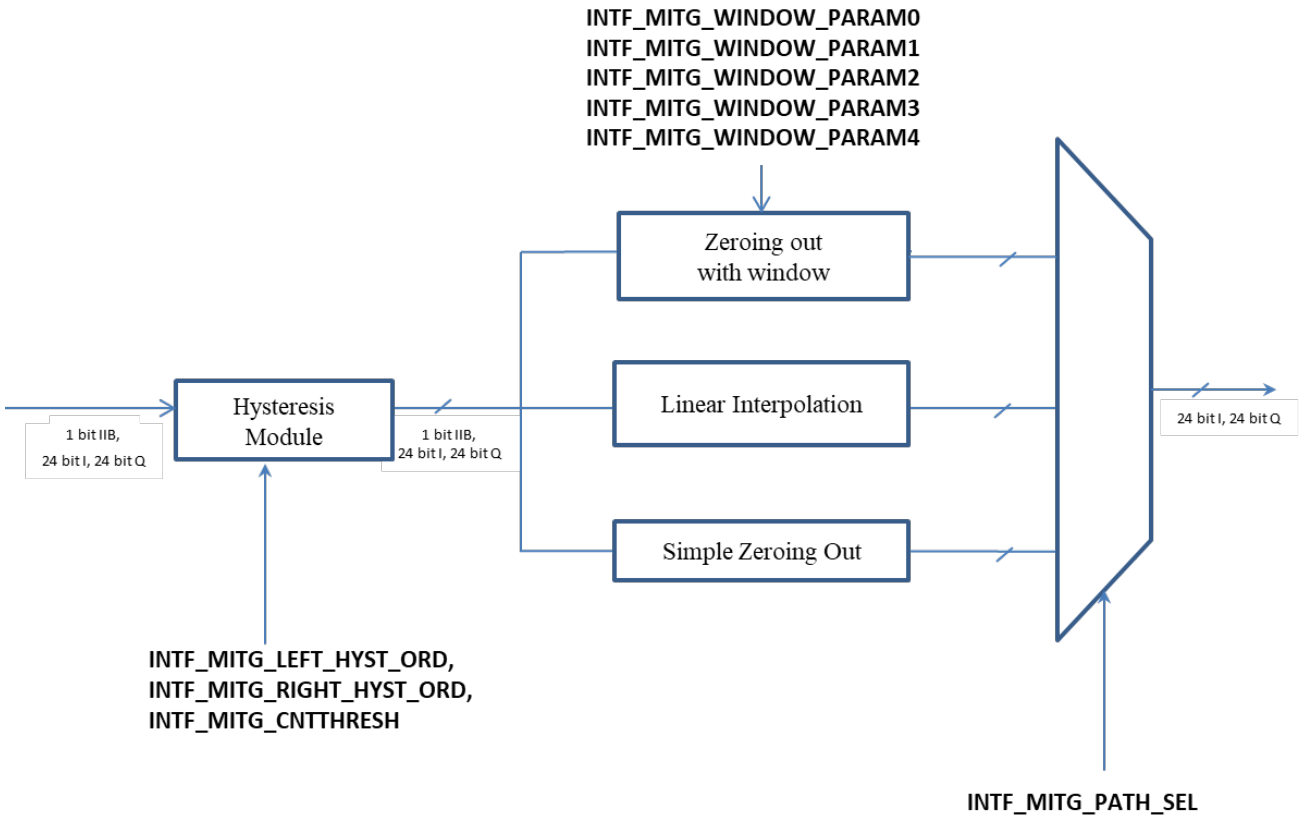

Figure 7-115. Interference Mitigation Block

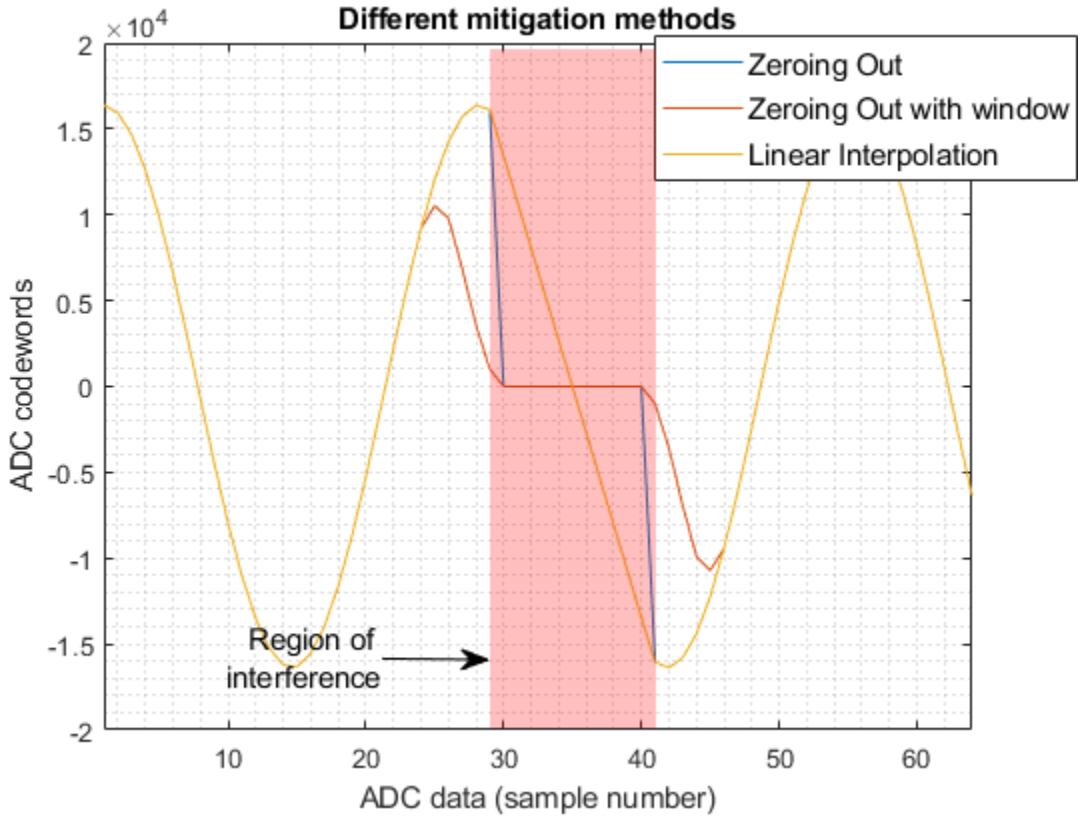

Figure 7-116. Interference Mitigation Methods

If INTF_MITG_PATH_SEL = 1, then the interference mitigation block performs a windowed zero-out, where a smoothing window is applied to the edge samples of the interference-affected set of samples, in order to reduce the side-lobe increase that can happen with abrupt windowing. The windowing function that is applied is programmable via the INTF_MITG_WINDOW_PARAM <n> registers. The manner in which this smoothing window is applied is as follows.

Assume that the input sample array is: [x[0], x[1], x[2], x[3], x[4], x[5], x[6], x[7], x[8], x[9], x[10]]. Assume that the IIB array input is of the form [0, 0, 0, 0, 0, 1, 1, 0, 0, 0, 0]. (In other words, the 6th and 7th samples are corrupted by interference.) Then, the output of the windowed zero-out module would be:

[x[0]w[4], x[1]w[3], x[2]w[2], x[3]w[1], x[4]w[0], 0, 0, x[7]w[0], x[8]w[1], x[9]w[2], x[10]w[3]].

Where w[n] = INTF_MITG_WINDOW_PARAM<n>.

Note that the samples that are affected by interference are always zeroed out. The window is applied on the neighbours of these samples, so as to smoothen the transition to zero.

If INTF_MITG_PATH_SEL = 2, then the interference mitigation block performs a linear interpolation between the two good (i.e., non-interference-affected) samples at the start and end of the interference affected set of samples and this linear interpolation procedure is used to replace the interference affected samples themselves. The number of interference affected samples between these good samples can be any number. However, if it exceeds 32, then the ‘last good sample’ is pushed out in the place of affected samples until a new good sample arrives. Then linear interpolation will be performed across the 32 remaining affected samples.

7.4.7.6 Complex Multiplication

In addition to interference zero-out, the pre-processing block contains a complex multiplication sub-block. The purpose of this sub-block (Figure 7-117) is to enable several assorted capabilities that require complex multiplication of the input samples. The CMULT_MODE register is used to enable and configure the complex

multiplication functionality. The complex multiplication sub-block can be disabled (bypassed) by the setting CMULT_MODE to 0b0000.

There are nine modes of the complex multiplier supported as follows. They are frequency shifter mode, frequency shifter with auto-increment mode (a slow DFT mode), FFT stitching mode, magnitude squared mode, scalar multiplication mode, vector multiplication modes-1 & 2, recursive windowing and LUT based frequency shifter modes.

Inall the nine modes of the complex multiplier, one complex multiplication is performed every clock cycle.

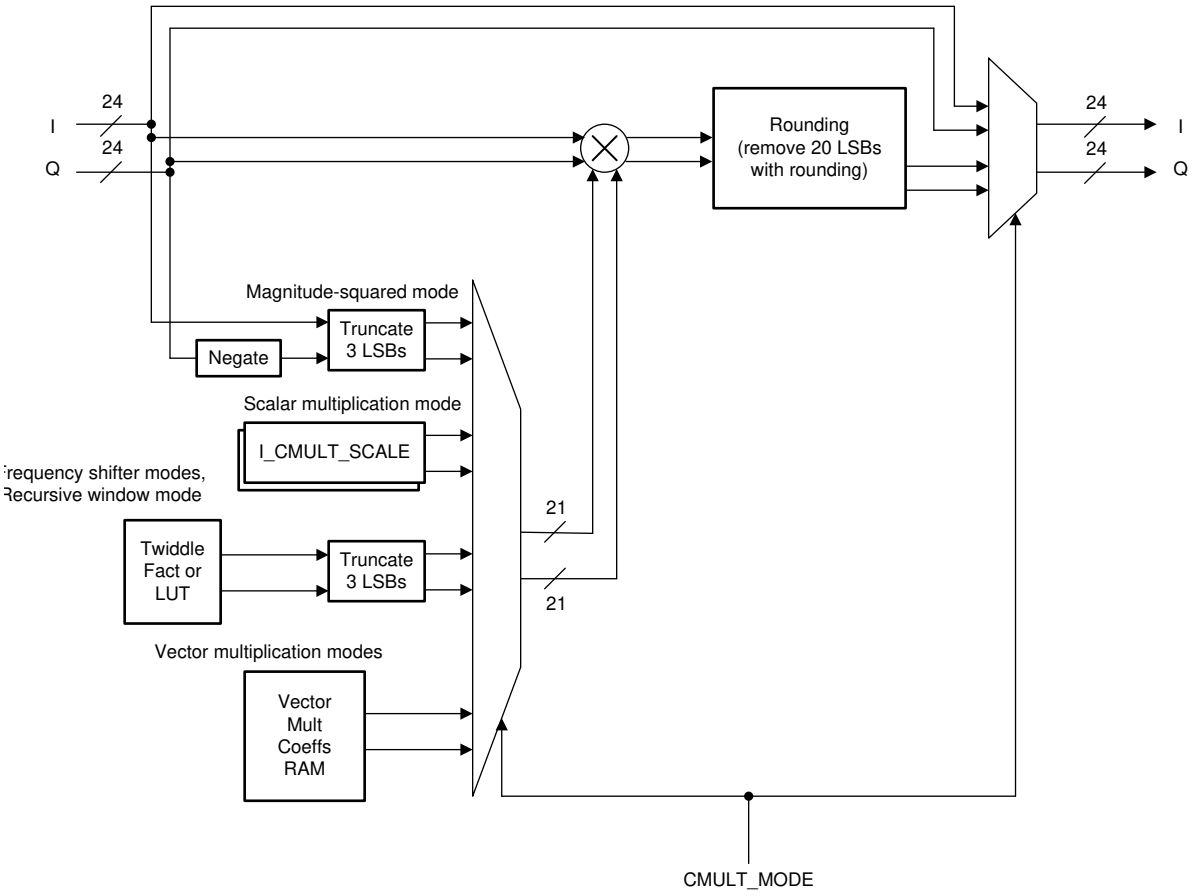

Figure 7-117. Complex Multiplication Capability in Pre-Processing Block

- **Frequency shifter mode**: If the register value is CMULT_MODE = 0001b, then the complex multiplier functions as a frequency shifter, which can be used to de-rotate the input samples by a certain frequency. This de-rotation is accomplished using cos, sin values from a twiddle factor look-up table (LUT). This LUT contains the (compressed) equivalent of the cos, sin values corresponding to the 16384 long sequence exp(–j*2*pi*(0:16383)/16384). TWIDINCR is used to specify the de-rotation frequency, by specifying how much the phase should change for each successive input sample (that register controls how much the LUT read index increments every sample) as shown in (Figure 9). The starting phase in this mode is always zero, since the 20-bit accumulator always starts at zero for each iteration.

  Note that although the figure shows another TWIDINCR_DELTA_FRAC register (portions shown in the red dotted box), that functionality is only applicable for CMULT_MODE = 1010b described later and it is not applicable in the present complex multiplier mode (0001b).

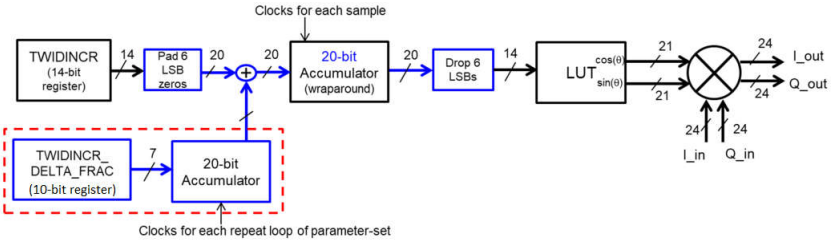

Figure 7-118. Frequency Shifter Mode

- **Frequency shifter with auto-increment mode (a slow DFT mode)**: If the register value is CMULT_MODE = 0010b, then the complex multiplier functions in a mode which enables Discrete Fourier Transform (DFT) computation. In this case, the complex multiplier performs a function that is very similar to frequency shifter mode, except that, at the end of each iteration, the de-rotation frequency is automatically incremented for the next iteration. Note that DFT computation for a given set of input samples involves de-rotating the samples by one frequency at a time, and computing a sum of the de-rotated samples for each such frequency. To achieve DFT computation, the Input Formatter should be configured to send the same set of input samples to the complex multiplier for multiple iterations (as many as the number of DFT bins required) and the complex multiplier de-rotates the samples by one frequency at a time and auto-increments to the next frequency for the next iteration. Also, the statistics block (explained in a later section) is used to compute the sum of the de-rotated samples corresponding to each iteration, which then becomes the final DFT value.

  The DFT computation is 'slow' in the sense that in each clock cycle, only one complex multiplication is performed. For example, for a 512-point input sample set, it would take 512 clock cycles per DFT bin. However, since the DFT mode is typically only used for FFT peak interpolation (very few bins), it is acceptable. The starting frequency for the DFT computation is specified in the TWIDINCR register (similar to the frequency shifter mode). The increment value by which the frequency increments every iteration is obtained from FFTSIZE register – Note that the DFT mode cannot be used simultaneously with FFT enabled, hence the FFTSIZE register has been over-loaded for providing the increment value in this mode. The increment value is calculated as 2^(14 – FFTSIZE) and hence the DFT resolution is 16384/2^(14 – FFTSIZE) = 2^FFTSIZE. As an example, if FFTSIZE = 1011b, then the DFT resolution is 2048. This is equivalent to computing DFT points corresponding to 2K size FFT grid. The highest resolution for the DFT would be obtained when FFTSIZE = 1110b (max allowed value), in which case the DFT resolution is 16384 (corresponding to 16K size FFT grid). In effect, for the kth iteration (with k starting from 0), the input samples x(n) for n = 0 to SRCACNT-1 are multiplied by the sequence, exp(–j*2*pi*(TWIDINCR+2^(14-FFTSIZE)*k)*(0:SRCACNT-1)/16384).
- **FFT Stitching mode**: If the register value is CMULT_MODE = 0011b, then the complex multiplier functions in FFT stitching mode. This mode is useful when large size FFTs (4K and 8K) are required. Since the FFT block natively supports only up to 2048 size, for 4096 and 8192 point FFT, an FFT Stitching procedure using two steps (two parameter-sets) can be used. As an example, when an 8K size FFT is needed, it is achieved in two steps as follows. In the first step, every 4th input sample is passed through a 2K size FFT (four 2K point FFTs are performed on decimated input samples). Then, in the next step, the resulting 4x2048 FFT outputs are sent through four-point "stitching" FFTs (2048 four- point FFTs), with an additional pre-multiplication by the complex multiplier block to achieve FFT stitching. This pre-multiplication uses the twiddle factor LUT in a specific pattern, for which additional configuration information is available in 2 LSBs of TWID_INCR register. Value '01' is for 4K (2x2048) size FFT stitching. If '10', then the twiddle factor pattern will correspond to what is required for 8K (4x2048) size FFT stitching. In the FFT stitching mode of operation, the 12 MSBs of TWID_INCR must be kept as 0.

  The last section includes a more detailed explanation and configuration information for the FFT stitching example for 4K and 8K FFT, including the use of WINDOW_INTERP_FRACTION register for extending the window RAM using linear interpolation to more than 2048 coefficients. Note that Window Symmetry and Interpolation modes can't be used simultaneously.
- **Magnitude squared mode**: If the register value is CULT_MODE = 0100b, then the complex multiplier functions in magnitude squared mode. In this case, the complex multiplier takes a complex input and

produces the magnitude squared as the output. This can be used together with the statistics block (explained in Section 3) to compute the mean squared sum of the input samples.

- **Scalar multiplication mode**: This mode is selected by setting CMULT_MODE = 0101b. It supports two options – multiplication by a complex scalar that remains constant across all iterations or by a complex scalar that changes per iteration.

  If the register bit CMULT_SCALE_EN = 0, then the complex multiplier functions in constant scalar multiplication mode. This feature is useful if the input samples need to be scaled by some constant factor. In this case, the complex multiplier will multiply each input sample with a 21-bit scalar complex number that is programmed in ICMULT_SCALE0 and QCMULT_SCALE0 registers (for I and Q value, each having 21 bits). The ICMULT_SCALE0 and QCMULT_SCALE0 registers are common registers and not part of parameter-set.

  To multiply the input samples for different iterations (channels) with different complex scalars, set CMULT_SCALE_EN = 1. In this mode, upto 12 different complex scalars are supported, viz. from ICMULT_SCALE0, QMULT_SCALE0 to ICMULT_SCALE11, QMULT_SCALE11 that are used for multiplication per iteration. TWID_INCR Register has no implication in this mode.
- **Vector multiplication mode 1**: If the register value is CMULT_MODE = 0110b, then the complex multiplier functions in vector multiplication mode 1. The purpose of this mode is to enable element-wise multiplication of two complex vectors, as well as dot-product capability (using statistics block to sum the element-wise multiplication output). The samples from the Input Formatter block constitute one of the two vectors, whereas the other vector is taken from a pre-loaded 'Vector Multiplication Coefficient RAM' inside the core computational unit. This Vector Multiplication Coefficient RAM can store 1024-complex samples and hence the vector multiplication can support a maximum of 1024 elements of multiplication. The Vector multiplication is not a highly parallelized operation, in the sense that only one complex multiplication is done per clock cycle. Note that the vector multiplication coefficient RAM should ideally be pre-programmed once upfront, and should not normally be re-programmed dynamically when the hardware accelerator is in active execution. If such a dynamic re-programming is required, then it can only be done when CMULT_MODE is set to 0b0000. For any other value of the CMULT_MODE register, the Vector multiplication coefficient RAM access is locked and hence cannot be re-programmed.

  The operation of the vector multiplication mode 1 is as follows. The streaming set of samples from the Input Formatter block is element-wise multiplied with successive samples from the Vector Multiplication Coefficient RAM. The statistics block (described in a later section) can be used to compute the sum for every iteration, which enables a dot-product implementation if desired. At the end of every iteration, the addressing from the Vector Multiplication Coefficient RAM is reset, so that for the next iteration, the samples are picked up from the start index of the Vector Multiplication Coefficient RAM. It is possible to choose a non-zero start address for the Vector Multiplication Coefficient RAM, by programming the TWID_INCR register. The top 12 MSBs of the TWID_INCR register functions as a sample address offset for the RAM. The 2 LSBs must be kept zero. For example, if TWID_INCR = 20, then the vector multiplication happens starting from the 5th coefficient in the RAM (zero-based count).

  When the size of vectors is small (<=12 coefficients), this mode can also be realized by setting the bit CMULT_SCALE_EN = 1 and programming ICMULT_SCALE0, QCMULT_SCALE0 to ICMULT_SCALE11, QCMULT_SCALE11 registers to store the successive coefficients. This mode can be used for example in RX channel gain and phase mismatch equalization. Because these ICMULT_SCALE<n> and QCMULT_SCALE<n> registers are independent of the Vector Multiplication Coefficients RAM, the user can use the RAM approach for some parameter-set which may need vector multiplication coefficients up to 1024, while another parameter-set of the processing chain uses the registers approach.
- **Vector multiplication mode 2**: If the register value is CMULT_MODE = 0111b, then the complex multiplier functions in vector multiplication mode 2, which is slightly different from the earlier Vector multiplication mode 1. The only difference in this case is that at the end of every iteration, the addressing of the Vector Multiplication Coefficient RAM is not reset, so that for the next iteration, the samples from the Vector Multiplication Coefficient RAM are picked up with an address that continues from where it left off at the end of the previous iteration. This mode can be used when a given set of input samples needs to be element-wise multiplied with multiple vectors. In this case, the input formatter block can be configured to repeat the same set of samples for multiple iterations, and the Vector Multiplication Coefficient RAM can be loaded with all the

vectors, such that for successive iterations, the input samples are multiplied with successive vectors. As in previous mode, TWID_INCR functions as an address offset for the RAM.

- **Recursive windowing mode** (next Figure) is supported using CMULT_MODE = 1000b. In this mode, a set of possibly random phase values θ(n) is stored in an internal RAM. This internal RAM is shared with the Vector Multiplication Coefficient RAM, in the sense that each of the *θ(n) values takes up one coefficient location in the Vector Multiplication Coefficients RAM, and therefore use of Recursive Windowing mode comes at the expense of reduced number of coefficients storage for the other vector multiplication modes. For the purpose of recursive windowing the vector multiplication RAM must be programmed with appropriate values and it is as shown below:
  - If θ is in degrees, the corresponding code to be programmed in the RAM is (θ/360) *2^16
  - If θ is in radians, the corresponding code to be programmed in the RAM is (θ /(2*pi)) *2^16

  The operation of Recursive Windowing mode is explained as follows.

  Assuming that the Window RAM (which is separate) contains the window coefficients w0(n), the final window function is computed as: Wk(n) = W0(n) * exp(– j*K*θ(n)*2*pi/16384). This computed window function Wk(n) is used for the windowing prior to FFT operation. Here K is either the iteration count (zero-based count corresponding to B-dimension iterations) within the parameter-set, or the current execution count of the parameter-set where CMULT_MODE = 0b1000. This selection can be made using the register bit, RECWIN_MODE_SEL. A value of RECWIN_MODE_SEL = 0 indicates k is based on iteration count, and RECWIN_MODE_SEL = 1 indicates it is based on the said execution count. When REC_WIN_MODE_SEL = 0, the value of K resets to zero at the end of all iterations of the current parameter-set. On the other hand, when REC_WIN_MODE_SEL = 1, the value of k persists (and increments) across multiple loops of the parameter-set and it can be reset via software by writing to the register bit RECWIN_RESET_SW.

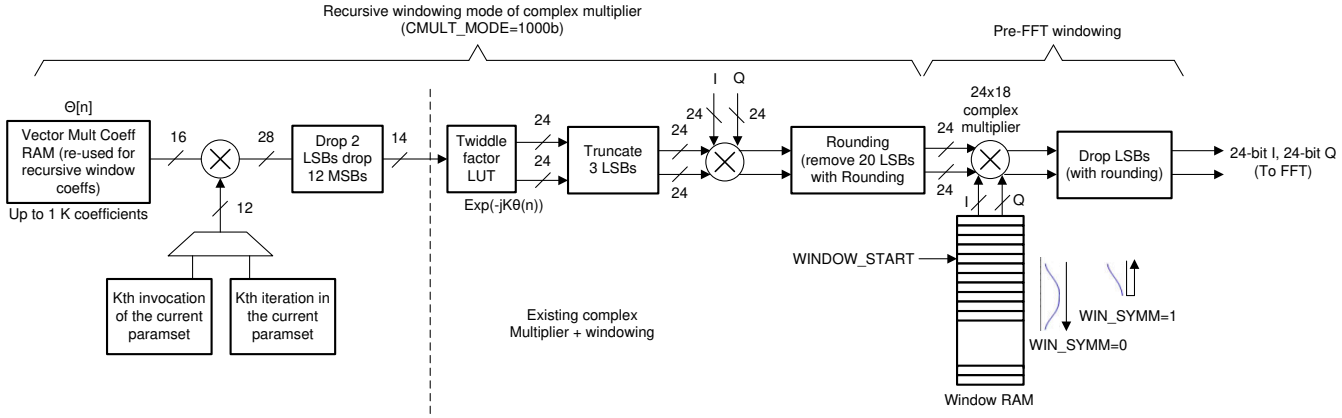

Figure 7-119. Recursive Windowing using the Complex Multiplier

- **LUT based frequency and phase de-rotation mode**: This mode is enabled using CMULT_MODE = 1001b. This mode is similar to Frequency shifter mode (previously explained, where CMULT_MODE = 0001b), except that it supports both frequency de-rotation and phase de-rotation based on a programmable RAM, TWID_ANGLE_RAM. Up to store 64 different frequency de-rotation and starting phase values can be programmed. Each entry in the RAM is 32 bits wide. The 16 MSBs contain starting phase word – TWID_PHA and in remaining 16 LSB, the top-most two bits are don't cares, the next 14 LSBs contain the de-rotation frequency word. The 6 LSBs of TWIDINCR register are used as a start address index to the TWID_ANGLE_RAM.

  There are two sub-modes of this feature, selectable by bit 13 of TWIDINCR register. If this bit set to 1 (Auto-increment mode), then the RAM index is incremented automatically after each iteration (i.e., B dimension), else (Non-increment mode), the RAM index is constant for all iterations, based on the 6 LSBs of TWIDINCR register. Further, bit 12 of TWIDINCR controls whether the RAM index saturates at 63 (behavior when the bit is set to 1) or wraps around (behavior when the bit is 0) in the Auto-increment mode.
- **Frequency shifter mode with fine frequency increment**: This mode is enabled using CMULT_MODE = 1010b. This mode is an extension of the Frequency shifter mode (previously explained, where CMULT_MODE = 0001b). In this mode, in addition to the previously explained frequency shifter functionality,

there is another signed 10-bit offset TWIDINCR_DELTA_FRAC that can be added to the de-rotation frequency, such that the de-rotation frequency changes incrementally after every “execution count”. The TWIDINCR_DELTA_FRAC value is automatically accumulated to the de-rotation frequency at the end of the current execution of the current parameter-set with CMULT_MODE = 1010b. The fixed-point design of this datapath is illustrated in Figure 9). In effect, the input samples x(n) for n = 0 to SRCACNT-1 are multiplied by the sequence: exp(–j * 2*pi * ((TWIDINCR + 2^(-6) * TWIDINCR_DELTA_FRAC * execution_count) * (0:SRCACNT-1) / 16384)). The execution_count here refers to the current execution count of the parameter-set with CMULT_MODE = 1010b. The TWIDINCR_DELTA_FRAC accumulator is reset only via software by writing to the TWID_INCR_DELTA_FRAC_RESET_SW register bit. Note that the TWIDINCR_DELTA_FRAC register is applicable only in this mode of the complex multiplier and is ignored in all other modes.

The memory layouts for different modes are illustrated in Figure 7-120.

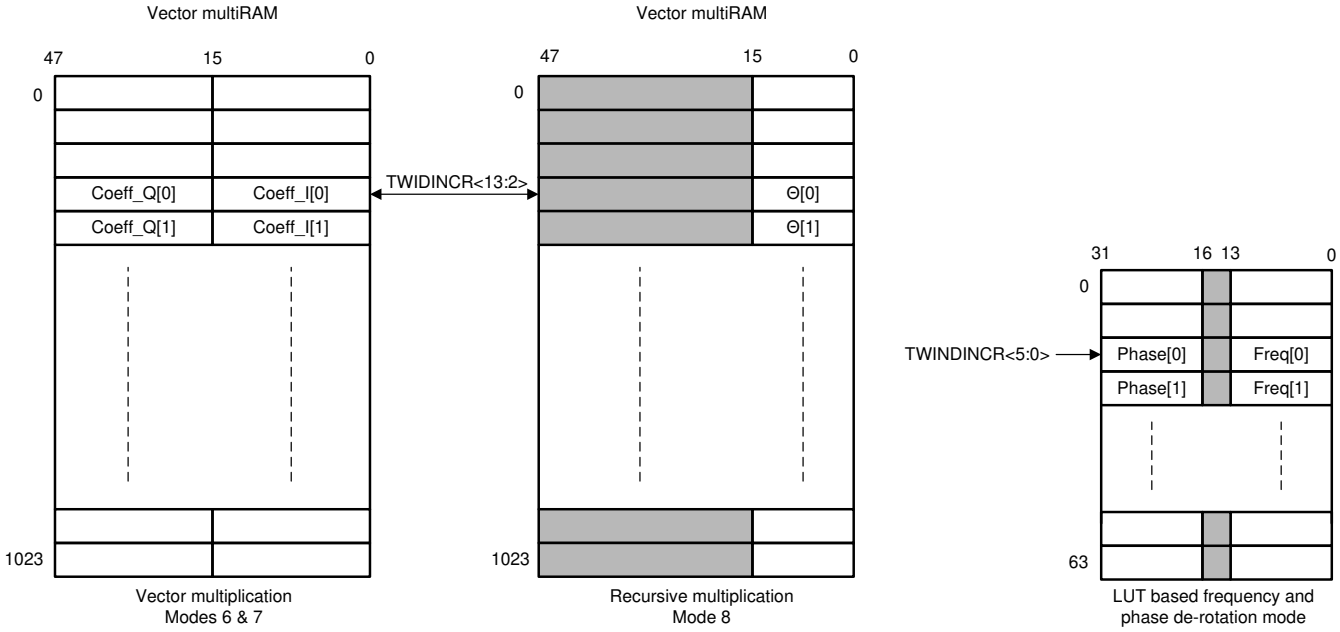

Figure 7-120. Memory Layout for Different Multiplication Modes

7.4.7.7 BPM Removal

Although not explicitly shown in Figure 2-1, it is possible to multiply the input samples going from the input formatter into the core computational unit with a +1/-1 programmable binary sequence (of length up to 256). This feature is enabled by setting the register bit BPM_EN in the parameter-set.

This feature may be useful when Binary Phase Modulation (BPM) is used during transmission of chirps. The BPM pattern is generally a pseudo-random sequence (chipping sequence) of 1’s and -1’s, which have already been applied to the radar transmit signal. Therefore, the radar signal processing of the resultant analog-to-digital converter (ADC) samples prior to FFT needs to undo the modulation. For instance, if each chirp is transmitted with a +1 or -1 polarity, then it is necessary to undo this sequence prior to the second dimension FFT processing across chirps. The BPM removal feature can be used to achieve this.

Note that an alternate way to achieve this is to pre-multiply the window coefficients, which are signed numbers, in the window RAM, so that the process of windowing prior to FFT takes care of undoing the BPM sequence.

When BPM removal is enabled, each input sample is multiplied by a +1 or -1, based on the bit sequence present in the eight 32-bit registers, BPMPATTERN0, BPMPATTERN1, … BPMPATTERN7. A bit value of 0 (1) multiplies the input sample with 1 (–1). The register BPMRATE is used to control for how many consecutive samples the same BPM bit is applied. For example, if BPMRATE = 4, then the same BPM bit is applied for 4 consecutive samples. Similarly, if BPMRATE = 1, then the BPM bit is changed for every sample.

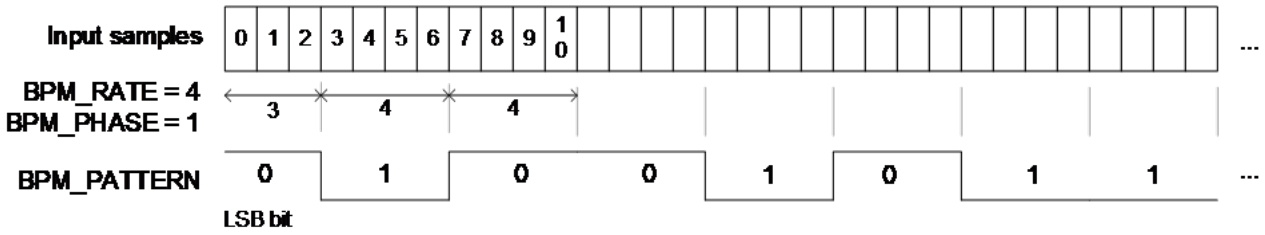

Figure 7-121. BPM Removal Capability

There is another register BPMPHASE that specifies the number of consecutive samples for which the first BPM bit is applied. Note that this is applicable only for the first BPM bit. If BPMPHASE = 0, then the first BPM bit is applied for BPMRATE number of samples. Otherwise, the first BPM bit is applied for BPMRATE – BPMPHASE number of samples. For example, if BPMPHASE = 1 and BPMRATE = 4, then the first BPM bit is applied for 4-1 = 3 samples, and then subsequent BPM bits are applied with periodicity of 4 samples for each bit. This is shown in Figure 7-121. If multiple iterations (for example, four back-to-back FFTs in a single parameter-set using BCNT=3) are done, then the same BPM pattern gets applied to the input samples in each iteration.

Notethe limitation that the BPM pattern register is 256 bits long, hence, the maximum BPM sequence length that is supported is 256. For higher BPM sequence length, the alternate approach of pre-multiplying the window coefficients stored in the window RAM may be considered.

7.4.7.8 Channel Combining

The accelerator allows combining of data samples from multiple channels into one effective channel. This is done via an accumulator that sums a set of successive samples along the A dimension. The samples to combine are indicated by a 256-length bit-vector, CHAN_COMB_VEC. A string of ‘1’ or a string of ‘0’ sums the samples corresponding to the indices. A ‘10’ or ‘01’ transition demarcates the groups. This results in a variable rate output based on the length of 1s-string & 0s-string. The down-stream processing stalls during the grouping. The LSB of this bit-vector corresponds to the first input sample. An additional register, CHAN_COMB_SIZE needs to be programmed to indicate the number of samples after this combination in A dimension. The combination pattern is the same across all iterations. The channel combining is feature is enabled only if CHAN_COMB_EN is set to 1. The bit-vector CHAN_COMB_VEC is specified through eight 32-bit registers, CHAN_COMB_VEC0, CHAN_COMB_VEC1, … CHAN_COMB_VEC7.

Channel combination is illustrated with an example here: if CHAN_COMB_VEC0 = 0x008C (and CHAN_COMB_VEC1-7 are 0s), SRCACNT = 11 (i.e. 12 samples), and CHAN_COMB_SIZE = 5, then the first 2 samples are combined into one output sample, the next 2 samples are combined into one output sample, and the next 3 samples are combined into one output sample, the next sample is output as another output sample, and the last 4 samples are combined into one output sample. Note that the 1s and 0s in CHAN_COMB_VEC can be flipped to achieve the same effect.

7.4.7.9 Zero Insertion

In addition to traditional zero padding before FFT, the accelerator includes a Zero Insertion feature. This feature allows filling of zeros at arbitrary locations in the A dimension, prior to windowing and FFT. Zero insertion is typically meant for angle-dimension FFT to account for missing antenna positions. The Zero Insertion capability is applicable to FFT sizes up to 256 .

In HWA2.0, ZERO_INSERT_MASK is a 256-bit vector (split in eight 32-bit registers) that holds the positions of zero-insertion. A bit value of ‘0’ inserts a zero and a value of ‘1’ means the input is passed through. Input streaming is stalled during the zero insertion. The register ZERO_INSERT_NUM is used indicate the number of zeros to be inserted. The register ZERO_INSERT_EN, if set to 1, enables this feature.

Zeros insert locations directly refer to FFT’s input sample indices. For example in HWA2.0, if FFT size is 16, SRCANT is 11, ZERO_INSERT_MASK0 = 0xFF0F means that the first 4 samples are passed through, 4 zeros

are inserted, and the next 8 samples are passed through. As with channel combination, the zero insertion pattern remains same across iterations.

This mode is not to be confused with zero padding mode where zeros are appended to an input stream. The number of zeros padded at the end depends on FFTsize, zero insertion and channel combination. It is recommended to avoid zero insertion for the last sample in the iteration (the last sample should come through input formatter).

Note

There is a known observation with the behavior in the readback values of the DSS_HWA_DEROT_RAM when using it as the zero-insertion mask register space. The RAM was designed to hold data up to 14-bits within 16-bit words (0x0000 to 0x3FFF) for frequency shifter phase values in CMULT_MODE = 1001 and the topmost 2 MSBs were not to be cared for. When using the zero-insertion feature in HWA 2.1, the RAM can be programmed with full range of 16-bit values (0x0000 to 0xFFFF) and the complete zero insertion for 2048 samples can be achieved as intended. The only thing to note would be that the readback value of the same which will read the top 2 MSBs as 0 (Eg : RAM programmed with 0xFFFF would have a readback value of 0x3FFF). This however does not represent the actual contents of the RAM nor will it affect the functionality of the zero-insertion feature. It is suggested that the user refer to the value programmed via software and treat it as the actual contents of the RAM. It can also be noted that in the HWA2.1, the ZERO_INSERT_MASK_<n> registers are obsolete.

7.4.7.10 Pre-Processing Block – Register Descriptions

Table 7-90 lists all the registers of the pre-processing block. As explained in the first part of this chapter, some of the registers are common (common for all parameter-sets) registers, whereas, some others are “part of each parameter-set”. For each register, this distinction is captured as part of the register description in Table 7-90.

Table 7-90. Pre-Processing Registers

Register.field	Width	Parameter-Set? (Y/N)	Description
DCEST_RESET_MODE	2	Y	2-bit field that controls the reset behavior for all 12 DC accumulators 00 : Hold Accumulator state without updating 01 : Reserved 10 : Reset at start of param-set (i.e., per-chirp DC estimation). 11 : Reset at start of param-set only if loop counter is 0 (i.e., per-frame DC estimation)
DC_EST_CTRL.dc_est_scale	9	N	Programmable fine scaling for DC estimation: 9-bit scale applied to all 12 DC accumulators. This is followed by right shift and truncation. Multiplies the accumulator output by DC_EST_SCALE/256. Default value is 256 giving a scale of 1.0. Setting it to 128, gives a scale of 0.5.
DC_EST_CTRL.dc_est_shift	4	N	Programmable right shift for DC estimation: Right bit-shift applied to all 12 DC accumulator outputs. Cannot be bypassed. Accumulator outputs are scaled by 2^(8 + 6 + DC_EST_SHIFT). Valid range for this register is 0 to 14 (i.e., scaling of 2^14 to 2^28). Note that DC_EST_SHIFT = 15 is not supported.
DC_ACC_I_<n>_VAL_LSB.Dc_acc_i_<n>_val_lsb n=0,1,..11	32	N	These read-only registers provide the lower 32 bits of 36b DC estimation accumulator values –I&Q for 12 streams for processor read-out.
DC_ACC_I_<n>_VAL_MSB.Dc_acc_i_<n>_val_msb n=0,1,..11	4	N	These read-only registers provide the upper 4 bits of 36b DC estimation accumulator values –I&Q for 12 streams for processor read-out.

Table 7-90. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
DC_EST_RESET_SW.dc_est_reset_sw	1	N	Software reset for DC accumulators: Setting this register bit to 1 resets all 12 DC estimation accumulators. This is a self-clearing reset bit.
DC_EST_I_<n>_VAL.dc_est_i_<n>_val DC_EST_Q_<n>_VAL.dc_est_q_<n>_val n=0,1,..11	24	N	These read-only registers provide the DC estimates – I&Q for 12 streams – for the processor to read.
DC_ACC_CLIP_STATUS.dc_acc_clip_status	12	N	Clip status indication (read-register) for the 12 DC accumulators (both I and Q combined). Value of 1 indicates a clipping event occurred.
DC_EST_CLIP_STATUS.dc_est_clip_status	12	N	Clip status indication (read-register) for the 12 DC estimates (both I and Q combined). Value of 1 indicates a clipping event occurred.
DCSUB_EN	1	Y	Enable or Disable DC subtraction. If this register bit is set to 1, DC subtraction is enabled. Else, it is disabled.
DCSUB_SELECT	1	Y	Source select for DC subtraction: 0 : Value comes from processor via DC_SW_I<n> & DC_SW_Q<n> 1: Value comes from built-in DC estimation hardware, i.e., DCEST_I<n> & DCEST_Q<n>
DC_I<n>_SW.dc_i<n>_sw DC_Q<n>_SW.dc_q<n>_sw n=0,1,..11	24	N	User-programmed DC values used for DC subtraction. These registers are relevant only when DCSUB_SELECT is 0.
DC_SUB_CLIP.dc_sub_clip	1	N	Clip status indication (read-register) for DC subtraction node (both I and Q combined). Value of 1 indicates a clipping event occurred.
INTF_LOC_THRESH_EN	1	Y	Enable/Disable for Interference localization (marking out): This registerbit controls the enable/disable for the interference marking (setting Interference Indicator Bit) feature. The feature is enabled if this register bit is set to 1.
INTF_LOC_THRESH_MAG<n>_SW.intf_loc_thresh_mag<n>_sw n=0..11	24	N	Software Interference threshold for Magnitude These registersare used to specify the user-programmed threshold for marking out samples affected by interference in the Interference localization block. The magnitude of each incoming samples is compared with this threshold to decide whether it is corrupted by interference or not.
INTF_LOC_THRESH_MAGDIFF<n>_SW.intf_loc_thresh_magdiff<n>_sw n=0…11	24	N	Software Interference threshold for Magnitude of backward difference These registersare used to specify the user-programmed threshold for marking out samples affected by interference in the Interference localization block. The magnitude of backward difference of incoming samples is compared with this threshold to decide whether it is corrupted by interference or not.
INTF_LOC_THRESH_MODE	2	Y	Interference detection mode selection: This register is used to control the mode for interference detection in the Interference localization block. 00 : Magnitude OR Magnitude difference 01: Only Magnitude difference 10: Only Magnitude 11 : Magnitude AND Magnitude difference

Table 7-90. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
INTF_LOC_THRESH_SEL	2	Y	Select the source of interference threshold 0 : User-defined threshold via INTERFTHRESH_MAG_SW and INTERFTHRESH_MAGDIFF_SW 1 : Single threshold based on built-in interference statistics outputs using sum value across collected interference statistics 2 : Threshold based on built-in interference statistics outputs, with each statistic being used for corresponding iteration (RX channel)
INTF_STATS_RESET_MODE	2	Y	Reset mode control for Interference statistics accumulators: Controls the reset behavior for all 12 magnitude and magdiff accumulators. 00 : Hold Accumulator state without updating 01 : Free-running accumulator mode 10 : Reset at start of parameter-set (i.e.,per-chirp accumulation). 11 : Reset at start of parameter-set only if loop counter is 0 (i.e., per-frame)
INTF_STATS_CTRL.intf_stats_mag_scale	8	N	Programmable fine scaling for Interference statistics Magnitude: Scaling applied to INTF_STATS_MAGACC<n> from interference statistics block.
INTF_STATS_CTRL.intf_stats_mag_shift	3	N	Programmable right shift for Interference statistics Magnitude: Right bit-shift applied to the interference magnitude accumulator. Total right shift of the accumulator is 2^(3+6+INTF_STATS_MAG_SHIFT). Valid range for this register is 0 to 6 (i.e., the total right shift can't be more than 2^15).
INTF_STATS_CTRL.intf_stats_magdiff_scale	8	N	Programmable fine scaling for Interference statistics MagDiff: Scaling applied to INTF_STATS_MAGDIFFACC<n> from interference statistics block.
INTF_STATS_CTRL.intf_stats_magdiff_shift	3	N	Programmable right shift for Interference statistics MagDiff: Right bit-shift applied to the interference magdiff accumulator. Total right shift of the accumulator is 2^(3+6+INTF_STATS_MAGDIFF_SHIFT). Valid range for this register is 0 to 6 (i.e., the right shift can't be more than 2^15).
INTF_STATS_MAG_ACC_<n>_LSB.intf_stats_mag_acc_<n>_lsb	32	N	These read-only registers provide the lower 32 bits of 36b magnitude accumulator values –I&Q 12 streams for processor read-out.
INTF_STATS_MAG_ACC_<n>_MSB.intf_stats_mag_acc_<n>_msb	4	N	These read-only registers provide the upper 4 bits of 36b magnitude accumulator values –I&Q 12 streams for processor read-out.
INTF_STATS_MAGDIFF_ACC_<n>_LSB.intf_stats_magdiff_acc_<n>_lsb	32	N	These read-only registers provide the lower 32 bits of 36b magnitude difference accumulator values –I&Q 12 streams for processor read-out.
INTF_STATS_MAG_ACC_<n>_MSB.intf_stats_mag_acc_<n>_msb	4	N	These read-only registers provide the upper 4 bits of 36b magnitude difference accumulator values –I&Q 12 streams for processor read-out.
INTF_STATS_RESET_SW.intf_stats_reset_sw	1	N	Software reset bit for all the interference statistics accumulators. This is a self-clearing reset bit.
INTF_LOC_THRESH_MAG<n>_VAL.intf_loc_thresh_mag<n>_val	24	N	Read-only thresholds – scaled and shifted INTF_STATS_MAGACC<n> of interference statistics block

Table 7-90. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
INTF_STATS_SUM_MAG_VAL.intf_stats_sum_mag_val	24	N	Sum of INTF_LOC_THRESH_MAG<n>_VAL, based on number of iterations. Useful as single magnitude threshold value across all iterations
INTF_LOC_THRESH_MAGDIFF<n>_VAL.intf_loc_thresh_magdiff<n>_val	24	N	Read-only thresholds – scaled and shifted INTF_STATS_MAGACCDIFF<n> of interference statistics block
INTF_STATS_SUM_MAGDIFF_VAL.intf_stats_sum_magdiff_val	24	N	Sum of INTF_LOC_THRESH_MAGDIFF<n>_VAL, based on number of iterations. Useful as single magnitude difference threshold value across all iterations
INTF_STATS_SUM_MAG_VAL_CLIP_STATUS.intf_stats_sum_mag_val_clip_status	12	N	Read-only clip status indication register for 12 interference statistics magnitude accumulators INTF_STATS_MAGACC<n>. Value of 1 indicates a clipping event occurred in atleast one accumulator
INTF_STATS_SUM_MAGDIFF_VAL_CLIP_STATUS.intf_stats_sum_magdiff_val_clip_status	12	N	Read-only clip status indication register for 12 interference statistics magnitude-difference accumulators INTF_STATS_MAGACCDIFF<n>. Value of 1 indicates a clipping event occurred in atleast one accumulator
INTF_STATS_ACC_CLIP_STATUS.intf_stats_mag_accumulator_clip_status	12	N	Read-only clip status indication register for 12 magnitude based interference threshold. INTF_LOC_THRESH_MAG<n>_VAL. Value of 1 indicates a clipping event occurred in atleast one estimate
INTF_STATS_ACC_CLIP_STATUS.intf_stats_magdiff_accumulator_clip_status	12	N	Read-only clip status indication register for magnitude-difference based interference threshold. INTF_LOC_THRESH_MAGDIFF<n>_VAL. Value of 1 indicates a clipping event occurred in atleast one estimate
INTF_STATS_THRESH_CLIP_STATUS.intf_stats_thresh_mag_clip_status	1	N	Read-only clip status for sum of all magnitude thresholds computed by the statistics block. Value of 1 indicates that the sum clipped.
INTF_STATS_THRESH_CLIP_STATUS.intf_stats_thresh_magdiff_clip_status	1	N	Read-only clip status for sum of all magnitude difference thresholds computed by statistics block. Value of 1 indicates that the sum clipped.
INTF_LOC_COUNT_ALL_CHIRP.intf_loc_count_all_chirp	12	N	Read-only register indicating the number of samples that exceeded the threshold in a given param-set. The count is saturated to 2^12 – 1.
INTF_LOC_COUNT_ALL_FRAME.intf_loc_count_all_frame	20	N	Read-only register indicating the number of samples that exceeded the threshold across multiple executions of same param-set. The count is saturated to 2^20 – 1.
INTF_MITG_EN	1	Y	If this bit is set, the interference mitigation path is activated, else it is bypassed.
INTF_MITG_PATH_SEL	2	Y	Based on the value of this register, one of the three paths is activated. 00b: Simple Zeroing out 01b: Windowed Zeroing out 10b: Linear Interpolation 11b: Reserved
INTF_MITG_WINDOW_PARAM_<n>.intf_mitg_window_param_<n> n=0..4	5 (each)	N	This is a programmable array of window parameters. Each window parameter is an unsigned 5 bit integer. The length of the array is 5. The parameters of the window are assumed to be monotonically ascending. For example : val = floor(hanning(14)*32) INTF_MITG_WINDOW_PARAM = val(2:6); If a shorter window (of length less than 5) is desired, some of the earlier window parameters can be set to 31. This sets the window parameter to 31/32 (or ~1).

Table 7-90. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
INTF_MITG_CNTTHRESH	5	Y	The (total) number of non-zero IIB within the 'Hysteresis window' should exceed this threshold for the sample-under-test to be considered to be affected by interference. Range : 0 to 31.
INTF_MITG_RIGHT_HYST_ORD	4	Y	The length of the IIB array considered on the right side of (i.e. after) the sample under test. Range : 0 to 15.
INTF_MITG_LEFT_HYST_ORD	4	Y	The length of the IIB array considered on the left side of (i.e. before) the sample under test. Range : 0 to 15.
CMULT_MODE	4	Y	Complexmultiplication mode selection: This registeris used to configure the mode of the complex multiplication sub-block. A value of 0000b disables/bypasses the complex multiplication. Any other value chooses one of nine available modes of operation . Detailed description of the nine modes in the main description section.
CMULT_SCALE_EN	1	Y	Complex multiplier iteration enable : This register bit is applicable in certain modes of the complex multiplication pre-processing to enable per-iteration change of the complex scalar coefficient. When using scalar multiplication mode of the complex multiplier (CMULT_MODE = 0101b), if CMULT_SCALE_EN is set to 1, then the input samples are multiplied by a different complex scalar (i.e., ICMULTSCALE0, QMULTSCALE0 to ICMULTSCALE11, QMULTSCALE11) for each iteration. Else, a constant complex scalar ICMULTSCALE0 and QCMULTSCALE0 is applied to all samples across all iterations. When using vector multiplication mode (CMULT_MODE = 0110b), if CMULT_SCALE_EN is set to 1, then instead of pulling the coefficients for vector multiplication from the Vector Multiplication Coefficients RAM, the input samples are multiplied successively by ICMULTSCALE0, QMULTSCALE0 to ICMULTSCALE11, QMULTSCALE11 registers.
ICMULT_SCALE<n>.icmult_scale<n> QCMULT_SCALE<n>.qcmult_scale<n> n = 0 ..11	21	N	Coefficients for Complex multiplication: Refer the description for CMULT_SCALE_EN register.
VEC_MULT_RAM[1024]	32	N	Vector multiplication RAM : Stores the complex vector multiplication coefficients used in modes 6, 7 and 8. Layout shown in Fig. 28-34

Table 7-90. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
TWIDINCR	14	Y	Frequency shifter configuration: When the complex multiplication sub-block is programmed in one of the frequency shifter modes (CMULT_MODE = 0001b or 0010b), this register is used to indicate the amount of frequency shift. When the complex multiplication sub-block is programmed in FFT stitching mode (CMULT_MODE = 0011b), the last two bits of this register specify whether it is 4K or 8K FFT stitching. Specifically, if the last two bits are 01b, then it is 4K FFT stitching and if the last two bits are 10b, then it is 8K FFT stitching. Values of 00b and 11b are reserved. Also, the 12 MSB bits of this register must be kept zero in the FFT stitching mode. In all other modes of the complex multiplication sub-block, this 14-bit register must be kept as 0. When the complex multiplication sub-block is programmed with CMULT_MODE = 0110b, 0111b or 1000b, then the 12 MSBs of this register are used as an address offset for the Vector Multiplication Coefficients RAM (the 2 LSBs must be kept 0). When the complex multiplication sub-block is programmed with CMULT_MODE = 1001b, then the 6 LSBs of this register are used an address offset for TWID_ANGLE_RAM, with bit 13 enabling auto-address increment over iterations and bit 12 enabling address saturation or address roll-over after 63.
TWID_INCR_DELTA_FRAC.twid_incr_delta_frac	10	N	Fractional frequency increment per execution of the parameter-set: Frequency shift value to be accumulated at the end of current parameter-set. Refer main description for more details.
DSS_HWA_DEROT_RAM	32	N	
RECWIN_MODE	1	Y	Recursive window mode select bit.(0) –the K value increments with iteration. (1) –the K value increments with paramset execution count. K always starts from 0
RECWIN_RESET_SW.recwin_reset_sw	1	N	Software reset bit for recursive window K value. This is a self-clearing reset bit.
RECWIN_INIT_KVAL.recwin_init_kval	12	N	RESERVED. This is a reserved register and should be always kept 0.
TWID_INCR_DELTA_FRAC_RESET_SW.twid_incr_delta_frac_reset_sw	1	N	Software reset bit for fine frequency increment accumulator (in CMULT_MODE = 1010b). This is a self-clearing reset bit.
TWID_INCR_DELTA_FRAC_CLIP_STATUS.twid_incr_delta_frac_clip_status	1	N	Read-only register bit that indicates clip status for the fine-frequency increment accumulator (in CMULT_MODE = 1010b).
BPM_EN	1	Y	Enable/Disable BPM removal: This registerbit specifies whether the BPM removal needs to be enabled or not. If this register is set, then BPM removal is enabled prior to feeding samples from the input formatter into the core computational unit.

Table 7-90. Pre-Processing Registers (continued)

Register.field	Width	Parameter-Set? (Y/N)	Description
BPM_PATTERN<n>. bpm_pattern_<n> n=0..7	256	N	BPM pattern: Specifies the BPM patternto be used to multiply the input samples if BPM removal is enabled. The 256-bit word is split into 8 32-bit words as [BPM_PATTERN_7, BPM_PATTERN_6, BPM_PATTERN_5, BPM_PATTERN_4, BPM_PATTERN_3, BPM_PATTERN_2, BPM_PATTERN_1, BPM_PATTERN_0]
BPM_RATE.bpm_rate	10	N	BPM rate: Specifies the numberof input samples corresponding to each BPM bit. Minimum valid value for this register is 1.
BPMPHASE	4	Y	BPM startingphase: Specifies the startingphase of the BPM pattern periodicity. For more information, see the detailed description.
CHAN_COMB_EN	1	Y	Enable/Disable channel combining: If this register bit is set to 1, then the channel combining feature is enabled.
CHAN_COMB_VEC_<n>.chan_comb_vec_<n> n=0..7	256	N	Sample index indicator for Channel combining : This register indicates the sample indices that need to be combined in the Channel combiner block. A ‘01’ or ‘10’ transition demarcates the groups. The 256-bit word is split into 8 32-bit words as [CHAN_COMB_VEC_7,CHAN_COMB_VEC_6, CHAN_COMB_VEC_5, CHAN_COMB_VEC_4, CHAN_COMB_VEC_3, CHAN_COMB_VEC_2 CHAN_COMB_VEC_1, CHAN_COMB_VEC_0]
CHAN_COMB_SIZE.chan_comb_size	8	N	This register indicates the number of samples after channel combination in each iteration.
CHANNEL_COMB_CLIP_STATUS.channel_comb_clip_status	1	N	Clip status indication (read-register) during channel combining. Value of 1 indicates a clipping event occurred.
ZERO_INSERT_EN	1	Y	Enable/Disable zero-insertion: If this register bit is set to 1, then the zero-insertion feature is enabled.
ZERO_INSERT_NUM.zero_insert_num		N	This register indicates the number of zeros to be inserted in each iteration.

7.4.8 Core Computational Unit - CFAR Engine

This section describes the CFAR engine block present in the core computational unit.

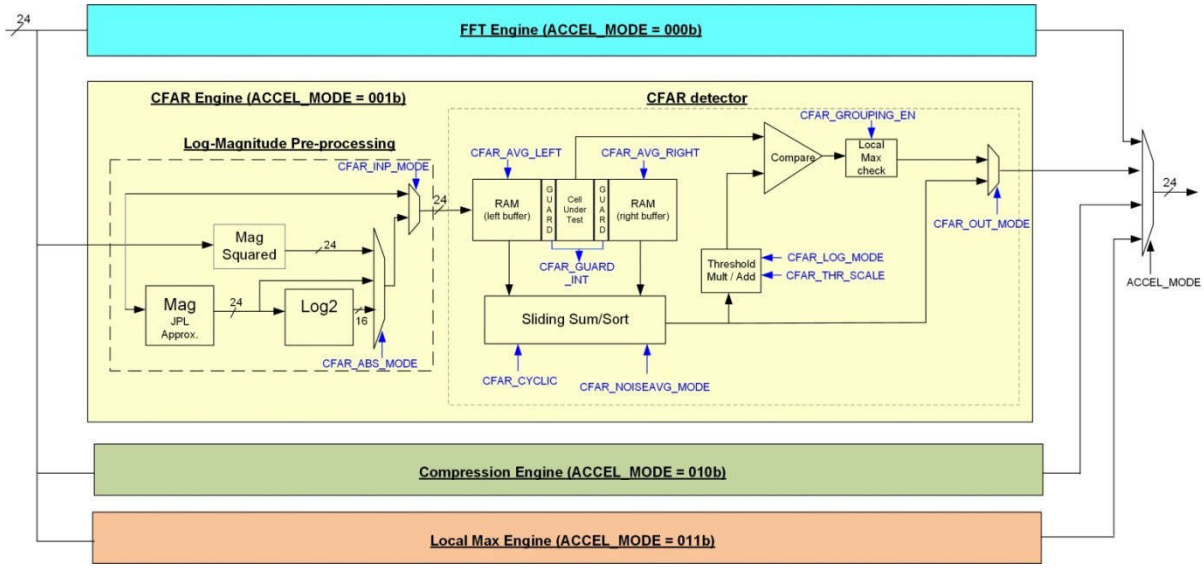

Figure 7-122. CFAR Engine

7.4.8.1 CFAR Engine

The CFAR engine (Figure 7-122) is a module that enables detection of objects, by identifying peaks in the FFT output. Although there are several detection algorithms, the accelerator supports CFAR-CA and CFAR-OS algorithms. CFAR-CA stands for constant false alarm rate – Cell Averaging. CFAR-OS stands for constant false alarm rate – Ordered Statistic.

As shown in figure, the CFAR engine path is selected by setting the accelerator mode ACCEL_MODE = 001b. In this mode, the FFT path is not usable simultaneously and the input 24-bit samples from the input formatter block will be routed into the CFAR engine. The CFAR engine has capability to perform CFAR- detection processing (both linear and logarithmic CFAR modes are available) and generate a peak list.

In CFAR, the processing steps involve computing a threshold for each sample under test (cell under test) and deciding whether a peak is detected or not based on whether the cell under test crosses that threshold. Additionally, peak grouping may be done, where a peak is declared only if the cell under test is greater than or equal to its most immediate neighboring cells to its left and right. One thing to note here is that for peak grouping, the left and right neighboring cells themselves are not required to be CFAR qualified.

In CFAR-CA case, for each cell under test, the computation of threshold is done by averaging the magnitude (or magnitude- squared or log-magnitude) of a specified number of noise samples to the left and right of the cell under test to determine a ‘surrounding noise level’ and then applying a scale factor (or addition factor in case log-magnitude is used) on that surrounding noise average to determine the threshold. Thus, the CFAR-CA detector takes one cell at a time, computes the threshold and decides whether a valid peak is present at that cell. In the case of CFAR-OS, for each cell under test, the computation of threshold is done by sorting the magnitude (or magnitude-squared or log-magnitude) of a specified number of noise samples to the left and right of the cell under test and selecting a specific “K-th” lowest value from the sorted list as representative of the surrounding noise level, and then applying a scale factor on that value to determine the threshold.

7.4.8.1.1 CFAR Engine – Operation

The CFAR engine receives 24-bit input samples from the Input Formatter block. Typically, these are real samples, representing the magnitude or magnitude-squared or log-magnitude of the FFT output. However, the input to CFAR engine can instead be complex samples, in which case, either magnitude or magnitude-squared or log-magnitude of the complex samples can be computed inside the CFAR engine itself. This is done by the log-magnitude pre-processing sub-block inside the CFAR engine (see Figure 7-122). The real unsigned result from this pre-processing operation is sent to CFAR detection processing. The registers CFAR_INP_MODE and CFAR_ABS_MODE are used to configure real vs. complex input, as well as the nature of pre-processing

required. The log-magnitude computation uses the same JPL approximation for magnitude calculation and the same look-up table (LUT) approximation for log2 computation as described in the section 28.5.1.8 for FFT engine post-processing. Note that for the case of real input (i.e., CFAR_INP_MODE = 1), the input samples must be unsigned. In this case, CFAR_ABS_MODE register has no effect.

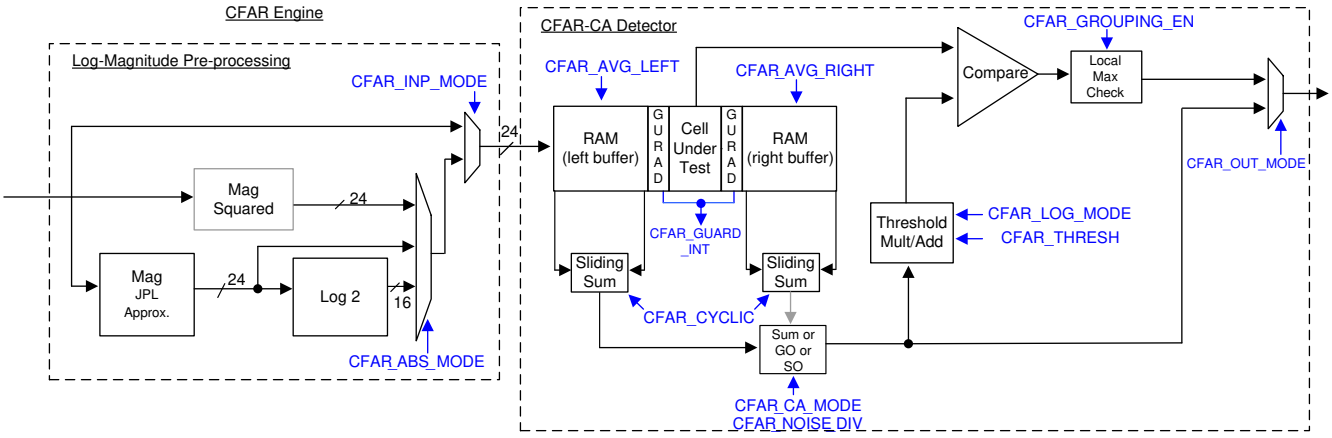

Figure 7-123. CFAR Engine Block Diagram

As described earlier, the CFAR detection processing involves finding a “surrounding noise average” for each cell under test and then determining a threshold that is a function of the surrounding noise average. The cell under test is compared against this threshold to decide whether a peak is present or not in that cell. To calculate the threshold, the surrounding noise average is multiplied with (or added to) a threshold scaling factor specified in CFAR_THRESH register.

There are two modes in which the CFAR detector can be used – in non-logarithmic mode (a.k.a linear CFAR), the threshold scale factor is multiplied, and in logarithmic mode (a.k.a logarithmic CFAR), the threshold scale factor is added. This is decided based on CFAR_LOG_MODE register.

Note: The linear and logarithmic modes are available for CFAR-CA and its variants. Their detection cores are built with 24-bit datapath width. Only the logarithmic mode is available for CFAR-OS. The CFAR-OS detection core is built with 16-bit datapath width, which is sufficient in logarithmic mode.

The final detection threshold that is so obtained is used to compare against the cell under test to determine whether a peak is detected in that cell.

Table 7-91 summarizes the register settings for the different CFAR modes of operation.

Table 7-91. CFAR Modes and Register Settings

Desired CFAR Mode	Input Real or Complex	Desired Pre-Processing	Register Values to Use		
			CFAR_INP_MODE	CFAR_ABS_MODE	CFAR_LOG_MODE
Linear CFAR	Real	N/A	1	00	0
	Complex	Magnitude	0	10	0
		Mag-squared	0	00	0
		Log2-Mag	0	11	0
Log CFAR	Real	N/A	1	00	1
	Complex	Log2-Mag	0	11	1

Desired CFAR-CA Algorithm	CFAR_CA_MODE Register Setting
CFAR-CA	00
CFAR-CAGO	01
CFAR-CASO	10

Desired CFAR-CA Algorithm	CFAR_CA_MODE Register Setting
CFAR-OS	11

The surrounding noise level computation has multiple options – cell averaging (CFAR-CA), cell averaging with greater-of selection (CFAR-CAGO), cell averaging with smaller-of selection (CFAR- CASO) and ordered statistic (CFAR-OS). The register CFAR_CA_MODE is used to select one among CFAR-CA, CFAR-CAGO, CFAR-CASO and CFAR-OS modes. In CFAR-CA, the noise samples on the left side and right side of the cell under test (after ignoring some guard cells on either side) are simply averaged to determine the surrounding noise level. In CFAR-CAGO, the noise samples on the left side and right side are averaged independently and the greater of the two is used to determine the threshold. In CFAR-CASO, the lesser of the two is used. In CFAR-OS, the noise samples on the left side and right side of the cell under test (after ignoring some guard cells on either side) are sorted and the “K-th” lowest value from the sorted list is selected as the surrounding noise level. The selection of “K-th value” from the sorted list is based on the register CFAR_OS_KVALUE (see table of registers for more details on this register).
